Class I Liquid. A liquid having a flash point below 100°F (37.8°C).

Fire Area. A portion of a building that is separated from other portions by construction with sufficient fire resistance to prevent fire of maximum anticipated severity from entering or leaving the area and with standard protection at all openings in the surrounding walls, floor, and ceiling. (*See NFPA 80, Standard for Fire Doors and Fire Windows*.)

Freight Transfer Area (Freight Platform, Freight Dock). The area wherein freight is received, sorted, shipped, and held for distribution.

Hazardous Material. A substance or material that has been determined by the Secretary of Transportation to be capable of posing an unreasonable risk to health, safety, and property when transported in commerce and that has been so designated in U.S. Department of Transportation Regulations 49 CFR, Parts 100-199.

Motor Freight Terminal. The area wherein the overall operation of freight transfer, vehicle repair and service, truck parking, and administrative functions are performed. The motor freight terminal might also include facilities for repair of crates, cases, barrels, cartons, or damaged goods; a storage area for undelivered freight or damaged goods pending settlement of claims;

rest rooms; a dormitory for drivers; locker rooms; and meal facilities.

Office Area. That part of the motor freight terminal used for administrative and general offices.

Parking Area. The lot or areas of the motor freight terminals used to park motor vehicles.

Vehicle Maintenance Area. The area wherein vehicles are repaired.

Vehicle Service Area. The area wherein vehicles are serviced, including refueling facilities. The area may include a lane in which vehicles are inspected before being dispatched.

Chapter 2 Construction and Building Arrangement

2-1* Freight Transfer and Administration Buildings.

2-1.1

If not in separate buildings, freight transfer and office areas shall be cut off from vehicle maintenance and service facilities by walls constructed of noncombustible materials having a fire resistance rating of not less than 2 hours. The requirement shall not apply to small offices, 600 ft^2 (54 m^2) or less, located within the vehicle maintenance area.

2-1.2

Walls required by 2-1.1 shall be parapeted at least 3 ft (0.9 m) above the building roof.

Exception: The parapet shall be permitted to be omitted where the wall fits tightly to the underside of a fire-resistive roof deck constructed of noncombustible materials.

2-1.3

Necessary door and other openings in the walls required by 2-1.1 shall be protected by fire doors having a fire protection rating of not less than $1^1/_2$ hours, installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

2-1.4

Stairways and other vertical shafts shall be enclosed with construction specified in NFPA 220, *Standard on Types of Building Construction*, or sealed off at each floor level with construction having the same fire resistance rating as the floor.

2-1.5*

Exits and other life safety features of freight transfer and administration buildings and sections of buildings shall comply with the requirements of Chapters 29 and 27, respectively, of NFPA *101®, Life Safety Code®*.

2-1.6

Power-operated doors that are installed in the terminals shall be arranged so that they can be operated manually from the floor in case of power failure.

2-1.7

The floor of any freight transfer area shall be constructed of noncombustible materials without cracks or openings into which trash or other combustible material might fall. This provision shall not prohibit openings for integral freight handling equipment and appurtenances such as slots for the operation of draglines and platform scales. Any open space beneath the floor shall be enclosed with noncombustible material.

2-1.8

Rooms for the storage, charging, and servicing of batteries shall comply with Article 480, NFPA 70, *National Electrical Code*®. "No Smoking" signs shall be posted at the entrance.

2-2* Vehicle Maintenance and Service Buildings.

2-2.1

Service areas that are not located in separate buildings shall be separated from other terminal operations by walls and fire doors in accordance with 2-1.1 through 2-1.3.

2-2.2

Maintenance and service area floors shall be constructed of noncombustible material. Floors shall be graded and equipped with drains so as to minimize the possibility that water or fuel will stand on the floor.

2-2.3

Floor drains shall be provided in areas where vehicles are maintained and serviced. Each floor drain shall be properly trapped and shall discharge through an oil separator to the sewer or outside vented sump.

2-2.4

Pits and subfloor work areas shall be constructed of masonry or concrete, and floors and piers shall be of suitable noncombustible material.

2-2.4.1 Pits shall have adequate exits to prevent trapping of personnel in the event of fire. Steps shall be noncombustible, slip-proof, and constructed with no accessible space underneath.

2-2.4.2 Ventilation and drainage of pits shall be in accordance with Section 5-3.

2-2.5*

Exits from vehicle maintenance and service areas shall comply with the requirements of Section 29-2 of NFPA *101*, *Life Safety Code*.

2-3 Employee Facilities.

2-3.1 Walls and Partitions.

2-3.1.1 Fire resistance ratings of walls or partitions separating the following rooms from surrounding areas shall be as follows:

Employee locker rooms	1 hour
Recreation rooms	1 hour
Sleeping facilities	2 hours

2-3.1.2 Door and other openings in the walls or partitions required by 2-3.1 shall be protected by self-closing fire doors having a fire protection rating of not less than 1 hour, installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

Exception: Door and other openings in walls or partitions separating sleeping facilities from surrounding areas shall be protected by self-closing fire doors having a fire protection rating of *not less than $1^1/_2$ hours.*

2-3.2 Floors.

2-3.2.1 Fire resistance ratings of floors separating employee locker rooms, recreation rooms, and sleeping facilities from surrounding areas shall be the same as required for walls or partitions in 2-3.1.

2-3.2.2 Openings in floors between the separated areas shall be enclosed in shafts with enclosing walls or partitions having the same fire resistance ratings as required for the walls or partitions in 2-3.1.

Exception: Ducts for heating, ventilating, and air conditioning shall be installed in accordance with NFPA 90A, Standard for the Installation of Air Conditioning and Ventilating Systems.

2-3.3

Exits and other life safety features of dormitory buildings and dormitory sections of buildings shall comply with the requirements of Chapter 17 of NFPA *101*, *Life Safety Code*.

Chapter 3 Building Services

3-1 Electricity.

3-1.1

All electrical installations shall be in accordance with the provisions of NFPA 70, *National Electrical Code*.

3-1.2

Table 3-1.2 (Table 5-3.5.3 from NFPA 30, *Flammable and Combustible Liquids Code*) shall be used for determining the extent of the hazardous area where flammable liquids are stored or handled.

Table 3-1.2 Electrical Area Classifications

Location	NEC Class I Division	Extent of Classified Area
Indoor equipment installed where flammable vapor-air mixtures may exist under normal operation	1	Area within 5 ft of any edge of such equipment, extending in all directions.
	2	Area between 5 ft and 8 ft of any edge of such equipment, extending in all directions. Also, area up 3 ft above floor or grade level within 5 ft to 25 ft horizontally from any edge of such equipment.*
Outdoor equipment of the type where flammable vapor-air mixtures may exist under normal operation	1	Area within 3 ft of any edge of such equipment, extending in all directions.
	2	Area between 3 ft and 8 ft of any edge of such equipment, extending in all directions. Also, area up 3 ft above floor or grade level within 3 ft to 10 ft horizontally from any edge of such equipment.

Tank—aboveground	1	Area inside dike where dike height is greater than the distance from the tank to the dike for more than 50 percent of the tank circumference.
Shell, ends, or roof and dike area	2	Within 10 ft from shell, ends, or roof of tank. Area inside dikes to level of top of dike.
Vent	1	Within 5 ft of open end of vent, extending in all directions.
	2	Area between 5 ft and 10 ft from open end of vent, extending in all directions.
Floating roof	1	Area above the roof and within the shell.
Underground tank fill opening	1	Any pit, box, or space below grade level, if any part i within a Division 1 or 2 classified area.
	2	Up to 18 in. above grade level, within a horizontal radius of 10 ft from a loose fill connection and withi a horizontal radius of 5 ft from a tight fill connection
Vent—discharging upward	1	Within 3 ft of open end of vent, extending in all directions.
	2	Area between 3 ft and 5 ft of open end of vent, extending in all directions.
Drum and container filling outdoors, or indoors with adequate ventilation	1	Within 3 ft of vent and fill openings, extending in all directions.
	2	Area between 3 ft and 5 ft from vent or fill opening, extending in all directions. Also, up to 18 in. above floor or grade level within a horizontal radius of 10 f from vent or fill openings.
Pumps, bleeders, withdrawal fittings, meters, and similar devices		
Indoors	2	Within 5 ft of any edge of such devices, extending in all directions. Also up to 3 ft above floor or grade level within 25 ft horizontally from any edge of such devices.
Outdoors	2	Within 3 ft of any edge of such devices, extending in all directions. Also up to 18 in. above grade level within 10 ft horizontally from any edge of such devices.
Pits		
Without mechanical ventilation	1	Entire area within pit if any part is within a Division or 2 classified area.
With adequate mechanical ventilation	2	Entire area within pit if any part is within a Division or 2 classified area.
Containing valves, fittings, or piping, and not within a Division 1 or 2 classified area	2	Entire pit.
Drainage ditches, separators, impouding		

basins		
Outdoors	2	Area up to 18 in. above ditch, separator, or basin. Als up to 18 in. above grade within 15 ft horizontally fro any edge.
Indoors		Same as pits.
Tank vehicle and tank car* loading through open dome	1	Within 3 ft of edge of dome, extending in all directions.
	2	Area between 3 ft and 15 ft from edge of dome, extending in all directions.
Loading through bottom connections with atmospheric venting	1	Within 3 ft of point of venting to atmosphere, extending in all directions.
	2	Area between 3 ft and 15 ft from point of venting to atmosphere, extending in all directions. Also up to 18 in. above grade within a horizontal radius of 10 ft from point of loading connection.
Office and rest rooms	Ordinary	If there is any opening to these rooms within the extent of an indoor classified area, the room shall be classified the same as if the wall, curb, or partition di not exist.
Loading through closed dome with atmospheric venting	1	Within 3 ft of open end of vent, extending in all directions.
	2	Area between 3 ft and 15 ft of open end of vent, extending in all directions. Also within 3 ft of edge o dome, extending in all directions.
Loading through closed dome with vapor control	2	Within 3 ft of point of connection of both fill and vapor lines, extending in all directions.
Bottom loading with vapor control Any bottom unloading	2	Within 3 ft of point of connections, extending in all directions. Also up to 18 in. above grade within a horizontal radius of 10 ft from point of connections.
Storage and repair garage for tank	1	All pits or spaces below floor level.
vehicles	2	Area up to 18 in. above floor or grade level for entire storage or repair garage.
Garages for other than tank vehicles	Ordinary	If there is any opening to these rooms within the extent of an outdoor classified area, the entire room shall be classified the same as the area classification a the point of the opening.
Outdoor drum storage	Ordinary	
Indoor warehousing where there is no flammable liquid transfer	Ordinary	If there is any opening to these rooms within the extent of an indoor classified area, the room shall be classified the same as if the wall, curb, or partition di not exist.
Piers and wharves		See Figure 5-3.5.6 in NFPA 30, *Flammable and Combustible Liquids Code*.

*The release of Class I liquids may generate vapors to the extent that the entire building, and possibly a zone surrounding it, should be considered a Class I, Division 2 location.

*When classifying extent of area, consideration shall be given to the fact that tank cars or tank vehicles may be spotted at varying points. Therefore, the extremities of the loading or unloading positions shall be used.

3-2 Heating.

3-2.1

Heating equipment shall be installed to conform with the following standards of the National Fire Protection Association, as applicable: NFPA 90A, *Standard for Installation of Air Conditioning and Ventilating Systems*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; NFPA 54, *National Fuel Gas Code*; NFPA 82, *Standard on Incinerators, Waste and Linen Handling Systems and Equipment*; NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*.

3-2.2

All heating equipment shall be of an approved type designed for the purpose. The use of makeshift or improvised heaters shall be prohibited.

3-2.3

Fuels used shall be of the type and quality specified by the manufacturer of the heating appliance.

3-2.4

Heating equipment shall be permitted to be installed in a special room separated from an area classified as Class I, Division 1 or 2, by walls having a fire-resistive rating of at least 1 hour and without any openings in the wall into the classified area within 8 ft (2.4 m) of the floor. This room shall not be used for combustible storage, and all air for combustion purposes shall come from outside the building. In classifying the areas, Table 3-1.2 shall be used. The area classifications are defined in Article 500 of NFPA 70, *National Electrical Code*.

3-2.5

Heating equipment using gas or oil fuel shall be permitted to be installed in maintenance service areas in which there is no dispensing or transferring of Class I liquids, provided that the bottom of the combustion chamber is at least 18 in. (457 mm) above the floor and the heating equipment is protected from physical damage.

3-2.6

Gas or oil-heating equipment approved for use in garages shall be permitted to be installed in the maintenance and service areas where Class I liquids are dispensed, provided the equipment is installed at least 8 ft (2.4 m) above the floor.

3-2.7

Electrical heating equipment shall be installed in accordance with the provisions of NFPA 70, *National Electrical Code*.

3-3 Ventilation.

3-3.1 Vehicle Maintenance and Repair Areas.

All vehicle maintenance and repair areas, when in operation, shall be continuously ventilated by a ventilating system having positive means for exhausting indoor air at a rate of not less than $^3/_4$ cu ft (0.0212 m^3) of air per minute for each sq ft (m^2) of floor area. Exhaust duct openings for required ventilation shall be located so as to remove effectively vapor accumulations at floor level from all parts of the repair area. An approved means shall be provided for introducing an equal amount of outdoor air.

3-3.2

Mechanical ventilating systems shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*. When blower and exhaust systems are installed for vapor removal, the system shall be installed in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

Chapter 4 Freight Handling Operation

4-1 Freight Transfer.

4-1.1

Aisles shall be provided to keep all portions of the freight handling areas readily accessible for fire fighting and to minimize the spread of fire.

4-1.2*

Hazardous materials shall be handled in accordance with the U.S. Department of Transportation Regulations 49 CFR, Parts 100-199.

4-1.3*

Combustible contents shall not be piled in contact with columns that are not of fire-resistive construction.

4-1.4

In sprinklered buildings, at least 18-in. (457-mm) clearance between sprinkler deflectors and the top of storage shall be maintained. In nonsprinklered buildings, at least 36-in. (914-mm) clearance shall be maintained between the top of the storage and the underside of the roof or ceiling in order to allow sufficient space for effective use of hose streams.

4-1.5*

Clearance shall be maintained between heat-producing appliances and combustible stock in accordance with NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*. Adequate clearance shall be maintained between incandescent lamps and combustible stock.

4-1.6

A clearance of 24 in. (610 mm) shall be maintained around the path of travel of fire doors.

Exception: If a barricade is provided, no clearance shall be required.

4-1.7

Commodities shall not be stored within 36 in. (914 mm) of a fire door opening.

4-2 Mechanical Handling Equipment.

4-2.1

Power-operated industrial trucks shall be of a type designated in Chapter 1 of NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*, in accordance with the hazards of the location in which they are used.

4-2.2

Industrial trucks, powered either by liquid or gaseous fuels, or by electricity, shall be inspected and maintained in accordance with Chapters 4 and 5 of NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*.

4-3 Motor Vehicles at Docks.

4-3.1*

Parking of vehicles in terminals shall be in compliance with applicable local, state, and federal regulations.

4-3.2

Accessibility to terminals and vehicle parking areas for fire fighting purposes shall be provided at all times. Vehicles shall be parked so that they will not block fire department access.

4-3.3

There shall be an emergency plan in effect for the removal of vehicles from the dock to a safe area to minimize fire exposure and loss and to ensure improved accessibility for the fire fighting equipment.

Chapter 5 Vehicle Maintenance and Service

5-1 General.

Major maintenance and servicing of motor vehicles shall not be performed on floors below grade level. This requirement shall not prohibit the use of pits.

5-2 Spray Painting and Undercoating.

Spray painting, drying, and undercoating of motor vehicles shall conform to NFPA 33, *Standard for Spray Application Using Flammable and Combustible Materials*, and NFPA 86, *Standard for Ovens and Furnaces*.

5-3* Inspection and Repair Pits.

5-3.1

Use of approved portable lights shall be minimized by installation of fixed lighting fixtures of the approved types in all pits in accordance with Article 511 of NFPA 70, *National Electrical Code*.

Exception: If gasoline is dispensed, Article 514 of NFPA 70, National Electrical Code, shall apply.

5-3.2

Drainage from inspection or repair pits shall not enter a storm or sanitary sewer system, unless it has passed through a separator to prevent flammable and combustible liquids from entering the sewer.

5-3.3

Smoking in pits shall be prohibited.

5-3.4

A scheduled maintenance program for the collection and removal of oil separators and traps shall be initiated to prevent flammable and combustible liquids from entering the sewer.

5-4 Repair of Fuel Tanks.

5-4.1

Repair work on fuel tanks of vehicles shall be in accordance with NFPA 327, *Standard Procedures for Cleaning or Safeguarding Small Tanks and Containers Without Entry*, and NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*.

5-4.2

Fuel drained from vehicle tanks and not discarded shall be stored in approved safety cans or returned to standard underground storage tanks.

5-5 Cleaning of Parts.

Cleaning of parts shall be performed with nonflammable solvent.

Exception: A combustible liquid with a flash point at or above 100°F (37.8°C) (closed cup) shall be permitted to be used for this purpose, provided adequate ventilation is supplied and no sources of ignition are present in the cleaning area.

5-6 Welding and Open Flame Operations.

5-6.1

All operations involving open flame or electric arcs, including fusion gas and electric welding, shall be restricted to the designated repair area. This provision includes, but is not limited to, fuel tank and radiator repairs. Responsibility for cutting and welding, and related fire prevention precautions, shall be in accordance with the requirements of NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

5-6.2

Welding equipment shall conform to Article 630 of NFPA 70, *National Electrical Code*, and the welding operations shall conform to NFPA 51, *Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes*.

5-7 Storage and Handling of Flammable and Combustible Liquids.

The storage and handling of flammable and combustible liquids shall be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*. The storage and handling of liquefied petroleum gas shall be in compliance with NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*.

5-8 Fueling of Vehicles.

5-8.1*

Gasoline dispensing units shall be of an approved type and shall be at least 20 ft (6 m) horizontally from any activity involving fixed sources of ignition.

5-8.2

Approved dispensing units shall be permitted to be located inside buildings upon specific approval of the authority having jurisdiction. The dispensing area shall be separated from other areas in a manner approved by the authority having jurisdiction. The dispensing area shall be provided with an approved mechanical or gravity ventilation system.

5-8.3

Class I liquids shall be transferred from tanks by means of fixed pumps designed and equipped to allow control of the flow and prevent leakage or accidental discharge.

5-8.4

The dispensing unit and its piping, except those units attached to containers, shall be mounted on a concrete island or protected against collision damage by suitable means. If located indoors, the dispenser also shall be mounted on a concrete island or shall be protected against collision damage by suitable means and shall be located in a position where it cannot be struck by an out-of-control vehicle that is descending a ramp or other slope.

5-8.5

If Class I liquids are dispensed by a person other than the attendant, the hose nozzle valve shall be a listed automatic-closing type without a hold-open latch.

5-8.6

One or more clearly identified and easily accessible switches or circuit breakers shall be provided at a location remote from dispensing devices, including remote pumping systems, to shut off the power to all dispensing devices in the event of an emergency. Controls shall not be more than 100 ft (30 m) from dispensers.

5-8.7

Operating instructions and “No Smoking” signs shall be conspicuously posted in the dispensing area.

5-8.8

The storage and handling of flammable and combustible liquids shall be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*.

5-8.9

Facilities for filling LP-Gas fuel tanks shall be located outside of any terminal building. For requirements for LP-Gas fueling, see NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*.

Chapter 6 Fire Protection

6-1* Automatic Sprinklers.

Where automatic sprinklers are provided, they shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

6-2 Portable Fire Extinguishers.

Portable fire extinguishers shall be installed, inspected, maintained, and used in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

6-3 Standpipes.

Where standpipe and hose systems are provided, they shall conform to NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

6-4* Alarm Service.

Where alarm service is provided, it shall be installed and maintained in accordance with NFPA 72, *National Fire Alarm Code*.

6-5 Outside Protection.

6-5.1*

The fire fighting needs of the terminal buildings and the requirements for fighting fires that might involve loaded and unloaded vehicles shall be considered when determining water supply and hydrant requirements.

6-5.2

Where private underground supply mains and hydrants are necessary, they shall be installed in accordance with NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

49 CFR, Parts 100-199, as amended.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document, but is included for informational purposes only.

A-2-1

Freight transfer and administration buildings should be of fire-resistive or noncombustible construction as defined in NFPA 220, *Standard on Types of Building Construction*. Consideration should be given to limitation of undivided fire areas in freight transfer facilities.

Factors to be considered when determining maximum sizes of undivided fire areas are (a) type of fire protection provided, (b) mechanical conveying equipment such as dragline operations, and (c) surveillance of goods to prevent possible theft.

A-2-1.5

The referenced sections of NFPA *101*, *Life Safety Code*, include requirements for types and capacity of exits, travel distances to exits, access to exits, exit lighting and signs, protection of vertical openings, interior finish, alarms, and air-conditioning equipment.

A-2-2

Areas used for repairing and servicing vehicles should be located in separate buildings from the freight transfer building. These buildings should be of fire-resistive or noncombustible construction.

A-2-2.5

Chapter 29 of NFPA *101*, *Life Safety Code*, includes requirements for types and capacity of exits, travel distances to exits, access to exits, exit lighting and signs, protection of vertical openings, interior finish, and alarms.

A-4-1.2

Certain commodities have characteristics that cause them to be classified as hazardous materials. These commodities are subject to special regulations governing packaging, storage, and transportation. Failure to abide by these requirements increases the danger of explosion, fire, the release of noxious or toxic fumes, damage to other freight, or other dangerous conditions. Section 177.848 of the *Code of Federal Regulations*, *Loading and Storage Guide*, sets forth those combinations of hazardous materials that should not be loaded or stored together, or with certain other types of freight, in the same vehicle. The *Loading and Storage Guide* does not prohibit the presence of these combinations of commodities in the same motor freight terminal so long as they are not stored adjacent to each other.

A-4-1.3

This requirement is necessary to permit water to wet columns during fire suppression operations to guard against column failure.

A-4-1.5

Surface temperature of lamps is discussed in the NFPA *Fire Protection Handbook*, 17th edition, pages 2-34.

A-4-3.1

In case of fire, there is a potential for mutual exposure between the terminals and vehicles parked adjacent to them. Consistent with operating conditions and security requirements, consideration should be given to minimizing the potential exposure by not parking vehicles at the dock longer than necessary. Priority should be given to the loading, unloading, and dispatching of vehicles transporting hazardous materials so that such cargoes will not be in the terminal longer than necessary.

A-5-3

Pits used to service gasoline-fueled vehicles should be provided with individual ventilating systems capable of providing 4 cu ft (0.1132 m^3) of air per minute per sq ft (m^2) of floor area. Such pits should have the floor pitched 1 in. (25.4 mm) for each 10 ft (3.05 m), and the exhaust air opening should terminate in an air opening that is perpendicular to the floor with the bottom of the opening extending to the floor at the lowest end of the pit.

A-5-8.1

In fuel dispensing, consideration should be given to the vapor recovery requirements of the U.S. Environmental Protection Agency.

A-6.1

Consideration should be given to sprinkler protection for:

(a) Freight transfer buildings and vehicle maintenance and service buildings.

(b) Truck loading areas. An open head deluge system or a closed head dry pipe or nonfreeze-solution wet system should be provided in colder regions to protect against the mutual fire exposure that can exist between terminals and vehicles parked adjacent to them. See Chapter 3, “System Requirements,” of NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A-6-4

Freight transfer facilities should be provided with one of the following types of alarm service: (a) central station supervision of sprinkler system water-flow, (b) central station supervision of automatic fire detection system, or (c) central station supervision of guard service. Details for the installation, maintenance, and use of guard, fire alarm, and sprinkler supervisory systems are found in NFPA 72, *National Fire Alarm Code*. Information on the selection and training of persons to perform guard services is found in NFPA 601, *Standard on Guard Service in Fire Loss Prevention*.

A-6-5.1

Where an adequate water supply for fire hydrants and sprinkler protection cannot be made available from public water mains, the following NFPA standards should be consulted: NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and NFPA 22, *Standard for Water Tanks for Private Fire Protection*.

Appendix B Referenced Publications

B-1

The following documents or portions thereof are referenced within this standard for informational purposes only and thus are not considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

B-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA

1995 Edition

Guide to the Fire Safety Concepts Tree

1995 Edition

This edition of NFPA 550, *Guide to the Fire Safety Concepts Tree*, was prepared by the Standards Council and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 14-16, 1994, in Toronto, Ontario, Canada. It was issued by the Standards Council on January 13, 1995, with an effective date of February 7, 1995, and supersedes all previous editions.

The 1995 edition of this document has been approved by the American National Standards Institute.

Origin and Development of NFPA 550

The NFPA Committee on Systems Concepts was organized to be responsible for developing systems concepts and criteria for fire protection in structures. A primary accomplishment of this committee was the development of the NFPA Fire Safety Concepts Tree. This guide to the Fire Safety Concepts Tree was developed by the Committee on Systems Concepts in 1985. Appreciation is extended to Dr. John M. Watts, Jr., of the Fire Safety Institute for his major contribution to the contents of this document.

The Committee on Systems Concepts was discharged in October 1990, and the Standards Council assumed the responsibility for this document.

The 1995 edition represents a reconfirmation of the 1986 edition with editorial clarifications.

Report of the Standards Council

NFPA 550
Guide to the
Fire Safety Concepts Tree

1995 Edition

NOTICE: Information on referenced publications can be found in Chapter 8 and Appendix A.

Chapter 1 Introduction

1-1 General.

The critical need for reliability in the U.S. space program generated a new discipline known as System Safety Analysis. Many analytical approaches to safety have evolved in this new field. One of the more powerful tools is Fault Tree Analysis. Fault Tree Analysis uses a tree-like diagram to describe the relationships of events that can lead to a system failure (*see Appendix B*). The NFPA Fire Safety Concepts Tree uses a similar diagram to show relationships of fire prevention and fire damage control strategies.

Fire safety features such as construction type, combustibility of contents, protection devices, and characteristics of occupants traditionally have been considered independently of one another. This can lead to unnecessary duplication of protection. On the other hand, gaps in protection can exist when these pieces do not come together adequately, as evidenced by the large losses that continue to occur.

The distinct advantage of the Fire Safety Concepts Tree is its systems approach to fire safety. Rather than considering each feature of fire safety separately, the Fire Safety Concepts Tree examines all of them and demonstrates how they influence the achievement of fire safety goals and objectives.

1-2 Scope and Application.

The Fire Safety Concepts Tree is useful in providing an overall structure with which to analyze the potential impact of various codes and standards on a particular fire safety problem. It can identify gaps and areas of redundancy in alternative fire protection strategies as an aid in making fire safety decisions. The use of the Fire Safety Concepts Tree should be accompanied by the application of sound fire protection engineering principles.

1-3 Purpose.

This guide is intended to answer questions that have been asked during the past twenty years and to stimulate new questions. Fire safety is not a static concept but evolves with the expansion of our knowledge of the nature of fire and with the imagination of the fire safety practitioner.

Chapter 2 Background

2-1 General.

In the 1960s, there was growing awareness that modern high-rise buildings designed in accordance with building codes and standards were deficient in fire safety protection. In response, a special workshop and follow-up conference of selected experts was convened to consider systematic ways of developing new or revised approaches to fire safety. These conferences, held in 1971, were brainstorming sessions that had the objective of producing a logical framework for providing adequate fire safety in high-rise structures. They were the stimulus for the organization of a special NFPA committee with the scope of being "responsible for developing systems concepts and criteria for fire protection in structures." A primary accomplishment of the Committee on Systems Concepts was development of the NFPA Fire Safety Concepts Tree.

2-2 Current Application.

The original committee document, published in 1974, was a logic diagram referred to as the "Decision Tree." This term was used to identify the tree as an aid to fire safety decision-making. While the Decision Tree incorporated the logic and structure of a fault tree, it described paths leading to success rather than failure. Another important distinction separating the Decision Tree from a fault tree was that components of fire safety are not always well-defined events to which a probability of occurrence can be assigned. In order to emphasize that the tree components are concepts rather than events, it was renamed the Fire Safety Concepts Tree when it was revised and updated in 1980.

The NFPA Fire Safety Concepts Tree is printed on a single large sheet of paper and folded approximately into letter size. Unfolding and spreading out the tree permits the entire fire safety process to be viewed at once.

Chapter 3 Structure of the Fire Safety Concepts Tree

3-1 Fire Safety Objectives.

At the top of the NFPA Fire Safety Concepts Tree is a box labeled "FIRE SAFETY OBJECTIVE(S)." The logic of the tree is directed toward the achievement of specified objectives, as in the recognized approach of "Management by Objectives" (MBO). In this case, the concern is for managing the fire risk. The concept is that the clearer the idea one has of the objective, the greater the chance of achieving it. The three basic fire safety objectives are life safety, property protection, and operational continuity. More specific operating objectives might include averting a catastrophic loss, avoiding public anxiety, preserving for posterity, and environmental protection.

Strategies for achieving fire safety objectives are divided into two categories: PREVENT FIRE IGNITION and MANAGE FIRE IMPACT. These concepts are connected through an "OR gate" to the fire safety objectives. This is shown on the printed tree by the lines drawn from the top of the boxes labeled PREVENT FIRE IGNITION and MANAGE FIRE IMPACT, which join together and lead upward through a circle with a plus symbol in it to the box labeled FIRE SAFETY OBJECTIVE(S) (*see Figure 3-1*). The circle containing the plus symbol (⊕) is used to designate an OR gate. An OR gate is a logic operation whereby any of several inputs will produce a specified output. Thus, the logic of the tree is that fire safety objectives can be accomplished by preventing a fire from starting *or* by managing the impact of the fire. Note that although there is a tendency to read the tree from the top down, the logic flow is upward, i.e., the inputs are below the outputs.

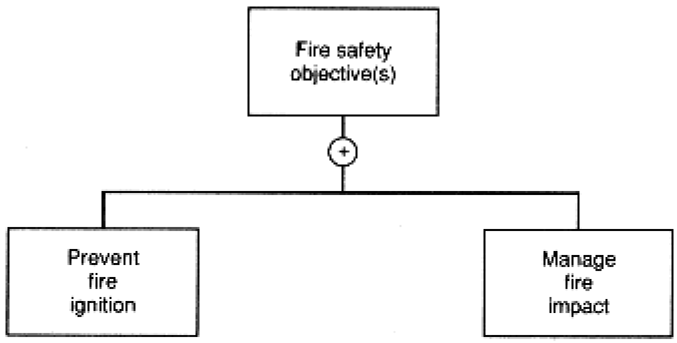

Figure 3-1 Top gate of Fire Safety Concepts Tree.

The OR gate is the "inclusive or," which means that all the concepts below the gate can be included, but only one of them is necessary. In theory, this implies that either prevention or management alone could be followed to achieve the objective. However, theoretically, it is not possible to achieve perfect prevention or management. In practice, principles of both fire prevention and fire impact management usually are applied together. The likelihood of achieving fire safety objectives is increased by the presence of both principles. This practice is an example of reliability through redundancy, e.g., using both a belt and suspenders to hold up a pair of pants. Thus, OR gates in the Fire Safety Concepts Tree indicate where reliability of achieving an objective is improved by implementation of more than one strategy. It is also important to note that the inputs to an OR gate are exhaustive. This means they encompass every possible way of achieving the indicated output.

3-2 Prevent Fire Ignition.

The PREVENT FIRE IGNITION branch of the Fire Safety Concepts Tree includes measures representative of a fire prevention code. Fire safety measures included in this branch of the tree require continuous monitoring to ensure their effectiveness. The responsibility, therefore, is more the owner's or occupant's than the designer's.

Ignition results from a heat source in contact with, or sufficiently close to, a combustible substance. Thus, PREVENT FIRE IGNITION branches into CONTROL HEAT-ENERGY SOURCE(S), CONTROL SOURCE-FUEL INTERACTIONS, *or* CONTROL FUEL [*see Figure 3-2(a)*]. Again, the OR gate indicates that any one of these three strategies, if carried out fully, is sufficient to prevent ignition, but use of more than one will improve the chances of prevention.

For example, control of heat-energy sources can be achieved by eliminating them. This also achieves the prevention of fire ignition, and no other strategy is needed. However, there is a reliability associated with the strategy of eliminating all heat-energy sources, i.e., it is possible that somehow an ignition source might find its way into the protected area. If the control fuel strategy also is applied, then the reliability that ignition will be prevented is increased.

CONTROL SOURCE-FUEL INTERACTIONS is the output of an “AND gate” with input strategies of CONTROL HEAT-ENERGY SOURCE TRANSPORT, CONTROL HEAT-ENERGY TRANSFER PROCESSES, *and* CONTROL FUEL TRANSPORT. On the printed tree, the symbol for an AND gate is a circle with a dot in the middle The AND gate is the logic operation that indicates all of the inputs must coexist simultaneously in order to produce the output. This means that the heat source should not be allowed to move too close to the fuel, excessive heat should be prevented from being transferred to the fuel, *and* the fuel should not be allowed to move too close to the heat source. All these concepts are necessary to achieve control of source-fuel interactions; there is no redundancy. AND gates in the Fire Safety Concepts Tree represent checklists of items that are necessary to achieve the output objective or strategy.

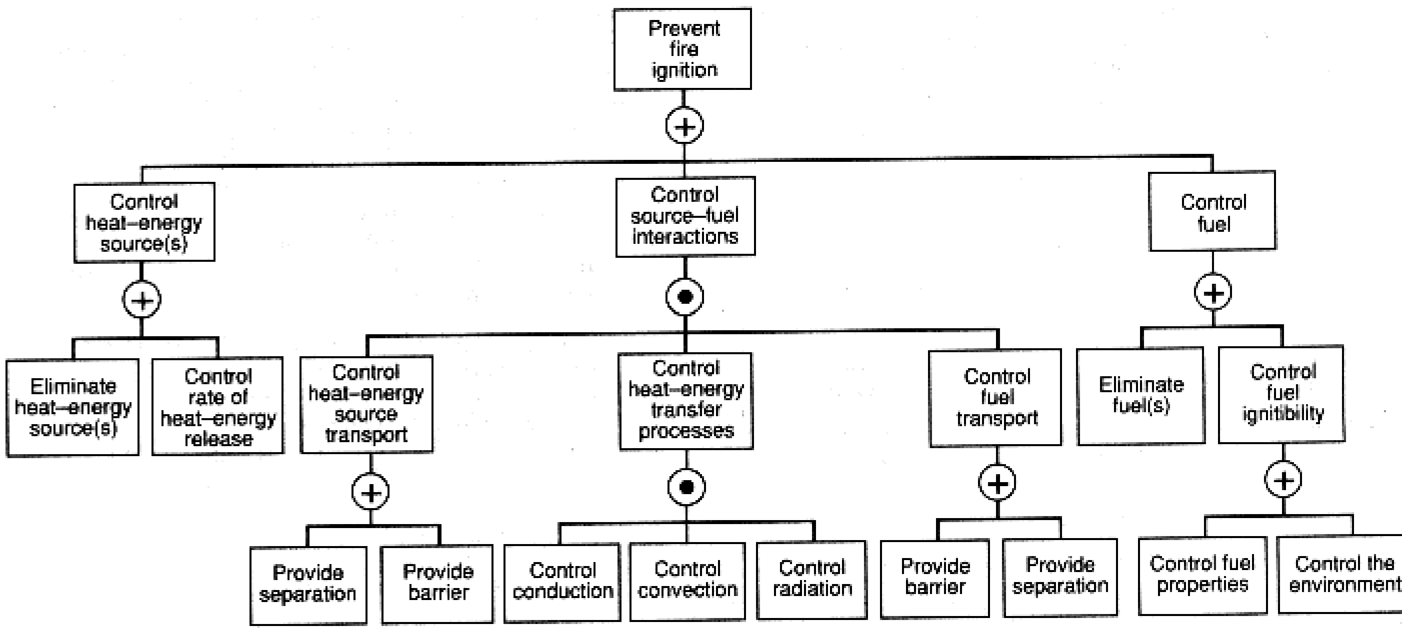

Figure 3-2(a) Prevent fire ignition branch of Fire Safety Concepts Tree.

The plus and dot symbols used for OR gates and AND gates [*see Figure 3-2(b)*] also are used in fault trees. They are the standard symbols for these logic operations, which are used in electronic circuit diagrams and Boolean algebra. They are derived from the algebra of probabilities. (*See Appendix C.*)

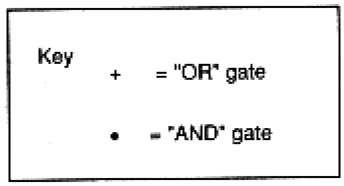

Figure 3-2(b) Logic symbols used in Fire Safety Concepts Tree.

3-3 Manage Fire Impact.

The MANAGE FIRE IMPACT side of the tree has two major branches as inputs to an OR gate: MANAGE FIRE and MANAGE EXPOSED (*see Figure 3-3*). This is the basic approach to loss control, i.e., to limit the magnitude of the hazard or to minimize the effects.

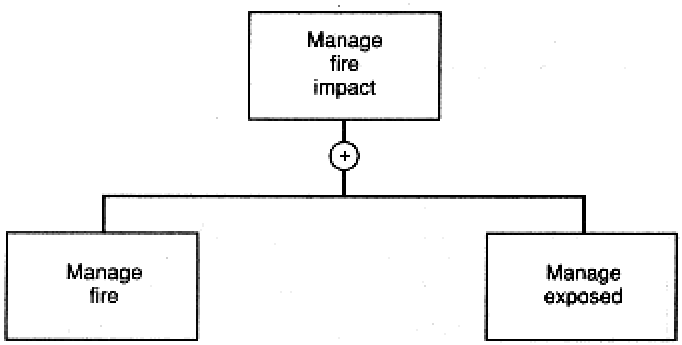

Figure 3-3 Major branches of manage fire impact.

3-3.1 Manage Fire.

The objectives of the MANAGE FIRE strategy are to reduce hazards associated with fire growth and spread, and to thereby reduce the impact of the fire. Approaches to fire management are (1) control the rate of production of smoke and heat through alteration of the fuel or the environment, (2) control the combustion process by manual or automatic suppression, and (3) control fire propagation with venting or containment, or both (*see Figure 3-3.1*). Again, the OR gate indicates that these strategies can be applied simultaneously for increased reliability of managing the fire.

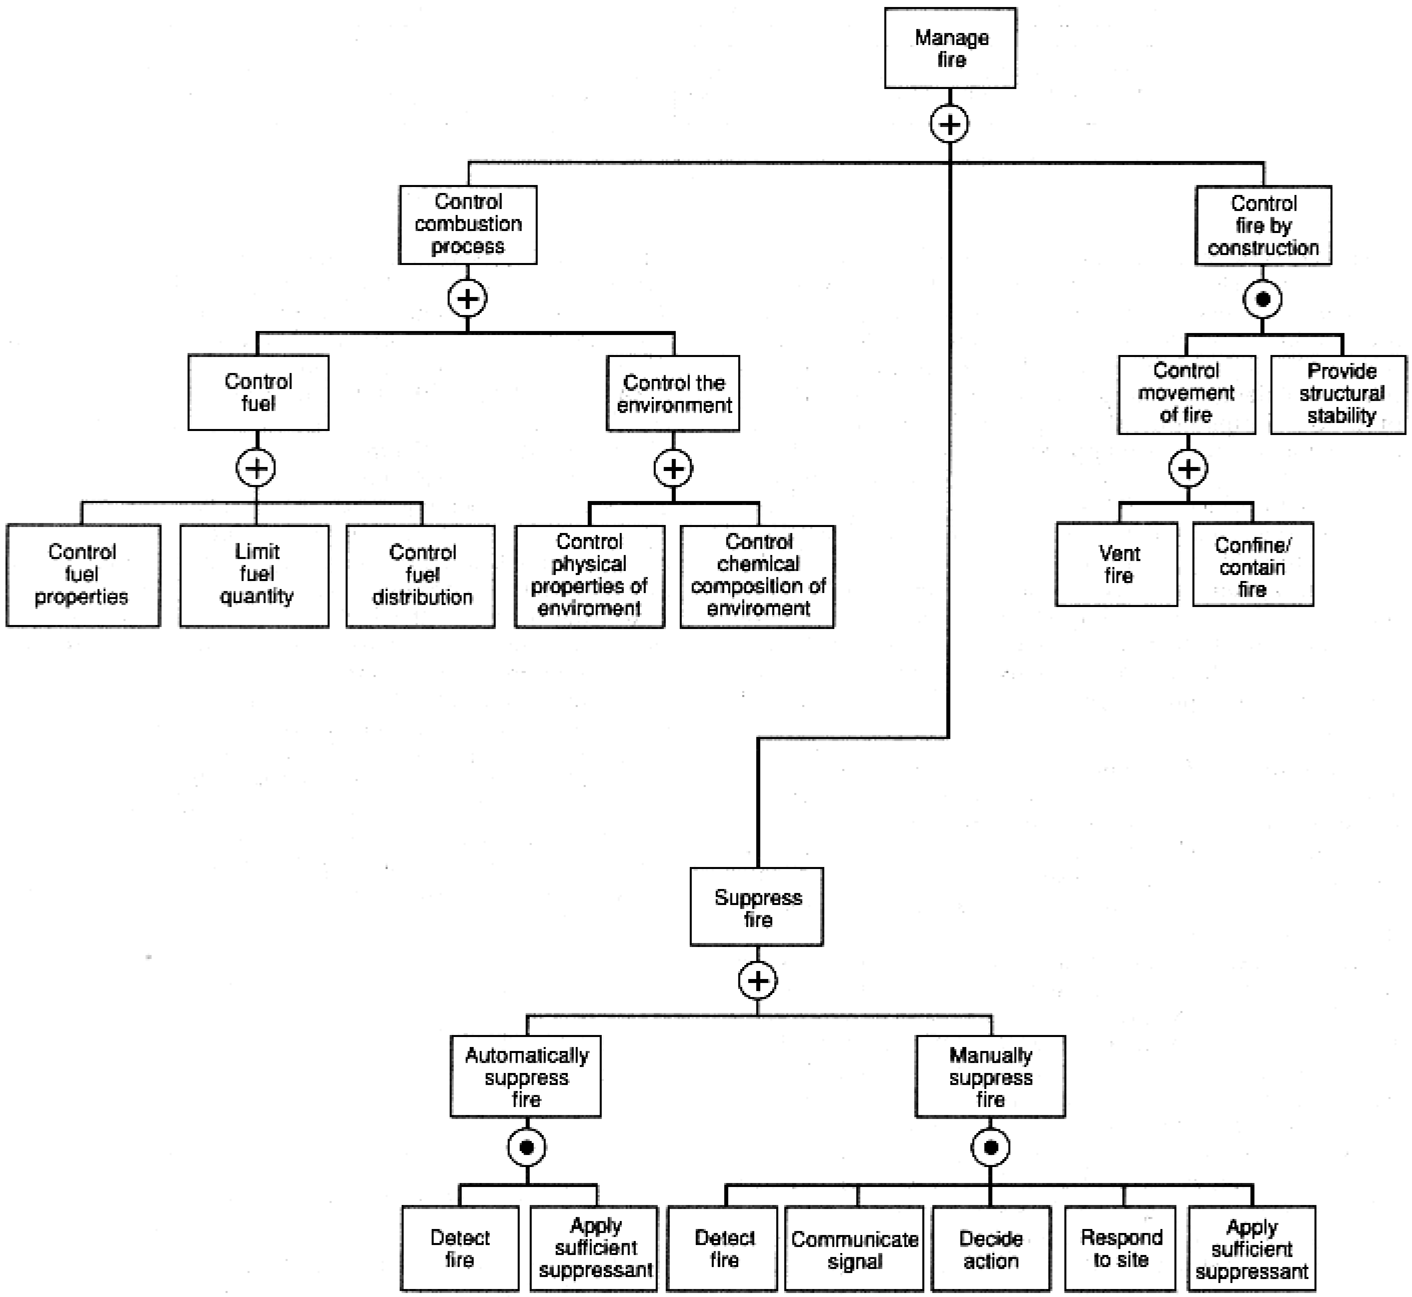

Figure 3-3.1 Manage fire branch of Fire Safety Concepts Tree.

3-3.2 Manage Exposed.

MANAGE EXPOSED means to coordinate measures involving any or all of the items specified in the fire safety objectives, e.g., people, property, activities, or other valuable considerations. The MANAGE EXPOSED branch is achieved by either limiting the number of individuals and amount of property that are exposed or safeguarding all persons and property subject to exposure [*see Figure 3-3.2(a)*]. In the case of property or immobile persons, such as nonambulatory hospital patients, the exposed is safeguarded most often by defending the occupied space from fire exposure. “Hardening against fire” is another term for the strategy of making the exposed resistant to the effects of fire. For more mobile occupants, the most common strategy for safeguarding the exposed is to relocate the exposed while protecting the route for the duration of transit.

The transfer symbol labeled “entry point” in the key to the Fire Safety Concepts Tree is shown in Figure 3-3.2(b).

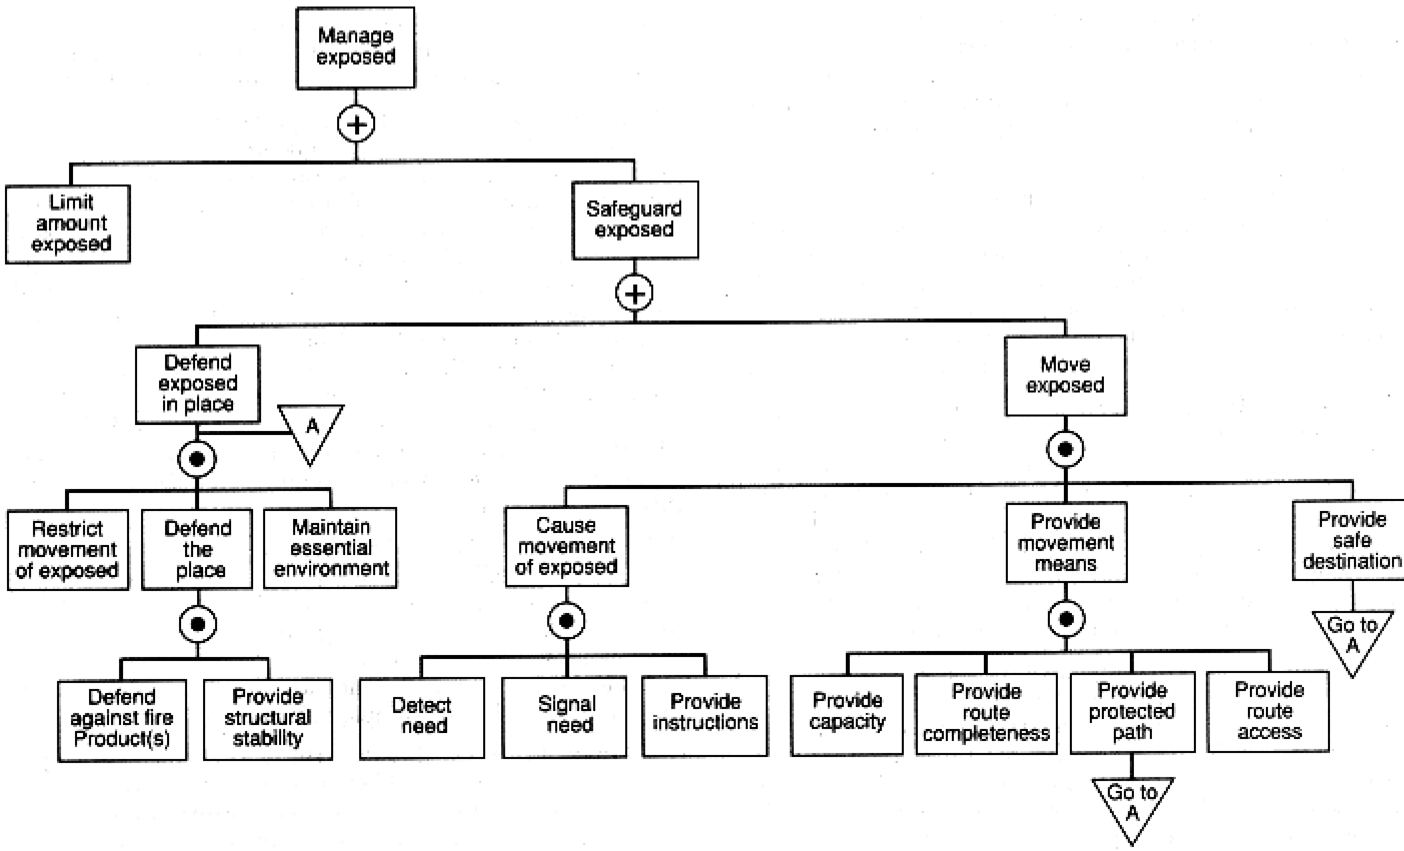

Figure 3-3.2(a) Manage exposed branch of Fire Safety Concepts Tree.

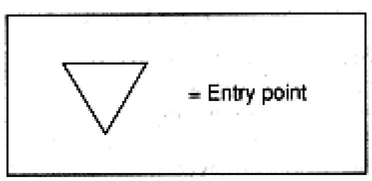

Figure 3-3.2(b) Transfer symbol.

This transfer symbol indicates where portions of the tree are repeated. In Figure 3-3.2(a), the portion of the tree under the element DEFEND EXPOSED IN PLACE is repeated under the elements PROVIDE SAFE DESTINATION and PROVIDE PROTECTED PATH.

Chapter 4 Applications

4-1 General.

The Fire Safety Concepts Tree is a general qualitative guide to fire safety. It is a flexible tool that can be used in a number of different ways.

4-2 Communications.

Perhaps the most important use of the tree is for communication with architects and other professionals involved in building design and management. Codes and standards are not intended to be tutorial; they presume a significant level of comprehension of the principles of fire protection engineering. The Fire Safety Concepts Tree is a simple visual representation of the total concept of fire safety incorporated in codes and standards. It can be used as a means of communication between fire safety specialists and others to help identify the role of specific requirements. The tree can be considered as a first level of education in fire protection engineering, i.e., as an introduction to the full breadth of the subject.

4-3 Code Equivalency.

A more specific application of the Fire Safety Concepts Tree is its use as an adjunct to building codes. An important feature in building codes is the provision for “equivalencies.” Equivalency clauses state that alternatives to specified code requirements are acceptable if they provide a degree of fire safety equivalent to that of the code. The Fire Safety Concepts Tree provides a guide to the determination of equivalency. OR gates indicate where more than one means of accomplishing a strategy in the tree is possible. A decrease in the quality or quantity of one input to an OR gate can be balanced by an increase in another input to the same gate. However, it should be emphasized that this application is subjective. Comparative values of tradeoffs usually are determined by experienced judgment. The importance of the tree is that it provides guidance in which concepts to assess.

4-4 Building Management.

The Fire Safety Concepts Tree can be used to assess fire safety in an existing building. Inputs to AND gates in the tree comprise a checklist of required components that should be maintained in order to accomplish their respective strategies. Thus, in a structure for which particular strategies are identified as necessary to achieve fire safety objectives, appraisal of inputs to those strategies constitutes a fire safety assessment of the structure.

4-5 Building Design.

Ideally, the Fire Safety Concepts Tree is a design tool. Once basic fire safety objectives for a building are identified, the designer can analyze the alternative tree paths through which these objectives can be met. Examination of the OR gates in the tree indicates where alternative strategies exist and where redundancies can be built into the design to improve reliability. The tree then can be used to communicate the fire safety concepts of the design to management and code officials.

4-6 Research.

Another application of the Fire Safety Concepts Tree is as a research tool. The tree can be used to classify fire safety strategies as a guide for research activities. In one case, an investigation to determine alternatives to federal fire safety requirements for housing projects began with an analysis of residential fire safety using the Fire Safety Concepts Tree. In another research project, qualitative techniques of fault tree analysis were applied to the Fire Safety Concepts Tree to produce an exhaustive set of fire safety strategies to compare the effectiveness of specific fire safety variables. A similar approach was used to link fire safety objectives with specific features in a study of hospital fire safety in the United Kingdom.

4-7 Other Applications.

The applications described above represent only some of the more common uses of the Fire Safety Concepts Tree. In addition, the tree has been used or proposed for use as a guide to code organization, standards organization, information retrieval, curriculum development, marketing, indexing, and fire investigation. A major U.S. corporation adapted the Fire Safety Concepts Tree as a table of contents to their “Fire Safety Practices,” and the U.S. Department of State developed an approach based on the Fire Safety Concepts Tree to evaluate their foreign property. Among the more than 10,000 trees that have been “planted” (i.e., distributed) by NFPA, there are hundreds of different applications likely, limited in scope only by the imagination of the user.

Chapter 5 Limitations

5-1 General.

The NFPA Fire Safety Concepts Tree has met with some success as a comprehensive qualitative guide to fire safety. It allows identification of alternatives and combinations of fire safety as well as the identification of redundancies and gaps. However, there are significant limitations to its application.

5-2 Interaction of Concepts.

The tree structure does not adequately consider multiple interactions of fire safety concepts, i.e., concepts that are inputs to more than one strategy. This is most apparent in regard to the combined contribution of detection systems to the management of fire and to the management of the exposed. The logic tree approach does not portray lateral influences of fire safety components, i.e., concepts at the same level in the tree that affect each other.

5-3 Time Factors.

One of the major limitations of fire safety trees is the lack of chronological sequences. Fire safety depends on the elimination of combustion products and people coexisting in the same place at the same time. That is, avoidance of fire casualties depends on the avoidance of exposure in both space and time. One can either endure a fire or escape it. To escape a fire means to move faster than the fire and its products of combustion. The temporal aspect of fire development is not represented in the Fire Safety Concepts Tree.

The Fire Safety Concepts Tree does not indicate where inputs to AND gates need to be sequential. For example, the basic elements that are inputs to MANUALLY SUPPRESS FIRE have an implied order in which they should occur. No distinction is made to identify AND gates where this implicit order exists.

5-4 Objectives.

The NFPA Fire Safety Concepts Tree is limited in its ability to deal simultaneously with multiple objectives. There can be ten or more distinct fire safety objectives for buildings, each requiring a different course of action. Although a series of trees can be used to evaluate the success of achieving each objective individually, there is no convenient way to deal with multiple objectives collectively.

5-5 Quantification.

Ideally, the Fire Safety Concepts Tree could be quantified like a fault tree. However, assigning probabilities or other numerical measures to fire safety tree “concepts” is much more difficult than identifying probabilities for fault tree “events.” It is unlikely that the NFPA tree in its present form will be satisfactorily quantified in the near future.

Chapter 6 Use of the Tree

6-1 General.

There are many methods for using the Fire Safety Concepts Tree. These range from cursory visual examination, through systematic consideration of each concept, to adaption for quantitative analysis. This section illustrates one systematic approach to qualitative assessment of fire safety. The references in Appendix A describe other approaches to using the tree.

6-2 A Procedure.

The following procedure is a step-by-step approach for one way in which the Fire Safety Concepts Tree can be used to evaluate fire safety. It should not be inferred that this is the only way the tree can be used. As indicated previously, there is a wide variety of applications and methods for using the Fire Safety Concepts Tree.

6-2.1 Step One.

Define the objectives. This is the most important step in making any decision. It is difficult to find the best solution to the wrong problem. This question should be asked: “What do I want the fire safety system to do?” (e.g., provide a high level of assurance that operations will not be interrupted; meet the intention of the code; minimize the possibility of a multiple fatality fire; etc.).

6-2.2 Step Two.

Assess each of the lowest elements in the tree, i.e., all elements that do not have any inputs. For the particular structure in question, estimate the extent to which each basic element is present as a fire safety feature. For example, consider a simple scale made up of four categories: nonexistent, below standard, standard, and above standard, where “standard” indicates an appropriate level of consensus. Next, label each of the lowest elements according to its applicable category. Evaluation should include consideration of the reliability of fire safety systems to perform as designed.

6-2.3 Step Three.

Where the lowest level elements are inputs to an OR gate, the value of the output will be at least as high as the highest valued input. For example, if compliance with the strategy

ELIMINATE HEAT-ENERGY SOURCE(S) is only partial, it might be evaluated as "below standard." Similarly, if the only heat-energy source is electricity and the installation is in accordance with NFPA 70, *National Electrical Code*®, CONTROL RATE OF HEAT-ENERGY RELEASE could qualify as "standard." Therefore, CONTROL HEAT-ENERGY SOURCE(S) as the output of an OR gate would be rated as at least "standard."

6-2.4 Step Four.

Where the lowest level elements are inputs to an AND gate, the quality of the output is limited to that of the least valued input. For example, consider an automatic sprinkler system with appropriately temperature-rated sprinklers spaced according to NFPA 13, *Standard for the Installation of Sprinkler Systems*. The strategy DETECT FIRE then could be considered "standard." If, however, the water supply to the sprinkler system is inadequate, APPLY SUFFICIENT SUPPRESSANT would be considered "below standard" and, therefore, AUTOMATICALLY SUPPRESS FIRE as an output of an AND gate also would be considered "below standard."

Thus, the AND gate represents a situation where the chain is only as strong as its weakest link. An OR gate, on the other hand, is analogous to a pair of pants held up by both belt and suspenders. The pants will not fall down if either one breaks.

6-2.5 Step Five.

Proceed "up" the tree in this manner, qualifying each output on the basis of the quality of the inputs and the logic gate that connects them. When each element has been evaluated, the entire tree can be examined to determine where improvements should be made to meet fire safety objectives. Alternatively, in the design stage, move down the tree, making certain that strategies are present that will yield the desired objectives.

Evaluation should include reliability assessment, such as examining the effect of system failures on achievement of objectives. For example, what happens to the various outputs if the alarm system fails, i.e., SIGNAL NEED is rated "nonexistent?"

6-3 Example.

The use of the Fire Safety Concepts Tree in this manner is illustrated by examining fire prevention in a hypothetical computer facility. That is, consideration is given only to the PREVENT FIRE IGNITION branch of the tree, demonstrating how a partial tree can be used for evaluation of a particular strategy.

6-3.1 Objectives.

The first step is to identify the objectives. The general goal is to provide life safety, property protection, and operational continuity through prevention of the occurrence of fire. More specifically, in this example, the Fire Safety Concepts Tree is used to identify a "standard" level of fire prevention for a data processing center and to identify ways to raise the level of fire prevention in the facility to "above standard." Concern for the reliability of the fire prevention design also is addressed. In other words, the identified fire safety objectives are those implicit in national codes and standards, and the most effective ways to exceed this identified level of fire prevention are sought.

6-3.2 Heat-Energy Sources.

On the left side of the PREVENT FIRE IGNITION branch, there are two basic strategies or lower elements dealing with ignition sources. The first strategy is ELIMINATE HEAT-ENERGY SOURCE(S). In a computer facility, it is standard practice to prohibit heating appliances, smoking, and any other open flame-type of ignition source. Provisions should include a security program with adequate attention to the potential for arson. If these features are satisfactorily in place, this strategy can be assessed as “standard.”

To improve on this level of assessment necessitates elimination of every potential ignition source including electricity. It is, of course, not feasible to eliminate completely the possibility of electrical ignition sources in a computer facility where electrically powered equipment is the nature of the occupancy. It is, however, possible to reduce the likelihood of an ignition by controlling the use of electricity. One way to do this is to conform to NFPA 70, *National Electrical Code*, Article 645, “Electronic Computer/Data Processing Equipment.” If these measures are taken, the strategy CONTROL RATE OF HEAT-ENERGY RELEASE can be considered as “standard.” It would be technically possible, though perhaps not practical, to improve the value of this element by using an intrinsically safe electrical system such as described in ANSI/UL 913, *Intrinsically Safe Apparatus and Associated Apparatus for Use in Class I, II, and III, Division 1 Hazardous Locations* (an intrinsically safe electrical system is one that does not release sufficient energy to ignite the combustibles in the environment).

6-3.3 Fuel.

Consider the CONTROL FUEL branch of PREVENT FIRE IGNITION. Common combustibles in computer facilities include paper, plastic insulation on wiring, certain components or parts of equipment, and plastic media such as tape and disks. Section 4-1 of NFPA 75, *Standard for the Protection of Electronic Computer/Data Processing Equipment*, identifies materials and equipment that may be permitted in a computer room. Compliance with NFPA 75 can be considered as a “standard” level for the strategy ELIMINATE FUEL(S).

Parts of Chapter 5 of NFPA 75 address the limits of flame spread and flash point for materials used in computer equipment. Compliance with these requirements can be construed as a “standard” level of the strategy CONTROL FUEL PROPERTIES.

Avoidance of flammable gases and oxygen-enriched atmospheres can be considered as “standard” for CONTROL THE ENVIRONMENT, although these ordinarily are not concerns in a computer facility. An “above standard” strategy is a habitable atmosphere that does not support combustion, as suggested for spacecraft and similar occupancies.

6-3.4 Source-Fuel Interactions.

Control of heat transfer between ignition sources and combustibles is not a common strategy in computer facilities. It is very difficult to isolate combustible media and components from the electrical power without significant alteration of construction or procedures. For example, the electrical insulating properties of polylvinylchloride make it a most efficient material to have in contact with electrical conductors, even though it is combustible. Thus, all of the basic strategies under the CONTROL SOURCE-FUEL INTERACTIONS branch could be classified as “nonexistent.” Note that, even though certain valuable media are sometimes stored in a fire-resistive container, this is primarily a strategy for managing the exposed, which is not likely to contribute significantly to preventing ignition.

6-3.5 Results.

The results of this process are shown in Figure 6-3.5. Now that a qualitative assessment of each lowest element in the PREVENT FIRE IGNITION branch has been made, it is possible to follow the procedures of steps 3 and 4 to evaluate the results. Input of a “standard” element (in this case, there are two) to CONTROL HEAT-ENERGY SOURCE(S) indicates that the output element also is “standard.” On the other side, “standard” inputs also indicate that CONTROL FUEL is “standard.” With only “nonexistent” elements as inputs, CONTROL SOURCE-FUEL INTERACTIONS is “nonexistent.” Then, the final OR gate leading to PREVENT FIRE IGNITION has two “standard” inputs so the output is “standard” (only one “standard” input is needed to be considered “standard,” since it is an OR gate).

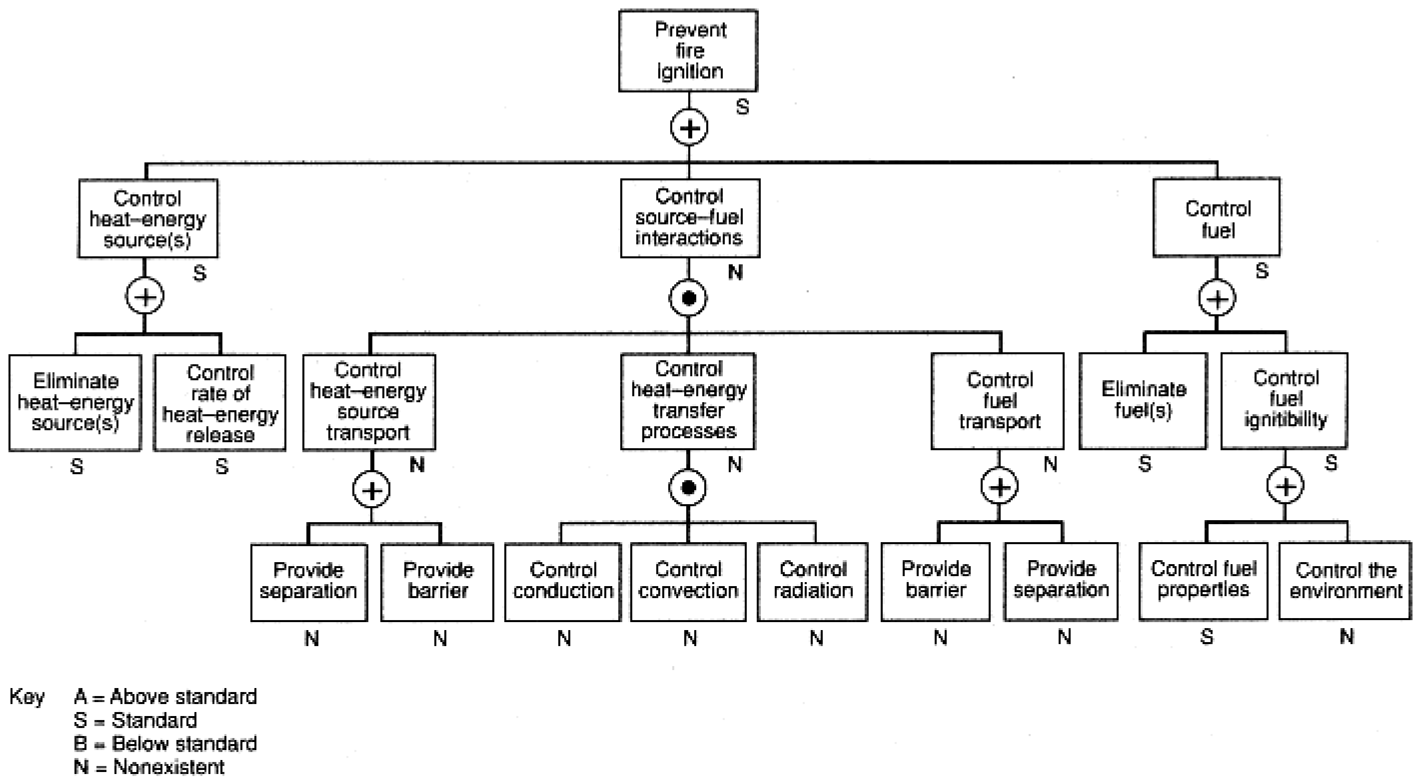

Figure 6-3.5 Fire prevention in a computer facility.

The results shown on the diagram can lead to several conclusions:

(a) Prevention of fire in the computer facility meets a level arbitrarily identified as “standard,” and reliability is provided by redundant (duplicate) “standard” inputs to the OR gate that yield PREVENT FIRE IGNITION.

(b) A “standard” level of CONTROL SOURCE-FUEL INTERACTIONS provides a third degree of redundancy.

(c) Ways exist to improve certain elements to “above standard,” but all the current “standard” elements need to be improved to provide consistent reliability.

This same process could be applied to other branches or to the entire Fire Safety Concepts Tree. However, it is important to keep in mind that this approach is not a general solution to any fire problem. The Fire Safety Concepts Tree provides support for a specific decision. It is a tool for examining a particular situation to discover possible alternatives, but it does not condone such alternatives automatically. Each situation is unique, and the tree can be used to provide a structure for an analysis based on accepted principles of fire protection engineering.

Chapter 7 Additional Information

7-1 General.

In order to provide an understanding of each concept in the tree, additional information was appended to the Fire Safety Concepts Tree published in 1980. This information appears in three parts: a description of elements in the tree, a glossary of terms, and an administrative action guide.

7-2 Description of Elements in the Fire Safety Concepts Tree.

Descriptions of tree elements or concepts have been provided to help convey the intent of the Systems Concepts Committee. These descriptions are intended as a guide to the thinking that framed the tree and should not restrict alternative interpretation of the concepts if such alternative descriptions are based on appropriate fire protection engineering principles. For example, it might be appropriate to a specific application of the tree to define PREVENT FIRE IGNITION in terms of a flame height or a rate of heat release. At the same time, this is the only published source of definitions of these concepts and is, therefore, a step toward better communication through common understanding.

The Fire Safety Concepts Tree
(A Qualitative Guide to Fire Safety Strategies)

The following set of descriptions is presented to offer the Systems Concepts Committee's best guidance on the application of the Fire Safety Concepts Tree. It is not intended to force a narrow or singular interpretation on those who find sound value in a broader or otherwise more relevant application of the elements in the Tree. This system of definitions is consistent with the thinking that the committee applied in naming the elements and terms used.

It will be noted that some of the lower level Tree elements are not defined here, but the essential terms used therein are defined in the Glossary.

Description of Elements in the Fire Safety Concepts Tree

Accomplish by Administrative Action means to eliminate, *limit, control,* or accomplish other actions referenced in the Fire Safety Concepts Tree.

Apply Sufficient Suppressant (*automatically*) means to *automatically* perform *suppressive* action in response to *automatic* detection.

Apply Sufficient Suppressant (*to manually suppress)* means to *manually* perform *suppressive* action given response to the proper site.

Automatically Suppress Fire means to *automatically* perform actions on a *fire* process in order to *limit* the growth of or to extinguish the *fire*.

Cause Movement of Exposed means to initiate movement of the *exposed* to and along a safe path.

Communicate Signal means to transmit knowledge of a detected *fire* via human or *automatic* or a combination of human and *automatic* means to a responsible recipient of the information.

Confine/Contain Fire means to provide building construction features and built-in equipment in order to *limit* the *fire* or *fire products,* or both, to within the *barriers* surrounding the area where the *fire* originated.

Control Combustion Process means to *control* the inherent *fire* behavior.

Control Fire by Construction means to *control* the growth of the *fire* and the movement of *fire products* by performing actions involving building construction features and built-in equipment without intentionally acting upon the inherent *fire* process.

Control Fuel (Manage Fire) means to influence the combustion process by *pre-ignition control* of the inherent or situational characteristics of the *fuel*.

Control Fuel (Prevent Fire Ignition) means to *limit* the characteristics and uses of *fuel(s)*.

Control Fuel Distribution means to *control* the arrangement of the *fuel* within its environment.

Control Fuel Ignitibility means to *control* the ease of *ignition* of *fuels* that are present.

Control Fuel Properties means to *control* the inherent properties of the *fuel*.

Control Fuel Transport means to prevent the *fuel* from moving to a location where *ignition* can result.

Control Heat-Energy Sources means to *limit* the characteristics and uses of *heat-energy sources*.

Control Heat-Energy Source Transport means to prevent the *heat-energy source* from moving to a location where an *ignition* can result.

Control Heat-Energy Transfer Processes means to alter the rate(s) at which the *fuel(s)* receives heat by *control* of the *heat transfer* mechanisms, such that *ignition* cannot result.

Control Movement of Fire means to *control* the movement of *fire* or *fire products*, or both, by providing and (where a normal functional necessity) activating building construction features and built-in equipment.

Control Rate of Heat-Energy Release means to *control* the rate of thermal energy release of existing *heat-energy sources*.

Control Source-Fuel Interactions means to *control* the relationships of *source* and *fuel* so as to *limit* the *heat* communicated from the *source* to the *fuel* in order that *fuel* temperature remains below that required for *ignition*.

Control the Environment means *control* of the inherent or situational characteristics of the environment.

Decide Action means to determine a proper reaction given the communication of the existence of a *fire*.

Defend Against Fire Products means to *safeguard* the *exposed* using measures that prevent the presence of, or *control* the impact of, *fire products* at the *place*.

Defend Exposed in Place means to *defend* the *exposed* in the *place(s)* where they were located at the time of *ignition*.

Defend the Place (*of the exposed*) means to *defend* the *place* occupied by the *exposed*.

Detect Fire (to *manually suppress fire*) means to identify the presence of *fire* either by human observation or by *automatic* mechanism(s).

Detect Fire (*automatically*) means to identify the presence of *fire* without reliance on human observation.

Eliminate Fuel(s) means to eliminate all *fuel*.

Eliminate Heat-Energy Source(s) means to eliminate all places, materials, or objects at which thermal energy can originate or from which thermal energy can be transferred.

Limit Amount Exposed means to *limit* the maximum amount of *exposed*.

Limit Fuel Quantity means to *limit* the amount of *fuel* that potentially can become involved in *fire*.

Maintain Essential Environment means to ensure the sufficient prevention, removal, dissipation, or neutralization of adverse conditions, other than *fire* or *fire products*, or both, as experienced by the *exposed* within the *place*.

Manage Exposed means to coordinate measures directly involving the *exposed*.

Manage Fire means to coordinate measures for *control* of the *fire* or *fire products*, or both.

Manage Fire Impact means to coordinate measures to *limit* any harm directly or indirectly resulting from *fire* or *fire products*, or both.

Manually Suppress Fire means to *manually* perform actions on a *fire* process in order to *limit* the growth of or to extinguish the *fire*.

Move Exposed means to safely relocate the *exposed* to safety.

Prevent Fire Ignition means to prevent initiation of destructive and *uncontrolled burning*.

Provide Movement Means means to provide the facilities necessary for a safe path through which the *exposed* can be relocated.

Provide Safe Destination (for the *exposed*) means to provide a safe location to receive the *exposed*.

Provide Separation (*fuel* transport) means to provide and maintain a *separation* between the *fuel* and the *source* by measures acting only upon the *fuel*.

Provide Separation (*source* transport) means to provide and maintain a *separation* between the *source* and the *fuel* by measures acting only upon the *source*.

Provide Structural Stability means to maintain the effectiveness of building construction features and built-in equipment.

Respond to Site means to respond to the proper site from which to *manually* initiate suppressive action.

Restrict Movement of Exposed means to prevent movement of the *exposed* beyond the boundaries of the *defended place*.

Safeguard Exposed means to act upon the *exposed* and the immediate surroundings of the *exposed* to *protect* the *exposed* against *fire impacts*.

Suppress Fire means to perform actions on a *fire* process in order to *limit* the growth of or to extinguish the *fire*.

Vent Fire means to provide building construction features and built-in equipment that can *control fire* by removal of the *fire* or *fire products*, or both.

7-3 Glossary.

Italicized terms in the descriptions of Fire Safety Concepts Tree elements are defined in the glossary. As in the case of the descriptions, these definitions are subject to interpretation, but to a lesser degree.

Automatic (automatically) means occurring without need of human action.

Barrier means a material obstacle (as opposed to *separation*).

Burning means continuous combustion including smoldering.

Capacity (of a *place* or location) means the maximum number or amount of *exposed* that a *place* or location can accommodate.

Capacity (of a route or path) means the maximum flow rate of *exposed* that a route or path can handle.

Conduction means a transfer of heat from a region of higher temperature through a material by a molecular mechanism not involving bulk motion to a region of lower temperature.

Control means to *limit*, affect, or alter the referenced factor(s).

Convection means transfer of heat by bulk motion of a fluid induced by mechanical devices or by gravitational effects due to nonuniform temperatures in the fluid.

Defend, as used in the Tree, means to *safeguard* the *exposed* using only those measures that prevent or *control fire impact* on the location of the *exposed*, without acting on the *fire* itself (see *safeguard*).

Exposed means any or all of the items specified in the fire safety objectives (e.g., persons, pieces of property, activities, or other valuable considerations).

Fire means any instance of destructive and *uncontrolled burning*, including explosions.

Fire Impact is a term used to denote the direct or indirect results of *fire*.

Fire Products, as used in the Tree, means flame, heat, smoke, and gas.

Fire Safety means the measures taken to *protect* the *exposed* so as to satisfy a specified objective.

Fuel means a substance that yields heat through combustion.

Heat-Energy is a term used to indicate that only the thermal forms of energy are of concern.

Heat-Energy Source (*source*) means any *place*, material, or object at which *heat-energy* can originate or from which *heat-energy* can be transferred.

Heat-Energy Transfer Process means the exchange of thermal energy from the *source* to the *fuel* by the mechanisms of *conduction*, *convection*, or *radiation*, or all three.

Ignitibility means the ease with which *fuel* undergoes *ignition*.

Ignition means the momentary event when *fire* first occurs.

Immobilize means to fix in place, so that no movement can occur.

Limit means to prescribe a minimum or maximum size, quantity, number, mass, extent or other dimension.

Manage means to coordinate broadly-ranging available methods toward accomplishment of objectives.

Manual means employing human action.

Place means an area within designated boundaries containing *exposed*.

Protect means the use of any or all available measures to *limit fire impact*.

Radiation means the combined process of emission, transmission, and absorption of energy traveling by electromagntic wave propagation (for example, infrared radiation) between a region of higher temperature and a region of lower temperature.

Safe Destination means a *protected place* of adequate capacity.

Safeguard as used in the Tree, means to *protect* the *exposed* by using only those measures directly involving the *exposed*, without acting on the *fire* itself (see *defend*).

Separation means an intervening space (as opposed to *barrier*).

Source — See *Heat-Energy Source*.

Suppression means extinguishment or active *limitation* of *fire* growth.

Thermal Energy — See *Heat-Energy*.

Transport means the movement of either the *heat-energy source* or the *fuel*.

7-4 Administrative Action Guide (see Figure 7-4

). The Administrative Action Guide uses the logic format to show various ways to regulate or promote fire safety strategies. It is intended as a generalized guide to encourage any of the measures described in the Fire Safety Concepts Tree.

Administration Action Guide

The NFPA Fire Safety Concepts Tree is a branching chain of goal/means relationships. However, beyond the Tree, an infrastructure exists in the form of an administrative scheme or social organization that is necessary to achieve the means deemed appropriate by the Tree. Such an administrative structure is shown in Figure 7-4.

This administrative scheme could pertain to any means throughout the Tree, since it represents only a generalized conceptual scheme (entirely nontechnical) for facilitating a means to achieve goals.

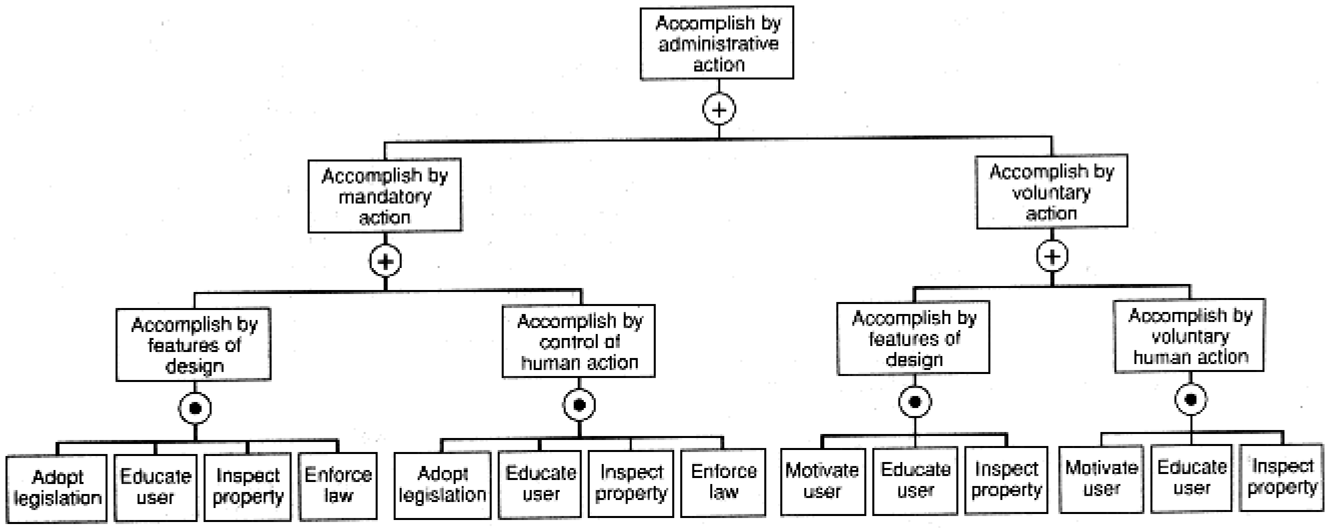

Figure 7-4 Administration action guide.

Appendix B Fault Tree Analysis

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

According to Recht (1), fault tree analysis was developed in 1962 by H.A. Watson of Bell Telephone Laboratories. The technique was subsequently made famous by the Boeing Company in its application to the Minuteman Ballistic Missile Program (2).

Fault tree analysis uses a tree-like diagram to describe and analyze an undesired or "top" event, so-called because it is located at the top of the diagram, with "branches" of the tree extending downward from it. These branches connect the events or conditions that cause the top event to occur. The relationships of these causative events are shown by connecting lines that pass through one of two basic "logic gates"   the "AND" gate and the "OR" gate. The AND gate indicates that a "fault" will occur when all the causative events happen simultaneously. If any single event in a group of events can produce the fault, then these events are inputs to an OR gate.

Fault trees are produced by identifying a specific failure and examining the system in a logical, well-organized way to determine those events that can produce the failure. Alternatively, a desirable top event can be considered. A "success tree" is based upon analysis of requirements and alternatives needed to achieve a specified goal or objective. The NFPA Fire Safety Concepts Tree is a success-type tree.

Fault tree analysis requires intimate knowledge of the system being analyzed. It is often time consuming, but if performed in a thorough manner, it is revealing. It often leads to the discovery of combinations of factors that otherwise might not have been recognized as causative of the event analyzed. The tree becomes a record of the thought process of the analyst and serves as an excellent visual aid for communication with designers and management. More detailed descriptions of fault trees and fault tree analysis are found in references 3 through 5, which follow.

Appendix C Logic Gates

This appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

The plus and dot symbols used for OR gates and AND gates in fault trees and the Fire Safety Concepts Tree are standard symbols for these logic operations used in electronic circuit diagrams and Boolean algebra. They are derived from the algebra of probabilities. The flip of a coin is an example. To calculate the probability of a head *or* a tail, the probability of a head (0.5) is added to the probability of a tail (0.5), i.e., 0.5 + 0.5 = 1. Thus, the symbol for an OR operation is a plus symbol. To calculate the probability of first showing a head *and* then a tail if the coin is flipped twice, the probabilities are multiplied, i.e., (0.5) • (0.5) = 0.25; thus, the symbol for an AND gate is a dot signifying multiplication. Some additional examples of these logic gates are illustrated below.

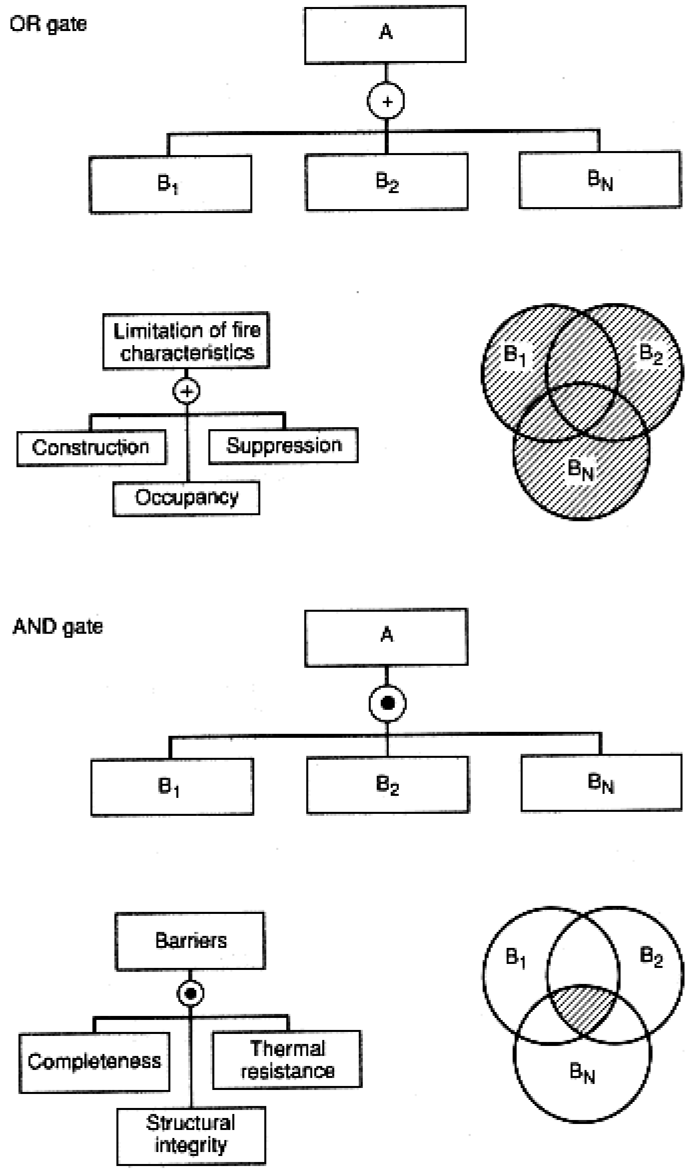

Figure C-1 Examples of logic gates.

1996 Edition

This first edition of NFPA 555, *Guide on Methods for Evaluating Potential for Room Flashover*, was prepared by the Technical Committee on Hazard and Risk of Contents and Furnishings and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 20-23, 1996, in Boston, MA. It was issued by the Standards Council on July 18, 1996, with an effective date of August 9, 1996.

This edition of NFPA 555 was approved as an American National Standard on July 26, 1996.

Origin and Development of NFPA 555

This guide is the first document prepared by the Technical Committee on Hazard and Risk of Contents and Furnishings. It was developed in recognition that life safety and property protection can be enhanced by preventing the occurrence of flashover or, at least, decreasing its probability.

Technical Committee on Hazard and Risk of Contents and Furnishings

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire hazard calculation procedures for use by other Committees in writing provisions to control the fire hazards of contents and furnishings. This Committee shall also provide guidance and recommendations to Committees in assessing the fire hazard of contents and furnishings. It shall establish classification and rating systems, request the development and standardization of appropriate fire tests, and identify and encourage necessary research as it relates to the fire hazards of contents and furnishings. It shall act in a liaison capacity between NFPA and the Committees of other organizations with respect to the hazard of contents and furnishings.

NFPA 555
Guide on Methods for
Evaluating Potential for Room Flashover

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix B. Detailed information on the references cited in brackets throughout the document can be found in B-1.2.3.

Chapter 1 Introduction

1-1 Scope.

1-1.1

This guide addresses methods for evaluating the potential for room flashover from fire involving the contents, furnishings, and the interior finish of a room. The methods addressed by this guide include prevention of ignition, installation of automatic fire suppression systems, control of ventilation factors, and limitation of the rate of heat release of individual and grouped room contents, furnishings, and interior finish.

1-1.2

The accuracy, precision, and relevance of this guide are a function of the accuracy, precision, and relevance of the data from the test methods and calculations used. The principles and concepts presented are among the most reliable available, and use of these principles and concepts can minimize the possibility of flashover but might not prevent it.

1-2 Purpose.

1-2.1

The purpose of this guide is to provide tools for those individuals or organizations attempting to implement methods to prevent the occurrence of flashover or, at least, to decrease its probability.

1-2.2

Any limitations on the availability of data, of appropriate test procedures, of adequate fire models, or of state of the art scientific knowledge places significant constraints upon the procedures described in this guide.

1-2.3

Some standard tests under controlled laboratory conditions are described. Such tests should not be deemed to establish performance levels for all situations.

1-3 Instructions for Use of This Guide.

See Figure 1-3.

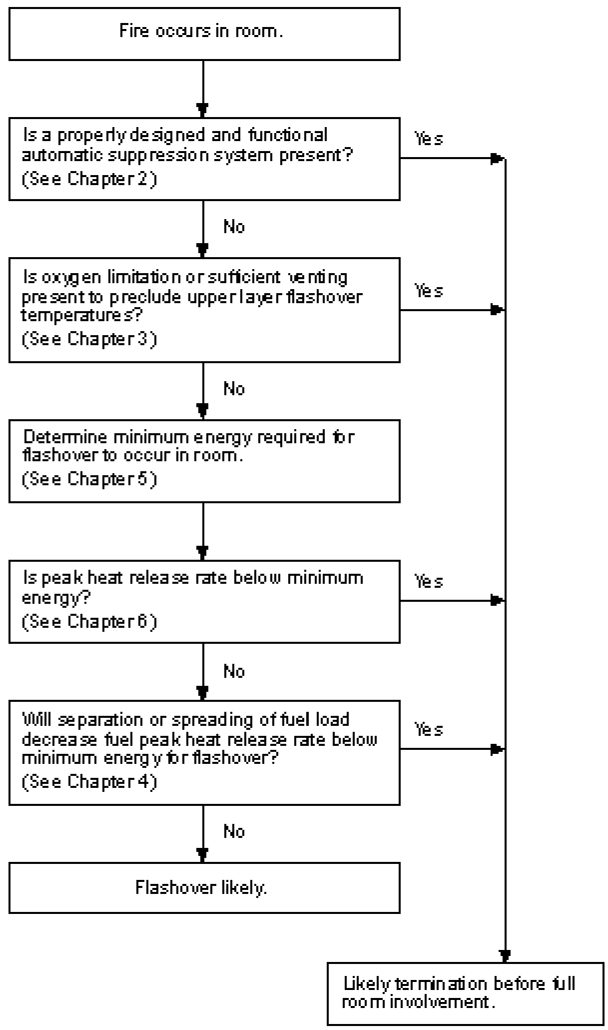

Figure 1-3 Flow chart for use of guide.

1-3.1

This guide is best used with a proper understanding of the various procedures it contains. Its core consists of five chapters that guide the user through analyses and procedures that are used to determine the likelihood of the compartment under investigation to reach flashover under fire conditions and to minimize the potential for flashover.

1-3.2

After conducting the analysis provided in each chapter, the user can make the determination of whether the potential for flashover has been decreased sufficiently or whether additional analysis is necessary. However, the user need not necessarily complete the analysis of each chapter before moving on to another chapter.

1-3.3

The first considerations in the analysis are the means of fire control, either via the existence of a properly designed and functional automatic suppression system or via techniques for smoke venting or reduction in oxygen availability. These issues are addressed in Chapter 2 and Chapter 3, respectively. A properly designed and functional system of either kind is likely to be a satisfactory means of reduction of potential for flashover.

1-3.4

If either of the following conditions exists, the user should conduct the analysis specified in Chapters 4 through 6:

(a) There is neither a properly designed and functional automatic suppression system, nor a similarly adequate method of reduction in oxygen availability; or

(b) Added precautions are desired.

1-3.5

Chapter 5 contains techniques for predicting flashover in compartments, irrespective of the contents, furnishings, or interior finishes involved. Chapter 6 indicates how the fire performance of contents, furnishings, or interior finishes can be used to assess the potential for flashover. Chapter 4 explains how the techniques in Chapter 6 can be expanded to include groups of items or products as fuel packages.

1-4 Definitions.

Contents and Furnishings. Any movable objects in a building that normally are secured or otherwise put in place for functional reasons, excluding the following:

(a) Parts of the internal structure of the building; and

(b) Any items meeting the definition of interior finish.

Flashover. A stage in the development of a contained fire in which all exposed surfaces reach ignition temperatures more or less simultaneously and fire spreads rapidly throughout the space. Flashover occurs when the surface temperatures of combustible contents rise, producing pyrolysis gases, and the room heat flux becomes sufficient to heat all such gases to their ignition temperatures. (*See Section 5-1.*)

Fuel Package. A fuel package is a grouping of one or more furnishing or contents items, or both, whose proximity is sufficiently close that the ignition of one item can be expected to cause the spread of fire to the remaining items in the fuel package. For a given group of items, there is no precise grouping that constitutes a fuel package. The purpose of the fuel package definition guidance provided in Chapter 4 is solely to facilitate the application of the methods described in Chapter 6 for estimating heat release rates.

Interior Finish. Exposed interior surfaces of buildings, excluding movable items that can be removed when occupants change. Interior finish includes interior wall and ceiling finish and interior floor finish. With respect to interior wall and ceiling finish, this means the exposed interior surfaces of buildings including, but not limited to, fixed or movable walls and partitions, columns, and ceilings. With respect to interior floor finish, this means the exposed floor surfaces of buildings including coverings that might be applied over a normal finished floor or stairs, including risers. Furnishings, which in some cases are secured in place for functional reasons, should not be considered as interior finish.

Item. A single combustible object within the compartment that is permanent or transient, movable, or fixed. An item can be a collection of combustible materials such as chairs, wastebaskets with contents, or a combustible wall or floor. A precise definition of an item is not generally possible or necessary.

Chapter 2 Automatic Suppression Systems

2-1 General.

Automatic suppression systems are the most widely used method for automatically controlling a fire. Consideration should be given to the utilization of an automatic suppression system for limiting the fire hazard potential in a room in order to reduce the probability of room flashover.

2-2 System Failure.

Although automatic suppression systems have an outstanding record of success, it is possible for such systems to fail. Failures are often due to weaknesses in the system that could have been avoided if appropriate attention had been given at the time of design, installation, or inspection. Issues pertaining to system integrity should be addressed carefully to increase the probability of successful operation of a suppression system. If a properly designed and functioning automatic suppression system is used in the design of a room, a fire that occurs in that room is likely to be controlled or terminated by the suppression system prior to full room involvement (flashover).

2-3 Hazard Protection.

Many standards and guides exist to aid a designer in the development of appropriate automatic suppression system design criteria for a wide range of occupancy types and hazards. Since the range and severity of occupancy types and fire types are rather broad, and since protection goals vary from minimal property protection to large-scale life safety, it is essential that hazards be adequately identified and evaluated and appropriate design guides be employed.

2-4 Automatic Suppression System Evaluation Considerations.

2-4.1

In those cases where a recognized design standard is not the basis for a suppression system design or where a unique or innovative suppression system approach is proposed, an evaluation of suppression system capabilities should be considered. Such an approach should include an analysis of the time to activation of the proposed suppression system compared to an evaluation of the "design fire" growth time with respect to the onset of flashover.

2-4.2

Significant factors affecting the ability of an automatic suppression system to prevent flashover include fire growth rate, quantity and arrangement of combustibles; enclosure characteristics; oxygen availability; fire detector (sprinkler) response characteristics; agent application rate (density); agent discharge characteristics, and duration of agent supply. Depending on the circumstances of the hazard and the level of protection required, some or all of the above factors might have to be evaluated to establish confidence in the ability of an automatic suppression system to reduce the probability of flashover significantly.

2-5 Design, Installation, and Maintenance.

The design, installation, and maintenance of automatic suppression systems are covered by a number of NFPA standards, including:

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*.

NFPA 13, *Standard for the Installation of Sprinkler Systems*.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*.

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*.

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*.

NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*.

Chapter 3 Oxygen Availability and Ventilation

3-1 Considerations.

Oxygen availability or ventilation parameters can play a significant role in fire growth, the combustion process, and conditions that influence flashover potential in various types of fire scenarios.

3-1.2 Typical Fire Scenarios.

Normal air contains 20.9 percent oxygen, 79.1 percent nitrogen, and traces of other gases. In the combustion process, fuel combines with oxygen in air and the size of a resulting fire can be limited by either the amount of fuel or oxygen available for the combustion process. In most common fire scenarios, it should be reasonable to assume that oxygen is supplied to the fire from the surrounding air and that sufficient ventilation or air leakage paths are present to allow a continued supply of air and oxygen. The continued availability of air allows the growth of the fire and the continued burning of contents, furnishings, or interior finishes in a compartment.

3-1.3 Tightly Closed Compartments.

In fire scenarios, where a compartment is tightly closed or lacks sufficient ventilation or air leakage paths, the available oxygen is consumed in the combustion process until the oxygen volume concentration is reduced to between 8 percent and 12 percent. At these reduced oxygen levels, the flaming combustion of contents, furnishings, or interior finishes in a compartment can cease and the remaining oxygen will not be consumed. These conditions can prevent the fire from growing to a size sufficient to produce flashover conditions. However, sudden introduction of air (and oxygen) can result in a highly dangerous, rapid combustion of products of incomplete combustion called a backdraft. This might occur when doors are opened or windows are broken in the process of manual fire fighting.

3-1.4 Vented Scenarios.

In some fire scenarios, there is an abundance of ventilation in the form of a smoke/heat venting means or other exhaust mechanism that relieves sufficient heat and gases from a compartment, precluding the temperature rise conditions necessary to induce flashover [Hinkley, 1988].

3-2 Oxygen Consumption.

3-2.1 Principle of Oxygen Consumption.

It has been determined that the heat released per unit mass of oxygen consumed is nearly constant for most organic fuels. This value can be useful in air-limited fire scenarios to determine if the fire duration or maximum heat release rate predicted to cause flashover can be achieved. The value of heat released per unit mass oxygen consumed is 13.1 kJ/g (on an oxygen basis). The value of heat released per unit volume of oxygen consumed, $\Delta h_c \times \rho_{O_2}$, is 18.7 x 10^3 kJ/m^3 (on an oxygen basis), at 0°C. The corresponding values on an air basis are 3 kJ/g and 3.9 x 10^3 kJ/m^3 (also at 0°C).

3-2.2 Tightly Closed Compartments.

3-2.2.1 In tightly closed compartments, flashover potential exists only if the heat released by the fire can exceed the heat release rate necessary for flashover using the oxygen supply available in the compartment.

3-2.2.2 The duration of burning in a tightly closed compartment can be estimated for steady fires and for unsteady fires in which the heat release rate grows proportionally to the square of time (t-square fires). Estimations are based on the volume of the space and the heat release rate as shown in equation 3.1 for steady fires and equation 3.2 for unsteady fires.

Steady Fires:

$$t = \frac{V_{O_2}}{\dot{Q}}\left(\Delta h_c \times \rho_{O_2}\right) \qquad (3.1)$$

Unsteady (t-square) Fires:

$$t = \left(\frac{3V_{O_2}}{\alpha}\left(\Delta h_c \times \rho_{O_2}\right)\right)^{1/3} \qquad (3.2)$$

where:

t = Time (sec).

V_{O_2} = Volume of oxygen available to be consumed in combustion process [*see* 3-2.2.3] (m^3).

$\Delta h_c \times \rho_{O_2}$ = Heat release per unit mass of oxygen consumed (kJ/m^3).

$\dot{Q}$ = Heat release rate from steady fire (kW).

α = A constant governing the speed of fire growth (kJ/sec^3).

Values for typical fire growths are as follows:

Slow	2.93×10^{-3} kJ/sec^3	(0.00278 Btu/sec^3)
Medium	11.72×10^{-3} kJ/sec^3	(0.01111 Btu/sec^3)
Fast	46.88×10^{-3} kJ/sec^3	(0.04444 Btu/sec^3)

The maximum heat release rate for the unsteady (t-square) fire can be estimated as follows in equation 3.3:

$$Q = \alpha t^2 \qquad (3.3)$$

where t is the time, as determined from equation 3.2. The equations consider the energy associated with the mass (or volume) of oxygen consumed in the compartment and the energy is divided by the anticipated heat release rate of the fire.

3-2.2.3 It can be estimated that the maximum volume of oxygen available to be consumed in the combustion process is approximately half of the total available oxygen, since flaming combustion usually is not sustained once oxygen concentrations fall to the range of 8 percent to 12 percent.

3-2.3 Temperature Rise in Compartment.

3-2.3.1 With the times of fire duration determined from equations 3.1 and 3.2, equation 3.4, based on the compartment volume (containing air as an ideal gas at constant pressure with constant specific heat), can be used to estimate the temperature rise in the compartment and to determine if temperature conditions are sufficient for flashover [Milke & Mowrer, 1993].

$$\Delta T = T_o \left[\exp\left(Q_n / Q_o\right) - 1\right] \qquad (3.4)$$

3-2.3.2 In equation 3.4, Q_n is the net total heat released, which can be determined from equation 3.5 or 3.6, depending on the type of fire, and Q_o is the total ambient energy of air in the compartment, calculated using equation 3.7.

$$Q_n = \left(1 - X_L\right)\dot{Q}\left(\Delta t\right) \quad \text{(Steady fires)} \qquad (3.5)$$

$$Q_n = \left(1 - X_L\right)\frac{\alpha t^3}{3} \quad \text{(Unsteady [t − square] fires)} \qquad (3.6)$$

$$Q_0 = \rho_0 \; c_p T_0 \; V \qquad (3.7)$$

3-2.3.3 Description of Terms.

X_L = Fraction of heat loss to compartment boundaries (typical range, 0.6 to 0.95).

$\dot{Q}$ = Heat release rate of the fire (kW).

α = A constant governing the speed of fire growth (kJ/sec^3).

ΔT = Time period (sec).

ρ_0 = Density of air (kg/m^3).

c_p = Specific heat of air [kJ/(kg K)].

T_0 = Initial air temperature (K).

V = Volume of air in compartment (m^3).

3-2.4*

Other than the method of analysis outlined using equations 3.1 through 3.7, there are computer-based models that can evaluate the oxygen depletion, ventilation, and heat transfer effects that impact the flashover potential in tightly closed compartments.

3-3 Venting and Exhaust of Hot Smoke Layer.

3-3.1

Smoke produced from a flaming fire in a space is assumed to be buoyant, rising in a plume above the fire and striking the ceiling or stratifying due to temperature inversion. The space can be expected to begin to fill with smoke, with the smoke layer interface descending. The descent rate of the smoke layer interface depends on the rate at which smoke is supplied to the smoke layer from the plume. This assumes a two-zone model in which there is a distinct interface between the bottom of the smoke layer and the ambient air. For engineering purposes, the smoke supply rate from the plume can be estimated to be the air entrainment rate into the plume below the smoke layer interface.

3-3.2

The heat that is convected upward into the space or compartment results in an increase in temperature in the smoke layer in the space. The provision of vents or mechanical means of exhaust can serve to remove the hot gases from the rising fire plume, which increases the amount of air entrainment and promotes a lower smoke layer temperature. With appropriate consideration given to the amount of venting or exhaust and the expected fire size, the compartment smoke layer gas temperatures can be limited below the 600°C threshold indicator for flashover. Additional guidance and calculation methods can be found in NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, and NFPA 204M, *Guide for Smoke and Heat Venting*.

Chapter 4 Fuel Package Definition

4-1 Introduction.

This chapter provides methods for defining a fuel package for use in predicting heat release rates, compartment temperatures, and flashover potential.

4-2 Fuel Package.

The two aspects of fuel packages that are discussed in this chapter include the definition of a fuel package and the ignition of a fuel package due to heating by another fuel package within the compartment.

4-3 Defining Fuel Packages.

4-3.1 Guidance.

This section includes some simple definitions of fuel packages. These definitions should be used for guidance rather than as strict definitions.

4-3.1.1 Objects that are close enough in physical proximity so that continuous flame spread from item to item is possible generally are considered to be a fuel package. In such a situation, the ignition delays associated with object-to-object spread do not dominate the heat release rate history.

4-3.1.2 Items that are far enough away from other items or fuel packages that cannot be ignited by heat transfer from other items or fuel packages are not considered a part of a fuel package.

4-3.1.3 Items that are near enough to other items or fuel packages so that ignition of an item is possible due to heat transfer from other items or fuel packages are not included as part of a fuel package if any of the following apply:

(a) The ignition delay is sufficiently large that the peak heat release rate will have passed before the item reaches its peak burning rate; or

(b) The methods of Chapter 6 cannot be reasonably used if the item is included as part of a nearby fuel package; or

(c) Both 4-3.1.3(a) and (b) apply.

4-4 Methods/Tools.

4-4.1

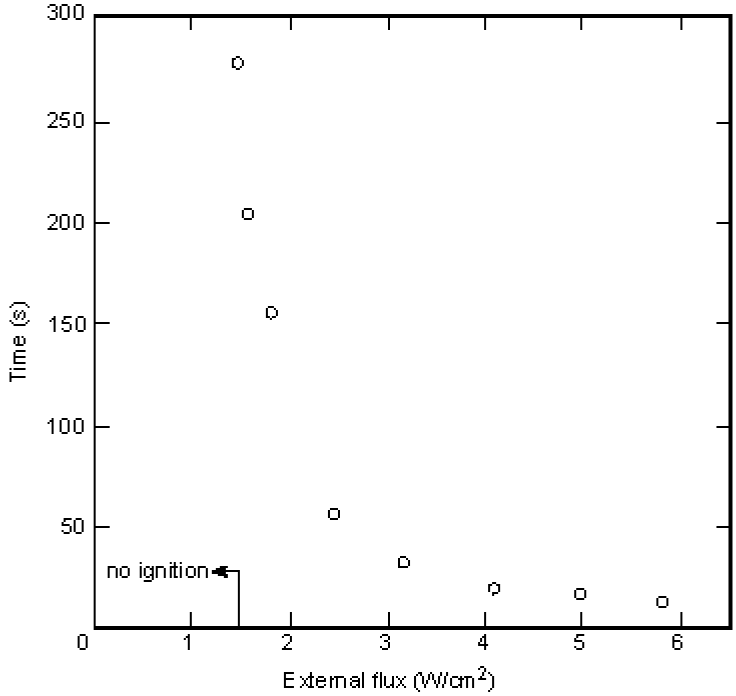
A set of analytical methods or tools is needed to provide a means for performing the evaluations embodied by the definitions in Section 4-3. In particular, methods are needed to predict the heating to ignition of materials contained within a fuel package as well as the radiative heat transfer to the material from other fuel packages or the hot gas layer. This section focuses on the radiative ignition of a material not in direct contact with a flame.

4-4.2 Radiative Ignition of Materials.

4-4.2.1* Many different models of radiative ignition of materials exist with varying levels of sophistication and usability. This section focuses on the method developed by Quintiere and Harkleroad [Quintiere & Harkleroad, 1985]. As with many of the available models, this model assumes that surface temperature can be used as a criterion for piloted ignition. This directly implies that ignition cannot occur if the radiant heat flux is less than a critical heat flux, $\dot{q}''_{o,ig}$. The ignition time, t_{ig}, varies with radiant flux above this critical flux. Based on a very simple heat transfer model, the time to ignition is determined as follows by equation 4.1:

$$t_{ig} = \left(\frac{\dot{q}''_{o,ig} / \dot{q}''_e}{b} \right)^2 \qquad (4.1)$$

where $\dot{q}''_e$ is the incident radiative heat flux and b is related to the thermal properties of the material. This data normally is obtained using the LIFT apparatus (ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*) but also can be obtained using the cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*). Figure 4-4.2.1 illustrates the ignition behavior of one type of fiberboard using this method [Quintiere & Harkleroad, 1985]. This method is valid for constant values of the incident heat flux, $\dot{q}''_e$. More general methods are also available in the referenced literature.



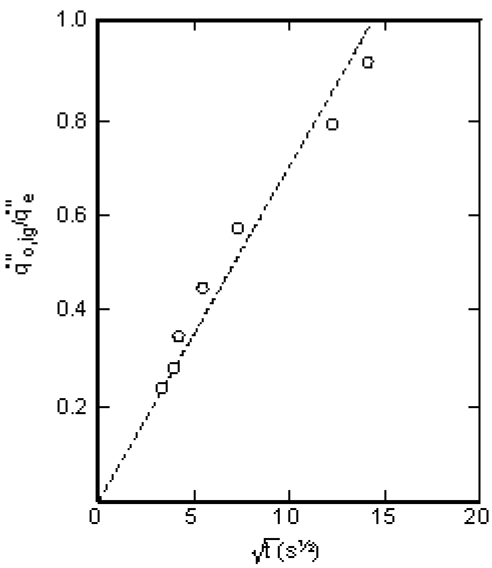


Figure 4-4.2.1 Ignition behavior of a particular type of fiberboard.

4-4.2.2 Equation 4.1 is based on a model of surface temperature (T_s) rise during heating given by equation 4.2 as follows:

$$T_s - T_0 = \left(\dot{q}''_e / h\right) F(t) \tag{4.2}$$

Where F(t) is determined from equation 4.3 or 4.4 as follows:

$$F(t) = 2ht^{1/2} / (\pi k\rho c)^{1/2} \quad \text{for } t < t_m \tag{4.3}$$

$$F(t) = 1 \quad \text{for } t \geq t_m \tag{4.4}$$

with t_m being the time necessary for equilibration of the surface temperature.

4-4.2.3 The first regime, for $t < t_m$, is modeled assuming no heat losses, while the second regime, for $t \geq t_m$, is modeled as a steady state. The ignition condition is derived by setting the surface temperature equal to the ignition temperature. The critical flux for ignition, $\dot{q}''_{o,ig}$, is defined by the flux necessary to reach the ignition temperature when $t \geq t_m$. Equation 4.1 is developed from the use of these considerations.

4-4.2.4 The product of the thermal conductivity, k, the density, ρ, and the heat capacity, c, is a fundamental material property often described simply as "kρc." Because of the simplifying assumptions used, the value kρc derived from LIFT (ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*) or cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*) data is to be regarded as an effective $k\rho c$ and should not be expected to be equal to the $k\rho c$ derived from methods used to measure these heat transfer properties.

4-4.3 Radiative Heating.

4-4.3.1 In order to evaluate the ignition of a material contained in a target fuel package, the radiative heat flux to the material from other fuel packages and the hot layer need to be determined. A number of methods can be used to make this determination.

4-4.3.2 The radiative heat fluxes generated by a range of fuel packages over a range of distances from the fuel package have been investigated [Babrauskas, 1981-82]. Based on knowledge of the burning rate of the radiating fuel package, the heat flux at specific distances from the fuel package can be estimated. Incident flux levels of 10 kW/m^2, 20 kW/m^2, and 40 kW/m^2 are defined as critical flux for ignition of general fuels and are described as easy, normal, and difficult to ignite, respectively. As noted in 4-4.2, the heat flux and duration of radiative exposure determine if ignition can occur.

4-4.3.3 Equations 4.5, 4.6, and 4.7 are used to determine the critical rate of heat release necessary to enable a burning object to ignite a target object that is classified as easy, normal, or hard to ignite, respectively, at a distance, D:

$$\dot{Q} = 30 \times 10^{\left(\frac{D+0.08}{0.89}\right)} \tag{4.5}$$

$$\dot{Q} = 30\left(\frac{D + 0.05}{0.019}\right) \qquad (4.6)$$

$$\dot{Q} = 30\left(\frac{D + 0.02}{0.0092}\right) \qquad (4.7)$$

where:

$\dot{Q}$ = Heat release rate (kW).

D = Distance (m).

If the rate of heat release of this burning object is increasing, the time at which the fire's rate of heat release is first reached is the time to ignition of the target object.

4-4.3.3.1 Equations 4.5, 4.6, and 4.7 are plotted in Figure 4-4.3.3.1. This graph can be used as a solution by reading up the appropriate curve to locate the separation distance and then finding the corresponding critical rate of heat release.

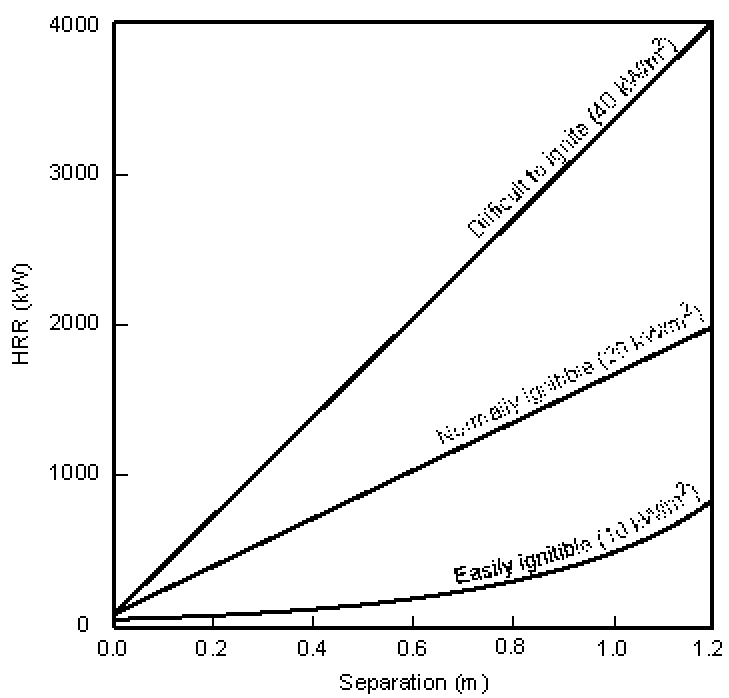

Figure 4-4.3.3.1 The inverse equation — separation distance versus rate of heat release.

4-4.3.3.2 Separation distance values of 140 cm, 90 cm, and 40 cm for easy, normal, and hard to ignite objects, respectively, represent distances beyond which the target objects are not considered part of the fuel package.

4-4.3.4 Two simple methods for evaluating radiation from pool fires to targets outside the flame have been developed [Mudan & Croce, 1988; Shokri & Beyler, 1989]. While these methods are based on pool fire test data, they can be applied to fuel packages. No studies have been performed to validate these methods where applied to furniture items. The pool fire data include diameters of 1 m to 50 m. Most fuel packages are at the low end of this range. The procedures for these methods are outlined below. Both methods model the flame as a cylindrical radiator with a specified emissive power. Configuration factors are then employed for the radiant heat flux calculation. The two methods differ only in their flame radiator height expressions and emissive power expressions.

4-4.3.4.1 The radiator is described as a cylinder with a radius determined by the size of the base of the fuel package. The height of the radiator is determined by a flame height correlation. Table 4-4.3.4.1 shows the flame height expressions used in the two models. The emissive powers used in the two models are given in Table 4-4.3.4.1 and are illustrated in Figures 4-4.3.4.1(a) and (b). The radiant flux to the target from the fuel package, $\dot{q}''_{r,fp}$, is determined by equation 4.8 as follows:

$$\dot{q}''_{r,fp} = F_{fp-dt}\,E \qquad (4.8)$$

where F_{fp-dt} is the configuration factor between the cylindrical radiator (fuel package) and the target, and E is the emissive power of the radiator.

Table 4-4.3.4.1 Flame Height and Emissive Power

	Mudan and Croce (1988)	Shokri and Beyler (1989)
Flame Height (m)	$H = 420\left(\frac{\dot{Q}}{\rho_a \Delta H_c \sqrt{gD}}\right)^{0.61}$	$H = 0.23\dot{Q}^{2/5} - 1.02\,D$ [m,kW]
Emissive Power (kW/m²)	$E = 140\left(e^{-0.12D}\right) + 20\left(1 - e^{-0.12D}\right)$ [m, kW]	$E = 58\left(10^{-0.00823D}\right)$ [m,kW/m²]

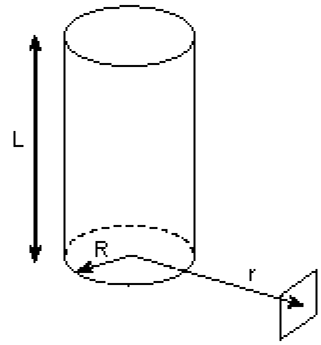
$$F_{d1\text{-}2,V} = \frac{1}{\pi S}\tan^{-1}\left(\frac{h}{\sqrt{S^2-1}}\right) - \frac{1}{\pi S}\tan^{-1}\sqrt{\frac{(S-1)}{(S+1)}} + \frac{Ah}{\pi S\sqrt{A^2-1}}\tan^{-1}\sqrt{\frac{(A+1)(S-1)}{(A-1)(S+1)}}$$

where

$$S = \frac{r}{R}, \quad h = \frac{L}{R},$$

$$A = \frac{(h^2 + S^2 + 1)}{2S}$$

$$B = \frac{1 + S^2}{2S}$$



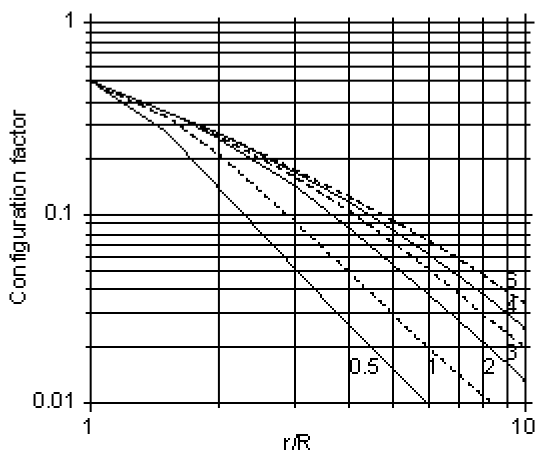


Figure 4-4.3.4.1(a) Configuration factor for a vertical target and a vertical cylindrical radiator (*adapted from C. L. Beyler*).

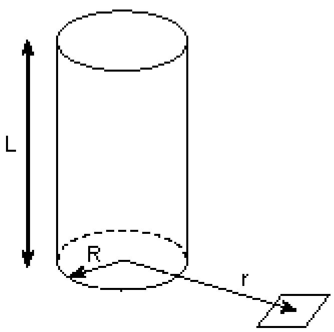
$$F_{d1\text{-}2,H} = \frac{(B - 1/S)}{\pi\sqrt{B^2 - 1}} \tan^{-1}\sqrt{\frac{(B+1)(S-1)}{(B-1)(S+1)}} - \frac{(A - 1/S)}{\pi\sqrt{A^2 - 1}} \tan^{-1}\sqrt{\frac{(A+1)(S-1)}{(A-1)(S+1)}}$$

where



$$S = \frac{r}{R}, \quad h = \frac{L}{R},$$

$$A = \frac{(h^2 + S^2 + 1)}{2S}$$

$$B = \frac{1 + S^2}{2S}$$

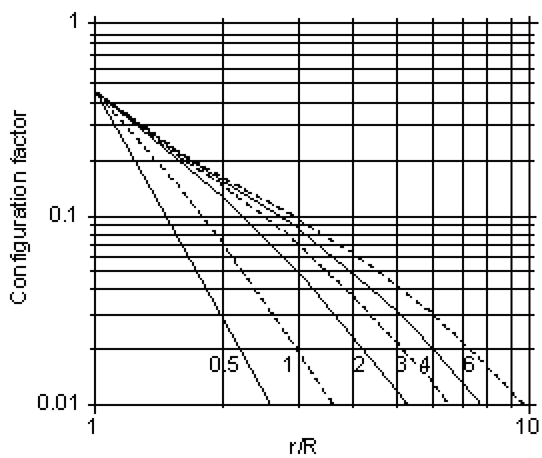


Figure 4-4.3.4.1(b) Configuration factor for a horizontal target and a vertical cylindrical radiator (*adapted from C. L. Beyler*).

4-4.3.4.2 The configuration factors for several relevant geometries are shown in Figures 4-4.3.4.1(a) and (b). These figures show the geometry, the equation, and a graph of the configuration factor. Configuration factors for other geometries related to those shown can be generated from the configuration factors provided, since configuration factors are cumulative. For instance, the worst case configuration at a given distance from the radiator is a target facing the flame at half the radiator height. This configuration factor can be created by considering the radiator to be composed of two cylinders, one above the target and one below. Since, in this case, the two cylinders are equal in size, the final configuration factor is simply twice the configuration factor for a radiator with a height equal to half the flame height.

4-4.3.5* The radiation from the hot gas layer can be estimated by methods similar to those described in 4-4.3.4 for the flame. The hot layer radiant can be modeled as a blackbody at the hot gas layer temperature, T_h. The configuration factor between the layer and the target, $F_{hL\text{-}dt}$, can be estimated based on the configuration factor between a flat rectangular radiator positioned at the location of the hot gas layer interface. The incident radiant heat flux from the layer to the target, $\dot{q}''_{r,h1}$, is determined by equation 4.9:

$$\dot{q}''_{r,h1} = F_{hL-dt}\, \sigma T_h^4 \qquad (4.9)$$

where σ is the Stefan-Boltzmann constant (5.67 x 10^{-11} kW/m^2 K^4) and T_h is the hot gas layer temperature in Kelvin (°C + 273). The worst case is a configuration factor of 1, which occurs if the target surface is facing the hot layer interface and is very close to the interface. The configuration factors for several relevant geometries are shown in Figures 4-4.3.5(a) and (b). These figures show the geometry, the equation, and a graph of the configuration factor. Configuration factors for other geometries related to those shown can be generated from the configuration factors provided, since configuration factors are cumulative. For instance, if the target is at the center of the room facing upward, the configuration factor is the sum of four configuration factors, one for each quadrant of the room. If the target is centered in the room, all four configuration factors are equal. If the target is close to the radiator, the maximum individual configuration factor is 0.25, and the maximum configuration factor is four times this value (i.e., 1.0, as previously discussed).

$$F_{d1\text{-}2} = \frac{1}{2\pi}\left[\frac{X}{\sqrt{1+X^2}}\tan^{-1}\left(\frac{Y}{\sqrt{1+X^2}}\right) + \frac{Y}{\sqrt{1+Y^2}}\tan^{-1}\left(\frac{X}{\sqrt{1+Y^2}}\right)\right]$$

where X = a/c and Y = b/c.

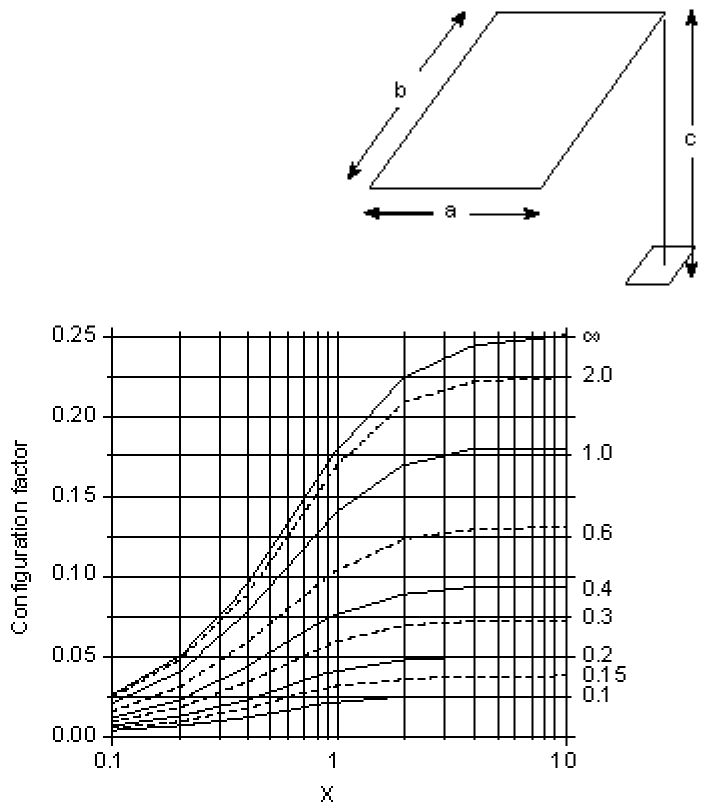

Figure 4-4.3.5(a) Configuration factor for one quadrant of the hot gas layer to a target facing the hot layer (*adapted from C. L. Beyler*).

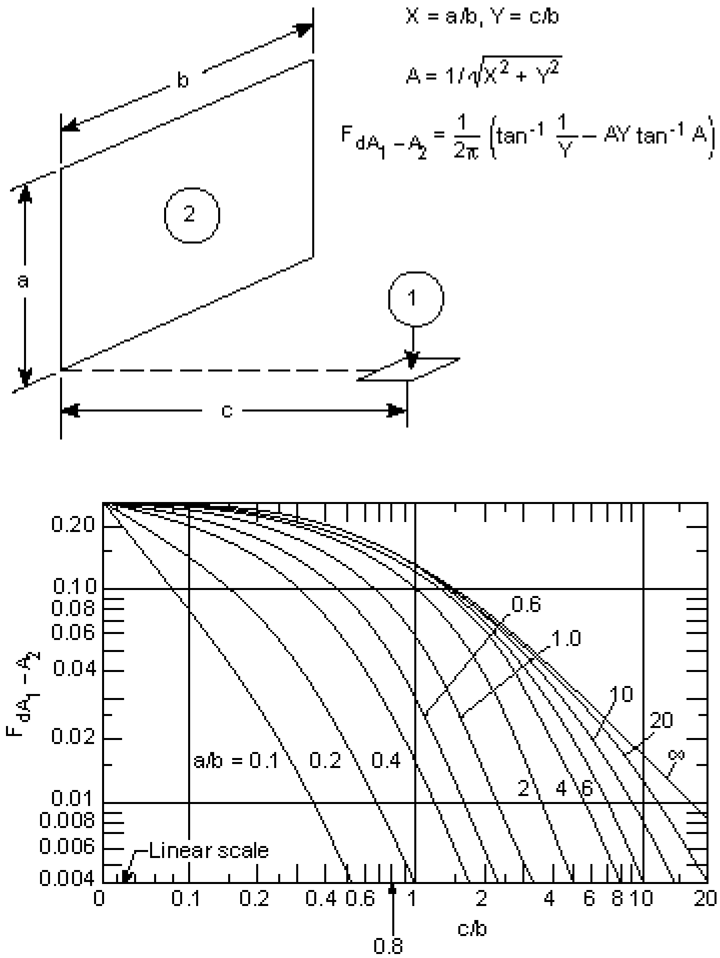

Figure 4-4.3.5(b) Configuration factor for one quadrant of the hot gas layer to a target not facing the hot layer (*adapted from E. M. Sparrow and R. D. Cess*).

4-4.3.6 The methods described in Section 4-4 are examples of those that can be used for this type of analysis. They might not be the best methods for every situation. Nothing in this section should be taken to exclude the use of better methods than those discussed.

Chapter 5 Predicting Flashover for Fire Hazard Calculations

5-1 Background.

5-1.1

The occurrence of flashover within a room is the ultimate signal of untenable conditions within the room of fire origin as well as a sign of greatly increased risk to other rooms within the building. A number of experimental studies of full-scale fires have been performed that provide an adequate but imprecise definition of flashover in terms of measurable physical properties. Computer simulations of the growth of a fire within a room are available.

5-1.2* Temperature.

Temperature rise in the upper layer of a compartment has been used as a criterion for indication of flashover. Documentation indicates that a gas temperature rise at flashover of 600°C is a reasonable expectation.

5-1.3* Heat Flux.

Heat flux at floor level also has been used as a criterion for indication of flashover. Documentation indicates that a heat flux at floor level at flashover of 20 kW/m^2 is a reasonable expectation.

5-2 Estimating Room Flashover Potential.

5-2.1*

The room flashover potential is best estimated by using Thomas' flashover correlation [Thomas, 1981], as provided in equation 5.1. The constants in equation 5.1 represent values correlated to experiments producing flashover.

$$\dot{Q} = 7.8 A_{room} + 378 \left(A_{vent}\sqrt{H_{vent}}\right)_{equivalent} \qquad (5.1)$$

$$A_{room} = A_{floor} + A_{ceiling} + A_{walls} - \left(A_{vents}\right)_{equivalent} \qquad (5.2)$$

$$W_{vent_{equivalent}} = \frac{\sum_{i=1}^{n}\left(A_{vent}\sqrt{H_{vent}}\right)_i}{\sqrt{H^3_{vent_{equivalent}}}} \qquad (5.3)$$

where $\dot{Q}$ = heat release rate of the fire (kW).

$A_{vent} = H_{vent} W_{vent}$ (m^2)

in which the product, $H_{vent} W_{vent}$, represents the dimensions of an equivalent vent defined by equation 5.1.

$H_{vent\ equivalent}$ equals the difference between the elevation of the highest point among all of the vents and the lowest point among all of the vents (m).

$W_{vent\ equivalent}$ equals the width of a virtual vent that has an area equivalent (for the purposes of determining flashover) to the combined area of all individual vents from the room of consideration (m).

5-2.2*

Alternative methods of estimating heat release at flashover also have been developed [Babrauskas, 1980a; Babrauskas & Krasny, 1985; McCaffrey et al., 1981; Quintiere, 1982].

5-2.3* General Information on Thomas' Correlation.

5-2.3.1 The formulation of the energy balance considered only the heat losses from the hot gas layer and heated walls to the cooler lower walls and floor surfaces. The term A_{room} actually should include all surfaces inside the room, exclusive of the vent area.

5-2.3.2 The fire area should not be subtracted from the floor area since the fire conducts and convects heat into the floor underneath the fuel footprint.

5-2.3.3 The equation is the same, irrespective of the location and form of the vent (a window or a door); however, the equation was developed from tests where venting was through a window as well as a door.

5-2.3.4 The equation does not address the external insulation of the walls. Thus, use of the equation for compartments with thin metal walls might be inappropriate.

5-2.3.5 The equation was developed from tests using fast-growth fires and has not been verified for fires that grow slowly or at moderate rates.

5-2.3.6 The equation was developed from experiments conducted in rooms not exceeding 16 m^2 in floor area. Extrapolation of the results from this equation for application to rooms with much larger floor areas might not be valid.

5-2.3.7 The equation is not valid for compartments without ventilation, since it would predict the possibility of flashover, which would be unlikely due to oxygen starvation of the fire.

5-2.3.8 The experiments used to develop this equation included the use of compartments with thermally thick walls and wood crib fires. The validity of the equation was later confirmed in gypsum-lined rooms using furniture fires [Parker & Lee, 1974]. Its validity for other surfaces or fire sources has not been fully established.

Chapter 6 Heat Release Rate Estimation Techniques

6-1 Introduction.

This chapter presents techniques for estimating the heat release rate for various individual items or products in a compartment, based on the results of direct measurements. Heat release rate is a crucial property for assessing fire safety because its maximum value is the numerical representation of the peak intensity of a fire. Therefore, estimates of heat release rate are critical in predicting whether flashover can occur in a compartment, based on the items or products contained in the compartment and the distances between them. Sections 6-2 through 6-8 present a hierarchy for the preferred techniques for such estimates.

6-2 Preferred Hierarchical Order.

6-2.1

The preferred hierarchical order indicates that the reliability of the results is likely to decrease as the order of technique descends from the optimal to other types. Tests on individual materials and comparative estimates are the techniques with the lowest reliability for assessing the potential for room flashover. The optimal technique is a full compartment test that includes items or products contained in it, with the distances between items and products that are identical to those in the compartment of interest. The applicable techniques are described in more detail in Sections 6-3 through 6-8. The preferred hierarchical order is as follows:

(a) A full compartment fire test, including all items expected to be contained within it;

(b) Full-scale fire tests on individual items;

(c) Tests on large-scale mock-ups of individual items;

(d) Bench-scale tests, using composite samples representative of the end-use composite assemblies;

(e) Bench-scale tests using individual materials rather than composites as samples;

(f) Use of estimation techniques for calculating heat release rate in the compartment as determined from the results of tests in 6-2.1(b) through (e). This might be done by one of the following:

1. Quantitative estimation techniques; or

2. Relative estimation techniques.

6-3 Full Compartment Fire Tests.

6-3.1

Ideally, the heat release rate from the combination of contents, furnishings, and interior finishes contained in a compartment is obtained by carrying out a full compartment fire test, wherein each major combustible item, product, or fuel package is included, replicating as much as possible the locations where the items are to be placed in the compartment under investigation. ASTM E 603, *Standard Guide for Room Fire Experiments,* provides proper guidance for the various choices that need to be made. These include information on operator safety and on the most appropriate experimental techniques for various measurements. This approach is best suited for cases where multiple compartments with very similar contents and distributions are to be constructed.

6-3.2

One of the most important issues that needs to be addressed by the designer of a full-scale test is the selection of an ignition source.

6-3.2.1 If the only objective is to ensure that flashover cannot occur with the existing combustible contents, the size of the ignition source used is of little importance, as long as it is not large enough to cause flashover on its own. An initial test should be carried out, with the ignition source as the only item present, to confirm that flashover does not occur in the absence of other combustible items. The objective of this test is extremely limited.

6-3.2.2 If the experiment is being carried out to determine the fire hazard inherent in the compartment being considered, the choice of ignition source and its location are crucial to the results of the test. They should be chosen to represent a realistic fire source in the occupancy under investigation.

6-3.2.3 If the experiment is being carried out in order to make a decision between various types of items or fuel packages of a particular type (e.g., an upholstered chair or a mattress), the ignition source should be sufficiently large to be a realistic fire source but small enough so that total consumption of the item is not inevitable. Therefore, the ignition source for such a full-scale test should not be so large as to overwhelm the product, irrespective of its fire performance.

6-3.3

There are some disadvantages in carrying out full compartment fire tests:

(a) They are costly, both in terms of actual expense and in terms of preparation;

(b) They are less susceptible to generalization, since small differences in item or fuel package location can have major effects on fire performance; and

(c) They cannot easily identify the effects of individual items or fuel packages on the overall fire performance of the whole compartment.

6-3.4

The ultimate objective of the tests should be to determine whether the compartment, as configured, is expected to reach flashover. If flashover is not reached, the results can be used for comparisons between items or products with similar functions but different construction or materials. Results from tests that do not reach flashover should be compared with the calculated heat release rates necessary for flashover or the upper gas layer temperatures necessary for flashover. The potential for flashover should be assessed in light of the reproducibility of test results and the impact of test result variability on achieving flashover conditions.

6-4 Full-Scale Tests on Individual Items or Fuel Packages.

6-4.1 General.

6-4.1.1 Full-scale tests have been developed for a variety of individual items, including wall finish, upholstered furniture, and mattresses. Full-scale tests also can be conducted on individual fuel packages in the same way in which they are conducted for individual items. The choice of ignition source and location are crucial to the results of the test. They should be chosen to represent a realistic fire source in the occupancy under investigation.

6-4.1.2 If it is possible that items or fuel packages could deteriorate through normal use or special situations, such as vandalism, additional tests might be necessary to evaluate the items after a suitable period of use or after the occurrence of such special situations (e.g., slashed cover and barrier).

6-4.1.3 Where quantitative precision or bias statements have not been developed for the full-scale tests used, appropriate compensation should be made for the lack of information regarding precision or bias.

6-4.1.4 Aesthetic design as well as geometric and spatial configuration can have significant influence on the ignition and burning properties of all items used for room contents, furnishings, and interior finishes. The issues of design, geometry, and spatial configuration are far too complex, important, and detailed to cover in this document. The references contained in Chapter 7 and Appendix B provide a resource on these subjects.

6-4.1.5* There are nearly an infinite number of material combinations that can be used in the construction of room furnishings. Heat release rate values for each of the composite items are likely to vary significantly and unpredictably from one composite type to another. Component materials can produce significantly different heat release values, depending on the presence of the other materials and on the physical design or geometry of the item. Thus, the value of design rules of thumb are limited and do not guarantee low rate of heat release values. Product testing therefore is necessary to determine the heat release rate for any given item.

6-4.2* Wall Finish.

Full-scale fire performance of wall finishes can be tested by means of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings,* or ISO 9705, *Fire Tests — Full Scale Room Fire Tests for Surface Products.*

6-4.3 Upholstered Furniture.

6-4.3.1 Full-scale fire performance of upholstered furniture can be tested by means of NFPA 266, *Standard Method of Test for Fire Characteristics of Upholstered Furniture Exposed to Flaming Ignition Source*, or ASTM E 1537, *Standard Test Method for Fire Testing of Real Scale Upholstered Furniture Items.*

6-4.3.2 Models exist that allow the effects of reradiation from room walls on heat release rate to be added to the results of the tests carried out in a furniture calorimeter. These effects are negligible unless the peak heat release rate of the furniture item exceeds 600 kW if tested in a furniture calorimeter or in a room of dimensions ranging from 2.5 m × 3.7 m to 3.1 m × 3.7 m, with a height of 2.5 m. If the heat release rate is that high, the importance of minor effects are probably of little consequence in a flashover prevention strategy [Parker et al., 1990].

6-4.4 Mattresses.

6-4.4.1 Full-scale fire performance of mattresses can be tested by means of NFPA 267, *Standard Method of Test for Fire Characteristics of Mattresses and Bedding Assemblies Exposed to Flaming Ignition Source*, or ASTM E 1590, *Standard Test Method for Fire Testing of Real Scale Mattresses*.

6-4.4.2 Models exist that allow the effects of reradiation from room walls on heat release rate to be added to the results of the tests carried out in a furniture calorimeter. These effects are negligible unless the peak heat release rate of the mattress exceeds 600 kW if tested in a furniture calorimeter or in a room of dimensions ranging from 2.5 m x 3.7 m to 3.1 m x 3.7 m, with a height of 2.5 m. If the heat release rate is that high, the importance of minor effects are probably of little consequence in a flashover prevention strategy.

6-4.5 Other Items.

6-4.5.1 Full-scale fire performance testing of other items should be performed by designing specialized tests for the item under consideration. Similar types of criteria should be developed to those documents referenced in 6-4.2, 6-4.3, and 6-4.4. Items or fuel packages of potential interest include pallets of storage commodities, case goods, and cleaning supplies.

6-4.5.2 It is recommended that ASTM E 603, *Standard Guide for Room Fire Experiments,* be used as a guide for developing the test and for making the measurements.

6-4.5.3 Currently, no standard full-scale fire test exists for floor finish (*see A-6-6.4*). In general, floor finish is not involved in fires until flashover is approached.

6-4.6

The use of tests on individual items has both advantages and disadvantages over testing all components of a compartment.

6-4.6.1 The advantages of testing individual items include:

(a) Lower cost;

(b) Greater specificity on the individual importance of the item under test; and

(c) Easier identification of the effects of composition or construction of the item under test on anticipated fire performance.

6-4.6.2 The major disadvantage of testing individual items is that the test is incapable of identifying the effect of the item being tested on the remaining items in the compartment.

6-4.7

In order to assess whether the compartment, as configured, is likely to reach flashover, tests should be carried out on all major items and the results should be combined. The simplest way to combine the results is by adding the peak heat release rates obtained from the individual items and comparing them with the predicted heat release rate necessary for flashover as determined from Chapter 5. This method can be improved by combining the concept of ignition of "second" items due to the radiation from burning items, based on the ignition propensity of each item and the distance between them [Babrauskas, 1981-82] (*see also 4-4.3.3*). A further improvement involves the use of an appropriate modeling technique, incorporating experimental fire test data, to predict the potential interactions between the burning items.

6-5 Tests on Large-Scale Mock-ups of Individual Items.

6-5.1

The effects of product composition on fire performance can be predicted to a considerable extent by carrying out large-scale fire tests on mock-ups of individual items (e.g., for upholstered furniture see ASTM E 1537, *Standard Test Method for Fire Testing of Real Scale Upholstered Furniture Items*). Such tests should be done in the same way as the tests on full-scale products.

6-5.2

This technique does not provide the investigator with an understanding of the effects of construction on fire performance.

6-5.3

Where testing upholstered furniture, it has been suggested that fire performance predictions can be improved by including factors associated with the mass, the type of frame, and the style of construction [Babrauskas, 1979, 1980b, 1983; Ames et al., 1992]. All of the aforementioned variables have important effects on heat release; insufficient quantitative information exists to allow estimates of the full-scale effects to be made.

6-5.4

Such testing should not be confused with testing on small-scale mock-ups, which very often is unsatisfactory because the effects of radiation from the flame are missing.

6-6 Bench-Scale Tests on Composite Samples.

6-6.1

Heat release and other fire test response characteristics of upholstered furniture or mattress composites in bench-scale can be determined by using an application of the cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*), as specified in NFPA 264A, *Standard Method of Test for Heat Release Rates for Upholstered Furniture Components or Composites and Mattresses Using an Oxygen Consumption Calorimeter*, or ASTM E 1474, *Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*, at an incident radiant heat flux of 35 kW/m^2.

6-6.1.1 A number of studies have been conducted attempting to relate test results from bench-scale tests to fire performance in full-scale tests and some of these are discussed in the 6-6.1.2 through 6-6.1.8. It is important to note that the data published to date have failed to show consistent correlation between bench-scale and full-scale testing for fire test response characteristics.

6-6-1.2 Estimations of peak heat release rate in the full-scale furniture fire test specified in ASTM E 1537, S*tandard Test Method for Fire Testing of Real Scale Upholstered Furniture Items,* based on cone calorimeter (NFPA 264A, *Standard Method of Test for Heat Release Rates for Upholstered Furniture Components or Composites and Mattresses Using an Oxygen Consumption Calorimeter*, or ASTM E 1474, *Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*) data have been made. The initial work, done cooperatively by NIST and the California Bureau of Home Furnishings, suggested that the average (3-min) heat release rate is capable of predicting full-scale peak heat release rate (*see* Figure 6-6.1.2). The work suggested that there is a threshold at approximately 100 kW/m^2, so that systems that generated values below this threshold are not likely to develop self-propagating fires when they are made into actual furniture. Similarly, it suggested that average heat release rate values above 200 kW/m^2 are likely to result in furniture that can cause self-propagating fires. Equation 6.1 determines the non-self-propagating fire region found by that study as follows:

$$\dot{Q}(\text{full-scale}) = 0.75 \times \dot{Q}'' \qquad (6.1)$$

where $\dot{Q}$ (*full-scale*) is the peak rate of heat release in ASTM E 1537 (in kW), and $\dot{Q}''$ is the average (3-min) heat release rate per unit area in ASTM E 1474 at an incident flux of 35 kW/m^2 [Parker et al., 1990].

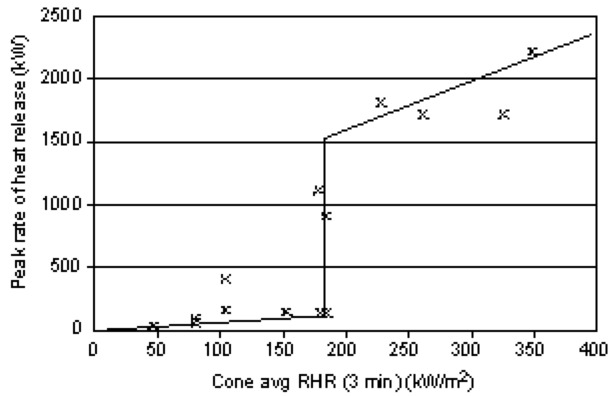

Figure 6-6.1.2 Relation of the results of full-scale ASTM E 1537 upholstered furniture tests with the average rate of heat release from the cone calorimeter (ASTM E 1354), at an incident flux of 35 kW/m2.

6-6.1.3 Another series of tests was carried out in which nine chairs were tested in ASTM E 1537, *Standard Test Method for Fire Testing of Real Scale Upholstered Furniture Items*, and the systems were also tested in the cone calorimeter (although not following the procedure in ASTM E 1474, *Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*). All systems had the same foam, interliner and chair construction but used different fabrics. Figure 6-6.1.3 illustrates a linear relationship between the peak (not average) heat release rate in the cone and the peak heat release rate in the full-scale test, with a regression correlation coefficient of 86 percent from the results of that study [Hirschler, 1995].

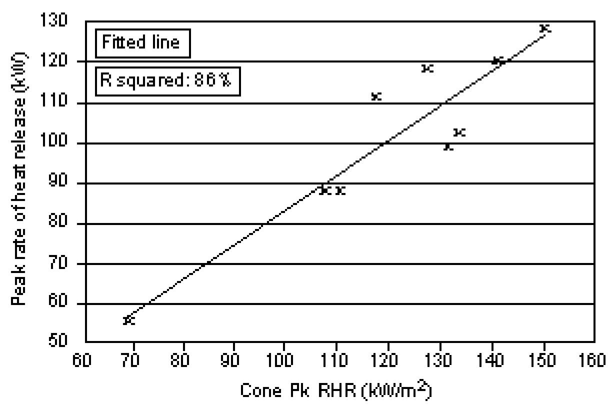

Figure 6-6.1.3 Relation of the results of one series of full-scale ASTM E 1537 upholstered furniture tests with the peak rate of heat release from the cone calorimeter (ASTM E 1354), at an incident flux of 35 kW/m^2. Correlation coefficient: 86%.

6-6.1.4 It should be stated, however, that such estimations are heavily dependent on the systems tested. Figure 6-6.1.4 indicates that, for three separate series of tests, the regressions found, although all linear, corresponded to different linear equations [Hirschler, 1995]

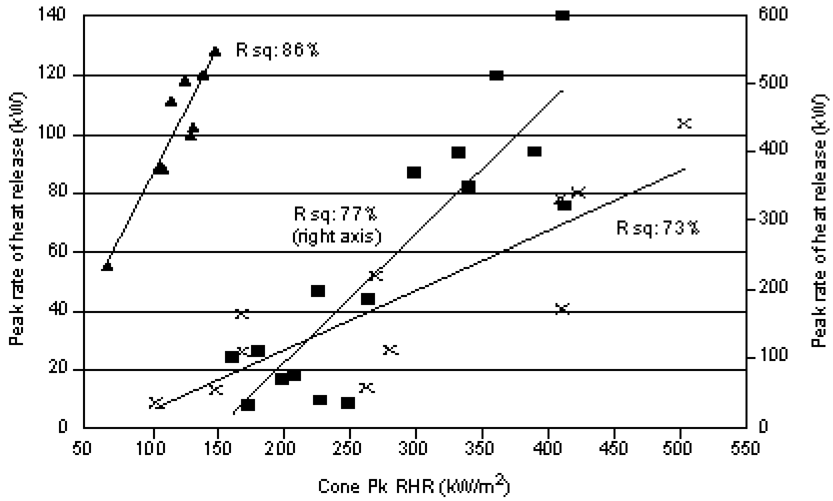

Figure 6-6.1.4 Relation of the results of three series of full-scale ASTM E 1537 upholstered furniture tests with the peak rate of heat release from the cone calorimeter (ASTM E 1354), at an incident flux of 35 kW/m^2. Correlation coefficients: 86%, 77% and 73%.

6-6.1.5 Other studies have also been made [Sundstrom, 1995; Forsten, 1995; Ohlemiller and Shields, 1995; ACT/DFA, 1995]. They have shown different types of estimations and have highlighted some difficulties.

6-6.1.6 Other studies in the cone calorimeter using incident heat fluxes of 25 kW/m^2 [Hirschler and Smith, 1990] and 30 kW/m^2 [Ames et al., 1993] have also been made.

6-6.1.7* Input from the cone calorimeter (NFPA 264A, *Standard Method of Test for Heat Release Rates for Upholstered Furniture Components or Composites and Mattresses Using an Oxygen Consumption Calorimeter*, or ASTM E 1474, *Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*) and from the LIFT apparatus (ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*) can be used for predictions of furniture fire growth in a compartment.

6-6.1.8 Correlation between bench-scale and full-scale test results may be improved by incorporating factors that represent the effects of total mass, frame materials, frame style, and furniture design.

6-6.2 Bedding Materials.

6-6.2.1 Recent work has shown that estimates similar to those for upholstered furniture also apply to mattresses, relative to ASTM E 1474, *Standard Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*, and ASTM E 1590, *Standard Test Method for Fire Testing of Real Scale Mattresses* [Babrauskas, 1993].

6-6.2.2 Experience has shown that bedding materials can substantially affect heat release from mattresses, particularly where the mattress itself has demonstrated fairly poor fire performance.

Thus, in general, tests with mattresses and bedding are of interest mainly for those systems with fairly high heat release rate values.

6-6.3 Wall Lining Materials.

6-6.3.1* Several fire models can predict heat release and fire growth of wall linings in a compartment.

6-6.3.2 Standard application procedures for using the cone calorimeter with wall linings have not been fully developed, but some of the issues that need to be resolved regarding mounting techniques have been investigated [Fritz & Hunsberger, 1992].

6-6.4*

It has been shown that carpets can be tested in the cone calorimeter (NFPA 264, *Standard Method of Test for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*, or ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*) at incident heat fluxes of 25 kW/m^2 to 30 kW/m^2 [Briggs et al., 1992; Ames et al., 1993; Hirschler, 1992a; Tomann, 1993]. Lower heat fluxes might be more appropriate for testing floor finish products.

6-7 Bench-Scale Tests on Individual Materials.

6-7.1

Tests on individual materials offer important input information to fire safety analyses resulting from products burning in a room. This is especially important in terms of the emitted heat release rate. However, information on materials cannot address the issue of the potential interaction (synergistic or antagonistic) between the various materials contained in a product.

6-7.2

Results of fire tests on materials, therefore, are useful either as a predictor of the relative performance of the materials (based on the assumption that interactions between materials are negligible) or as input into specific fire models developed to predict the fire performance of products from that of the component materials.

6-7.3

Two methods have been proposed as empirical relative analyses of overall material fire performance. Both methods require testing of materials in the cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*).

6-7.3.1 The first method is an empirical relationship for predicting time to flashover from room wall lining materials in the same test as that covered by the Eurefic model specified in ISO 9705, *Fire Tests — Full Scale Room Fire Tests for Surface Products* (options 100 kW and 300 kW; three walls and ceiling covered). It uses input data from the cone calorimeter and equation 6.2, which follows:

$$t_{fo} = k_a \times \frac{t_{ign}\sqrt{\rho}}{\Sigma Q''_{Pk}} + k_b \qquad (6.2)$$

where t_{fo} is the predicted time to flashover in ISO 9705, (in sec), t_{ign} is the time to ignition in the cone calorimeter at an incident flux of 25 kW/m^2 (in sec), ρ is the density (in kg/m^3), $\Sigma\dot{Q}''_{Pk}$ is the total heat released per unit area during the peak period in the cone calorimeter at an incident heat flux of 50 kW/m^2, and k_a and k_b are constants [2.76×10^6 J (kg m)$^{-0.5}$ and –46.0 sec, respectively]. This method has been applied successfully to the Eurefic test data.

6-7.3.2 The other method is even simpler. It is a first order approximation for relative time to flashover in a room-corner scenario, as shown in equation 6.3:

$$t_{fo} \propto FPI = \frac{t_{ign}}{Pk\,\dot{Q}''} \qquad (6.3)$$

where the t_{ign}, the time to ignition (in sec), is measured in the cone calorimeter at an incident flux that is relevant to the scenario in question, Pk $\dot{Q}''$ is the peak heat release rate per unit area at that same incident flux (in kW/m^2), and FPI is the fire performance index (in sec m^2/kW). If the material does not ignite, t_{ign} can be assigned a value of 10,000 seconds. The incident heating flux to be used should be relevant to the fire scenario being investigated and is to be specified by the investigator. This method is useful as a relative indication of propensity to flashover and cannot be used quantitatively [Hirschler, 1992a, 1992b, 1992c]. However, it has been applied to two series of large-scale tests: FAA aircraft panels in a full-scale simulated aircraft interior [Lyon, 1994] and the Eurefic test data. Both test series were compared to cone calorimeter data at 540 kW/m^2. (*See Figure 6-7.3.2.*)

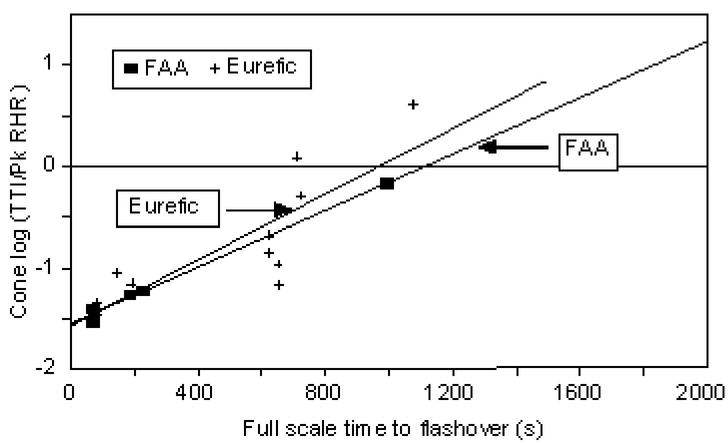

Figure 6-7.3.2 Comparison between full-scale times to flashover for FAA panels within an aircraft and for wall lining materials in ISO 9705, with the ratio of time to ignition to peak rate of heat release in the cone calorimeter (ASTM E 1354) at an incident flux of 50 kW/m^2.

6-8 Other Prediction Methods.

6-8.1*

Several methods exist that can be used as partial predictors of relative adequacy of performance of products and as additional tools.

6-8.2

Experienced observers are also capable of investigating which factors in the construction of upholstered furniture are most critical for potentially worsening fire performance to such an extent that a self-propagating fire can result.

A-4-4.2.1 Table A-4-4.2.1(a) shows values of the critical heat flux, $\dot{q}''_{o,ig}$, b, which is related to the thermal properties of the material, and t_m, the time required for equilibration of the surface temperature, for a wide range of materials. Table A-4-4.2.1(b) illustrates that ignition properties within a generic category of materials can vary substantially. The values provided in the tables are intended as hypothetical results only. They provide a general indication of the magnitudes and ranges of the parameters. The materials tested were not sufficiently characterized to allow specific use of the data in particular applications.

Table A-4-4.2.1(a) Ignition Properties of Materials (Quintiere & Harkleroad, 1985)

	$\dot{q}''_{o,ig}$	b	t_m
Material	(W/cm^2)	($sec^{-0.5}$)	(sec)
Plywood, plain, 0.635 cm	1.6	0.07	190

BC yellow pine	1.27	140	35

A-4-4.3.5 Equation 4.9 assumes that the upper layer can be taken as a blackbody radiator. The emissivity is a function of the concentration of soot and gaseous combustion products, such as carbon monoxide, carbon dioxide, and water. It is assumed that, when the temperature of the upper layer is high enough to contribute significant radiative heat, the concentration of soot and gaseous combustion products is high enough for the upper layer to be optically thick, and an emissivity value of 1 is appropriate. This estimate is conservative with regard to upper layer contribution to ignition. This estimate can be reduced on the basis of a detailed radiation analysis.

A-5-1.2 Temperature. Observations include:

(a) In a series of full-scale compartment burnout tests (surface area of 55 m^2), the average upper gas temperature rises ranged from 198°C to 959°C, with an average of 584°C for fully developed fires in an enclosure [Harmathy, 1972a, b].

(b) In a study of the behavior of fully developed fires in single compartments by several laboratories, gas temperatures that were centrally measured at a point below the ceiling that was one-fourth the distance to the floor reached an average of 1070°C to 1145°C during three series of tests [Thomas & Heselden, 1972; Heselden, 1973].

(c) Flames exiting the doorway (a criterion for possible flashover) were observed during tests when the gas temperature measured approximately 10 mm below the ceiling reached 600°C [Hågglund et al., 1974]. When this criterion was applied to a series of full-scale mattress fires, two out of ten exhibited potential to flashover [Babrauskas, 1977]. These two mattress fires produced maximum gas temperatures of 938°C and 1055°C.

(d) In full-scale enclosure experiments, an average upper room temperature ranging from 450°C to 650°C provided sufficient radiation transfer to ignite crumpled newspaper at floor level in the compartment [Fang, 1975]. The average upper room gas temperature needed for ignition of the newspaper was 540°C ± 40°C [some temperatures were measured at the mid-height of the room (low values); temperatures measured 25 mm (1 in.) below the ceiling almost always exceeded 600°C].

(e) During tests in the living room of a mobile home, ignition of crumpled newspaper indicators was observed with upper room temperatures ranging from 673°C to 771°C [Budnick, 1978; Klein, 1978; Budnick & Klein, 1978, 1979]. In those tests where there was no full room involvement, maximum upper room temperatures ranged from 311°C to 520°C. Tests reaching flashover and starting in the master bedroom of a typically constructed, single-width mobile home showed peak temperatures ranging from 634°C to 734°C at flashover. Temperatures were measured 25 mm (1 in.) below the ceiling in the center of the room.

(f) Full-scale and quarter-scale tests of submarine hull insulation found ignition of newspaper on the floor at room air and doorway air temperatures of at least 650°C and 550°C, respectively [Lee & Breese, 1979]. For tests where flashover was not obtained, the maximum temperatures achieved were 427°C and 324°C, respectively. The authors note, however, that ignition of newsprint or a particular minimum doorway or interior air temperature is only a rough indicator of flashover because of the variation in the thermal and physical properties of crumpled newsprint, the nonuniform distribution of temperatures throughout the compartment, and the differences between tests of the combined thermal radiation from the smoke, the hot air, and the heated surfaces. The hot air inside the compartment usually became well mixed by the time it exited through the doorway. Thus, it was concluded that doorway temperatures might be more reliable flashover indicators than interior air temperatures.

(g) Maximum temperatures of over 800°C were observed during a flashover test of a urethane foam block chair [Babrauskas, 1979]. For tests of upholstered chairs where flashover did not occur, temperatures remained below 600°C.

(h) During a series of sixteen full-scale fire tests of residential basement rooms, ignition of paper flashover indicators at floor level with an average upper room gas temperature of 706°C ± 92°C indicated a possibility of flashover of 90 percent [Fang & Breese, 1980].

(i) During a study of burning wood cribs and plastic cribs in a room, a gap was found between low temperature fires (ceiling layer gas temperature < 450°C) and high temperature fires (ceiling layer gas temperature > 600°C) [McCaffrey & Rockett, 1977; Quintiere & McCaffrey, 1980]. The potential for flashover was identified by the fact that cellulose filter paper indicators ignited or were destroyed in the five cases (out of sixteen) involving high gas temperatures.

(j) Thomas' semiempirical calculation of the rate of heat release necessary to cause flashover in a compartment [Thomas, 1981] is based on a simple model of flashover. It predicts a temperature rise of 520°C and a blackbody radiation level of 22 kW/m^2 to an ambient surface that is not in the proximity of burning wood fuel at the predicted critical heat release rate necessary to cause flashover.

A-5-1.3 Heat Flux. Generalizations include:

(a) The concept of using the heat flux to exposed items within the fire room as a criterion for flashover was first suggested in 1974 [Parker & Lee, 1974]. It was stated that, at a heat flux of 20 kW/m^2 at floor level, cellulosic fuels in the lower part of the room are likely to ignite.

(b) Table A-5-1.3 provides the critical ignition fluxes for some materials for a 60-second exposure [Babrauskas, 1977]. The unpiloted values are probably more appropriate for determination of full room involvement, since the distance between the flames and the item to be ignited is considerable. A value of 20 kW/m^2 represents, according to W. K. Smith [Smith, date unknown], an unpiloted ignition time of approximately 180 seconds for box cardboard and is close to an ultimate asymptotic value.

Table A-5-1.3 Critical Ignition Heat Flux at a 60-Second Exposure

Material	Flux (kW/m^2)	
	Piloted	Unpiloted
Newspaper want ads	46	48
Box cardboard	33	43
Polyurethane foam	19	

(c) In one study of a series of room burns, strips of newsprint placed at floor level ignited at fluxes of 17 kW/m^2 to 25 kW/m^2, while 6.4-mm ($^1/_4$-in.) thick fir plywood ignited at 21 kW/m^2 to 33 kW/m^2 [Fang, 1975].

(d) In mobile home tests in which flashover occurred, the minimum total incident heat flux at the center of the floor was 15 kW/m^2 [Budnick, 1978].

(e) In submarine compartments, average heat fluxes at floor level of 17 kW/m^2 to 30 kW/m^2 at flashover were found [Lee & Breese, 1979].

(f) In basement room tests, substantial agreement was found between the time to ignition of newsprint flashover indicators and the time at which the incident heat flux measured at the center of the floor in the burn room reached a level of 20 kW/m^2 [Fang & Breese, 1980].

(g) Ignition of filter paper flashover indicators in tests with wood and plastic cribs was observed at a minimum heat flux of 17.7 kW/m^2, applied for at least 200 seconds [Quintiere & McCaffrey, 1980]. Under more controlled laboratory conditions, with radiant exposure to the same target configuration, the paper was charred black at 25 kW/m^2 and ripped at 120 seconds but only decomposed to a brown color under 15 kW/m^2. Thus, the criterion recommended was a heat flux of 20 kW/m^2.

A-5-2.1 Two alternative approaches to that of Thomas [Thomas, 1981] have been proposed to estimate the onset of flashover within a room.

A-5-2.2

(a) The first approach [Babrauskas, 1980a; Babrauskas & Krasny, 1985] is based on a simple combustion model with a flashover criterion of $\Delta T = 575°C$. It provides a simple rule to estimate the minimum heat release rate to produce flashover, as determined in equation A-5-2.2(a):

$$\dot{Q} = 0.6 A_{vent} \sqrt{H_{vent}} \qquad \text{[A-5-2.2(a)]}$$

where $\dot{Q}$ is the estimated rate of heat release, in MW, A is the door area, in m^2, and H is the door height (in m), with the $A_{vent}\sqrt{H_{vent}}$ product usually designated as the "ventilation factor."

(b) Equation A-5-2.2(a) results from assuming that the rate of heat release of the fire is proportional to the energy released per kilogram of air consumed (approximately 3.00 MJ/kg) and to the fraction of the maximum airflow into the compartment at the onset of flashover (an assigned value of 0.4).

(c) Equation A-5-2.2(a) has been shown to generate adequate agreement with experimental data. In two-thirds of the cases studied, the rate of heat release of the fire ranges between the results of the following two equations:

$$\dot{Q} = 0.45\,A_{vent}\sqrt{H_{vent}}$$ and [A-5-2.2(c)1]

$$\dot{Q} = 1.05\,A_{vent}\sqrt{H_{vent}}$$ [A-5-2.2(c)2]

A-5-2.3

(a) Another approach was based on a regression analysis in order to provide a correlation to predict upper layer gas temperature [McCaffrey et al., 1981; Quintiere, 1982]. Using data from over 100 experiments, the correlation found needed two dimensionless quantities, as shown in equation A-5-2.3(a):

$$\Delta T = 480\left[\frac{\dot{Q}}{\sqrt{g}\,C_p\rho_0 T_0\,A\sqrt{H}}\right]^{\frac{2}{3}}\left[\frac{h_k A_w}{\sqrt{g}\,C_p\rho_0 A\sqrt{H}}\right]^{-\frac{1}{3}}$$ [A-5-2.3(a)]

with ΔT in °C, and where ΔT is the temperature rise relative to ambient in °C, h_k is the effective heat transfer coefficient to ceilings/walls, A_w is the effective surface area for heat transfer, including door area, g is the gravitational constant, C_p is the specific heat of gas, ρ_0 is the ambient gas density, and T_0 is the initial ambient absolute temperature. A method for calculating the effective heat transfer coefficient, h_k, ranges has also been published [Pape & Waterman, 1976].

(b) The correlation coefficient between the experimental data and the predictions of equation A-5-2.3(a) ranges between 0.959 and 0.947, depending on whether the floor is included in the calculation of the wall area and the effective heat transfer coefficient.

(c) By substituting typical values for C_p, ρ_0 , T_0 , and a flashover criterion of ΔT = 500°C, equation A-5-2.3(a) can be reduced to equation A-5-2.3(c) as follows:

$$\dot{Q} = 0.61[h_k A_w A(h)^{1/2}]^{1/2}$$ [A-5-2.3(c)]

where $\dot{Q}$ is in MW, A_w and A are in m^2, h is in meters, and h_k is in $kW/(m^2\,K^{-1})$.

A-6-4.1.5 Several preliminary fire research projects have investigated the role of materials and product design characteristics on the flammability properties of room contents and furnishings [Babrauskas, 1981-82; Babrauskas et al., 1982; Babrauskas & Walton, 1986; Damant et al., 1989; Smiecinski et al., 1989; Schuhmann & Hartzell, 1989; Hirschler & Smith, 1990; Parker et al., 1990; Damant & Nurbakhsh, 1991; Hirschler & Shakir, 1991; Villa & Babrauskas, 1991; Gallagher, 1992; Barile, 1993; Grand et al., 1994].

A-6-4.2 NFPA *101®*, *Life Safety Code®*, includes some requirements on the use of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings*, while international specifications often reference ISO 9705, *Fire Tests — Full Scale Room Fire Tests for Surface Products*. Comparative details of the tests have been discussed recently [Hirschler, 1994]. The fire performance of wall finish is often assessed according to test results in the Steiner tunnel .test (NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, or ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*). However, the results of this test are not suitable for use in the calculations cited in this document [Belles et al., 1988].

A-6-6.1.7 The Dayton University Furniture Fire Model takes input data from the cone calorimeter (ASTM E 1474, *Standard Test Method for Determining the Heat Release Rate of Upholstered Furniture and Mattress Components or Composites Using a Bench Scale Oxygen Consumption Calorimeter*) and the LIFT apparatus (ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*) and uses it to predict the furniture fire growth and burnout in a room and the spread of combustion products (gases, smoke, heat) to other rooms [Dietenberger, 1992]. It is a zone model, associated with the FAST room fire model developed by the National Institute of Standards and Technology [Jones & Peacock, 1989], and has significant flexibility. It can simulate a piece of furniture with up to four cushions. However, this fire model is of high complexity and uses a complex set of data inputs. The LIFT apparatus is used in the Dayton University model to derive three parameters associated with flame spread: the thermal inertia [$k\rho c$ in units of $(kW/m^2\ K)^2$ sec], the ignition temperature T_{ig} in °C, and the flame heating parameter (F, in units of kW^2/m^3). It has been shown [Janssens, 1992a] that information on concurrent-flow flame spread (i.e., where the flame moves in the same direction as the prevalent wind) can be obtained directly from cone calorimeter data. On the other hand, opposed-flow flame spread probably still needs LIFT data, especially to determine the flame heating parameter. The flame spread rate, V_p, is calculated using equation A-6-6.1.6 (where T_s is the initial surface temperature in °C):

$$V_p = \frac{\Phi}{k\rho c\left(T_{ig} - T_s\right)^2} \qquad \text{(A-6-6.1.6)}$$

A-6-6.3.1 The Ohio State University (OSU) model is one of the first comprehensive fire models of a room corner fire, and it was developed at Ohio State University by E. E. Smith [Smith, 1972, 1977, 1978; Smith & Satija, 1983]. It predicts fire growth of wall linings on the basis of ignition, flame spread, and heat and smoke release data obtained from the OSU small-scale heat release calorimeter (ASTM E 906, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products*). The model has been shown to be adequate for wood materials but is less satisfactory for some other materials. The two main disadvantages of using this model include:

(a) Work on its development has been virtually discontinued; and

(b) The bench-scale apparatus on which it is based has been somewhat superseded by the cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*).

The Eurefic method predicts time to flashover of wall linings as tested in the international room-corner test fire standard (ISO 9705, *Fire Tests — Full Scale Room Fire Tests for Surface Products*, options 100 kW and 300 kW; three walls and the ceiling are covered). Time to flashover also is predicted by the full-scale heat release rate curve as a function of time from the results of the cone calorimeter [ASTM E 1354 or ISO 5660, *Fire Tests — Reaction to Fire — Part 1: Rate of Heat Release from Building Products (Cone Calorimeter Method)*]. This model does not seek any results on factors such as airflow rates and hot layer depths, and it is, thus, a reasonably simple empirical approach. The model is based on three major assumptions:

(a) There is no direct relationship between the burning area growth rate and the heat release rate;

(b) The burning area growth rate is directly proportional to the ease of ignition (i.e., it is inversely proportional to the time to ignition in the cone calorimeter); and

(c) The history of the heat release rate per unit area at each location is the same in full scale as in small scale (cone calorimeter). Unfortunately, the full-scale test model does not have universal approval in the United States, where it is rarely used. The model is also known as the Eurefic model, because it was developed by the European Nordic countries within their particular program of research, with the objective of developing a unified classification system for building products in terms of their fire response characteristics, as a replacement for the various classification systems in existence in individual European countries [Wickström & Göransson, 1987, 1992].

The Lund model also predicts a number of room fire parameters of wall linings, with the same objective as the Eurefic model, and originated at Lund University (Sweden) [Karlsson & Magnusson, 1991, 1992]. It differs from the Eurefic model in a number of ways. First, it uses input from the lateral ignition and spread of flame apparatus (LIFT, ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*) as well as from the cone calorimeter (ASTM E 1354 or ISO 5660), while the Eurefic model uses cone data only. Second, it predicts a large number of room fire test variables in addition to heat release rate and time to flashover. Third, this fire model, while based on the same room-corner test for wall linings (ISO 9705), uses a scenario with material on the walls only, rather than on the walls and ceiling. Finally, this model is based on a fundamental, rather than an empirical, approach. The model assumes that the total heat release rate comes from the following five sources:

(a) The gas burner;

(b) The vertical wall area behind the burner flame;

(c) A horizontal strip of material at the ceiling/wall intersection corresponding to the vertical height of the ceiling jet;

(d) The wall material in the upper layer, after flame spread has started; and

(e) The wall linings burning below the hot gas layer.

The model has limited direct applicability, because the test is rarely conducted under the necessary conditions. Nevertheless, the Lund model has greater potential than the Eurefic model, because its fire scenario can be altered with greater flexibility.

The Cleary-Quintiere model provides for the development of a set of equations that predicts different full-scale fire parameters, primarily those associated with flame spread, based on input data from the lateral ignition and flame spread test (ASTM E 1321, LIFT) and cone calorimeter (ASTM E 1354) heat release rate test methods [Cleary & Quintiere, 1991]. The main fire properties necessary for input include:

(a) The average peak heat release rate per unit area at a certain incident heat flux in the cone calorimeter (in kW/m^2);

(b) The burn time in the cone calorimeter at the same incident heat flux (i.e., the time during which a significant amount of heat is released), in (a);

(c) The time to ignition, T_{ig}, in the cone calorimeter or the LIFT apparatus at an incident heat flux corresponding to the minimum flux for wind-aided flame spread (in sec);

(d) The flame heating parameter for opposed flame spread, from the LIFT apparatus (Φ, in sec kW^2/m^3); and

(e) The minimum temperature for opposed flow flame spread (also from the LIFT) in °C. The data can be used to predict time to flashover or to peak heat release rates as well as actual peak heat release rates. The model is flexible enough that it can be applied to both the ISO 9705 and NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings*. The input parameters are partially empirical.

An extension of the Cleary-Quintiere model also exists that includes the added effect of thermal feedback due to the increase of temperature within the room [Quintiere, 1993]. It has been applied to predict ISO 9705 wall lining material data and is in the process of being applied to predict NFPA 265 data. Its reliability is still unknown.

A number of other room fire models have been proposed and have been discussed recently [Janssens, 1992b].

A-6-6.4 Fire performance of floor finish items is often assessed by determining the critical radiant flux in the flooring radiant panel (NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, or ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor-Covering Systems Using a Radiant Heat Energy Source*). However, the results of this test are not suitable for use in the calculations cited in this document [Briggs et al., 1992; Lawson, 1993; Tomann, 1993].

A-6-8.1 The use of a "backyard test" can be a useful screening method for prediction of the heat release rate of upholstered furniture. In this test, an actual piece of furniture (or a full-scale mock-up) is exposed to the same ignition source as that in ASTM E 1537, *Standard Test Method for Fire Testing of Real Scale Upholstered Furniture Items*, in a relatively draft-free environment. Visual observations of the results are made, but no heat release measurements are made. This setup allows reasonable predictions of some heat release rate results in the actual instrumented fire tests. It does not provide any estimation of total heat release. Figure A-6-8.1(a) represents results where chairs were divided into those that produce peak rates of heat release of under 40 kW and over 300 kW. Of fourteen systems tested and deemed to give off low heat release rates, none actually exceeded peak values of 250 kW, and four exceeded 80 kW. Of six systems tested and deemed to give off high heat release rate, none gave off peak values lower than 80 kW, and three gave off values between 100 kW and 250 kW. The actual experiments for which results are represented in Figure A-6-8.1(a) were all carried out with balanced, woven fabrics of different types but with the same foam and interliner barrier. A number of other individual experiments were made with other materials, and the reliability of the results was much less satisfactory. However, this work indicates the clear value of visual observation conducted by those who are experienced.

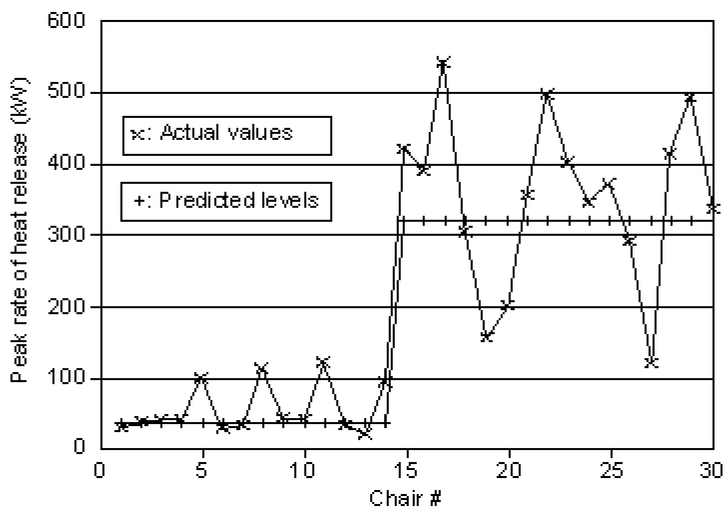

Figure A-6-8.1(a) Predictions of the results of full-scale ASTM E 1537 tests with upholstered furniture items (backyard test) and actual observed values.

An attempt also has been made to predict peak heat release rate values based on fabric weight. It has been shown that fabric weight alone might not be a reliable indicator of furniture heat release rate. In this case, a number of tests were carried out using a single specific fabric/interliner/foam/chair construction system. The only variable was the weight of the fabric. In a follow-up series of tests, a different type of fabric was used. All the results are shown in Figure A-6-8.1(b), which indicates that a five-fold increase in fabric weight was not sufficient, in this particular case, to differentiate significantly among the fire performance of the chairs. In one series, a definite trend towards increased heat release with increased fabric weight was evident, even though the error bars overlapped. In the other case, all systems produced nondifferentiable results. This is somewhat surprising since other work has shown that, in some systems, the effect of the fabric is the dominant one on fire performance [Hirschler & Shakir, 1991].

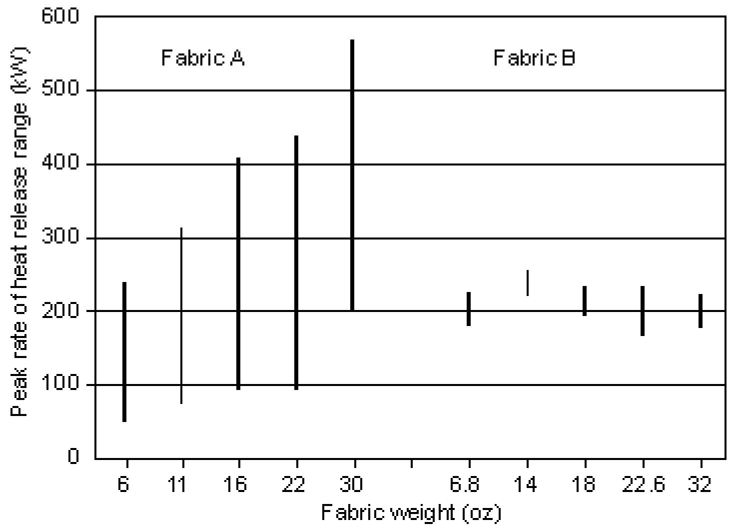

Figure A-6-8.1(b) Effect of fabric weight on heat release rate in full-scale ASTM E 1537 upholstered furniture tests using two fabrics, A and B.

NFPA 560

1995 Edition

Standard for the Storage, Handling, and Use of Ethylene Oxide

for Sterilization and Fumigation

1995 Edition

This edition of NFPA 560, *Standard for the Storage, Handling, and Use of Ethylene Oxide for Sterilization and Fumigation*, was prepared by the Technical Committee on Industrial and Medical Gases and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995.

This edition of NFPA 560 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 560

In June, 1990 a request was made by a manufacturer of ethylene oxide to develop a new standard for the storage, handling, and use of ethylene oxide for sterilization and fumigation. This request addressed the replacement of the nonflammable mixture of ethylene oxide and freon with pure ethylene oxide, which was occurring concurrent with the reduced use of freon for environmental reasons. The request was reviewed by the NFPA Standards Council, which published a notice in the August, 1990 edition of *Fire News* asking for public input on the recommendation.

At its January, 1991 meeting, the NFPA Standards Council approved the request and the development of the standard was assigned to the NFPA Technical Committee on Industrial and Medical Gases (IMGAS). The IMGAS Committee established a task force on ethylene oxide, which developed a draft standard that was made available for public review and notice of its availability was published in the December 1993/January 1994 edition of *Fire News* with a public proposal closing date of January 21, 1994. The IMGAS Committee reviewed the proposals and the Committee's report was published in the 1995 Annual Meeting Report on

Proposals. Further revisions were published in the 1995 Annual Meeting Report on Comments.

Committee Scope: This Committee shall have primary responsibility for documents on the storage, transfer, and use of industrial gases. Included are the storage and handling of such gases in their gaseous or liquid phases; the installation of associated storage, piping, and distribution equipment; and operating practices. The Committee also has a technical responsibility for contributions in the same areas for medical gases and clean rooms.

NFPA 560
Standard for the
Storage, Handling, and Use of
Ethylene Oxide for Sterilization and Fumigation

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 13 and Appendix C.

Chapter 1 General

1-1 Scope.

This standard shall apply to the storage and handling of ethylene oxide in portable containers for its use in sterilization and fumigation. It also shall apply to flammable mixtures of ethylene oxide with other chemicals.

This standard shall not apply to:

(a) Nonflammable mixtures of ethylene oxide with other chemicals.

(b) Ethylene oxide manufacturing facilities, and container filling, refilling, or transfilling facilities.

(c) The off-site transportation of portable containers of ethylene oxide.

NOTE: For regulations on the transportation of gases, see *Code of Federal Regulations*, 49 CFR Parts 100 through 179 (*Transportation*), and Transportation of Dangerous Goods Regulations of Transport Canada.

(d) Facilities using ethylene oxide as a chemical feed stock.

(e) Ethylene oxide in chambers 10 ft^3 (0.283 m^3) or less in volume, or for containers holding 200 g (7.05 oz) of ethylene oxide or less.

1-2 Alternate Materials, Equipment, and Procedures.

The provisions of this standard are not intended to prevent the use of any material, method of construction, or installation procedure not specifically prescribed by this standard, provided any such alternate is acceptable to the authority having jurisdiction (*see Section 1-4, Definitions*). The authority having jurisdiction shall require that sufficient evidence be submitted to substantiate any claims made regarding the safety of such alternates.

1-3 Retroactivity.

Unless otherwise stated, the provisions of this standard shall not be applied retroactively to existing systems that were in compliance with the provisions of the standard in effect at the time of installation.

1-4 Definitions.

Aeration Room. A room or area with controlled temperature or airflow where ethylene oxide sterilized products are held initially for offgassing.

Atmospheric Vents. All points where pipes, stacks, or ducts are open to the atmosphere including discharge points from emissions control devices, vent pipes from safety valves, vent pipes from filters or pumps, and other vents.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Chime Ring. The two raised rings circling the outer shell of DOT 5P (1A1) ethylene oxide drums. These rings protect the drum but are not intended for lifting purposes.

Container. For the purposes of this standard, a cylinder, drum, or other pressure vessel built to DOT, ASME, or other pressure vessel code and used to transport or store ethylene oxide.

Cylinder. A portable compressed gas container, fabricated to or authorized for use by the U.S. Department of Transportation (DOT), or fabricated to Transport Canada (TC) or the ASME *Boiler and Pressure Vessel Code*, Section VIII, *Rules for the Construction of Unfired Pressure Vessels*.

Drum. For the purposes of this standard, containers built to DOT specification 5P (1A1).

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Limited-Combustible Material. A material (as defined in NFPA 220, *Standard on Types of Building Construction*) not complying with the definition of noncombustible material which, in the form in which it is used, has a potential heat value not exceeding 3500 Btu per lb (8141 kJ/kg), and complies with one of the following paragraphs (a) or (b). Materials subject to increase in combustibility or flame spread rating beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible.

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of $^1/_8$ in. (3.2 mm), which has a flame spread rating not greater than 50.

(b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread rating greater than 25 nor evidence of continued progressive combustion. (*See NFPA 259, Standard Test Method for Potential Heat of Building Materials.*)

Listed. Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Outgassing. Release of adsorbed and absorbed ethylene oxide after sterilization.

Pressure Relief Device. A spring-operated pressure relief valve or rupture disc.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Special Buildings. For the purposes of this standard, a building used exclusively for the ethylene oxide sterilization process.

Special Room. A separate enclosed area that is part of or attached to a building and is used exclusively for the ethylene oxide sterilization process.

Storage. An inventory of compressed or liquefied gases in containers that are not in the process of being examined, serviced, refilled, loaded, or unloaded.

Chapter 2 Receiving and Unloading Ethylene Oxide Containers

2-1 Scope.

This chapter applies to the handling of both full and empty ethylene oxide containers at a facility, including:

(a) Handling of the containers between the truck and the dock,

(b) Container inspection at the dock,

(c) Handling of the containers within the facility.

2-2 Procedures.

2-2.1

Drums shall not be lifted by placing the forks under the chime rings on the drums.

2-2.2

Prior to the unloading of ethylene oxide containers, the vehicle engine shall be turned off, the brakes set, and the wheels chocked.

2-2.3

Smoking or open flames shall not be permitted within 20 ft (6.1 m) of any area where ethylene oxide containers are handled.

2-2.4

Ethylene oxide cylinders shall be secured to hand trucks or lift trucks during movement.

2-2.5

Ethylene oxide containers shall be kept upright at all times. Containers shall not be stacked or rolled.

2-2.6

Immediately after off-loading, ethylene oxide containers shall be inspected and the following checks shall be performed:

(a) An examination for evidence of damage to the container or valves,

(b) A confirmation that the valves are equipped with valve outlet plugs or caps,

(c) An inspection of the container labeling to confirm that each container is labeled ethylene oxide,

(d)* A leak test of the container including valves and fuse plugs.

Ethylene oxide containers shall not be moved to storage until the inspection is complete.

2-2.7

In the event that any container fails incoming inspection, the ethylene oxide supplier shall be notified. If a leaking container is found, the facility procedures for handling ethylene oxide leaks and spills shall be followed.

2-2.8

Ethylene oxide containers shall not be stored in the receiving area.

Exception: Areas dedicated to the receiving and storage of ethylene oxide only.

Chapter 3 Storage of Ethylene Oxide

3-1 General.

3-1.1

Storage areas shall be secured against unauthorized entry.

3-1.2

Storage of ethylene oxide in combination with other compressed or liquefied gases shall be in accordance with NFPA 55, *Standard for the Storage, Use, and Handling of Compressed and Liquefied Gases in Portable Cylinders*.

3-1.3

Ethylene oxide containers shall be kept upright at all times. Containers shall not be stacked.

3-2 Indoor Storage.

3-2.1 Storage Within Buildings.

Storage within buildings shall not be permitted except in special buildings and special rooms. (*See Chapter 11*.)

Exception: One cylinder containing up to 400 lb (181 kg) of ethylene oxide shall be permitted to be stored in a production area where required for production within eight hr.

3-2.2 Storage Within Special Buildings or Special Rooms.

3-2.2.1* The maximum quantity of ethylene oxide stored in a special building or special room shall be 10,000 lb (4540 kg).

3-2.2.2 The construction of all such special buildings, and rooms within, or attached to, other buildings, shall comply with Chapter 11.

3-2.2.3 Special buildings or rooms shall be classified for purposes of ignition source control in accordance with 7-1.1.

3-2.2.4 Heated indoor storage areas shall be arranged so that stored cylinders or other containers cannot be spot-heated or heated above 125°F (51.7°C).

3-3 Storage Outside of Buildings.

3-3.1 Location of Storage Outside of Buildings.

Storage outside of buildings shall be located in accordance with Table 3-3.1.

Table 3-3.1 Outdoor Storage of Ethylene Oxide
Minimum Horizontal Distance to:

Quantity of EO Stored [lb (kg)]	Nearest important building or group of buildings or line of adjoining property that can be built upon.	Busy thoroughfares or sidewalks, line of adjoining property occupied by schools, churches, hospitals, athletic fields, or other
800 (363 kg) or less	0	0
801 (363 kg) to 2400 (1089 kg)	0	10 ft (3 m)
2,401 (1089 kg) to 6,000 (2722 kg)	10 ft (3 m)	10 ft (3 m)
6,001 (2722 kg) to 10,000 (4536 kg)	20 ft (6 m)	20 ft (6 m)
Over 10,000 (4536 kg)	25 ft (7.6 m)	25 ft (7.6 m)

3-3.2 Requirements for Outdoor Storage Areas.

Outdoor storage areas shall have a minimum of 25 percent of the perimeter open to the atmosphere. This open space shall be permitted to incorporate chain link fence, lattice construction, open block, or similar materials for the full height and width of the opening.

(a) Storage areas shall be kept clear of dry vegetation and combustible materials for a minimum distance of 15 ft (4.6 m).

(b) Cylinders stored outside shall not be placed on the ground (earth) or on surfaces where water can accumulate.

(c) Storage areas shall be provided with physical protection from vehicle damage.

(d)* Storage areas shall be permitted to be covered with canopies of noncombustible construction.

Chapter 4 Piping Systems

4-1 Scope.

This chapter shall apply to ethylene oxide piping systems including pipe, tubing, flanges, gaskets, valves, fittings, flexible connectors, and the pressure containing parts of other components such as expansion joints and strainers, and devices used to mix, separate, distribute, meter, and control the flow of ethylene oxide. This chapter shall not apply to scrubber and vent systems.

4-2 Materials for Piping, Valves, and Fittings.

4-2.1 Materials.

All metallic materials used shall be specified in ASME B31.3, *Chemical Plant and Petroleum Refinery Piping*. The requirements of the hazardous materials section shall apply. The following restrictions shall also apply:

(a) All metallic materials used shall have a minimum melting point of greater than 1500°F (815.6°C).

(b) No furnace butt-welded steel product shall be used.

4-2.2* Joining Methods.

Joints shall be made gas-tight and shall be either welded, flanged, brazed, or threaded. Joints shall be welded when located in concealed spaces within buildings. The following shall also apply:

(a) *Welding.* All welding processes and procedures shall be in conformance with the ASME *Boiler and Pressure Vessel Code,* Section IX . The Oxy-Fuel Gas Welding (OFW) procedure shall not be used on any component or system fabricated to this standard.

(b) *Brazing.* All brazing processes and procedures shall be in strict conformance with the ASME *Boiler and Pressure Vessel Code,* Section IX . All braze alloys shall have a minimum melting point of 1000°F (537.8°C). The failure of the braze joint in the event of a fire exposure shall not in any way result in the release of additional fuel that can accelerate or spread the existing fire.

(c) *Soldering.* Soldering shall not be used for pressure containment or structural purposes. Soldering for hermetic/environmental sealing purposes as part of a mechanical sealing system shall be permitted. The failure of any soldering application in the event of a fire shall not allow a release of fuel that can accelerate or spread the existing fire.

(d) *Threading.* Threaded joints shall be made with a thread sealant or lubricant compatible with ethylene oxide.

4-3* Preparation for Dismantling of Piping.

Any piping and valves that have been used to transport ethylene oxide to or from a sterilizer to the emission control or release point shall be drained and purged prior to dismantling. The piping shall be purged free of flammable concentrations of ethylene oxide prior to cutting or welding on the lines. The piping shall be inspected for evidence of polymer prior to cutting or welding. If found, all polymer shall be removed prior to cutting or welding.

NOTE: For information on safety in cutting and welding see NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes.*

4-4 Valves.

Valves shall be designed for a minimum operating pressure of 150 psi (1030 kPa). All material used, including valve seat discs, packing, seals, and diaphragms shall be in accordance with Section 4-2.

4-5 Testing.

Pressure piping systems shall be tested and demonstrated to be free of leakage at 150 percent of the maximum anticipated operating pressure, prior to use. Vacuum piping shall be tested at the lowest anticipated operating pressure.

NOTE: For information on testing of piping systems see ASME B31.3, *Chemical Plant and Petroleum Refinery Piping*.

4-6 Identification.

Ethylene oxide lines shall be identified.

NOTE: For information on identification of piping see ASME A13.1, *Scheme for the Identification of Piping Systems*.

Chapter 5 Gas Dispensing Areas

5-1 General.

In addition to the requirements in Chapter 3, Storage of Ethylene Oxide, the following shall apply to areas where ethylene oxide is dispensed from containers. Ethylene oxide storage shall be permitted in dispensing areas.

5-1.1

Indoor dispensing areas shall be equipped with a continuous gas detection system that provides an alarm when ethylene oxide levels exceed 25 percent of the lower limit of flammability (7,500 ppm).

NOTE: Additional detection at lower levels may be required to meet the requirements of the Occupational Safety and Health Administration of the U. S. Department of Labor (29 CFR 1910.1047).

5-1.2*

Exhaust ventilation shall be installed in all indoor dispensing areas used for ethylene oxide. Exhaust ventilation shall comply with the following:

(a) Mechanical ventilation shall be operated continuously at a rate of not less than 1 ft^3 per min per ft^2 (0.3 m^3 per min per m^2)of floor area of dispensing area.

(b) Exhaust ventilation shall not be recirculated within a room or building.

Exception: Where the air is treated to reduce the ethylene oxide concentration to below that which represents a hazard, recirculation shall be permitted. Controls shall be provided to ensure the performance of the treatment and recirculation system.

(c) The ventilation system shall be designed to prevent accumulation of ethylene oxide anywhere in the dispensing area.

(d) Loss of ventilation shall activate a visual and audible alarm and shall stop the flow of ethylene oxide at the remotely operated shutoff valve closest to the container.

5-2* Ethylene Oxide Containers.

5-2.1

No more than two ethylene oxide containers shall be connected to each sterilizer.

5-2.2

Before connections are made, containers shall be grounded.

5-2.3

The ethylene oxide supply line shall have a reverse flow prevention device to prevent contamination of the supply container where automatic switchover of containers is used.

5-2.4

Each ethylene oxide piping system from the containers to the process chamber shall have two remotely operated shutoff valves in the flow stream.

5-2.5

The valve required in 5-2.4 closest to the container shall be located 5 ft (1.5 m) or less from the container. The valves shall be operable from the sterilizer control room or other location outside the dispensing area.

5-2.6

Any supply piping containing liquid ethylene oxide that can be isolated shall be equipped with a pressure relief device.

5-3 Nitrogen System.

5-3.1

Nitrogen used for head space pressurization shall be no less than 99.9 percent nitrogen and shall contain no impurities that are chemically incompatible with ethylene oxide.

5-3.2

A reverse flow prevention device shall be provided to prevent ethylene oxide from entering the nitrogen supply system.

5-3.3

A particulate filter shall be provided to prevent rust from being introduced into an ethylene oxide container.

5-3.4

Refillable containers shall be pressurized with nitrogen to 50 psi (345 kPa) prior to disconnection and shipment to the supplier.

5-4 Vaporizer.

5-4.1

A valve shall be provided to control liquid flow to the vaporizer. This valve shall be permitted to be one of the valves required in 5-2.4.

5-4.2*

An indicating or recording device shall be provided at the control panel to demonstrate that ethylene oxide temperature is within the range of 60°F (16°C) to 200°F (93.3°C). An alarm shall be provided for out-of-range conditions.

5-5 Liquid Ethylene Oxide Piping.

Liquid ethylene oxide shall not be piped indoors beyond a special room.

Chapter 6 Operations

6-1 Operating Procedures Manual.

6-1.1

Each facility shall prepare and maintain an operating procedures manual covering facility startup, operation, and shutdown. These manuals shall include procedures for the safe operation of the facility under normal and nonroutine operation conditions. Manuals shall be accessible to facility operators at all times.

6-1.2

Operating procedures manuals shall include operator actions to be taken if toxic or flammable concentrations of ethylene oxide are detected in the facility.

6-1.3

Operating procedures shall include procedures for purging and inerting equipment and piping.

6-1.4

Operating procedures shall include procedures for addressing leakage and spills of ethylene oxide.

6-2* Sterilizer Operation.

6-2.1 Purging.

The vessel shall be purged to reduce the ethylene oxide concentration to less than 25 percent of the lower limit of flammability prior to opening the chamber door.

NOTE 1: Lower concentrations of ethylene oxide are required by OSHA (29 CFR 1910.1047) for personnel exposure.

NOTE 2: The use of nitrogen in enclosed spaces can pose an asphyxiation hazard.

6-2.2 Post-Cycle Ventilation.

A nonrecirculating ventilation system or equivalent means shall be provided to prevent ethylene oxide accumulation due to product outgassing prior to and during unloading of the sterilizer.

NOTE: Outgassing, depending on product characteristics, can be of sufficient magnitude to produce flammable mixtures of ethylene oxide.

6-2.3 Cycle Abort.

Ethylene oxide sterilizers shall be equipped with a manually initiated cycle abort feature accessible to the operator. This also shall be operable from outside the sterilizer area. A key-locked device shall not be permitted. The cycle abort operation shall remove flammable concentrations of ethylene oxide from the sterilizer.

6-3 Area Monitoring for Ethylene Oxide.

Ethylene oxide sterilizer areas shall be monitored continuously for ethylene oxide concentrations.

6-3.1

The gas detection system shall provide an audible and visual warning signal to indicate when concentrations of ethylene oxide reach a level of 25 percent of the lower limit of flammability of ethylene oxide.

6-3.2*

The gas detection system shall automatically shut off the supply at the ethylene oxide containers when the concentration of ethylene oxide exceeds 25 percent of the lower limit of flammability.

NOTE: Additional detection at lower levels may be required to meet the requirements of OSHA (*Code of Federal Regulations*, Title 29, Part 1910.1047).

6-4 Emergency Stop.

An emergency stop device shall be provided to halt all operating equipment including valves, rotating equipment, and heating apparatus on the sterilizer and gas dispensing equipment. The emergency stop shall be activated by a manually initiated feature accessible in the control room or at the control panel.

Chapter 7 Electrical Installation

7-1 Area Electrical Classification.

7-1.1

The sterilizer room, gas dispensing room, ethylene oxide container storage area, aeration rooms, and emission control area shall be classified as a Class I, Division 2, Group B area in accordance with NFPA 70, *National Electrical Code®*.

Exception: Aeration rooms shall be permitted to be unclassified electrically where it is demonstrated that flammable concentrations of ethylene oxide can not occur during all normal and nonroutine operating conditions, including power failure.

7-1.2

The interior of the sterilization vessel shall be classified Class I, Division 1, Group B.

7-2 Static Electricity Control.

All piping shall be bonded to an earth ground.

NOTE: For information on prevention of static electricity see NFPA 77, *Recommended Practice on Static Electricity*.

7-3 Grounding Requirements.

All equipment shall be grounded in accordance with NFPA 70, *National Electrical Code*, Article 250 and Section 501-16.

Chapter 8 Sterilizer Construction

8-1* Vessel.

Sterilizers operating at 15 psig (100 kPa) or higher shall be designed, built and stamped in accordance with the ASME *Boiler and Pressure Vessel Code*, Section VIII.

8-2 Rotating Equipment.

Rotating equipment exposed to flammable concentrations of ethylene oxide shall be designed to prevent sparking and localized overheating of surfaces during normal and nonroutine operation.

8-3 Pressure Relief Device.

A pressure relief device, set to open at the sterilizer's design pressure, shall be installed on each sterilizer. Pressure relief devices shall be inspected annually for corrosion or accumulation of material (such as polymer buildup) that could prevent operation.

8-3.1

The point of discharge of the pressure relief device shall not be located in an area where potential ignition sources exist or where ethylene oxide vapors could re-enter the building.

8-3.2

Shutoff valves shall not be installed in relief device discharge piping.

Chapter 9 Disposal and Emissions

9-1 Scope.

This chapter shall apply to the disposal and emission of ethylene oxide from sterilization facilities.

NOTE: The emphasis of this chapter is on those issues specifically related to fire safety. Sterilization facilities are required to comply with federal, state, and local environmental health and safety regulations.

9-2 Wet Scrubbers.

Where a wet scrubber is used, the following requirements shall apply:

(a) Wet scrubbing systems shall be designed so that scrubber solution cannot enter ethylene oxide vent or process lines.

(b) Sources of pure ethylene oxide liquid shall be prevented from being fed directly to scrubber systems designed only for ethylene oxide gas treatment.

9-3 Flare Stacks.

Where a flare stack is used, the following requirements shall apply:

(a) Flame arrestors shall be installed to prevent flame flashback into the sterilizer.

(b) Flare stack failure shall initiate a shutdown of the flare stack feed and an audible alarm.

9-4 Catalytic Converter.

Where a catalytic converter is used, it shall be designed to shut down or be bypassed if the temperature exceeds the maximum temperature determined by the catalyst supplier.

Chapter 10 Maintenance

10-1 General Requirements.

A written program shall be developed for the following maintenance activities:

(a) Confined space entry,

(b) Purging of equipment and piping,

(c) Welding (hot work) permit system,

(d) Lockout/tagout,

(e) Preventive maintenance for key equipment.

10-2 Maintenance Manuals.

Manuals shall be accessible to facility operators and maintenance personnel at all times.

Chapter 11 Construction

11-1 Scope.

This chapter covers the construction, ventilation, and heating of structures that house ethylene oxide storage, dispensing, and use. These structures shall be used exclusively for these purposes and for the housing of other materials having similar hazards, or they shall be permitted to be rooms attached to, or located within, buildings used for other purposes.

11-2 Separate Structures or Buildings.

11-2.1 Construction of Structures or Buildings.

11-2.1.1 Separate structures or buildings shall be one story in height and shall have walls, floors, ceilings, and roofs constructed of noncombustible or limited combustible materials. Exterior walls, ceilings, and roofs shall be constructed as follows:

(a) Of lightweight material designed for explosion venting, or

(b) If of heavy construction, such as solid brick masonry, concrete block, or reinforced concrete construction, explosion venting windows or panels in walls or roofs shall be provided.

NOTE: For information on venting of deflagrations, see NFPA 68, *Guide for Venting of Deflagrations.*

11-2.1.2 The floor of such structures or buildings shall not be located below ground level. Any space beneath the floor shall be of solid fill, or the perimeter of the space shall be entirely unenclosed.

11-2.2* Structure or Building Ventilation.

The structure or building shall be provided with general ventilation through the use of air supply inlets and exhaust outlets. These inlets and outlets shall be arranged to provide movement of well-mixed air throughout the space. Air circulation shall be at least 1.0 cfm per sq ft (0.3 m^3 per m^2) of floor area and shall be permitted to be provided by natural or mechanical means.

11-2.3 Structure or Building Heating.

Heating shall be by electrical appliances listed for Class I, Group B, Division 2 locations in accordance with NFPA 70, *National Electrical Code*, or shall be by means of steam or hot water radiation or other heating transfer medium with the heat source:

(a) Outside of the building, or

(b) In a separate room with a 2-hr fire resistance rating pressurized relative to the remainder of the building.

11-3 Special Rooms.

11-3.1 Construction of Special Rooms.

11-3.1.1 Special rooms attached to structures or special rooms located within structures shall have walls, floors, ceilings, and roofs constructed of noncombustible or limited-combustible materials.

11-3.1.2 The floor of a special room shall not be located below ground level. Any space beneath the floor shall be of solid fill, or the perimeter of the space shall be entirely unenclosed.

11-3.1.3 At least 25 percent of the room perimeter shall be an exterior wall designed as explosion venting.

Exception: Interior rooms shall be permitted in one-story buildings if the entire room roof is designed as explosion venting.

NOTE: For information on venting of deflagrations see NFPA 68, *Guide for Venting of Deflagrations*.

11-3.1.4 All interior walls shall have a fire resistance rating of at least 2 hr. Openings in interior walls shall be equipped with a minimum of 1-$^1/_2$-hr rated (B) fire doors.

NOTE: For information on fire doors, see NFPA 80, *Standard for Fire Doors and Fire Windows*.

11-3.1.5 All interior walls, and other walls of the room not designed as explosion venting, shall be designed to withstand an overpressure of at least 100 lb per ft^2 (4.8 kPa).

11-3.1.6 In multifloor buildings, where the space above the room ceiling is occupied or used, the ceiling shall be designed to withstand an uplift pressure of at least 100 lb per ft^2 (4.0 kPa).

11-3.2 Room Ventilation.

The room shall be provided with ventilation in accordance with 11-2.2.

11-3.3 Room Heating.

The room shall be provided with heating in accordance with 11-2.3.

Chapter 12 Fire Protection

12-1 Sprinklers.

All facilities storing or using ethylene oxide shall be protected by an automatic sprinkler system in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

12-2 Ethylene Oxide Storage Areas.

Ethylene oxide storage areas shall be equipped with a deluge system in accordance with NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*.

Chapter 13 Referenced Publications

13-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

13-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, 1994 edition.

NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, 1995 edition.

NFPA 55, *Standard for the Storage, Use, and Handling of Compressed and Liquefied Gases in Portable Cylinders*, 1993 edition.

NFPA 70, *National Electrical Code*, 1996 edition.

NFPA 220, *Standard on Types of Building Construction*, 1995 edition.

13-1.2 Other Publications.

13-1.2.1 ASME Publications. American Society for Mechanical Engineers, 345 East 47th St., New York, NY 10017.

ASME *Boiler and Pressure Vessel Code*, 1992 edition.

ASME B31.3–1993, *Chemical Plant and Petroleum Refinery Piping*.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-2-2.6(d) Ethylene oxide containers should be tested for leakage prior to moving them inside a facility. Leak detection solutions can be used to test for leaks around valves and fuse plugs. This is often referred to as a soap test. Inexpensive hand-held leak detection instruments also are available.

A-3-2.2.1 Storage of over 5,000 lb (2268 kg) of ethylene oxide can also be covered by 29 CFR 1910.119 (OSHA). Hazard analyses are required by OSHA for facilities storing more than 5,000 lb (2268 kg) of ethylene oxide in one location. Hazard analyses are recommended for all facilities that store, use, and handle ethylene oxide. Refer to 29 CFR 1910.119, *Process Safety*

Management of Highly Hazardous Chemicals, for guidance on conducting such an analysis. The analysis should address the hazards of the operation, identification of any previous incidents, engineering and administrative controls to protect against hazards, consequences of the failure of engineering and administrative controls, facility site, and human factors, and qualitative evaluation of the range of possible effects on employee safety and health due to the failure of controls.

A-3-3.2(d) The rate of formation of ethylene oxide polymers increases as the temperature increases. Therefore, to minimize polymer formation, ethylene oxide containers should be sheltered from intense sunlight. Ethylene oxide containers should not be stored under plastic sheets. This can produce a greenhouse effect that results in release of the fusible plugs.

A-4-2.2

Welding is the preferred method of joining pipe. The use of welding is important in preventing leakage of ethylene oxide.

A-4-3

Cleaning the inside of lines used for ethylene oxide is necessary prior to opening the piping system to remove the combustible, oily ethylene oxide by-products (which also contain absorbed ethylene oxide), such as polymers or glycols. These by-products can build up gradually over time.

A-5-1.2

Local exhaust hoods are an effective means used to control ethylene oxide levels at the source of potential release.

A-5-2

Typical ethylene oxide drum hookup and piping are shown in Figures A-5-2 (a) and (b).

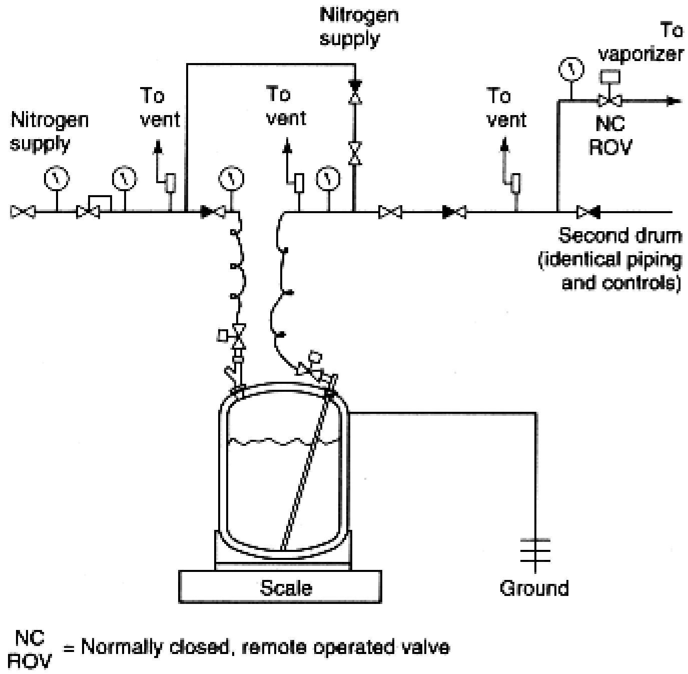

Figure A-5-2(a) Typical ethylene oxide drum hookup 1.

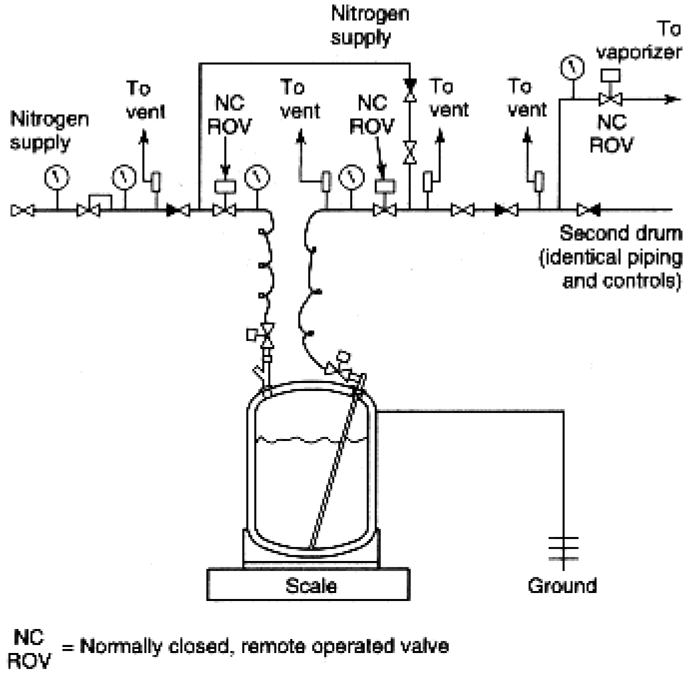

Figure A-5-2(b) Typical ethylene oxide drum hookup 2.

A-5-4.2

Monitoring of temperature in the ethylene oxide vapor stream provides a means to detect liquid ethylene oxide downstream of the vaporizer. The vaporizer should be equipped with a controller to maintain the desired temperature range for vaporization of ethylene oxide or ethylene oxide mixtures.

A-6-2 General.

Sterilization is performed in a closed vessel under controlled conditions of temperature, humidity, pressure, and ethylene oxide gas concentration. The process is a single-pass, batch operation where a number of steps are performed to complete the cycle. Process cycle parameters can vary widely to meet product sterilization requirements and can use flammable gas mixtures in the sterilizer.

A-6-3.2

Ethylene oxide gas supply shutoff is a minimum requirement; other operations such as emergency ventilation might also be appropriate.

A-8-1

Flame arrestors should be installed to prevent flame propagation from potential ignition sources external to the vessel. Locations for consideration are the vacuum pump suction line, air inbleed port, relief valve discharge, and other potential problem areas where flashbacks could occur.

A-11-2.2

In order to comply with this requirement and OSHA (29 CFR 1910.1047), specific local exhaust ventilation might be necessary in storage and dispensing areas, on the sterilizer, and in aeration rooms.

Appendix B Significant Properties of Ethylene Oxide

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

B-1 Hazards of Ethylene Oxide

(Based on NFPA 49, *Hazardous Chemicals Data*).

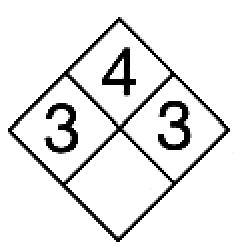

Figure B-1 Hazards of ethylene oxide.

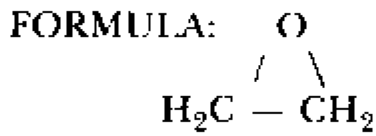
SYNONYMS: di-methylene oxide; EO; EtO; 1,2-epoxyethane; oxirane

FORMULA:



DOT CLASS: Class 2.3, Poisonous gas

SHIPPING LABEL: POISON GAS and FLAMMABLE GAS

ID NO.: UN 1040

CAS NO.: 75-21-8

MOL. WT.: 44.0

STATEMENT OF HAZARDS: Flammable gas. Low ignition energy. Explosive decomposition may occur. Hazardous polymerization may occur. Serious health hazard.

EMERGENCY RESPONSE PERSONAL PROTECTIVE EQUIPMENT: Wear special protective clothing and positive pressure self-contained breathing apparatus.

SPILL OR LEAK PROCEDURES: Eliminate all ignition sources. Releases may require isolation or evacuation. Approach release from upwind. Stop or control the leak, if this can be done without undue risk. Use water spray to cool and disperse vapors, protect personnel, and dilute spills to form nonflammable mixtures. Water solutions no longer flammable in open areas when diluted as 1 part in 22 parts water. In enclosed areas such as sewers, dilution to 1 part in 100 parts water may be required to eliminate flash potential. Control runoff and isolate discharged material for proper disposal.

FIRE-FIGHTING PROCEDURES: Use flooding quantities of water as fog. Use water spray, dry chemical, “alcohol resistant” foam, or carbon dioxide. Use water spray to keep fire-exposed containers cool. Explosive decomposition may occur under fire conditions. Fight fire from protected location or maximum possible distance.

HEALTH HAZARDS: Serious health hazard. May be harmful if absorbed through skin or inhaled. Pulmonary edema may result. Irritating to skin, eyes, and respiratory system.

FIRE AND EXPLOSION HAZARDS: Flammable gas. Volatile flammable liquid below room temperature. Explosive decomposition may occur in vapor or liquid phases. Vapor forms explosive mixtures with air over a wide range. Vapors are heavier than air and may travel to a source of ignition and flash back. Closed containers may rupture violently when heated.

FLASH POINT: 4°F (–20°C)

AUTOIGNITION TEMPERATURE: 804°F (429°C) [AIT in the absence of air is 1058°F (570°C)]

FLAMMABLE LIMITS: LOWER 3.0% UPPER 100.0%

INSTABILITY AND REACTIVITY HAZARDS: Highly reactive. Hazardous polymerization may occur especially if contaminated. Reacts with acids, alkalies, salts, combustible materials. May undergo runaway reaction with water. Many materials may accelerate this reaction.

STORAGE RECOMMENDATIONS: Store in a cool, dry, well-ventilated location. Store away from heat, oxidizing materials, and sunlight. Separate from acids, alkalies, salts, and combustible materials. Outside or detached storage is preferred. May react in insulation forming low molecular weight polyethylene glycols that can spontaneously heat and ignite at less than 212°F (100°C).

USUAL SHIPPING CONTAINERS: Insulated steel cylinders; pressurized tanks on trucks, rail cars, barges. Safety relief valves required.

PHYSICAL PROPERTIES: Colorless gas with sweet ether-like odor.

MELTING POINT: 170°F (–112°C)

BOILING POINT: 51°F (11°C)

SPECIFIC GRAVITY: 0.89 @ 0°C

SOLUBILITY IN WATER: soluble

VAPOR DENSITY: 1.51

VAPOR PRESSURE: 1095 mm Hg @ 20°C

ELECTRICAL EQUIPMENT: Class I, Group B (C)

B-2 Nonflammable Mixtures of Ethylene Oxide.

Ethylene oxide is often mixed with a second, inert component and shipped as a liquefied gas mixture for use by sterilizer operators. Several of these mixtures are nonflammable. Table B-2 indicates the maximum amount of ethylene oxide that a nonflammable mix can contain, as well as typical ethylene oxide contents of commercially available nonflammable mixtures.

Table B-2 Nonflammable Mixtures of Ethylene Oxide*

Second Component Chemical Name	Common Name	Chemical Formula	Max. EO Wt %	Typical EO Wt %	Max. EO Vol %
Dichloro difluoromethane	CFC-12	CF_2Cl_2	12.5	12.0	28.0
Carbon Dioxide	–	CO_2	9.0	8.5	9.0
2 Chloro-2,1,1,1 Tetrafluoroethane	HCFC-124	$CHClF\text{-}CF_3$	9.3	8.6	24.2
2,1,1,1,Tetrafluoroethane	HFC-134a	CH_2FCF_3	6.1	N/A	13
2,2,1,1,1 Pentafluoroethane	HFC-125	CHF_2CF_3	8.5	N/A	21.2

*Measured in accordance with ASTM E 681, *Standard Test Method for Concentration Limits of Flammability of Chemicals*, with an ignition energy of 40 j.

NFPA 600

1996 Edition

Standard on Industrial Fire Brigades

1996 Edition

This edition of NFPA 600, *Standard on Industrial Fire Brigades*, was prepared by the Technical Committee on Loss Prevention Procedures and Practices and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 600 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 600

In 1902 NFPA adopted *Suggestions for Organizing Private Fire Departments* recommended by the Committee on Private Fire Department Regulations. In 1912 NFPA adopted two pamphlets, *Organization and Execution of Exit Drills and Organization and Drilling of Private Fire Brigades*, on recommendation of the Committee on Private Fire Departments and Fire Drills. In 1924 the NFPA adopted *Suggestions for the Organization, Drilling and Equipment of Private Fire Brigades* on recommendation of the Committee on Field Practice, and revisions were adopted in 1930, 1937, and 1949.

Jurisdiction for the publication was transferred in 1948 to the new Committee on Fire Brigades and Watchmen, and a revised edition was published in 1955. The guide was completely revised in 1967.

In 1969 the Committee was reorganized as the Technical Committee on Loss Prevention Procedures and Practices, and the guide was reconfirmed in 1975. In 1981 a complete revision was accomplished, and partial revision was made in the 1986 edition, as well as a redesignation from NFPA 27 to NFPA 600.

In 1992 the document was completely revised to a standard to provide a minimum level of occupational safety and health for industrial fire brigade members consistent with OSHA. The standard incorporates for the first time the concepts of advanced exterior fire fighting and site-specific hazards. These are needed for industrial fire brigades to properly address the types of situations they encounter.

In 1996, the document was revised to include industrial fire departments which were previously addressed in NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*. This assists the authority having jurisdiction and owner/operators in determining which standard they must comply with and if they are in compliance. Other changes make the document more user friendly and better clarify the requirements of the standard.

Committee Scope: This Committee shall have primary responsibility for documents on fire brigades, guard services, and techniques for securing effective fire loss prevention programs in industrial, commercial, institutional, and similar properties.

NFPA 600

Standard on Industrial Fire Brigades

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix B.

Foreword

A major concern of industrial fire protection professionals is the protection of employees and property from the threat of fire in the workplace. In 1980 the Occupational Safety and Health Administration defined its requirements for fire brigades. These requirements apply to fire brigades once corporate or local management, in its role as an authority having jurisdiction, has determined that it wants a fire brigade at a facility.

In the *Code of Federal Regulations*, Title 29, Part 1910.156, Subpart L, OSHA, two types of fire brigades are defined in an attempt to establish levels of fire brigade function and to identify the training and safety requirements for each of those levels. Ever since that time industrial fire protection professionals have wrestled with categorizing every existing fire brigade into either the incipient stage category or the interior structural category.

In attempting to develop a state-of-the-art industrial fire brigade standard, the Technical Committee on Loss Prevention Procedures and Practices has followed OSHA’s lead in setting requirements based on the incipient and interior structural fire brigade definitions.

The adoption of NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, by the NFPA in 1987 brought about an entirely new perspective — that of inclusion of the industrial fire brigades in the same category as municipal fire departments. While the work done by the Technical Committee on Fire Department Occupational Safety and Health is admirable and is intended to safeguard all fire fighters, the Loss Prevention Procedures and Practices Committee believes that a separate industrial fire brigade standard is needed.

While each and every fire brigade is unique, just as each and every municipal fire department is unique, industrial fire brigades, including those that can be referred to as industrial fire departments, have far different needs in many respects from those of municipal fire departments.

The primary difference between industrial fire brigades and municipal fire departments is that industrial fire brigades must deal with conditions and hazards that are limited to those that exist within a given facility that is generally privately owned and operated. While these site-specific hazards can and do represent the same degree of hazard to both industrial fire brigade members and municipal fire fighters, industrial fire brigade members are not usually concerned with, nor are they expected to deal with, hazards and emergencies beyond the boundaries of the facility that the brigade serves.

In addition to this primary difference, it must be remembered that at an industrial facility a program of Occupational Safety and Health has already been established for all personnel including members of the fire brigade. Further, fire brigades constituted in accordance with this standard will, of necessity, have a much more thorough knowledge of the buildings and facilities where they respond than do municipal fire fighters who must respond to a significantly greater variety of buildings and facilities, many of which have unidentified and undisclosed hazards.

A municipal fire department, as a local government function, must provide a service to a very broad-based municipality, with a multitude of unknown factors at every given response. Such variables as property size and accessibility; building size, construction, and contents; manufacturing process hazards; fixed fire extinguishing systems and special agent availability; storage and use of solvents, oils, chemicals, or other hazardous materials are all potential unknown factors that can hinder the effectiveness of any municipal fire department and place a greater safety risk on the fire fighters.

It is this distinct advantage that achieves a higher level of fire brigade safety and allows for the fundamental difference between a municipal fire department and an industrial fire brigade.

Chapter 1 General

1-1 Scope.

1-1.1

This standard contains minimum requirements for organizing, operating, training, and equipping industrial fire brigades. It also contains minimum requirements for the occupational safety and health of industrial fire brigade members while performing fire fighting and related activities.

1-1.2*

This standard shall apply to any organized private, industrial group of employees having fire fighting duties, such as emergency brigades, emergency response teams, fire teams, and plant emergency organizations.

1-1.3*

This standard shall not apply to industrial fire brigades that respond to fire emergencies outside the boundaries of the industrial facility when the off-site fire involves unfamiliar hazards or enclosed structures with layout and contents that are unknown to the fire brigade.

1-2* Purpose.

The purpose of this standard is to provide minimum requirements for organization, operation, training, and occupational safety and health for industrial fire brigades.

1-3 Alternate Requirements.

The application of the performance objectives of this standard can vary for many industrial operations. The authority having jurisdiction shall be permitted to examine and approve organization, operations, training, and occupational safety and health requirements that provide an equivalent level of safety to that required by this standard.

1-4* Limits of Actions and Responsibilities of Brigade.

1-4.1

The degree of potential exposure to a hazardous environment and the degree of training shall determine the limits of any fire brigade action and responsibility. The written fire brigade organizational statement and standard operating procedures shall define these limits.

1-4.2*

At facilities where designated employees are intended to function as the first responders to incipient fires, the fire brigade shall assume command of the incident once it arrives on the fire scene.

1-4.3 Limits for Fire Brigades Assigned Incipient Fire Fighting Duties.

1-4.3.1 Interior and exterior fires shall be considered incipient stage when fire brigade members:

(a) are able to safely fight the fire in normal work clothing, and

(b) are not required to crawl or take other evasive action to avoid smoke and heat, and

(c) are not required to wear thermal protective clothing or self-contained breathing apparatus, and

(d) are able to fight the fire effectively with portable extinguishers or handlines flowing up to 125 gpm (473 L/min).

1-4.3.2 Exterior fires shall be considered appropriate for defensive action outside of the hot and warm zones by fire brigade members who have been assigned incipient fire fighting duties when:

(a) The organizational statement lists it as a duty of the fire brigade, and it is covered by the standard operating procedures, and

(b) The fire brigade has received training for that activity, and

(c) Self-contained breathing apparatus and thermal protective clothing are not required, and

(d) Personal evasive action is not required, and

(e) They are able to perform defensive action effectively, using handlines flowing up to 300 gpm (1140 L/min), master streams, or similar devices for the manual application of specialized agents.

1-4.4 Limits for Fire Brigades Assigned Only Advanced Exterior Fire Fighting Duties.

Exterior fires shall be considered appropriate for offensive action within the hot zone by fire brigade members who have been assigned advanced exterior fire fighting duties when:

(a) The organizational statement lists it as a duty of the fire brigade, and it is covered by the standard operating procedures, and

(b) The fire brigade has received training for that activity, and

(c) Self-contained breathing apparatus and thermal protective clothing are provided, and

(d) They are able to perform offensive action effectively, using handlines flowing up to 300 gpm (1140 L/min), master streams, or similar devices for the manual application of specialized agents.

1-4.5 Limits for Fire Brigades Assigned Only Interior Structural Fire Fighting Duties.

Interior structural fires shall be permitted to be attacked within the hot zone by fire brigade members who have been assigned interior fire fighting duties when:

(a) The organizational statement lists it as a duty of the fire brigade, and it is covered by the standard operating procedures, and

(b) The fire brigade has received training for that activity, and

(c) Self-contained breathing apparatus and protective clothing for structural fire fighting are provided, and

(d) Brigade members are able to perform offensive actions effectively using handlines flowing up to 300 gpm (1140 L/min), master streams, or similar devices for the manual application of specialized agents.

1-4.6 Limits of Fire Brigades Assigned Both Advanced Exterior and Interior Structural Fire Fighting Duties.

Both exterior fires and interior structural fires shall be considered appropriate for offensive actions within the hot zone for fire brigade members who have been assigned both advanced exterior and interior fire fighting duties when:

(a) The organizational statement lists it as a duty of the fire brigade, and it is covered by the standard operating procedures, and

(b) The fire brigade has received training for that activity, and

(c) Self-contained breathing apparatus and protective clothing for structural fire fighting are provided, and

(d) They are able to perform offensive action effectively, using handlines flowing up to 300 gpm (1140 L/min), master streams, or similar devices for the manual application of specialized agents.

1-5 Definitions.

Advanced Exterior Fire Fighting. Offensive fire fighting performed outside of an enclosed structure when the fire is beyond the incipient stage (*see definition*). Advanced exterior fire fighting often requires fire brigade members to contain, control, and extinguish exterior fires involving site-specific hazards, such as flammable and combustible liquid spills or leaks, liquefied petroleum gas releases, and electrical substations. Advanced exterior fire fighting is usually performed using handlines flowing up to 300 gpm (1140 L/min), master streams, or similar devices for the manual application of specialized agents. Thermal protective clothing is required and the use of self-contained breathing apparatus (SCBA) could be required.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Cold Zone. The safe area immediately surrounding and outside the boundary of the established warm zone of a fire. Personnel positioned in the cold zone are safe from the adverse effects of a fire.

Combustible Liquid. A liquid having a flash point at or above 100°F (38.8°C).

Defensive Fire Fighting. The mode of manual fire control in which the only fire suppression activities taken are limited to those required to keep a fire from extending from one area to another.

Designated Employee. An employee who is not a member of a fire brigade but who has been properly trained to use portable fire extinguishers or small hose lines to fight incipient fires in the employee's immediate work area.

Drill. An emergency exercise involving a credible emergency requiring the fire brigade to perform emergency operations.

Drug. Any substance, chemical, over-the-counter medication, or prescribed medication that affects the performance of the fire brigade member.

Duty. A fire-related service, function, or task identified in the fire brigade organizational statement and assigned to a member to perform.

Education. The process of imparting knowledge or skill through systematic instruction. It does not necessarily require formal classroom instruction.

Emergency Operations. Activities related to emergency incidents, including response to the scene of the incident and specific duties performed at the scene.

Enclosed Structure. A structure with a roof or ceiling and at least two walls that can present fire hazards to employees such as accumulations of smoke, toxic gases, and heat, similar to those found in buildings.

Fire Brigade. An organized group of employees within an industrial occupancy who are knowledgeable, trained, and skilled in at least basic fire fighting operations, and whose full-time occupation might or might not be the provision of fire suppression and related activities for their employer.

Fire Brigade Apparatus. A fire brigade emergency response vehicle designed and intended primarily for fire suppression, rescue, or other specialized function. This apparatus includes pumpers, foam apparatus, aerial ladders, rescue vehicles, and other such apparatus.

Fire Brigade Management. The individual designated by top management as being responsible for the organization, management, and functions of the industrial fire brigade.

Fire Brigade Training Coordinator. The designated company representative with responsibility for coordinating effective, consistent, and quality training within the fire brigade training and education program.

Flammable Liquid. A liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psi (2068 mm Hg) at 100°F (37.8°C).

Hazardous Atmosphere. Any atmosphere that is oxygen deficient or that contains a toxic or disease producing contaminant. A hazardous atmosphere might or might not be immediately dangerous to life and health.

Hot Zone. The area immediately surrounding the physical location of a fire. The outer boundary of the hot zone extends far enough from the fire to protect fire brigade members positioned outside the hot zone from being directly exposed to flames, dense smoke, or extreme temperatures.

Incident Management System. The management system or command structure used during emergency operations to clearly identify who is in command of the incident and what roles and responsibilities are assigned to various members.

Incipient Fire Fighting. Fire fighting performed inside or outside of an enclosed structure or building when the fire has not progressed beyond incipient stage.

Incipient Stage. Refers to the severity of a fire where the progression is in the early stage and has not developed beyond that which can be extinguished using portable fire extinguishers or handlines flowing up to 125 gpm (473 L/min). A fire is considered to be beyond the incipient stage when the use of thermal protective clothing or self-contained breathing apparatus is required or a fire brigade member is required to crawl on the ground or floor to stay below smoke and heat.

Industrial Occupancy. For the purpose of this standard, industrial occupancies include industrial, commercial, mercantile, warehouse, power plant (utility), and institutional or similar occupancy, including for-profit, not-for-profit, and governmental facilities.

Interior Structural Fire Fighting.* The physical activity of fire suppression, rescue, or both, inside of buildings or enclosed structures that are involved in a fire situation beyond the incipient stage.

Master Stream. A portable or fixed fire fighting appliance supplied by either hose lines or fixed piping and that has the capability of flowing in excess of 300 gpm (1140 L/min) of water or water-based extinguishing agent.

Medically Fit. There are no known medical limitations that would interfere with the process of making decisions and providing direction while exposed to a stressful environment, as determined by a qualified physician.

Offensive Fire Fighting. The mode of manual fire control in which manual fire suppression activities are concentrated on reducing the size of a fire to accomplish extinguishment.

Performance Standards. Minimum requirements for knowledge and skills that must be provided to or demonstrated by the fire brigade member upon completion of a training or education session.

Physically Fit. As determined by a qualified physician, there are no known physical or medical limitations that would interfere with the performance of strenuous heavy lifting and pulling or with the use of self-contained breathing apparatus (SCBA) that can be required during emergency operations.

Qualified Physician. A licensed medical doctor qualified to provide professional expertise in the areas of occupational safety and health as they relate to emergency response activities.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Site-Specific Hazard. A hazard that is present at the specific facility for which the fire brigade has been organized.

Specialized Agents. Fire extinguishing agents, such as dry chemicals, dry powders, carbon dioxide, halon, and other such non-water-based agents.

Standard. A document that contains only mandatory provisions using the word “shall” to indicate requirements. Explanatory material may be included only in the form of fine-print notes, in footnotes, or in an appendix.

Standard Operating Procedure. A written procedure that establishes a standard course of action and documents the functional limitations of the fire brigade members in performing emergency operations.

Support Member.* Personnel assigned to the fire brigade to perform specific duties, including those people who have specific technical knowledge or skills or who have been given specific assignments that indirectly support manual fire suppression efforts.

Thermal Protective Clothing. Protective clothing such as helmets, footwear, gloves, hoods, trousers, and coats that are designed and manufactured to protect the fire brigade member from the adverse effects of fire.

Training. The process of achieving proficiency through instruction and hands-on practice in the operation of equipment and systems that are expected to be used in the performance of assigned duties.

Warm Zone. The control area immediately surrounding and outside the boundary of the established hot zone of a fire. The outer boundary of the warm zone extends far enough from the outer boundary of the hot zone to protect personnel positioned outside the warm zone from the adverse effects of the fire.

Chapter 2 Requirements for All Fire Brigades

2-1 General Administration.

2-1.1* Corporate or Local Management.

Corporate or local management shall be responsible for:

(a) Evaluating the site-specific conditions and hazards to determine site-specific duties to be assigned to the fire brigade.

(b) Assigning the site-specific duties of the fire brigade.

(c) Establishing, reviewing, and maintaining a written fire brigade organizational statement.

(d) Establishing lines of authority and assigning responsibilities to ensure that the components of the fire brigade organizational statement are accomplished.

(e)* Establishing a written policy for the occupational safety and health of fire brigade members.

(f)* Establishing a written policy for the medical and job-related physical performance requirements for fire brigade members.

(g) Developing or adopting performance-based standards that establish baseline levels of proficiency in skills, knowledge, and the safety measures necessary for fire brigade members to accomplish the site-specific duties described in the fire brigade organizational statement.

(h) Developing, reviewing, and maintaining written standard operational procedures for site-specific conditions and hazards.

(i) Ensuring that a system exists to advise fire brigade management of changes in eligibility of an employee for participation on a fire brigade resulting from changes in employee's medical condition.

(j) Establishing a policy to ensure that the records required in this standard are maintained.

(k) Establishing a policy to ensure that annual funds are budgeted and available for equipment, vehicles, training and education, medical and job-related physical performance evaluations, and other necessary items to accomplish these objectives.

2-1.2

Management shall establish, review, and maintain a fire brigade organizational statement.

2-1.2.1* A written fire brigade organizational statement shall be prepared and maintained. This policy statement, which establishes the existence of the fire brigade, shall include:

(a) Basic organizational structure.

(b) The type, amount, and frequency of training and education to be provided.

(c) The expected number of members in the brigade.

(d) The duties that the brigade is expected to perform in the workplace, which define the limits of fire brigade responsibility.

(e) The shifts during which the brigade shall be available for response.

2-1.2.2* The organizational statement shall be available for inspection by the authority having jurisdiction, the fire brigade members, and their designated representatives.

2-1.3

Management shall establish lines of authority and assign responsibilities to ensure that the components of the fire brigade organizational statement are accomplished.

2-1.3.1 Management shall designate the responsible individual for the administration of the fire brigade organizational statement and the training and education program.

2-1.3.2 Management shall establish responsibility for initiating, maintaining, and enforcing standard operational procedures to ensure the safety and health of fire brigade members.

2-1.3.3 Management shall establish a policy to ensure that each fire brigade member cooperates, participates, and complies with the provisions of the fire brigade organizational statement and the training and education program.

2-1.4*

Management shall ensure that fire brigade members are a part of a corporate or local company occupational safety and health policy that identifies specific goals and objectives for the prevention and elimination of accidents, injuries, illness, and fatalities while performing fire brigade duties.

2-1.4.1 Management shall ensure that fire brigade members are adequately represented on corporate or local company occupational safety and health committees as they relate to members performing assigned fire brigade duties.

2-1.4.2* Management shall delegate the duties and responsibilities of the fire brigade safety program to a qualified individual(s).

2-1.4.3 The safety program shall include:

(a) Records and data management.

(b) Liaison with management, equipment suppliers, site or corporate safety, and medical and health departments.

(c) Development and maintenance of standard operating procedures.

(d) Accident prevention.

(e) Equipment specification and maintenance.

(f) Accident investigation.

(g) Incident scene safety.

(h) Training and education.

2-1.5*

All records associated with the operation of the fire brigade required in this standard shall be maintained in a location where they are available for inspection by the authority having jurisdiction.

2-2 General Operations.

2-2.1*

An incident management system shall be established with written procedures applying to all members involved in emergency and training operations, and shall be utilized to manage all emergency and training operations.

2-2.1.1 All members involved in emergency operations shall be familiar with the incident management system.

2-2.1.2 The incident management system shall identify roles and responsibilities relating to the safety of fire brigade operations. Safety responsibilities shall be assigned to supervisory personnel at each level of the organization.

2-2.1.3 This system shall include the roles and responsibilities of any responding public fire department and other outside agencies.

2-2.1.4* A standard system shall be used to identify and account for each fire brigade member present at the scene of the emergency.

2-2.1.5* Performance-based standards that establish minimum levels of proficiency in both skills and knowledge to permit all fire brigade members to safely accomplish the site-specific duties described in the fire brigade organizational statement shall be developed or adopted.

2-2.1.6 The incident management system shall ensure that the risk to members is evaluated prior to taking action. In situations where the risk to fire brigade members is unacceptable, the emergency response activities shall be limited to defensive operations.

Regardless of the risk, actions shall not exceed the scope of the organizational statement and standard operating procedures.

2-2.2

Standard operating procedures for site-specific conditions and hazards shall be developed, reviewed, and maintained.

2-2.2.1 These procedures shall be maintained in written form and shall address the site-specific functions identified in the fire brigade organizational statement.

2-2.2.2* These procedures shall include information regarding site-specific hazards to which fire brigade members can be exposed during a fire or other emergency.

2-2.2.3 These procedures shall address the site-specific limitations of emergency operations.

2-2.2.4 These procedures shall be accessible to all fire brigade members.

2-2.2.5 These procedures shall ensure that the shift fire brigade leader is notified of all major fire protection systems and equipment that are out of service.

2-2.3

A risk management policy for emergency response shall be established by fire brigade management.

2-2.3.1 The risk management policy shall be routinely reviewed with fire brigade members and shall be based on the following recognized principles:

(a) Some risk to the safety of fire brigade members is acceptable where there is a potential to save human lives.

(b) Minimal risk to the safety of the fire brigade members, and only in a calculated manner, is acceptable where there is a potential to save endangered property.

(c) No risk to the safety of fire brigade members is acceptable where there is no possibility of saving lives or property.

2-2.4

Operational safety requirements for fire brigade members responding to a fire emergency shall be established and shall at a minimum include the following:

(a) Personnel who are not trained in accordance with this standard shall not be permitted to enter the warm or hot zones established for a fire emergency.

(b) Self-contained breathing apparatus and thermal protective clothing shall be worn by fire brigade members entering the hot zone.

(c) Thermal protective clothing shall be worn by fire brigade members entering the warm zone.

(d) Fire brigade members shall operate in teams of two or more in response to fires that have advanced beyond the incipient stage.

(e) Fire brigade members operating in the hot and warm zones shall have an established communications system.

(f) When fire brigade members are operating in the hot zone, at least one fire brigade member with the capability to call for assistance shall remain outside the hot zone and shall maintain an awareness of the safety of fire brigade members located inside the hot zone.

(g) When fire brigade members are operating in the hot zone, additional brigade members shall be standing by in the warm zone with appropriate equipment to provide assistance or rescue.

(h) Fire brigade members positioned in the warm zone shall be clearly visible to command positions at all times.

(i) Personnel and fire brigade members positioned in any fire zone shall have reasonable opportunity to relocate to an alternate position should conditions of the fire change.

(j) Experienced fire brigade members shall oversee activities of less experienced brigade members during fire fighting operations.

2-3 General Education, Training, and Drills.

2-3.1

A training and education program shall be established and maintained for all fire brigade members to ensure that they are able to perform their assigned duties in a safe manner that does not pose a hazard to themselves or other members. All members shall be trained to a level of competency commensurate with the duties and functions that they are expected to perform, including the operation of all of the fire fighting and rescue equipment and systems they are expected to use.

2-3.2*

Members shall meet the minimum skills and knowledge requirements of a performance based training and education program. Skill levels shall be obtained by meeting documented job performance requirements for each site-specific task expected to be performed by brigade members before participating in emergency operations.

2-3.3

Fire brigade members shall not perform any duties they have not been trained and educated to perform.

2-3.4*

The quality and frequency of training and education provided shall ensure that fire brigade members are capable of performing their assigned duties in a safe manner that does not present a hazard to themselves or endanger other personnel.

2-3.5

It shall be an established goal of training and education to prevent accidents, injury, death, or illness while performing any fire brigade function.

2-3.6*

A designated fire brigade training coordinator shall provide instruction to the fire brigade or shall verify the qualifications of other instructors providing training and education to fire brigade members.

2-3.7*

Fire brigade members designated as leaders shall receive training and education commensurate with their duties. Such training and education shall be more comprehensive than that provided to the other fire brigade members.

2-3.8*

Drills shall be conducted as often as necessary to evaluate the effectiveness of the fire brigade training and education program and the competence of fire brigade members in performing assigned duties. Lessons learned shall be evaluated and documented, and additional training shall be provided as necessary to improve performance that is below established standards.

2-3.9*

The training and education provided to members shall include a review of the applicable provisions of this standard.

2-3.10

The training and education program shall include the principles and practices of fire fighting and emergency response to the extent required by the type of industrial fire brigade established and by the assignment within the brigade.

2-3.11

The training and education program shall address new hazards, equipment, and procedures introduced into the facility.

2-3.12*

Training provided to fire brigades shall develop and increase competency in life safety, property conservation, and reduction of business interruption.

2-3.13

Training shall include site-specific hazards. (*See 2-2.2.2.*)

2-3.14 Training Records.

2-3.14.1 Individual training records shall be maintained for each member of the fire brigade.

2-3.14.2 Training records shall include, but not be limited to, courses completed, subjects studied, refresher courses completed, and other evaluations of skills and knowledge, drill attendance records, and leadership or other special accomplishments related to fire brigade activities.

2-3.14.3 Training records shall be maintained and be available for inspection by the authority having jurisdiction.

2-3.14.4 Training records shall be reviewed periodically by fire brigade management and the fire brigade training coordinator to evaluate training needs and equipment needs of the brigade.

2-4 Organization of the Fire Brigade.

2-4.1

Fire brigade management shall be responsible for:

(a) Establishing programs to accomplish the items identified in the fire brigade organizational statement.

(b) Establishing the size and organization of the fire brigade.

(c) Coordinating and scheduling necessary meetings.

(d) Establishing and maintaining fire protection equipment inspection programs for fire brigade equipment.

(e) Coordinating the maintenance and review of necessary reports and records.

(f)* Maintaining liaison with local fire authorities.

(g) Making information on hazardous materials and processes to which the brigade might be exposed available to brigade members.

(h) Establishing job-related physical performance requirements for fire brigade members.

2-4.2 Fire Brigade Leader.

The fire brigade leader shall:

(a) Establish a chain of command within the brigade to act in the absence of the brigade leader.

(b) Assist in the selection process of brigade members.

(c) Establish and maintain a brigade roster.

(d) Select assistant fire brigade leaders as appropriate to the size of the brigade and keep them informed of all operations of the brigade.

(e) Develop pre-emergency plans for site-specific hazards and make information on hazardous materials and processes to which the fire brigade may be exposed available to all fire brigade members.

(f) Select and maintain equipment used by the brigade.

(g) Issue written reports on the status of the fire brigade to management, at least annually.

(h) Assist in fire investigations.

2-4.3 Assistant Fire Brigade Leaders.

The assistant fire brigade leader shall complete all tasks assigned by the fire brigade leader and substitute in his or her absence.

2-4.4 Fire Brigade Members.

2-4.4.1 Members of the fire brigade shall be selected from employees at the facility. They shall meet the requirements established for fire brigade members and shall represent as many separate areas and departments of the facility as is practical.

2-4.4.2 Each fire brigade member shall cooperate, participate, and comply with the provisions of the fire brigade organizational statement and the training and education program.

2-4.4.3 Fire brigade leaders or designated representatives shall ensure that support members are trained for their assigned duties. Support members shall demonstrate awareness of the plant's pre-fire plan prior to an incident and also shall demonstrate their assigned duties for those tasks.

2-4.5 Identification.

Members of the brigade shall be issued identification for the purpose of:

(a) Assistance in reaching the incident in an emergency.

(b) Identification by security personnel.

(c) Establishing authority.

2-4.6 Fire Brigade Communications.

(a) A means shall be established to notify brigade members of a reported incident.

(b) A means shall be established for communications between brigade members during an emergency.

2-5 Medical and Job-Related Physical Requirements.

2-5.1 General.

2-5.1.1* Prior to being accepted for fire brigade membership, employees shall be examined and certified by a qualified physician as being medically and physically fit. The medical and physical fitness requirements shall take into account the risks and the tasks associated with the individual's assigned fire brigade duties.

2-5.1.2 Fire brigade members who are under the influence of alcohol or drugs shall not participate in any fire brigade operations.

2-5.2 Medical Requirements.

Fire brigade members who perform advanced exterior fire fighting or interior structural fire fighting shall be medically evaluated by a qualified physician annually, and after each medical leave of absence.

2-5.3* Job-Related Physical Performance Requirements.

2-5.3.1* Fire brigade management shall establish job-related physical performance requirements for fire brigade members.

2-5.3.2 Fire brigade members shall meet the job-related physical performance requirements of 2-5.3.1 prior to assignment to the fire brigade.

2-5.3.3 Fire brigade members shall be evaluated annually to ensure they continue to meet the job-related physical performance requirements of 2-5.3.1.

2-5.3.4 When the evaluation required in 2-5.3.3 concludes that a fire brigade member does not meet the job-related physical performance requirements of 2-5.3.1, the member shall not be permitted to continue to perform those task specific activities.

2-5.4* Physical Fitness.

Fire brigade members shall be required to report to management any changes in their physical condition that could impact their performance as a fire brigade member.

2-6 Fire Brigade Equipment.

2-6.1

The fire brigade shall be provided with the appropriate equipment to enable it to perform the duties assigned in the organizational statement.

2-6.2*

The equipment selected shall be based on the nature of the facility and the site-specific hazards present.

2-6.3

Storage space for the fire brigade equipment shall be provided so that fire fighting equipment is readily accessible.

2-6.4

A written list shall be maintained of the equipment on the site that the fire brigade is expected to use. The list shall include the location of the equipment and procedures for obtaining the equipment when needed. This list shall be updated at least annually.

2-6.5

Operation and maintenance manuals for fire brigade equipment shall be available to the fire brigade.

2-6.6

Maintenance reports of fire brigade equipment shall be available to the fire brigade.

2-7 Fire Brigade Apparatus.

2-7.1

Fire brigade management shall consider fire brigade health and safety as primary concerns in the specification, design, construction, acquisition, operation, maintenance, inspection, and repair of all apparatus.

2-7.1.1* Fire brigade apparatus shall be operated only by members who have been qualified in its proper operation by formal training using performance-based standards.

2-7.1.2 Drivers of fire brigade apparatus shall have valid driver's licenses for the type of vehicle as required by state law or corporate policy. Vehicles shall be operated in compliance with all applicable traffic laws.

2-7.1.3 Drivers of fire brigade apparatus shall be directly responsible for safe and prudent operation under all conditions.

2-7.1.4 Standing while riding shall not be permitted.

2-7.1.5 Riding on tailsteps or in any other exposed position on fire brigade apparatus shall not be permitted.

2-7.1.6 All persons riding on fire brigade apparatus shall be seated and secured with seat belts.

2-7.2

All fire brigade apparatus shall be maintained in accordance with the manufacturer's recommendations.

2-7.3

All fire brigade apparatus shall be inspected at least weekly and within 24 hours after any use or repair to identify and correct unsafe conditions.

2-7.4

Fire brigade apparatus found unsafe shall be placed out of service until repaired.

2-7.5

Fire pumps on apparatus shall be service tested in accordance with the frequency and procedures specified in NFPA 1911, *Standard for Service Tests of Pumps on Fire Department Apparatus*.

2-7.6

All aerial devices shall be inspected and service tested in accordance with the frequency and procedures specified in NFPA 1914, *Standard for Testing Fire Department Aerial Devices*.

Chapter 3 Fire Brigades That Perform Incipient Stage Fire Fighting

3-1 General.

Fire brigades organized to perform incipient stage fire fighting shall meet the following requirements in addition to all applicable requirements of Chapters 1 and 2 of this standard.

3-2 Training.

3-2.1*

All fire brigade members shall receive training and education at least annually.

3-2.2

All fire brigade members shall participate in a drill at least annually.

3-2.3*

Training and drills involving live fire evolutions shall be performed in accordance with recognized safety precautions.

3-3 Protective Clothing and Equipment.

Thermal protective clothing and self-contained breathing apparatus shall not be required.

3-4 Medical.

Each fire brigade member shall meet the medical and job-related physical performance requirements as specified in Section 2-5.

Chapter 4 Fire Brigades That Perform Advanced Exterior Fire Fighting Only

4-1 General.

Fire brigades organized to perform advanced exterior fire fighting only shall meet the following requirements in addition to all applicable requirements of Chapters 1 and 2 of this standard.

4-2 Training and Education.

4-2.1

All fire brigade members shall receive training and education at least quarterly to meet the requirements of Section 2-3.

4-2.2

All fire brigade members shall participate in a drill at least semi-annually to meet the requirements of Section 2-3.

4-2.3

Live fire training shall be conducted at least annually. Training and drills involving a live fire evolution shall be performed in accordance with recognized safety precautions.

4-2.4

Live fire training shall include simulated props that are representative of the hazards that could be encountered by the fire brigade member.

4-3 Protective Clothing and Protective Equipment.

4-3.1

Thermal protective clothing and protective equipment shall be available in sufficient quantity and sizes to fit each brigade member expected to enter the hot and warm zones. Thermal protective clothing and protective equipment meeting the following requirements shall be required to be worn by all fire brigade members entering the hot and warm zones.

(a) Protective clothing shall be in accordance with NFPA 1971, *Standard on Protective Clothing for Structural Fire Fighting*.

(b) Helmets shall be in accordance with NFPA 1972, *Standard on Helmets for Structural Fire Fighting*.

(c) Gloves shall be in accordance with NFPA 1973, *Standard on Gloves for Structural Fire Fighting*.

(d) Footwear shall be in accordance with NFPA 1974, *Standard on Protective Footwear for Structural Fire Fighting*.

4-3.2

SCBA and PASS devices meeting the following requirements shall be provided for and shall be used by all fire brigade members working in the hot zone.

(a) PASS devices shall be in accordance with NFPA 1982, *Standard on Personal Alert Safety*

Systems (PASS) for Fire Fighters.

(b) Open-circuit type, self-contained breathing devices shall be in accordance with NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*.

(c) Closed-circuit type, self-contained breathing devices shall be NIOSH/MSHA approved with a minimum service duration of 30 minutes and shall operate in the positive pressure mode only.

4-3.3

Protective clothing and protective equipment shall be used and maintained in accordance with manufacturer's instructions. A maintenance and inspection program shall be established for protective clothing and protective equipment. Specific responsibilities shall be assigned for inspection and maintenance.

4-3.4

Members using SCBA shall operate in teams of two or more who are in communication with each other through visual, audible, physical, safety guide-rope, electronic, or other means to coordinate their activities, and are in close proximity to each other to provide assistance in case of an emergency.

Where members are involved in operations that require the use of SCBA or other respiratory protective equipment, at least one member shall be assigned to remain outside the area where respiratory protection is required. This member shall be responsible for maintaining a constant awareness of the number and identity of personnel using SCBA, their location, function, and time of entry. Members with SCBA shall be available for rescue.

4-3.5

All fire brigade members entering the hot zone shall be provided with approved protective hoods or a combination of ear flaps and collar that provide protection for the ears and neck and interface with the self-contained breathing apparatus facepiece, thermal protective coat, and helmet.

4-4 Medical.

Each fire brigade member shall meet the medical and job-related physical performance requirements as specified in Section 2-5.

Chapter 5 Fire Brigades That Perform Interior Structural Fire Fighting Only

5-1 General.

Fire brigades organized to perform interior structural fire fighting only shall meet the following requirements in addition to all applicable requirements of Chapters 1 and 2 of this standard.

5-2 Training.

5-2.1

All fire brigade members shall receive training and education at least quarterly to meet the requirements of Section 2-3.

5-2.2

All fire brigade members shall participate in a drill at least semi-annually to meet the requirements of Section 2-3.

5-2.3

Live fire training shall be conducted at least annually. Training and drills involving a live fire evolution shall be performed in accordance with NFPA 1403, *Standard on Live Fire Training Evolutions in Structures*.

5-2.4

Live fire training shall include simulated props that are representative of the hazards that could be encountered by the fire brigade member.

5-3 Protective Clothing and Protective Equipment.

5-3.1

Protective clothing for structural fire fighting and protective equipment shall be available in sufficient quantity and sizes to fit each brigade member expected to enter the hot and warm zones. Protective clothing and protective equipment meeting the following requirements shall be required to be worn by all fire brigade members entering the hot and warm zones.

(a) Protective clothing shall be in accordance with NFPA 1971, *Standard on Protective Clothing for Structural Fire Fighting*.

(b) Helmets shall be in accordance with NFPA 1972, *Standard on Helmets for Structural Fire Fighting*.

(c) Gloves shall be in accordance with NFPA 1973, *Standard on Gloves for Structural Fire Fighting*.

(d) Footwear shall be in accordance with NFPA 1974, *Standard on Protective Footwear for Structural Fire Fighting*.

(e) PASS devices shall be in accordance with NFPA 1982, *Standard on Personal Alert Safety Systems (PASS) for Fire Fighters*.

(f) Open-circuit type, self-contained breathing devices shall be in accordance with NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*.

(g) Closed-circuit type, self-contained breathing devices shall be NIOSH/MSHA approved with a minimum service duration of 30 minutes and shall operate in the positive pressure mode only.

5-3.2

All fire brigade members entering the hot zone shall be provided with approved protective hoods or a combination of ear flaps and collar that provide protection for the ears and neck and interface with the self-contained breathing apparatus facepiece, protective coat for structural fire fighting, and helmet.

5-3.3

Protective clothing and protective equipment shall be used and maintained in accordance with manufacturer's instructions. A maintenance and inspection program shall be established for protective clothing and protective equipment. Specific responsibilities shall be assigned for inspection and maintenance.

5-3.4

Fire brigade members performing emergency operations below ground level shall be provided with self-contained or externally supplied breathing apparatus and shall use that apparatus unless the safety of the atmosphere can be established by testing and continuous monitoring.

5-3.5

Members using SCBA shall operate in teams of two or more who are in communication with each other through visual, audible, physical, safety guide-rope, electronic, or other means to coordinate their activities, and are in close proximity to each other to provide assistance in case of an emergency.

Where members are involved in operations that require the use of SCBA or other respiratory protective equipment, at least one member shall be assigned to remain outside the area where respiratory protection is required. This member shall be responsible for maintaining a constant awareness of the number and identity of personnel using SCBA, their location, function, and time of entry. Members with SCBA shall be available for rescue.

5-4 Medical.

Each fire brigade member shall meet the medical and job-related physical performance requirements as specified in Section 2-5.

Chapter 6 Fire Brigades That Perform Both Advanced Exterior and Interior Structural Fire Fighting

6-1 General.

Fire brigades intended to perform both advanced exterior and interior structural fire fighting duties shall meet the requirements of Chapters 1, 2, 4, and 5 of this standard.

Chapter 7 Referenced Publications

7-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

7-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 1403, *Standard on Live Fire Training Evolutions in Structures*, 1992 edition.

NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, 1992 edition.

NFPA 1911, *Standard for Service Tests of Pumps on Fire Department Apparatus*, 1991 edition.

NFPA 1914, *Standard for Testing Fire Department Aerial Devices*, 1991 edition.

NFPA 1971, *Standard on Protective Clothing for Structural Fire Fighting*, 1991 edition.

NFPA 1972, *Standard on Helmets for Structural Fire Fighting*, 1992 edition.

NFPA 1973, *Standard on Gloves for Structural Fire Fighting*, 1993 edition.

NFPA 1974, *Standard on Protective Footwear for Structural Fire Fighting*, 1992 edition.

NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*, 1992 edition.

NFPA 1982, *Standard on Personal Alert Safety Systems (PASS) for Fire Fighters*, 1993 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.2

This standard is intended to meet or exceed the fire brigade-related requirements of the Occupational Safety and Health Standards, Subpart L, Fire Protection (*Code of Federal Regulations*, Title 29, Chapter XVII, Part 1910), of the Occupational Safety and Health Administration (OSHA), Department of Labor-U.S. Government. Further, this standard is intended to ensure the industrial fire brigade member with an appropriate degree of occupational safety and health while performing fire brigade duties just as NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, ensures an appropriate degree of occupational safety and health for the municipal fire department member.

For additional information on fire brigade organization, see Chapter 4 in the NFPA *Industrial Fire Hazards Handbook*.

A-1-1.3

It is the intent that fire brigade members, who are trained and qualified under the guidance of this standard, respond to familiar hazards that are common to the industrial facility being protected.

Industrial fire brigades complying with the requirements of this standard may respond to fires outside the boundaries of the industrial facility only when the fire brigade is trained and familiar with the hazards associated with the fire. For example, a fire brigade having appropriate training in accordance with this standard may respond to a fire involving an enclosed structure outside the boundaries of the industrial facility, if such response was anticipated and preplanned by brigade management. Each brigade member should be familiar with the layout and contents of the structure and be provided with the opportunity to tour the structure at least quarterly.

A-1-2

Requirements for the establishment of industrial fire brigades are established by the authority having jurisdiction.

A-1-4

It is the potential exposure and training that separate an organized fire brigade from designated employees (as defined by OSHA) who have some fire response duties in the general work area. The scope of brigade actions and responsibilities are based on the specific duties that the fire brigade members are expected to perform. If a brigade member is not expected to perform a particular fire fighting function, then management has no obligation to train or equip the fire brigade member to perform that function.

A-1-4.2

Designated employees who are intended to respond to incipient fires in their immediate work area should receive training commensurate with the duties they are expected to perform. Their responsibilities are normally limited to sounding an alarm, taking immediate action to extinguish the fire, and evacuation of the area.

A-1-5 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-5 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-5 Interior Structural Fire Fighting.

This definition is taken from OSHA, *Code of Federal Regulations*, Title 29, Part 1910.

Rescue is the activity of removing victims by a fire brigade as part of fire fighting activities. Rescue activities requiring specialized equipment and training, such as confined space and high angle rescue, are not included in this standard.

A-1-5 Support Member.

When organizing the industrial fire brigade, management should take into consideration the need for specialized duties required in the event of a fire or related emergency and assign personnel to the brigade to ensure that these duties are accomplished.

In most cases, personnel are not expected to perform manual fire suppression activities in the event of an emergency but are expected to perform only those specialized tasks for which they have been chosen.

Some of these specialized assignments include:

(a) *Building evacuation.* Personnel are expected to perform specialized duties to ensure that personnel are safely evacuated from an enclosed structure or the facility in the event of fire. They may be known as fire brigade wardens or a variety of other titles.

(b) *Sprinkler system control.* Personnel are assigned to perform specialized duties to ensure that control of the automatic sprinkler protection system within the fire area or the facility is maintained by facility personnel in the event of fire. They may be known as fire brigade sprinkler valve operators or a variety of other titles.

(c) *Electrical power control.* Personnel are expected to perform specialized duties to ensure that control of electrical power within the fire area or the facility is maintained by facility personnel in the event of fire. They may be known as fire brigade electricians or a variety of other titles.

(d) *Utility control.* Personnel are expected to perform specialized duties to ensure that control of plant utilities (steam, water, natural gas, and other liquid or vapor piping systems) within the fire area or the facility is maintained by facility personnel in the event of fire. They may be known as fire brigade utility control technicians or a variety of other titles.

(e) *Fire pump operation.* Personnel are expected to perform specialized duties to ensure that stationary fire pumps are placed into operation or are operating properly in the event of fire. They may be known as fire brigade fire pump operators or a variety of other titles.

(f) *Salvage.* Personnel are expected to perform specialized duties to ensure that actions are taken during and after manual fire suppression activities to minimize the resultant damage from the fire. They may be known as fire brigade salvage personnel or a variety of other titles.

(g) *Traffic control.* Personnel are expected to perform specialized duties to ensure that control of foot and vehicular traffic in and around the fire area or the facility is maintained in the event of fire and to ensure that any responding agency is directed to the fire area. These operations may be accomplished by facility security personnel who have been assigned to the fire brigade.

A-2-1.1

In order to maintain the safety and operational effectiveness of the fire brigade, it should be recognized that even during times of economic stress it is necessary to provide adequate funds for proper equipment and training.

The structure of the brigade should be determined based on an analysis of all factors present in the areas where the brigade will operate, including, but not limited to:

(a) Property size;

(b) Property accessibility;

(c) Building size and construction;

(d) Building contents;

(e) Fire protection equipment;

(f) Fire hazards;

(g) Personnel safety;

(h) Public fire department assistance;

(i) Availability of personnel;

(j) Shift and vacation schedule of the facility;

(k) Other duties of the brigade (fire watch, maintenance of fire fighting equipment, etc.).

A-2-1.1(e) The establishment of a written policy for the occupational safety and health of fire brigade members is intended to help prevent accidents, injuries, and exposures, and to reduce the severity of those accidents, injuries, and exposures that do occur. It is possible that an existing corporate safety program or policy may satisfy the requirements of this standard.

A-2-1.1(f) The establishment of a written policy for medical and job-related physical performance requirements will help ensure that fire brigade members will be medically and physically capable of performing their required duties and will help to reduce the risk of injuries and illnesses.

A-2-1.2.1 Sample Fire Brigade Organizational Statements.

ABC Fire Brigade Organizational Statement

January 1990

Purpose: The ABC Fire Brigade was organized to safeguard the employees and the property of the ABC Corporation from the threat of fire. The fire brigade is intended to function as an incipient stage fire brigade as identified by the *Code of Federal Regulations*, Title 29, Part 1910, Subpart L of the Occupational Safety and Health Administration.

Membership: Anyone who works at the ABC Corporation is welcome to join the fire brigade, although certain specific members are appointed, based on their particular job and location within the facility. At the present time, there are a total of 25 members on the brigade.

Members are identified as fire fighting members and support members. Fire fighting members are expected to perform fire fighting duties, utilizing both hand portable fire extinguishers and wheeled fire extinguishers and the $1^1/_2$-in. (38-mm) hose lines stationed throughout the facility.

Support members are not expected to fight fires but are expected to perform specialized duties that are intended to support the fire fighting operations. These support functions include:

(a) Ensuring that the building is evacuated.

(b) Ensuring that sprinkler valves are open.

(c) Ensuring that the fire department is directed to the scene of the fire.

(d) Ensuring that the fire pump is operating properly.

(e) Ensuring that other logistical needs of the fire fighting members are met.

Organization: The brigade is headed by a brigade chief. A shift fire brigade leader is also assigned to each shift. In the absence of the chief, the shift chief is in charge of the brigade. During a fire incident, the shift chief or brigade chief is in charge of the incident until the

Washington Volunteer Fire Department arrives. At this time, the officer in charge of the fire department forces on scene and the shift chief will establish a joint incident command.

Functions: The primary function of the fire brigade is to perform fire fighting operations that do not exceed the capabilities of the members present to prevent fires that begin from spreading prior to the arrival of the fire department or operation of the sprinkler system.

Additional functions include the provision of advanced first aid assistance in any salvage operations that are necessary during any type of incident, including a fire, and the checking of fire protection and life safety equipment throughout the facility on a daily basis.

Training: The primary source of training for fire fighting members is that conducted within the facility by the fire brigade training officer. This training is conducted on a monthly basis, with training being done in accordance with the ISFSI *Performance Standards for Incipient Stage Fire Brigade Member II*.

Support members receive training on a bimonthly basis in the operation of the fire protection equipment, building evacuation information, and other related topics. This training is provided by the fire brigade training officer and other personnel from the facility, such as the maintenance supervisor, the emergency coordinator, and the safety director.

Safety: While this fire brigade exists to help safeguard the people and property of the ABC Corporation, the first and foremost consideration must be for the safety of the members of the fire brigade. The brigade has limited resources and training and thus has limited abilities. These limits must be recognized by all members to ensure that members are not extended beyond their capabilities or the limitations imposed by the equipment with which they must operate.

Sample Organizational Statement

ABC Company, under contract with the XYZ Corporation for management and operation of the XYZ Plant, will use an Emergency Response Team (ERT) for the protection of those facilities.

The ERT is composed of employees whose normal job duties are not that of an ERT. In the event of an emergency, ERT members will leave their normal assigned duties and assume the duties of the ERT. Responding ERT members will be grouped into teams, and designated ERT leaders (ERTLs) using the Incident Management System will direct and supervise emergency operations. The total number of available ERT members responding to an emergency will vary from two to forty depending on the particular site, the time of day, and response times. As dictated by the size and duration of the emergency, this number could increase to over one hundred with response by trained ERT members and leaders from other XYZ Plant sites.

For fires involving enclosed structures, the ERT will perform only incipient fire fighting and will not enter into a building or enclosed structure involved with fire beyond the incipient stage. For a building involved with fire beyond the incipient stage, ERT members will notify local municipal fire departments or mutual aid organizations to respond and will assist with evacuation, account for personnel, perform first aid, and protect adjacent exposures.

For emergency fire response to the site-specific hazards associated with the storage and transfer of crude oil, the ERT will perform advanced exterior fire fighting. In performing advanced exterior fire fighting, ERT members will wear protective gear and will have responsibilities for rescue, emergency first aid, isolation of fuel sources, and application of water, foam, and dry chemical from the perimeter of the fire, which does not require entry into the interior of enclosed structures involved with fire beyond the incipient stage. Emergency contractors will be employed as necessary for complex fire emergencies that are beyond the training of the ERT.

For response to site-specific hazardous materials emergencies, the ERT will perform limited functions. In performing the limited hazardous materials functions, ERT members will be provided with appropriate personal protective equipment and will approach the source of a spill or leak and attempt to contain, control, and terminate the emergency conditions for which they have been trained. Emergency contractors will be employed as necessary for complex spills, leaks, and cleanup that are beyond that for which the ERT are trained.

Each ERT member will receive training and education commensurate with the duties and functions they are expected to perform. Forty hours of fire, safety, and hazardous materials response training will be provided annually at the ERT Training Academy using established performance-based standards. Training at the academy will include, but not be limited to, hose and nozzle handling, fire fighter safety, use of protective gear, strategies and tactics, first aid, CPR, hazard identification, spill control, and live fire fighting involving flammable liquids and gases. ERT members must attend and successfully complete one ERT Training Academy before participating in emergency operations.

ERT members will receive additional fire training quarterly. Training will be provided at each of the National Oil Supply facilities by qualified personnel to meet established performance standards. Such training will include class room instruction and hands-on training that has been selected to keep ERT members familiar with site-specific equipment, systems, and standard operating procedures.

Designated ERTLs will annually receive eight hours of specialized classroom instruction and will train and function as a leader in all live fire and hazardous materials training exercises at the ERT Training Academy and at the sites. Such training will be over and above that provided to other members and will be provided by qualified personnel. Instruction will include, but not be limited to, such subjects as leadership, methods of teaching, incident command, communications, tactics and strategies, and standard operating procedures.

A-2-1.2.2 The purpose of the fire brigade organizational statement is to demonstrate management's commitment to the establishment of a fire brigade. This statement identifies all of the information pertinent to the fire brigade and is intended to provide the fire brigade member with a clear picture of the organization of the brigade and the duties that he or she is expected to perform as they relate to the fire brigade.

In addition to the information required in the organizational statement, the following information should also be included:

(a) the line of authority of each fire brigade member;

(b) the number of fire brigade leaders;

(c) the number of fire brigade instructors;

(d) a list and description of the types of awards or recognition that brigade members may be eligible to receive.

The fire brigade organizational statement is intended to represent the foundation of the fire brigade. It is much like the mission statement of the organization. Thus, everything that the brigade does should be in accordance with the information in the organizational statement. As such, the organizational statement may need periodic revision as the mission, organization, or duties of the brigade change.

A-2-1.4

Example of a safety policy statement: It is corporate or local company policy to operate an industrial fire brigade and to provide all fire brigade members with the highest possible levels of safety and health while performing their assigned fire brigade duties.

A-2-1.4.2 The determination of whether the individual will have a full-time or part-time assignment should be made by the management. This should depend on the size and structure of the fire brigade; the activity level; the level of risk in the fire brigade's work environment; and the history of accidents, injuries, occupational illness, deaths, and exposures.

A-2-1.5

Medical records shall be permitted to be stored elsewhere in accordance with company policies.

A-2-2.1

For information on incident management systems, see NFPA 1561, *Standard on Fire Department Incident Management System*.

A-2-2.1.4 Fire brigades are often organized in such a manner that they respond to the emergency scene and assemble upon arrival. A system should be established to identify each fire brigade member arriving at the emergency scene and to organize them into groups with appropriate supervision. This requires a standard system of "reporting in" at the incident and becoming a part of the organized system of operation.

A-2-2.1.5 For information on performance standards for fire brigade members, see *Performance Standards for Industrial Fire and Emergency Management Training*, ISFSI or Chapter 3 of NFPA 1001, *Standard for Fire Fighter Professional Qualifications*, or other performance standards.

A-2-2.2.2 Site-specific special hazards should be identified and itemized for the fire brigade, along with a detailed explanation of the hazard. Special hazards may involve operations or materials. Typical operations are data processing and electronic control equipment where the discharge of a special extinguishing agent may present a hazard to fire brigade members, engine test areas, paint dip, mix and storage rooms, spray booths, flammable liquid tank farms, oil quenching and machinery operations, energized electrical equipment, hazardous materials, and combustible dusts.

A-2-3.2

It is recognized that job training requirements may vary significantly from one location to another. Those requirements should be documented based on site-specific needs. In order to meet the requirements of 2-3.2, fire brigade management should perform an analysis of required fire brigade duties.

The training should be equivalent to ISFSI *Fire Suppression Training of Industrial Fire Brigade Members and Emergency Responders*; Chapter 3 of NFPA 1001, *Standard for Fire Fighter Professional Qualifications*; or other performance standards.

A-2-3.4

Management should develop a plan and schedule to provide training, education, and drills at the minimum specified frequencies required by this standard.

It is recognized that scheduling difficulties in the industrial setting will make it difficult to provide training, education, or drills on a specific day for each individual brigade member. For this reason, the following clarifications are intended to provide the necessary flexibility for planning and scheduling these activities:

(a) Quarterly requirements should be accomplished every 90 days and should not exceed 120 days between sessions.

(b) Semi-annual requirements should be accomplished every 183 days and should not exceed 243 days between sessions.

(c) Annual requirements should be accomplished every 365 days and should not exceed 455 days between sessions.

A-2-3.6

The fire brigade training coordinator should be an employee who is recognized or certified as a fire brigade or fire service instructor by a government authority or national certification organization, or the coordinator should demonstrate the competency to meet the requirements of management in its role as an authority having jurisdiction.

For information on performance standards for fire brigade instructors, see *Performance Standards for Industrial Fire and Emergency Management Training*, ISFSI or NFPA 1041, *Standard for Fire Service Instructor Professional Qualifications* or equivalent.

Where fire brigade training is contracted and provided by individuals or agencies outside of the company organization, the designated fire training coordinator should verify and ensure that instructors providing the training are knowledgeable in the subjects being presented. Such training should be accomplished using prepared lesson plans and performance-based standards that have been approved by the fire brigade training coordinator.

Employees and members of the fire brigade who have been trained in the methods of teaching and are recognized by the fire training coordinator as knowledgeable in the subject being presented may provide instruction to the fire brigade with the use of prepared lesson plans and performance-based standards that have been approved by the fire training coordinator.

The fire brigade training coordinator should oversee the fire brigade training and education program to ensure quality and consistency of the training provided.

A-2-3.7

Fire brigade leaders should be provided training on the incident management system established in 2-2.1 of this standard. For information on performance standards for fire brigade leaders, see ISFSI for fire brigade leader, Chapter 2 of NFPA 1021, *Standard for Fire Officer Professional Qualifications*, or other performance standards.

A-2-3.8

Management should designate the person(s) responsible for planning and scheduling drills based on realistic scenarios for credible site-specific emergencies.

Where mutual aid or other outside agencies play an important role in the emergency response procedures of the site, drills and pre-emergency planning should be conducted in conjunction with these agencies.

Management should designate the person(s) responsible for observing drills and for critiquing fire brigade or outside agency performance. Lessons learned should be incorporated into the training and education program to improve any performance that is below established standards.

While there are recognizable training benefits achieved through drills exercising the knowledge and skills of the fire brigade, drills should not be considered as training (*see definition of a drill*). For example, if fire brigade members were never trained in the operation of a piece of fire brigade apparatus or in the proper strategies and tactics for emergency fire operations, then the fire brigade member could not demonstrate competence in performing these tasks in a drill. Drills can be valuable in determining the frequency of refresher training necessary to maintain fire brigade skills.

Responses to actual emergencies may reduce the necessity to conduct drills, providing the actual responses occur with sufficient frequency and as long as the fire brigade performance during these responses is evaluated in accordance with established performance objectives and properly documented.

A-2-3.9

Since members will be required to meet the provisions of this standard that apply to the type of fire brigade of which they are members, it is important that the applicable provisions of this standard be reviewed in the training program.

A-2-3.12

Members of the industrial fire brigade should be afforded opportunities to improve their skills and knowledge of fire prevention and fire fighting through attendance at outside meetings and special training classes. Members who belong to volunteer fire departments and who receive certified training from a qualified instructor as a part of their public fire department activities may have this training documented in their individual fire brigade training records.

A-2-4.1(f) Fire brigade management should maintain a close working relationship with all emergency response organizations that might reasonably be expected to respond to the facility during an emergency. This relationship should include items such as:

(a) A written mutual aid agreement signed by management and the emergency response organization.

(b) Establishment of an incident management system that identifies the roles and responsibilities of both the fire brigade and the emergency response organization.

(c) Inviting the emergency response organizations to participate in a pre-fire planning walk-through or tour of the facility.

(d) Inviting the emergency response organizations to participate in fire brigade drills at least annually.

(e) Ensuring that a means of communication is established between the fire brigade and the emergency response organizations. This may be accomplished by the use of common radio frequencies, the exchange of respective portable radios, or other means.

(f) Ensuring that fire hose threads are compatible or that adequate adapters are provided and available.

(g) Knowledge by both the fire brigade and the emergency response organizations of the other's available equipment. This should include items such as water supply, pump size, foam capabilities, portable or fixed master stream devices, or both, and other specialized equipment.

A-2-5.1.1 For information on medical requirements, see OSHA requirements in the *Code of Federal Regulations*, Title 29, Part 1910.156 or NFPA 1582, *Standard on Medical Requirements for Fire Fighters*.

A-2-5.3

Minimum physical performance requirements should be established to ensure that fire brigade members are able to satisfactorily perform their assigned emergency response activities under adverse conditions.

A-2-5.3.1 Many critical emergency response activities may be physically demanding. These tasks require muscular strength, muscular endurance, aerobic capacity, flexibility, equilibrium, and anaerobic power. Fire brigade management should include the capabilities noted above for the evaluation of fire brigade members.

A-2-5.4

Fire brigade members should be encouraged to maintain good physical condition.

A-2-6.2

In selecting the equipment necessary to allow the fire brigade members to perform their duties as specified in the fire brigade organizational statement, it should be recognized that such a selection may be drawn from a wide range of equipment. The following is a sample of the equipment more commonly selected:

(a) Portable fire extinguishers. Portable fire extinguishers should be in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

(b) Hose and hose accessories. Fire hose should be in accordance with NFPA 1961, *Standard for Fire Hose*. Hose should be maintained in accordance with NFPA 1962, *Standard for the Care, Use, and Service Testing of Fire Hose Including Couplings and Nozzles*.

(c) Portable lighting equipment. Portable lighting equipment, including portable electric generators, extension cords, electrical adapters, hand-held lights, and spare batteries.

(d) Forcible entry tools. Forcible entry tools, including axes, saws, power tools, plaster hooks, pike poles, claw tools, door openers, crowbars, sledgehammers, wire and bolt cutters, and battering rams.

(e) Ladders.

(f) Salvage and overhaul equipment.

(g) Rescue and first aid equipment.

(h) Special purpose equipment, such as portable foam- making equipment.

(i) Personnel protective equipment.

A-2-7.1.1 For information on performance standards for industrial fire brigade apparatus operators, see ISFSI Training of Industrial Fire Brigade Apparatus Operators, Chapters 2 through 6 of NFPA 1002, *Standard for Fire Department Vehicle Driver/Operator Professional Qualifications*, or other performance standards.

A-3-2.1

Training and education objectives can be accomplished in the same session.

A-3-2.3 Fire Field Safety Recommendations.

(a) Site Selection Preparation:

Select an open area with a safe clearance from important buildings, dry vegetation, and storage containers holding flammable liquids and gases and compressed gases.

(b) Safety Procedures:

1. Smoking should be permitted only in designated areas.

2. Fuel and ignition sources should be separated by safe distances.

3. If high winds or other adverse weather conditions present a hazard to members or adjacent property, live fire training should not be conducted.

4. Only appropriate ignition sources should be used.

5. Each student should utilize a charged extinguisher when participating in an evolution.

6. Fire attack should be from the upwind side.

7. Care should be taken to ensure that members are not placed at risk to the products of combustion.

8. For Class B fires, at least two portable extinguishers of the appropriate size and rating should be available for each evolution.

9. Retreat from an extinguished fire should be done in an organized manner, always being alert for possible reflash or rekindle.

(c) Fire Training Evolutions:

Evolutions should be commensurate with the size of fires that the members are expected to extinguish in their normal duties.

(d) Student Clothing:

Individuals participating in field evolutions should be attired in the type of clothing they would normally wear during the performance of their day-to-day job function.

(e) Instructors:

1. An instructor should guide each student while approaching, extinguishing, and retreating from each live fire training evolution.

2. The instructor should provide for the proper supervision of members who are not participating in the current evolution.

(f) Fuels:

1. Flammable liquids should not be used as accelerants to ignite Class A training fires.

2. Only approved safety containers should be used to dispense combustible liquids used as accelerants.

3. The person fueling and lighting the fire should be properly instructed and should wear appropriate protective clothing.

4. A qualified person equipped with a charged hand- line or appropriate extinguisher should stand by in any case where a combustible liquid is being used to light a training fire.

Performance Standards for Industrial Fire and Emergency Management Training.

Performance Standards for Industrial Fire and Emergency Management Training — Fire Brigade Leader.

Performance Standards for Incipient Stage Fire Brigade Member II.

NFPA 601

1996 Edition

Standard for Security Services in Fire Loss Prevention

1996 Edition

This edition of NFPA 601, *Standard for Security Services in Fire Loss Prevention*, was prepared by the Technical Committee on Loss Prevention Procedures and Practices and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

This edition of NFPA 601 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 601

The text dates from 1925 when the NFPA Committee on Field Practice presented a set of advisory rules called *The Watchman*, which was adopted and published by the NFPA and reprinted in 1930, 1936, and 1949. Jurisdiction for the publication was transferred in 1948 to the Committee on Fire Brigades and Watchmen, which presented revisions under the title *The Watchman, Recommended Manual of Instruction and Duties for the Plant Watchman or Guard*, which was adopted in 1951. Further amendments were adopted in 1956. In 1968, the document was revised under the title *Recommendations for Guard Service in Fire Loss Prevention*. It was at this time that NFPA 601A, *Standard for Guard Operations in Fire Loss Prevention*, was published as a separate standard.

In 1969, the Committee was reorganized as the Technical Committee on Loss Prevention Procedures and Practices.

NFPA 601 was revised in 1969, 1975, 1981, and 1986.

NFPA 601A was revised in 1981. In 1986 the document was reconfirmed and redesignated NFPA 602.

In 1992, NFPA 601 and 602 were combined for the benefit of the user.

In 1995, the standard was completely revised to reflect modern security methods, terminology, and techniques.

Committee Scope: This Committee shall have primary responsibility for documents on fire brigades, guard services, and techniques for securing effective fire loss prevention programs in industrial, commercial, institutional, and similar properties.

NFPA 601

Standard for Security Services in Fire Loss Prevention

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix B.

Chapter 1 Introduction

1-1 Purpose.

Protection of persons and property against hazards of fire is a management responsibility. The requirements of this standard are intended to aid management in defining the requirements, duties, and training for individuals to perform security services to protect a property against fire loss.

1-2 Scope.

This standard shall apply to the selection, requirements, duties, and training of security personnel who will perform fire loss prevention duties. It shall cover the following three categories of security services:

(a) Protection of the property, including times when management is not present.

(b) Access and egress control into and within the confines of the protected property.

(c) Carrying out procedures for the orderly conduct of various operations at the property.

1-3 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Drill. An exercise involving a credible simulated emergency that requires security personnel to perform planned emergency operations for the purpose of evaluating the effectiveness of the training and education programs and the competence of security personnel in performing required duties and functions.

Fire Brigade. An organized group of employees who are knowledgeable, trained, and skilled in at least basic fire-fighting operations, and whose full-time occupation may or may not be the provision of fire suppression and related activities for their employer.

Fire Loss Prevention Manager. A person responsible for:

(a) The preparation and implementation of a fire loss prevention plan, and

(b) Revisions to the plan as changes occur at the site.

Hazardous Area. An area that contains a hazardous atmosphere and those areas of the structures or buildings used for processes that involve quantities of flammable liquids, liquids processed at or above their flash point, flammable gases, or explosive materials that have the potential for catastrophic loss. This includes processes that constitute a high fire hazard because of the form, character, or volume of the material used.

Hazardous Atmosphere. Any atmosphere that is oxygen deficient or that contains a toxic or disease-producing contaminant. A hazardous atmosphere may or may not be immediately dangerous to life and health.

Hot Work. Any welding, cutting, brazing, or grinding that generates sparks capable of causing combustion.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Performance Standards. Minimum requirements for knowledge that must be provided to and/or demonstrated by the individual upon completion of a training program.

Protective Signaling System. Any alarm or system of alarms designed to give notification or warning, whether audible at the location or at a central receiving area, of the existence of a probable emergency or other unusual occurrence that might involve life safety or property protection.

Security. The branch of an organization, public or private, charged with the responsibility of safeguarding the assets (people, physical plant, properties, and products and reputation) of an organization. The process of security can be proprietary, contractual, or a combination of both. Proprietary security involves the use of company employees charged with the responsibility of protection. Contractual security makes use of an outside firm to supply individuals for the purpose of protection and loss prevention.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Management Responsibilities

2-1* Management Responsibilities.

Management shall have the responsibility of providing protection from the hazards of fire for persons and property. The fire loss prevention manager shall be consulted in the design and implementation of the security policies and procedures affecting fire loss prevention.

2-2* Procedures and Instructions.

Procedures and instructions involving security shall be specific with respect to duty responsibilities and actions required.

2-3 Succession to Supervisory Responsibility.

Management shall establish a clear line of succession in the event of absences.

2-4* Contract Security Service.

Supervision of security officers from outside firms shall be provided.

2-5 Maintenance of Equipment.

Management shall establish procedures for the maintenance of equipment provided for use by security personnel.

2-6* Identification.

Security officers shall be provided with a means of identifying themselves as authorized representatives of fire loss prevention management. The method of identification shall be acceptable to the authority having jurisdiction.

Chapter 3 Security Functions and Duties

3-1 General.

Where permitted by the authority having jurisdiction, security personnel shall be permitted to be supplemented or supplanted by an approved protective signaling system.

3-2 Other Duties of Security Officers.

Security officers shall be permitted to perform other duties in addition to their security responsibilities. These other duties shall not compromise the security functions.

3-3 Patrol Service.

3-3.1 Routes to be Patrolled.

3-3.1.1 Each route to be covered by a security officer shall be designated by the manager responsible.

3-3.1.2 The security officer assigned to each route shall be provided with instructions, all details regarding the route, and the functions to be carried out in covering the route.

3-3.1.3 The route shall be explicitly defined to ensure that the security officer patrols the correct area.

3-3.1.4* Security officers shall monitor hazardous areas remotely through methods acceptable to the authority having jurisdiction to afford prompt detection of fire or conditions likely to cause fire or other loss.

3-3.2 Rounds.

3-3.2.1 A security officer shall make rounds at intervals determined by management. When operations in the property normally are suspended, officers shall make rounds hourly or as assigned by management. Where special conditions exist, such as the presence of exceptional hazards or when fire protection equipment is impaired, management shall institute additional rounds.

3-3.2.2* The first round shall begin within one-half hour after the end of activities of the preceding work shift. During this round, the security officer shall make a thorough inspection of all buildings or spaces.

3-4 Control of Pedestrian and Vehicular Movement.

Security shall be established to:

(a) Prevent entry of unauthorized persons.

(b) Control the activities of people authorized to be on the property, but who are not aware of procedures established for the prevention of fire.

(c) Control pedestrian and vehicular traffic throughout the normal working day as directed by management, and during exit drills, and evacuation of the property due to emergencies.

(d) Control gates and vehicular traffic to facilitate access to the property by the public fire department, members of any private fire brigades, law enforcement, emergency medical services, and off-duty management personnel in the event of fire and other emergencies.

3-5* Fire Protection Function of Security.

Where management assigns fire protection functions to security and provides training therein, procedures shall be established for orderly conduct of the operations at the property, including procedures for fire loss prevention both by employees of the property protected and by outside contractors, and the prompt reporting of any fires discovered by calling the public fire department and the fire brigade of the property (if available on the shift).

3-6 General Duty Requirements.

3-6.1 Reporting for Duty.

Security officers shall report for duty at times specified by their superiors. When, due to illness, injury, or other causes, officers are unable to report for duty, they shall notify their superiors at the earliest possible time.

3-6.2 Fitness for Duty.

An on-duty security officer shall not accept relief by another officer who is not in a condition to work. The on-duty security officer shall ensure that the relief officer is fit for duty.

3-6.3 Emergencies on Duty.

Security officers shall not leave their assigned areas except in an emergency. In such cases, they shall notify either their superiors or another officer as soon as practicable or send an appropriate signal to a constantly attended location, such as a control center or a police or fire station.

3-7 Reports.

3-7.1 Report of Conditions Requiring Immediate Action.

Security officers shall promptly report conditions needing immediate attention, such as:

(a) Sprinkler system valves found closed, or

(b) Potential damage caused by freezing, or

(c) Process or service equipment that is believed to be out of order, or

(d) Other site-specific matters that would affect the operation or security of the facility.

These reports shall be in accordance with written instructions that indicate persons to whom reports are to be distributed and any immediate verbal notifications that are to be made.

3-7.2 Incident Reports.

Security officers shall make incident reports as required. These reports shall cover:

(a) Where — the exact location.

(b) When — the exact time.

(c) What — the act or thing done.

(d) How — the method by which an act was done.

(e) Who — the identity of the person or persons.

3-7.3* Daily Report.

Security officers shall complete daily reports as required.

Chapter 4 Selection and Conduct of Security Officers

4-1* Character Investigation.

Management shall require individuals considered for a security officer position to satisfactorily pass a character investigation.

4-2 Skills and Ability.

The applicant shall have the skills and ability to perform prescribed duties and to meet all job qualifications.

4-3* Criminal Convictions.

Applicants for a position as a security officer shall provide information on all criminal convictions, including the location of the conviction, the nature of the crime, and the judicial disposition. Prior to an offer of employment, the applicant shall furnish certified copies of criminal history checks from the location of residence for the past ten years.

4-4 Contract Service.

Contracts for security service shall include a provision stating that the service provider will replace any of its employees who, in the judgment of the company purchasing the service, are not qualified.

4-5 Medical Requirements.

The employer shall establish medical and fitness requirements based on the risks and the functions associated with the individual's duties and responsibilities.

4-6 General Conduct of Security Officers.

4-6.1 Conduct on Duty.

Security officers shall conduct themselves in such a way as not to interfere with the proper performance of their duties. They shall not sleep or consume alcohol or drugs on duty, or report for duty under the influence of alcohol or drugs.

4-6.2 Information.

Security officers shall not release any information without the approval of management.

4-6.3 Authorized Persons.

Security officers shall not release any details of their assignments except to authorized persons.

4-6.4* Enforcing Rules.

Security officers shall follow and enforce rules adopted by the management of the property.

Chapter 5 Training and Education

5-1* General.

Management shall establish an initial and ongoing performance-based training and education program for security officers to meet their assigned duties and functions.

5-2* Site-Specific Knowledge.

Management shall establish programs for security officers to ensure they are familiar with the property being protected, including:

(a) All buildings, occupancies, and hazards.

(b) Fixed fire protection systems.

(c) Manual and automatic detection and alarm systems.

(d) Portable fire protection equipment.

(e) Emergency shutdown procedures and equipment for which they are responsible.

(f) The facility emergency action plan.

5-3 Materials and Processes.

Management shall ensure that security officers are knowledgeable in site-specific hazardous materials and processes. This shall be done prior to a security officer being assigned to the hazard area and when new hazardous materials and processes are introduced into the facility. The management shall ensure that security officers are familiar with the location and interpretation of Material Safety Data Sheets.

5-4* Construction Operations.

Management shall ensure that security officers are knowledgeable in the hazards associated with construction, demolition, alteration, and repair operations.

5-5 Emergency Plans.

Management shall ensure that security officers are familiar with the site-specific emergency plans for dealing with fires and other emergencies.

5-6 Emergency Procedures.

Management shall ensure that security officers are familiar with the procedures to follow in the recognition and reporting of an emergency, including:

(a) When and how to use radio equipment, telephone, and private or public alarm boxes to summon aid.

(b) How to notify the fire brigade, the municipal fire department, and other emergency response organizations.

(c) The personnel to be contacted.

Chapter 6 Communications

6-1* Communication Systems.

Security officers shall be provided with a means for continuous communication with a constantly attended location.

6-2 Protective Signaling Systems.

Protective signaling systems, where provided, shall be installed, designed, and operated in accordance with NFPA 72, *National Fire Alarm Code*.

6-3* Security Tour Supervision Systems.

Where security tour supervision systems are provided, they shall be listed or approved, or shall conform with NFPA 72, *National Fire Alarm Code*.

6-3.1

Management shall ensure that:

(a) Security officers are not permitted to change the time record charts.

(b) The changing and review of time record charts is done by the property manager or the manager's responsible designee, such as the fire loss prevention manager.

(c) Time record charts of security officers are promptly reviewed.

(d) Files are maintained for review by representatives of any authority having jurisdiction.

(e) All irregularities are investigated, recorded, and corrective action is taken.

6-4* Directory.

A continuously updated directory of names, telephone numbers, and other information to assist in making emergency calls shall be kept at the security control center. This directory shall include the telephone numbers of key management personnel to be notified in an emergency, fire, police and emergency medical service departments, and other outside agencies needed in an emergency.

Chapter 7 Referenced Publication

7-1

The following document or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for the reference is the current edition as of the date of the NFPA issuance of this document.

7-1.1 NFPA Publication.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269–9101.

NFPA 72, *National Fire Alarm Code*, 1993 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-3 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1

Management of any property has a responsibility for fire loss prevention and for creating detailed plans for specific actions that are to be followed in the event of a fire. This responsibility can be delegated to an individual, such as the fire loss prevention manager.

Where there is a public fire department and that department has not already initiated a pre-fire plan for the property, the management should initiate such a plan, involving the proper officers of the public fire department to develop response plans for various situations on the property. The objective should be to anticipate, as far as possible, emergencies and types of hazards that are likely to confront security officers and other personnel.

The term "fire prevention manager" is used to describe the function of the contact person in the property management. It is not necessarily intended to be a model title for all persons to whom the described responsibilities are assigned.

A-2-2

General instructions or superficial training are of little value. Detailed, understandable instructions, which should be in written form, cannot be prepared without management's investment of time, thought, and expertise.

A-2-4

The following are some of the important items to consider when choosing the security company:

(a) Does the company make a pre-employment investigation of all its employees, including a criminal history check confirmed with a check of fingerprints?

(b) Does the company make use of psychological tests, such as the Minnesota Multiphasic Personality Inventory (MMPI) or other similar instrument conducted by a person licensed to administer same for determination of applicant qualification?

(c) Does the company have a continuous training program for its officers that deals with topics relevant to the duties expected of the officers at the facility protected?

(d) Does the company have an adequate supervisory system?

(e) Does the company have a reporting system to keep the property management informed of occurrences on the protected property?

(f) Does the company have sufficient insurance to cover any incident that can occur as a result of negligence or criminal activity on the part of one of the officers? (Ask to be made an additional insured under the policy of the company selected and get a copy of the insurance certificate to protect your company.)

(g) What are the basic qualifications for employment as a security officer with the company?

(h) Does the contracting security company have good references? (Check references whenever and wherever possible, including visitation of other installations protected by the security service.)

A-2-6

Identification of security officers is necessary for outside agencies and, in larger facilities, internal personnel to rapidly identify who is authorized by the fire loss prevention manager to perform fire loss prevention duties. The form of identification should be communicated to all involved agencies during pre-planning and should be included in the facility's emergency action plan.

A-3-3.1.4 Areas where hazardous processes or materials are located might require monitoring more frequently than other areas due to the potential for immediate catastrophic loss. In addition to the protection of property, the use of remote monitoring methods reduces or eliminates the exposure of the security officer to the hazard.

A-3-3.2.2 The first round of a patrol is very important. Unless an emergency (fire, medical emergency, perimeter breech) causes the security officer to divert efforts to another location or task, the first patrol round should be taken promptly. The purpose is to gain familiarization with the patrol site, to observe what is occurring, to find events/conditions that might cause a fire or other loss to the property, and to report them, as directed in the security procedures. The matters for specific attention in the first patrol round should be outlined in the officer's instructions for the patrol and should include the monitoring of items such as:

(a) Outside doors and gates closed and secured, and windows, skylights, fire doors, and fire shutters closed.

(b) All oily waste, rags, paint residue, rubbish, and similar combustible items removed from the buildings or reported.

(c) All fire protection equipment in place and not obstructed.

(d) Aisles clear.

(e) Motors or machines not required to run continuously.

(f) All unsecured offices, conference rooms, and smoking areas checked for carelessly discarded smoking materials.

(g) All gas and electric heaters, coal and oil stoves, and other heating devices in open or unsecured areas on the premises checked.

(h) The conditions of hazardous manufacturing processes noted as assigned. The temperature of dryers, annealing furnaces, and similar equipment that continue to operate during the night and on holidays and weekends should be noted on all rounds.

(i) Flammable and combustible materials properly stored in approved containers or storage areas.

(j) All sprinkler valves open and sealed, with gauges indicating normal pressures. If not open, that fact should be reported immediately.

(k) Areas checked to determine if heating or air conditioning systems are working properly.

(l) Water faucets and air valves examined for leaks. All water faucets and air valves found leaking should be reported and recorded.

(m) Particular attention should be given to areas under construction or involved in alteration.

A-3-5

Examples of procedures for fire loss prevention include:

(a) Checking permits for hot work, including cutting and welding, and standing by, where required, to operate fire extinguishing equipment at the location of such work.

NOTE: For information on fire watchers, see NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

(b) Detecting conditions likely to cause a fire, such as leaks or spills of flammable liquids and faulty equipment.

(c) Detecting conditions that reduce the effectiveness with which a fire can be controlled, such as sprinkler valves not open, obstructed sprinkler heads, water supplies impaired, or portable fire extinguishers not in place or in working order.

(d) Performing operations to ensure that fire equipment will function effectively. These can include testing automatic sprinkler and other fixed fire protection systems; testing fire pumps and other equipment related to these systems and assisting in maintenance service on this equipment; checking portable fire extinguishers and fire hose and assisting with pressure tests and maintenance service on these items; testing fire alarm equipment; and checking equipment provided on any motorized fire apparatus and making the periodic tests and maintenance operations required for it.

(e) Operating equipment provided for control and extinguishment of incipient stage fires after giving the alarm and before the response of other persons to the alarm.

(f) Monitoring receipt of signals due to the operation of protective signaling systems provided, including trouble signals.

(g) Making patrols along routes chosen to ensure surveillance of the entire property at appropriate intervals.

A-3-7.3

The daily report form should be a brief summary of the work done and the events encountered by the officer during the shift. The format of the report form can be varied to fit either company or facility policy but should be designed to ensure that all relevant information is included. The format can consist, for example, of questions that can be responded to by either “yes,” “no,” or “N/A,” with a space made available for remarks. Examples of typical questions are:

Fires in progress or property damaged?

Stations missed?

Rule violations?

Fire hazards observed?

Exits obstructed?

Doors/windows open or broken?

Fire equipment missing or inoperative?

Sprinkler system defects found?

Areas unsecured?

Exits obstructed/blocked?

Fire door blocked or inoperative?

Smoking violations discovered?

Other events noted?

A-4-1

Character background investigations involve more than taking the information provided on the application as fact. The employing agency should institute a procedure to confirm and clarify the information provided on the completed, signed application for employment. Information regarding employment, positions held, education, and residences needs to be confirmed. Information as to military service and discharge status (DD-214), if applicable, should be confirmed. Special attention should be made in regard to periods of unemployment or self-employment and confirmation obtained from an independent third party. Personal references listed by the applicant should be contacted, as well as any other individuals who might possess information as to the suitability of the individual to be a security officer. A complete employment history is desirable, but a ten-year history from the date of the application is usually acceptable.

The employer should also consider drug screening of security officers. Examinations should be in compliance with directives established by the authority having jurisdiction. Where no directives are established or in place, testing should be in compliance with the Department of Transportation (DOT) standards for a five-panel test for illegal drug identification, administered through a National Institute for Drug Abuse (NIDA) approved laboratory.

It should be noted that the DOT requirements are for illegal drugs only. Screenings are available that can determine the presence of prescription and certain over-the-counter drugs whose abuse could be counterproductive to a safe and productive work environment.

A-4-3

Although conviction of a criminal offense should not automatically disqualify an individual for employment as a security officer, the employing firm should make every effort to obtain the complete criminal conviction history of security officer applicants. States that license security officers might require a criminal history covering a specific period of time but, for nonregulated areas, a history of no less than five years should be undertaken. This should include criminal history checks from all areas lived in for the ten years preceding the application. The employer can confirm criminal history via a set of an applicant's fingerprints. Individual states that regulate security officers might not allow applicants with felony convictions or convictions involving moral turpitude to do security work. Companies in nonregulated states should use this direction as base hiring standards.

A-4-6.4

The security officer is the most visible representative of a company, whether that officer is an employee or contractor of the company. The security officer's actions directly reflect on the image of the company and the services afforded by the company. If security gives the appearance that they are "above the law," compliance with safety and security regulations could be minimal.

A-5-1

The scope of the training and education program should be established by management or the fire protection manager acting for management.

Advantage can be taken of courses for security officers offered through vocational/technical colleges, community and junior colleges, universities, and private training agencies. Companies should schedule officers so that they can take advantage of job-related training and education opportunities. Tuition reimbursement, either complete or partial, should be considered.

Security officers should be made aware of meetings that could provide job-related knowledge. These meetings might involve groups that are dedicated to fire protection, safety, loss prevention, crime prevention, or other related areas.

Facility management should have available relevant professional publications and journals in the areas of fire and general loss prevention and safety for their information as well as for use in the training and education of security officers.

Membership in the National Fire Protection Association is recommended as one source for obtaining useful publications.

All methodologies of training should be used in the training of security officers. Training bulletins, motion pictures, videotape, audiotape, and workshop formats should be used as means to further the knowledge, skills, and abilities of the security officer.

Training aids are available from various sources. Local fire departments, state fire marshals' offices, insurance organizations, and community/junior colleges and universities can be of invaluable assistance in the training of security personnel. Manuals from manufacturers of specific equipment can also be of use.

A-5-2

The use of a training officer or mentor can prove to be more beneficial than the use of print material for the initial site training of the security officer. The training officer should be an individual who best exemplifies the quality of security desired. The training officer should be thoroughly familiar with the facility protected.

A-5-4

Construction, demolition, alteration, and repair operations create temporary conditions that might alter the fire hazards and fire protection within and nearby the facilities. Furthermore, depending on the type of project, conditions might be constantly changing. Security officers should be knowledgeable of items such as:

(a) Maintenance of unobstructed fire department or fire brigade access routes throughout the facility.

(b) Clear access to fire protection equipment such as fire hydrants, automatic sprinkler and standpipe connections, standpipe hose lines, and portable fire extinguishers.

(c) Locations where cutting, welding, and other hot work operations are being conducted, or have been conducted within the last four hours of the start of the security officer's shift.

(d) Maintenance of unobstructed access to exits, and changes in exits.

(e) Proper storage of combustible materials, including flammable and combustible liquids, combustible construction materials, and debris, away from heat sources.

(f) Location of temporary heating devices.

(g) Location of roofing operations that are being conducted, or that have been conducted within 12 hours of the start of the security officer's shift.

(h) Locations with restricted access such as asbestos abatement areas.

(i) Location of impaired fire protection systems.

For additional information on fire loss prevention during construction operations, see NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

A-6-1

Communications systems can use telephones, cellular telephones, telegraph, radio, and other components. For security service communications, ordinary extension telephones and portable radios can be used if sufficient personnel are provided for and if there exists a high degree of reliability of operation and maintenance of equipment. A constantly attended location is a facility that receives signals or communications and that has personnel in attendance at all times to respond to these signals or communications.

A-6-3

Supervisory services systems are designed to continually report the performance of a security officer in connection with the intervals determined by management. The following describes some of the common systems used to perform this function.

Supervised Tours

In the first case, a series of patrol stations along the security officer's intended route are successively operated by the security officer with each station sounding a distinctive signal at a central headquarters. Customarily, the security officer is expected to reach each of these stations at a definite time, and failure to do so within a reasonable grace period prompts the central station to investigate the security officer's failure to signal. Frequently, manual fire alarm boxes that ordinarily transmit four or five rounds of signals for fire can also be actuated by a special watch key carried by the security officer to transmit only a single round to the central station, thus signaling that the box has been visited.

Deliberate distribution of stations will compel a security officer to take a definite route through the premises, and variations from that route would appear as misplaced signals on the recording tape. A further advantage is that the order of station operation can be varied from time to time in the interests of security or to meet special conditions within the building.

Compulsory Tours

In the second case, one or more stations are connected to the central station, and preliminary mechanical stations condition the security officer's key to operate the connected station after, and only after, the preliminary stations have been operated in a prearranged order. This second arrangement is somewhat less flexible than the first, but has the advantage of the absence of interconnection between the preliminary stations and, thus, the reduction of signal traffic. The usual arrangement is to have the security officer transmit only start and finish signals that must be received at the central point at programmed reception times.

Delinquency Indicators

Delinquency indicator systems contain a series of connected stations that transmit a signal if the security officer does not reach the particular station within the anticipated preset period.

A-6-4 Security Control Center.

A control center provides a point at which security officers can monitor electronic systems, sensors, or video cameras to provide prompt detection of problems or potential problems. The center should have the ability to communicate with and monitor points outside the property as well as points within the protected property.

Staffing the Security Control Center. Where the communication equipment, including equipment used on patrol, requires that communications from security officers be monitored, the control center should be provided with an operator. Additional operators and around-the-clock operator service should be provided at the control center according to the character of the security service provided. Security officers who can be dispatched to investigate signals should also be provided as necessary. The control center should not go unstaffed during times when the control center is operational.

NFPA 650

1990 Edition

Standard for Pneumatic Conveying Systems for Handling

Combustible Materials

1990 Edition

This edition of NFPA 650, *Standard for Pneumatic Conveying Systems for Handling Combustible Materials*, was prepared by the Technical Committee on Fundamentals of Dust Explosion Prevention and Control, released by the Correlating Committee on Dust Explosion Hazards, and acted on by the National Fire Protection Association, Inc. at its Fall Meeting held November 13-15, 1989 in Seattle, WA. It was issued by the Standards Council on January 12, 1990, with an effective date of February 5, 1990, and supersedes all previous editions.

The 1990 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 650

NFPA 650 had its origin as NFPA 66, *Standard for Pneumatic Conveying Systems for Handling Feed, Flour, Grain and Other Agricultural Dusts*. NFPA 66 was adopted as a tentative standard in 1963, and as a standard in 1964. Revised standards were adopted in 1970 and 1973.

NFPA 650-1984, *Standard for Pneumatic Conveying Systems for Handling Combustible Materials*, in addition to being different in title from NFPA 66, differs in scope and represents a complete rewrite of NFPA 66. The rewrite makes the standard applicable to the pneumatic conveying of combustible materials, both agricultural and non-agricultural.

The 1990 edition of NFPA 650 is a reconfirmation of the 1984 edition.

NFPA 650
Standard for
Pneumatic Conveying Systems for Handling Combustible Materials

1990 Edition

NOTE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.

Information on referenced publications can be found in Chapter 9 and Appendix B.

Chapter 1 General

1-1 Scope.

1-1.1

This standard shall apply to the pneumatic conveying of combustible materials.

1-1.2

This standard shall not apply to the pneumatic conveying of materials covered by:

NFPA 43A, *Code for the Storage of Liquid and Solid Oxidizing Materials, (Class 3 and 4 oxidizing materials only)*

NFPA 61A, *Standard for the Prevention of Fire and Dust Explosions in Facilities Manufacturing and Handling Starch*

NFPA 61B, *Standard for the Prevention of Fires and Explosions in Grain Elevators and Facilities Handling Bulk Raw Agricultural Commodities*

NFPA 61C, *Standard for the Prevention of Fire and Dust Explosions in Feed Mills*

NFPA 61D, *Standard for the Prevention of Fire and Dust Explosions in the Milling of Agricultural Commodities for Human Consumption*

NFPA 65, *Standard for the Processing and Finishing of Aluminum*

NFPA 85F, *Standard for the Installation and Operation of Pulverized Fuel Systems*

NFPA 120, *Standard for Coal Preparation Plants*

NFPA 480, *Standard for the Storage, Handling, and Processing of Magnesium*

NFPA 482, *Standard for the Production, Processing, Handling, and Storage of Zirconium*

NFPA 495, *Code for the Manufacture, Transportation, Storage and Use of Explosive Materials*

NFPA 651, *Standard for the Manufacture of Aluminum and Magnesium Powder*

NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities.*

1-2 Purpose.

1-2.1

The purpose of this standard is to prescribe reasonable requirements for safety to life and property from fire and explosion and to minimize the resulting damage should a fire or explosion occur.

1-2.2

This standard is not intended to prevent the use of systems, methods, or devices that provide equivalent protection from fire and explosion, providing that suitable data is available to demonstrate equivalency.

1-3 Retroactivity.

This standard applies to facilities on which construction is begun subsequent to the date of publication of this standard. When major replacement or renovation of existing facilities is planned, provisions of this standard shall apply.

1-4 Definitions.

For the purposes of this standard, the following terms shall have the meanings given below.

Approved. Acceptable to the “authority having jurisdiction.”

NOTE: The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The "authority having jurisdiction" is the organization, office or individual responsible for "approving" equipment, an installation or a procedure.

NOTE: The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner since jurisdictions and "approval" agencies vary as do their responsibilities. Where public safety is primary, the "authority having jurisdiction" may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the "authority having jurisdiction." In many circumstances the property owner or his designated agent assumes the role of the "authority having jurisdiction"; at government installations, the commanding officer or departmental official may be the "authority having jurisdiction."

Combustible Dust.* Any finely divided solid material 420 microns or smaller in diameter (material passing a U. S. No. 40 Standard Sieve) that presents a fire or explosion hazard.

Detachment. In the open air or in a separate building.

Duct. That part of a system that conveys air to or from primary and/or secondary air-material separators.

Header. That part of a system located between the air discharge of a primary or secondary air-material separator and the air intake of the prime air mover (blower or fan), which conveys the air discharge from only a single separator at any one time.

Hybrid Mixture. A combination of combustible dust and flammable gas or vapor that can be ignited.

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The "authority having jurisdiction" should utilize the system employed by the listing organization to identify a listed product.

Manifold. A header that simultaneously serves more than one air-material separator on a suction-type pneumatic system and that normally operates at a negative pressure.

Multiple Strand. The arrangement of several suction-type pneumatic systems served by a single manifold.

Pneumatic Conveying System. A system consisting of an enclosed tubing system in which a material is transported by a stream of air having a sufficiently high velocity to keep the conveyed material in motion. Noncombustible, nonreactive gases may be used in place of, or mixed with, air.

Such systems are of two principal types or a combination of the two types.

(a) *Positive Pressure-Type.* Pressure-type systems transport material by utilizing air at greater than atmospheric pressure. Such systems basically consist of a blower drawing air through a filter; an air-lock feeder for introducing materials into the system; tubing or ducts; and a suitable air-material separator.

(b) *Negative Pressure-Type.* Negative pressure-type systems transport material by utilizing air at less than atmospheric pressure. These systems basically consist of a material and air intake; tubing or ducts; a suitable air-material separator; and a fan or blower.

Primary Air-Material Separator. A collector that removes the bulk of the product or material from the conveying air stream.

Secondary Air-Material Separator. A device for removing the residual dust or product remaining in the air stream after the primary air-material separator.

Tubing. The part of a system located between the point of infeed and the primary air-material separator through which heavy concentrations of product are conveyed.

1-5 General Design.

1-5.1

All system components shall be conductive. Bonding and grounding shall be provided. (*See NFPA 77, Recommended Practice on Static Electricity*.)

1-5.2

All electrical equipment in and around the pneumatic system shall be designed and installed in accordance with NFPA 70, *National Electrical Code*®.

1-5.3

All systems shall be designed to be air-tight and dust-tight except at openings designed for intake and discharge of air and material.

1-5.4

Where more than one material is to be handled by a system, compatibility tests shall be run; and where incompatibility is found, provisions shall be made for cleaning of the system prior to transport of a new material.

1-5.5

Equipment and bins shall be provided with explosion prevention or explosion protection in accordance with either 1-5.5.1, 1-5.5.2, or 1-5.5.3.

1-5.5.1 Explosion venting may be provided. (*See NFPA 68, Guide for Venting of Deflagrations*.)

1-5.5.2 The container and system may be designed to contain the explosion pressure.

1-5.5.3 Explosion prevention systems in accordance with NFPA 69, *Standard on Explosion Prevention Systems*, may be installed.

1-5.6 Hybrid Mixtures.

1-5.6.1* Where inert gas is used, oxygen monitors shall be required and shall sound an alarm at a preset level.

1-5.6.2 When hybrid mixtures are transported, recycling of the gas stream to any work space shall not be permitted.

Chapter 2 Tubing, Headers, Manifolds, Ducts

2-1* Design.

2-1.1

Where a system or any part of a system operates as a positive pressure-type system and the blower discharge pressure is 15 psig (103 kPa) or greater, the system shall be designed in accordance with ASME *Boiler and Pressure Vessel Code*, Section VIII or ANSI/ASME B31.3, *Chemical Plant and Petroleum Refinery Piping*.

2-1.2 Elbows.

2-1.2.1 All elbows shall be of air- and dust-tight construction.

2-1.2.2 Joints shall be butted squarely and air- and dust-tight.

2-1.3

All parts of a system located within buildings shall be permanently assembled with no temporary connections that may be left open and permit the escape of material from the system.

2-1.4

Connections between individual lengths, elbows, or other pneumatic equipment shall be air- and dust-tight.

2-1.5 Support.

2-1.5.1 All tubing, headers, manifold, and ducts shall be supported so as to avoid excessive stress or strain.

2-1.5.2 Supports shall be designed to include the weight of the system and the transported material.

2-1.5.3 Vertical runs through floors shall be securely fastened at each floor level.

2-1.5.4 Tubing or ducts that pass through fire barrier or fire walls shall be rigidly supported on both sides, and the opening around the duct shall be sealed to the full thickness of the wall with a material of a fire resistance rating equivalent to that of the wall.

2-1.6 Sight Glasses.

2-1.6.1 Sight glasses, if installed, shall be of a material that is not readily damaged. Tubing shall be supported above and below each sight glass so that the sight glass does not carry any of the system weight and is not subject to stress or strain.

2-1.6.2 The electrical bonding of the system shall be continuous around all sight glasses. The strength of the sight glass and its mounting mechanism and its inside diameter shall be equal to the adjoining tube system.

2-1.6.3 Connections between the sight glass and tubing shall be butted squarely and sealed so as to be air-tight and dust-tight.

2-1.7

All tubing, headers, manifolds, and ducts shall be provided with access panels for examining and cleaning of system in accordance with NFPA 91, *Standard for the Installation of Blower and Exhaust Systems for Dust, Stock, and Vapor Removal or Conveying*.

Chapter 3 Valves

3-1 Pressure Relief Valves.

One or more relief valves for both positive pressure and negative pressure pneumatic systems shall be located, sized, and set to relieve at pressures designed to protect the system components. Valves to protect the blower package shall be installed on the clean air side of the system.

3-2 Multiple Direction Valves.

Multiple direction valves shall be of air- and dust-tight construction and shall effect a positive diversion of the conveyed product. Diversion of the product in one direction shall mechanically and automatically seal all other directions from air and dust leakage.

3-3 Air Flow Control Valves.

3-3.1

Air flow control valves installed in multiple strand suction-type pneumatic systems shall be of air- and dust-tight construction and shall inject sufficient static resistance to allow air flow adjustment for system balancing purposes. Valves shall be sized to pass the total air flow of the system with dampers in the wide open position. Valves shall be so constructed as to totally shut off air flow in the system.

3-3.2

Valves shall have visible scales to indicate the position of control dampers.

3-3.3

Manually adjusted valves shall have a locking device to prevent movement of dampers once set.

Chapter 4 Air-Material Separators

4-1 General.

4-1.1

Air-material separators that are located outside and on top of structures shall be provided with lightning protection in accordance with NFPA 78, *Lightning Protection Code*.

4-1.2

Material discharge outlets from air-material separators shall be provided with a positive choke device.

4-1.3

Exhaust air from air-material separators shall be discharged outside of building.

Exception No. 1: Where provision is made to recycle transport air directly back into the pneumatic conveying system.

Exception No. 2: Where all ducts returning air to the building are equipped and protected as indicated in 4-1.4.

4-1.4 Return Air Ducts.

4-1.4.1 Ducts shall be equipped with a filter other than the primary or secondary air-material separator.

4-1.4.2 Filters shall have a 99.5 percent efficiency for particle sizes of 1.0 micron diameter and greater.

4-2 Construction.

4-2.1

Air-material separators shall be constructed of noncombustible materials.

Exception: Filter media may be of combustible material.

4-2.2

Air-material separators shall be constructed so as to eliminate internal ledges or other points of dust accumulation. Hopper bottoms shall be sloped, and the discharge conveying system shall be designed to handle maximum flow.

4-2.3

Cleanout doors or panels shall be provided for access to the interior.

4-2.4

Air-material separators shall be provided with explosion relief. (*See NFPA 68, Guide for Venting of Deflagrations*.)

Exception: When protection is provided in accordance with 4-4.1, 4-4.2, or 4-4.3.

4-3 Location.

Air-material separators shall be located outside of buildings.

Exception No. 1: Separators may be located inside of buildings if located adjacent to an exterior wall and vented to the outside through straight and short ducts, not exceeding 10 ft (3.05 m) in length, designed according to information contained in NFPA 68, Guide for Venting of Deflagrations, and designed so that explosion pressures will not rupture the ductwork or the separator.

Exception No. 2: Separators protected in accordance with Section 4-4.

4-4* Protection.

4-4.1

Air-material separators may be equipped with an explosion suppression system. The explosion suppression system shall be designed and installed in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

4-4.2

Air-material separator systems may be designed to operate using an inert or oxygen deficient gas as a transfer medium provided that such systems are designed and installed in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

4-4.3

Air-material separators may be designed to withstand maximum peak explosion pressure.

Chapter 5 Feeding Methods

5-1 Hoppers.

When material is introduced into the pneumatic system through a hopper and feeding device, such hopper shall be dust-tight and designed for pressure equalization.

5-2* Mechanical Devices.

Mechanical feeding devices shall be equipped with a shear pin or overload detection device and alarm.

5-3 Drives.

All drives used in connection with feeders, air locks, and other devices shall be direct connected.

Exception: Belt or other indirect-type drives designed to have a sufficient service factor to stall the driving forces without slipping, and providing for the removal of static electric charges.

Chapter 6 Fans and Blowers

6-1 Design and Installation.

6-1.1

Fans and blowers shall be designed and installed in accordance with NFPA 91, *Standard for the Installation of Blower and Exhaust Systems for Dust, Stock, and Vapor Removal or Conveying*.

6-1.2

Bearings or bearing housings shall be designed to prevent overheating, oil leakage, and dust infiltration.

6-2 Maintenance.

6-2.1

Bearings shall be lubricated and checked for excessive wear on a periodic basis.

6-2.2

When the product has a tendency to stick to the rotor or housing, the rotor shall be cleaned periodically to maintain good balance, and the housing shall be cleaned periodically to minimize the possibility of ignition, especially when exposed to heated air.

6-2.3

The interior surfaces of fan housings shall be maintained free from rust. Aluminum paint shall not be used on interior steel surfaces that may be struck by foreign material because of potential heat of impact.

6-3 Operation.

6-3.1

Fans and blowers shall run at full speed before material is transported and after the material has ceased to be transported to clear the system of material.

6-3.2

Fans and blowers shall be checked periodically for excessive heat and vibration.

6-3.3

An interlock shall be provided to stop the material feed upon failure of the conveying system.

Chapter 7 Portable Conveying Units, Including Bulk Trucks

7-1 Engine and Motor Driven Equipment.

7-1.1

Engine and motor driven equipment used in confined hazardous areas shall be equipped with safety devices designed to reduce the potential fire hazard and electrical shock hazard.

7-1.2*

Requirements for engine and motor driven equipment shall meet or exceed the requirements of the *Firesafety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance and Operation*, NFPA 505, for the following designations:

(a) Diesel powered units — Type DS.

(b) Electrical powered units — Type EE.

(c) Gasoline powered units — Type GS.

(d) Liquefied petroleum gas powered units — Type LPS.

(e) Dual powered units — Type GS/LPS.

7-1.3

Spark arrestors shall be used on the exhaust stacks of all diesel powered units.

7-1.4

Refueling shall be conducted outdoors.

7-1.5*

Surface dust shall be removed from engine and motor driven equipment at regular intervals during operation.

7-1.5.1 Cleaning with compressed air shall not be conducted in Class II hazardous locations.

7-1.5.2 Spark arrestors shall be cleaned or replaced according to the manufacturer's recommendations.

7-1.6

Maintenance procedures shall comply with the manufacturer's instructions, especially with regard to replacement of insulation, covers, electrical enclosures, and parts of the electrical system designed to reduce chafing of insulation or termination failure.

7-2 Bonding and Grounding.

7-2.1

All equipment, such as truck, tank or hopper, conveyor tube, motor, or compressors, on a unit shall be electrically bonded and grounded.

7-2.2

Flexible tubing shall be electrically conductive. Connections from the transport vehicle to the receiving system shall be made on the outside of any building.

7-2.3

The operator shall ground the truck and bond the receiving tube to the truck and receiving equipment before starting the compressor. The compressor shall be at operating speed before transporting material.

7-2.4

Portable equipment electrical bonds shall be checked visually each time the equipment is used.

7-3 Dust Control.

7-3.1

The receiving bin or hopper shall have filtered open vents.

Exception: Filters may be omitted if the bin vent is piped back to the truck.

Chapter 8 Training and Inspection

8-1 Employee Training.

8-1.1

There shall be policies and requirements that provide for initial and continuing training for all employees. These shall include the development of operating procedures that are reviewed by the management at least once per year and after every process change.

8-1.2

All employees shall be carefully and thoroughly instructed at scheduled intervals regarding the hazards of their working environment. Their reactions in cases of equipment or process failures may reduce the incidence of fires and prevent explosions.

8-2 Periodic Inspection.

8-2.1

A thorough systematic inspection for safe operation of items listed in 8-2.2 shall be made at regular intervals and shall be submitted to plant management for review.

8-2.2

The inspection shall include, but not be limited to, the following:

(a) fire and explosion protection and prevention equipment;

(b) dust control equipment;

(c) housekeeping;

(d)* electrical and mechanical equipment, relief valves, and interlocks;

(e) procedures.

8-2.3

Competent persons shall conduct such inspections and the record of their findings and recommendations shall be recorded in the principal plant office.

Chapter 9 Referenced Publications

(*See Appendix B for other referenced publications that are advisory and thus do not constitute part of the requirements of this document*.)

9-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

9-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 43A-1980, *Code for the Storage of Liquid and Solid Oxidizing Materials* (1-1.2)

NFPA 480-1987, *Standard for the Storage, Handling, and Processing of Magnesium* (1-1.2)

NFPA 482-1987, *Standard for the Production, Processing, Handling, and Storage of Zirconium* (1-1.2)

NFPA 495-1985, *Code for the Manufacture, Transportation, Storage and Use of Explosive Materials* (1-1.2)

NFPA 505-1987, *Firesafety Standard for Powered Industrial Trucks* (7-1.2)

NFPA 651-1987, *Standard for the Manufacture of Aluminum and Magnesium Powder* (1-1.2)

NFPA 664-1987, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities* (1-1.2).

9-1.2 Other Publications.

9-1.2.1 ANSI Publication. American National Standards Institute, 1430 Broadway, New York, NY, 10018.

ANSI/ASME B31.3-1976, *Chemical Plant and Petroleum Refinery Piping* (2-1.1)

9-1.2.2 ASME Publication. American Society of Mechanical Engineers, 345 East 47th Street, New York, NY, 10017.

ASME *Boiler and Pressure Vessel Code,* Section VIII (2-1.1)

Appendix A

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

A-1-4 Combustible Dust.

Any time a combustible dust is processed or handled, a potential for explosion exists. The degree of explosion hazard will vary depending on the type of combustible dust and processing methods used.

A dust explosion has four requirements:

(a) A combustible dust,

(b) A dust dispersion in air or oxygen at or exceeding the minimum explosion concentration, and

(c) An ignition source such as a static, RF, or electric spark or arc; a glowing ember dust layer, hot surface, or weld slag; a friction heated bearing, pulley, rotor, fan; a flame or other source.

(d) *Confinement.* Evaluation of the hazard of a combustible dust should be determined by the means of actual test data. All combustible dusts that may produce a dust explosion should be tested so as to determine the following data:

(1) Particle size distribution.
(2) Moisture content as received and dried.
(3) Minimum dust concentration to ignite.
(4) Minimum energy required for ignition (joules).
(5) Maximum rate of pressure rise at optimum concentration.
(6) Layer ignition temperature.
(7) Maximum explosion pressure, at optimum concentration.
(8) Electrical resistivity measurement.
(9) Dust cloud ignition temperature.

Optional Testing.

(10) Maximum permissible oxygen content to prevent ignition.

A-1-5.6.1 For oxygen concentration levels see NFPA 69, *Standard on Explosion Prevention Systems*.

A-2-1

Ducts should be equipped, where applicable, with an automatic spark detection and extinguishing system.

A-4-4

Air-material separators containing combustible component parts should be equipped with an automatic sprinkling device in accordance with NFPA 13, *Standard for Installation of Sprinkler Systems*, or other special extinguishing system in accordance with NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*; NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*; or NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*.

A-5.2

Magnetic or other protective separating equipment should be provided to prevent entrance of ferrous materials into the pneumatic system. Removal of nonferrous material should be by screen or gravity separator or other device.

A-7-1.2

Refer to the following publications for further information:

UL 558, *Standard for Internal Combustion Engine Powered Industrial Trucks*.

UL 583, *Standard for Electric Battery Powered Industrial Trucks*.

(FM) *Approval Standard for Gasoline or Diesel Engine Powered Industrial Trucks, Types G, GS, D, or DS*.

(FM) *Approval Standard for Electrical Battery Powered Industrial Trucks, Types E and EE*.

(FM) *Approval Standard for LP-Gas Engine Powered Industrial Trucks, Types LP and LPS*.

ANSI/ASME B56.1, *Safety Standard for Powered Industrial Trucks*.

A-7-1.5

Cleaning should be done at 1-hour intervals during periods of steady operation and at the end of each work day.

A-8-2.2

(d) Safety interlocks should be calibrated and tested at scheduled intervals in the manner in which they are intended to operate with written test records maintained and reviewed by management.

NFPA 651

1993 Edition

Standard for the Manufacture of Aluminum Powder

1993 Edition

This edition of NFPA 651, *Standard for the Manufacture of Aluminum Powder,* was prepared by the Technical Committee on Combustible Metals and Metal Dusts and acted on by the

National Fire Protection Association, Inc. at its Annual Meeting held May 24-27, 1993, in Orlando, FL. It was issued by the Standards Council on July 23, 1993, with an effective date of August 20, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 651

NFPA 651, *Manufacture of Aluminum Powder*, was originally prepared by the Committee on Dust Explosion Hazards in 1938 and 1939. It was first adopted in 1939, and revised in 1946, 1952, 1959, 1963, 1967, and 1972. The 1967 edition was approved by the American National Standards Institute in 1967 and designated ANSI Z12.11.

NFPA 652, *Plants Producing or Handling Magnesium Powder*, was originally prepared by the Committee on Dust Explosion Hazards in 1942 and was first adopted in 1944. Amendments were adopted in 1945, 1946, 1952, 1959, and 1968. The 1968 edition was approved by the American National Standards Institute in 1968 and designated ANSI Z12.15.

In 1973 NFPA 651 and 652 were combined into a single standard, NFPA 651-T, and tentatively adopted at the 1973 Annual Meeting and officially adopted at the 1974 Annual Meeting. Revisions were adopted in 1980 and 1987.

For this 1993 edition, the Committee has added definitions, clarified the requirements for the location of aluminum powder production plants, revised the requirements for electrical power, machinery and operations, and for in-plant conveying of aluminum powder including the provisions for inert conveying. The requirements for explosion venting, manual fire fighting, and automatic sprinkler protection were also updated. This includes the change in terminology from “light metal powder” to “aluminum powder” to emphasize that the requirements for the manufacture of magnesium powder have now been incorporated into the 1993 edition of NFPA 480, *Standard for the Storage, Handling and Processing of Magnesium Solids and Powders*. The Committee has incorporated various style and editorial revisions to comply with the NFPA *Manual of Style* and to assist in making the document more usable, adoptable, and enforceable.

Technical Committee on Combustible Metals and Metal Dusts

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on safeguards against fire and explosion in the manufacturing, processing, handling and storage of combustible metals, powders and dusts.

NFPA 651
Standard for the

Manufacture of Aluminum Powder

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 9 and Appendix C.

Chapter 1 General

1-1 Scope.

1-1.1*

This standard shall apply to manufacturing facilities that produce aluminum flake powder, aluminum paste, atomized aluminum powder or aluminum granules, or any aluminum alloy powder that is combustible or explosive in an ambient atmosphere.

1-1.2

This standard shall not apply to the production of waste metal dust by operations such as grinding, buffing, and polishing of semifinished aluminum products. (*See NFPA 65, Standard for the Processing and Finishing of Aluminum.*)

1-1.3

This standard does not apply to the transportation of aluminum powder on public highways, waterways, or by air or rail.

1-2 Purpose.

The objective of this standard is to minimize the occurrence of and resulting damage from fire and explosion in areas where aluminum powder products are manufactured.

1-3 Retroactivity.

Unless otherwise stated, the requirements of this standard shall not be applied retroactively.

1-4 Equivalent Protection.

1-4.1

Existing plants, equipment, structures, and installations that do not comply strictly with the requirements of this standard shall be considered to be in compliance if it can be shown that an equivalent level of protection has been provided or that no specific hazard will be created or continued through noncompliance.

1-4.2

This standard is not intended to prevent use of systems, methods, or devices that provide equivalent protection from fire and explosion. NFPA 69, *Standard on Explosion Prevention Systems*, shall be referred to when considering the use of optional systems.

1-5 Definitions.

Approved. Acceptable to the “authority having jurisdiction.”

NOTE: The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The "authority having jurisdiction" is the organization, office or individual responsible for "approving" equipment, an installation or a procedure.

NOTE: The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner since jurisdictions and "approval" agencies vary as do their responsibilities. Where public safety is primary, the "authority having jurisdiction" may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the "authority having jurisdiction." In many circumstances the property owner or his designated agent assumes the role of the "authority having jurisdiction"; at government installations, the commanding officer or departmental official may be the "authority having jurisdiction."

Combustible Aluminum Dust.* Any finely divided aluminum material 420 microns or smaller in diameter (material passing a U.S. No. 40 Standard Sieve) that presents a fire or explosion hazard when dispersed and ignited in air.

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The "authority having jurisdiction" should utilize the system employed by the listing organization to identify a listed product.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Location and Construction of Aluminum Powder Production Plants

2-1 Location.

2-1.1

Aluminum powder production plants shall be located on a site large enough so that the buildings in which powder is manufactured are at least 300 ft (90.9 m) from public roads and from any occupied structure, such as public buildings, dwellings, business or manufacturing establishments, other than those buildings that are a part of the aluminum powder production plant.

2-1.2

Different powder production systems shall be located in separate buildings located at least 50 ft (15.2 m) from each other.

Exception: Two buildings less than 50 ft (15.2 m) apart shall be permitted if the facing walls of the exposed building shall be capable of resisting a blast pressure of 2.0 psig (13.8 kPa gauge) and shall be nonload-bearing, noncombustible, and without openings.

2-2 Security.

2-2.1

This section shall be applied to new and existing facilities.

2-2.2

The site on which the powder production plant is located shall be surrounded by strong fencing at least 6 ft (2 m) high with suitable entrance gates.

2-2.3

All gates that are not kept locked shall be under supervision.

2-3 Building Construction.

2-3.1

All buildings used for the manufacture, packing, or loading for shipment of aluminum powders shall, where practical, be single story, without basements, constructed of noncombustible materials throughout, and have nonload-bearing walls. The buildings shall be designed so that all internal surfaces are readily accessible to facilitate cleaning.

2-3.2

All buildings used for the manufacture of aluminum powders shall be subdivided into as many small units as practical by pressure-resistant, nonload-bearing, noncombustible, dusttight walls.

2-3.3

All walls of areas where dust can be produced, which are not of monolithic construction, shall have all masonry joints thoroughly slushed with mortar and troweled smooth so as to leave no interior or exterior voids where aluminum powder can infiltrate and accumulate.

2-3.4

Floors shall be hard-surfaced and nonslip, installed with a minimum number of joints in which aluminum powder can collect. The requirements of this section shall also apply to elevated platforms, balconies, floors, or gratings. (*See Appendix B.*)

2-3.5

Roofs of buildings that house dust-producing operations shall be supported on girders or structural members designed to minimize surfaces on which dust can collect. Where such surfaces are unavoidably present, they shall be covered by a smooth concrete, plaster, or noncombustible mastic fillet having a minimum slope of 55 degrees to the horizontal.

2-3.6

Roof decks shall be watertight.

2-3.7*

Explosion venting shall be provided where aluminum powder is processed and handled. Handling does not include storage in closed containers.

2-4 Doors and Windows.

2-4.1

All door and window frames shall be metal.

2-4.2

Each room shall have at least two widely separated exits to exit corridors or to the outside. All doors in interior fire-rated partitions shall be approved self-closing fire doors, installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*. Hardware for emergency exit doors shall conform to requirements of NFPA 80 and of NFPA *101*®, *Life Safety Code*®. (*See Section 5-11 and Chapter 14 of NFPA 101.*)

2-4.3

Emergency exit doors shall be provided from all areas, including balconies and elevated platforms.

2-4.4

Where two buildings are less than 50 ft (15.2 m) apart, only one of the facing walls shall have windows and doors. (*See also Exception to 2-1.2.*)

2-5 Communication Between Buildings.

2-5.1*

Where buildings are separated by not less than 50 ft (15.2 m) or where small units of one major process section communicate through enclosed passageways, such passageways shall be of noncombustible construction and be specifically designed to relieve internal pressure from an explosion and shall be protected by automatic self-closing 3-hour fire doors.

2-5.2

All enclosed passageways shall be provided with adequate means of egress as provided by NFPA *101*, *Life Safety Code*.

2-6 Grounding and Lightning Protection.

2-6.1*

All process equipment and all building steel shall be bonded and grounded in accordance with NFPA 780, *Lightning Protection Code*, and NFPA 70, *National Electrical Code*®.

2-6.2

Lightning rods shall be provided for all boiler stacks and chimneys and for the high points of all buildings.

2-6.3

Power lines shall be adequately protected against lightning. (*See NFPA 780, Lightning Protection Code*.)

2-6.4

A lightning arrestor system shall be provided around or within the building area of such capacity as to fully protect all buildings from lightning.

2-7 Electrical Power.

2-7.1

All electrical equipment and wiring shall be installed in accordance with NFPA 70, *National Electrical Code*.

2-7.1.1 All parts of powder manufacturing buildings shall be considered Class II, Group E locations.

Exception No. 1: Offices and similar areas so occupied and segregated as to be reasonably free from dust and so classed by the authority having jurisdiction.

Exception No. 2: Control equipment meeting the requirements of NFPA 496, Standard for Purged and Pressurized Enclosures for Electrical Equipment.

NOTE: For additional information on classification of dusty locations, see NFPA 497B, *Recommended Practice for the Classification of Class II Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*.

2-7.1.2 Wet solvent milling areas shall be considered Class I, Group D locations.

Exception No. 1: Offices and similar areas so occupied and segregated as to be reasonably free from solvent vapors and so classed by the authorities having jurisdiction.

Exception No. 2: Control equipment meeting the requirements of NFPA 496, Standard for Purged and Pressurized Enclosures for Electrical Equipment.

NOTE: For additional information on classification of areas containing solvent vapors, see NFPA 497A, *Recommended Practice for Classification of Class I Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*.

2-7.2

Provisions shall also be made for remote manual cutoff of all electrical power to manufacturing areas from one or more central locations, such as offices, guard's booth, or other appropriate locations.

2-7.3

All manufacturing buildings shall be provided with emergency lighting systems in accordance with Section 5-9 of NFPA *101, Life Safety Code*.

2-7.4

Electrical equipment shall be inspected and cleaned at least once each year or more frequently if conditions warrant.

2-7.5

Flashlights and storage battery lamps shall be listed for the locations in which they are used.

Chapter 3 Machinery and Operations

3-1 General Precautions.

3-1.1

This chapter shall be applied to new and existing facilities.

3-1.2

In powder handling or manufacturing buildings and in the operation of dust-conveying systems, precautions shall be taken to avoid the production of sparks from static electricity, electrical faults, or impact (e.g., iron or steel articles on stones, on each other, or on concrete).

3-1.3

Water leakage in or into any building where it can contact aluminum powder shall be prevented to avoid possible spontaneous heating.

3-1.4*

Frictional heating shall be minimized by the use of lubrication, inspection programs, and maintenance programs and techniques set forth by the equipment manufacturer's recommendation.

3-2 Requirements for Machinery.

3-2.1

All dust-producing machines and conveyors shall be constructed so that escape of dust is minimized.

3-2.2*

All machinery shall be bonded and grounded to minimize accumulation of static electric charge. This requirement shall be applicable to stamp mortars, mills, fans, and conveyors in all areas where dust is produced or handled, finishing and polishing equipment, filters, driers, dust screens, fixed storage bins, and dust collection and transport systems of all types. (*See also 2-6.1*.)

3-2.3*

Ball or roller bearings, properly sealed against dust, shall be used for shafts and high-speed equipment. Where exposed bearings are used, they shall be protected as well as possible to prevent ingress of aluminum dust.

3-2.4

Internal machine clearances shall be maintained to prevent internal rubbing or jamming.

3-2.5

High-strength permanent magnetic separators, pneumatic separators, or screens shall be installed ahead of mills, stamps, or pulverizers wherever there is any possibility that tramp metal or other foreign objects can be introduced into the manufacturing operation.

3-3 Heating of Aluminum Powder Production Buildings.

3-3.1

Heating of buildings shall be permitted by indirect hot air heating systems or by bare pipe heating systems using steam or hot water as the heat transfer medium or listed electric heaters. Indirect hot air shall be permitted if the heating unit is located in a dust-free area adjacent to the room or area where heated air is required.

3-3.2

Fans or blowers used to convey the heated air shall also be located in a dust-free location. The air supply shall be taken from outside or from a dust-free location.

3-3.3

Make-up air for building heating shall have a dew point low enough to ensure that no free moisture can condense at any point where the air is in contact with aluminum dust or powder.

3-3.4

The requirements of 3-3.1, 3-3.2, and 3-3.3 shall not apply to areas where metal is melted for purposes of atomization.

3-4 Start-up Operations.

All the machine processing contact areas shall be thoroughly cleaned and free from water before being charged with metal and placed into operation.

3-5 Charging and Discharging Aluminum Powders.

3-5.1

All in-plant containers shall be conductive and sealed with waterproof covers while in storage or transit.

3-5.2

When charging aluminum powders to machines (or discharging from), the containers shall be positively bonded and grounded by a conducting cable from the container to a suitable ground connection and to the machine.

3-6* Containers for Transport of Aluminum Powder.

Aluminum powder shall be packed into steel drums or other closed conductive containers acceptable to the U.S. Department of Transportation (DOT) or in containers specifically designed for in-plant transfer of aluminum powder. The containers shall be tightly sealed and stored with proper precautions to keep water from contacting the contents.

3-7* Wet Milling of Aluminum Powder.

3-7.1

Where aluminum is milled in the presence of a liquid which is chemically inert with respect to the metal, the milling shall be done in air in a vented mill or in an inerting atmosphere containing sufficient oxygen to oxidize any newly exposed surfaces as they are formed.

3-7.2

Where aluminum is slurried in tanks or processed in blenders or other similar equipment in the presence of a liquid that is chemically inert with respect to the metal, the operation shall be carried out in air or an inerting atmosphere containing sufficient oxygen to oxidize any newly exposed surfaces as they are formed.

3-7.3

The dew point of the atmospheres in 3-7.1 and 3-7.2 shall be maintained substantially below the point where condensation could occur.

3-7.4

Bearings of wet mills shall be grounded across the lubricating film by use of current collector brushes.

3-7.5

Ventilation, forced or natural, in accordance with NFPA 30, *Flammable and Combustible Liquids Code*, shall be maintained in areas where solvents are handled.

3-7.6

Solvent or slurry pumps shall be installed with proper controls to ensure that they are shut down when they run dry.

3-7.7

All electrical equipment shall be installed in accordance with appropriate provisions of NFPA 70, *National Electrical Code*.

Chapter 4 In-Plant Conveying of Aluminum Powder

4-1 Portable Containers.

4-1.1

Transfer of powders in-plant shall be done in suitable conductive containers as described in Chapter 3.

4-1.2

Powered forklift trucks shall be selected in accordance with NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*.

4-1.3

Containers approved by the U.S. Department of Transportation (DOT) for shipment of aluminum powders shall be permitted to be used.

4-1.4

All wheeled containers, hand trucks, and lift trucks shall have nonsparking, static conductive tires and wheels that have been bonded through or around the lubricating film in the bearings or shall have grounding straps.

4-2 Pneumatic Conveying.

4-2.1

Conveyor ducts shall be fabricated of nonferrous minimum-sparking metal or of nonmagnetic minimum-sparking stainless steel.

4-2.2*

Ducts shall be electrically bonded and grounded to minimize accumulation of static electric charge.

4-2.3

Plastics or other nonconductive ducts or duct liners shall not be used.

4-2.4*

If the conveying gas is air, the aluminum powder-to-air ratio throughout the conveying system shall be held below 50 percent of the lower flammable limit (LFL) of the aluminum powder at normal operating conditions.

4-2.4.1* Operation near or above the LFL shall be permitted if an inert gas conveying system is used. See NFPA 69, *Standard on Explosion Prevention Systems*.

4-2.4.2* The inert gas used shall be based on such gases as nitrogen, argon, helium, or flue gas, and shall have an oxygen concentration determined by test to be appropriate to the inerting gas and the particle size of the aluminum powder.

Exception: Where the product is never exposed to air, the oxygen content can be zero.

4-2.4.3 The inert gas shall have a dew point such that no free moisture can condense or accumulate at any point in the system.

4-2.4.4 The inert gas stream shall be continuously monitored for oxygen content and shall be arranged to sound an alarm if the oxygen content is not within a prescribed range.

4-2.5*

Where the conveying duct is exposed to weather or moisture, it shall be moisturetight.

4-2.6

A minimum conveying velocity of 4500 ft/min (1364 m/min) shall be maintained throughout the conveying system to prevent the accumulation of dust at any point and to pick up any dust or powder that can drop out during an unscheduled system stoppage.

4-2.7

If the conveying gas is inducted into the system in a relatively warm environment and the ducts and collectors are relatively cold, the ducts and the collectors shall be either insulated or provided with heating so that the gas temperature does not fall below the dew point, causing condensation.

4-2.8*

If the dust is collected in a liquid, such as in a spray tower, any liquid used shall not have a flash point below 100°F (37.8°C) and shall be nonreactive with metal dust or reactive at a controlled rate under favorable operating conditions. The liquid remaining in or on the product shall be compatible with subsequent processing requirements.

4-3 Ductwork for Conveying Systems.

4-3.1*

Explosion vents, openings protected by antiflashback swing valves, or rupture diaphragms, shall be provided on ductwork. Relief shall be to a safe location outside of the building.

4-3.2

Wherever damage to other property or injury to personnel can result from the rupture of the ductwork, or where explosion relief vents cannot provide sufficient pressure relief, the ductwork shall be designed to withstand a suddenly applied internal pressure of at least 100 psig (690 kPa gauge).

Exception: If a portion of the ductwork is so located that no damage to property or injury to personnel will result from its bursting, that portion shall be permitted to be of light construction so as to intentionally fail, thereby acting as an auxiliary explosion vent for the system.

4-4 Fan and Blower Construction and Arrangement.

4-4.1

Blades and housings of fans used to move air or inert gas in conveying ducts shall be constructed of conductive, nonsparking metal such as bronze, nonmagnetic stainless steel, or aluminum.

4-4.2

Wherever practical, the design shall not allow the transported dust or powder to pass through the fan before entering the final collector.

4-4.3

Personnel shall not be permitted within 50 ft (15.2 m) of the fan or blower while it is operating. No maintenance shall be performed on the fan until it is shut down.

Exception: If personnel approach the fan or blower while it is operating, such as for a pressure test, it shall be done under the direct supervision of competent technical personnel and with the knowledge and approval of operating management and with the flow of aluminum powder shut off.

4-4.4*

Fans or blowers shall be located outside of all manufacturing buildings and so located that entrance of dust from the fan exhaust into the building shall be minimized.

4-4.5*

Fans or blowers shall be equipped with ball or roller bearings. Bearings shall be equipped with suitable temperature-indicating devices and shall be arranged to sound an alarm in case of over-temperature.

4-4.6

Fans or blowers shall be electrically interlocked with powder-producing machinery so that the machines are shut down if the fan stops.

Chapter 5 Dust and Powder Collection

5-1* Collectors.

5-1.1

Dry-type collectors shall be located outside, in a safe location, and shall be provided with suitable barriers or other means for protection of personnel.

5-1.2

Collectors shall be constructed of nonferrous, minimum-sparking metal or of nonmagnetic, minimum-sparking stainless steel.

5-1.3

Ductwork shall comply with the provisions of Section 4-3.

5-1.4*

The entire collection system, including the collector, shall be completely bonded and grounded to minimize accumulation of static electric charge.

5-2 Fans and Other Air-Moving Equipment.

5-2.1

Fans and other equipment for moving air shall be located so the fan is on the clean air side of the collector.

5-2.2

Fans shall be provided with ball or roller bearings.

5-3 High Temperature Warning.

5-3.1

Cyclone or other dry-type collectors shall be equipped with suitable instruments for recording the surface temperature. An over-temperature alarm or warning device shall be included and the limit setting shall be below the maximum service temperature of the filter medium or 90°F (32°C) below the ignition temperature of the powder cloud, whichever is lower.

5-3.2

Alarms and actuating equipment shall be suitable for use in Class II, Group E locations, as specified in NFPA 70, *National Electrical Code*, or shall be located in a nonhazardous location.

NOTE: See NFPA 497B, *Recommended Practice for the Classification of Class II Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas.*

5-3.3

All such instruments shall give audible and visual alarm at normally attended locations.

5-4* Collector Filter Medium.

Collector filter medium made from synthetic fabrics that accumulate high static electric charges shall not be used. Replacement filter media shall be in accordance with this criteria.

Chapter 6 Prevention of Fugitive Dust Accumulations

6-1 General.

6-1.1

This chapter shall apply to new and existing facilities.

6-1.2

Dust shall not be permitted to accumulate. Spills shall be removed at once, using conductive, nonsparking scoops and soft brooms or brushes having natural fiber bristles.

6-1.2.1 Final cleanup shall be permitted to be accomplished using a vacuum cleaning system designed in accordance with Section 6-2.

6-1.2.2 Compressed air blowdown shall not be permitted.

Exception: In certain areas impossible to clean otherwise, compressed air blowdown shall be done under carefully controlled conditions with all potential ignition sources prohibited in or near the area and the equipment shut down.

6-1.3

The use of water for cleaning shall not be allowed in manufacturing areas unless the following requirements are met:

(a) It has been determined by competent technical personnel that the use of water will be the safest method of cleaning in the shortest exposure time.

(b) Operating management has full knowledge of and has granted approval of its use.

(c) Adequate ventilation, either natural or forced, is available to maintain the hydrogen concentration safely below the lower flammable limit (LFL).

(d) Complete drainage of all water and powder to a safe, remote area is available.

6-2* Vacuum Cleaning Systems.

6-2.1

Vacuum cleaning systems shall only be used for removal of dust accumulations too small or too dispersed to be thoroughly removed by hand-brushing.

6-2.2*

Vacuum cleaning systems shall be effectively grounded and bonded to minimize accumulation of static electric charge.

6-2.3

Where aluminum dust is present, the fixed vacuum cleaning system's electrical equipment shall be suitable for Class II, Group E locations.

6-2.4

Vacuum cleaner hoses shall be conductive and nozzles or fittings shall be made of conductive, nonsparking material.

6-2.5

Dust picked up by the vacuum cleaning system shall be discharged into a suitable receptacle or collector located outside the building.

6-2.6

Portable vacuum cleaners shall be used only if listed for use in the area in which they are to be used or shall be nonelectrically powered.

6-3 Cleaning Frequency.

6-3.1

Supervisors shall be alert to prevent the accumulation of excessive dust on any portions of buildings or machinery not regularly cleaned in daily operations.

6-3.2

Regular periodic cleaning of buildings and machinery, with all machinery idle and power off, shall be carried out as frequently as conditions warrant.

Chapter 7* Fire Fighting Procedures

7-1 Dry Aluminum Powders.

7-1.1

Sections 7-1 and 7-2 shall apply to new and existing facilities.

7-1.2

An incipient fire shall be ringed with a dam of dry sand, dry inert granular material, or a Class D extinguishing agent. Extreme care shall be exercised during application to avoid any disturbance of the aluminum powder, which could cause a dust cloud. The dry extinguishing material shall be stored in such a manner that it remains clean and dry.

7-1.3

The dry material shall be carefully applied with a nonsparking metal scoop or shovel or applied from an extinguisher equipped with a low-velocity nozzle.

7-1.4

Care shall be exercised to eliminate drafts by shutting off fans and machinery and by closing doors and windows.

7-1.5

Areas where dry aluminum powders are produced or handled shall not have fire extinguishers rated for Class A, B, or C fires.

Exception: Where Class A, B, or C fire hazards are in the powder area, extinguishers suitable for use on such fires shall be permitted, provided they are marked "Not for Use on Aluminum Powder Fires."

7-2* Solvent-Wetted Powders.

7-2.1

A fire occurring while the aluminum powder is in slurry form shall be permitted to be fought using Class B extinguishing agents.

Exception: Halogenated extinguishing agents shall not be used.

7-2.2

A fire occurring in semi-wet material or filter-cake shall be fought using suitable Class B extinguishing agent.

7-2.3*

Where carbon dioxide is used to extinguish fires involving solvent-wetted aluminum, the residual material shall be immediately covered with dry sand or with other suitable Class D extinguishing agent and the entire mass shall be allowed to cool until it reaches ambient temperature. When the material has cooled and it has been determined that there are no hot spots, the covered material shall be carefully removed for disposal. It shall be handled in small quantities in covered containers, preferably not more than 3 gal (11.5 L) each in 5-gal (19.2 L) containers.

7-2.4

Manual water application shall only be used on a solvent-metal powder fire as a last resort, when other methods of control have failed and the fire shows evidence of going out of control. Only low-velocity spray or fog nozzles shall be used. Extreme care shall be exercised to avoid creating a dust cloud. Once water is used, its use shall be continued until the fire is extinguished or until the area becomes untenable.

7-2.4.1 After extinguishment, the area shall be immediately cleaned of all wetted powder, paste, or slurry.

7-2.4.2 Adequate ventilation shall be provided during cleanup to avoid concentrations of hydrogen from the exothermic reaction of the aluminum with water.

7-2.4.3 Suitable drainage provisions to a safe area away from manufacturing buildings shall be provided.

7-3 Automatic Sprinkler Protection.

7-3.1

Automatic sprinkler protection shall not be permitted in areas where dry aluminum powders are produced or handled.

7-3.2

Automatic sprinkler protection shall be permitted in areas where solvents are stored or used (*see NFPA 30, Flammable and Combustible Liquids Code*); aluminum paste is produced or handled; or dry aluminum powder is stored in sealed containers.

7-3.2.1 The decision of whether or not to use automatic sprinkler protection shall be based on the need to minimize the damage to property and risk to life resulting from fires and explosions involving both wetted and dry aluminum powders.

7-3.2.2 The special hazards associated with aluminum powder in contact with water shall be considered in the selection, design, and installation of automatic sprinkler systems.

7-3.2.3 Automatic sprinkler systems shall be designed and installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

7-3.2.4 Special attention shall be given to employee training and organizational planning to ensure safe evacuation of the sprinkler protected area, in case of fire.

7-4 Fire Fighting Organization.

7-4.1

Only trained personnel shall be permitted to engage in fire control activity. All others shall be evacuated from the area. Training shall emphasize the different types of fires anticipated and the appropriate agents and techniques to be used.

7-4.2

Fire fighting personnel shall be given regular and consistent training in the extinguishment of test fires set in a safe location away from manufacturing buildings. Training shall include all possible contingencies.

7-4.3*

If professional or volunteer fire fighters are admitted onto the property in the event of a fire emergency, their activity shall be directed by the on-site ranking officer of the trained plant fire fighters.

Chapter 8 Safety Requirements

8-1* General.

This chapter shall apply to new and existing facilities.

8-2 Guidelines.

8-2.1

Training programs shall be instituted to properly inform employees about the hazards involved in the manufacture of aluminum powder, paste, or granules, or the manufacture of atomized aluminum powder. As a minimum, the following areas shall be addressed:

8-2.1.1 Dust Explosion Hazards.

8-2.1.2 Control of Ignition Sources.

8-2.1.2.1* No smoking, open flames, electric or gas cutting or welding equipment, or spark-producing operations shall be permitted in the section of the building where aluminum dust is produced or handled. This type of work shall be allowed only in the areas where all machinery is shut down and the area is thoroughly cleaned and inspected to ensure the removal of all accumulations of aluminum dust. Accepted lockout/tagout procedures shall be followed for the shutdown of machinery.

8-2.1.2.2 Smoking materials, matches, and lighters shall not be carried or used by employees or visitors about the premises adjacent to or within any building in which aluminum powder is produced, handled, or loaded for shipment.

8-2.1.2.3 Propellant-actuated tools shall not be used in areas where a dust explosion can occur unless all machinery in the area is shut down and the area and machinery are properly cleaned.

8-2.1.2.4* Nonsparking tools shall be used when making repairs or adjustments on or around any machinery or apparatus where aluminum dust is present.

8-2.1.3 Housekeeping.

8-2.1.3.1 The work area shall be maintained as clean, orderly, and sanitary as working conditions allow.

8-2.1.3.2 Brooms and brushes used for cleaning shall be of a natural bristle type. Synthetic bristles shall not be used. Scoops, dustpans, etc., used for collecting sweepings shall be made of nonsparking, conductive material.

8-2.1.3.3 Dry powder dust sweepings shall not be returned to any machine for processing.

8-2.1.4 Fire Protection Equipment and Practices. (*See Chapter 7*.)

8-2.1.5 Personal Protective Equipment.

8-2.1.5.1 Outer clothing shall be clean, flame resistant, and non-static generating and shall be designed to be easily removable. Tightly woven, smooth fabrics treated with a flame-retardant chemical, and from which dust can readily be brushed, shall be used, if necessary. Woolen, silk, or synthetic fabrics that can accumulate high static electric charges shall not be used.

8-2.1.5.2 Work clothing shall have no external pockets unless covered with a flap fitted with a closure of some sort. Trousers shall not have cuffs.

8-2.1.5.3* Safety shoes shall be conductive, have no exposed metal, and shall be appropriate for the type of operation taking place.

8-2.2*

Emergency procedures to be followed in case of fire or explosion shall be established. All employees shall be trained in these procedures.

8-2.3

Procedures shall be established for the recognition and control of employee exposure to air contaminants.

8-2.4

A thorough inspection of the operating area shall take place on an "as needed" basis to help ensure that the equipment is in good condition and that proper work practices are being followed. This inspection shall be conducted at least quarterly, but shall be permitted to be done more often.

8-2.4.1 It shall be conducted by a person(s) knowledgeable in the proper practices, who shall record the findings and recommendations.

8-2.4.2 Regular and periodic maintenance checks and calibration on equipment critical to employee safety and plant operation shall be performed.

8-2.5

Deluge showers shall be installed at strategic locations immediately outside critical working areas to quickly douse clothing fires.

8-2.6 Fire Blankets.

Fire blankets shall be provided throughout the plant area.

Chapter 9 Referenced Publications

9-1

The following documents or portions thereof are referenced within this standard and shall be

considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

9-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, 1991 edition.

NFPA 30, *Flammable and Combustible Liquids Code*, 1993 edition.

NFPA 69, *Standard on Explosion Prevention Systems*, 1992 edition.

NFPA 70, *National Electrical Code*, 1993 edition.

NFPA 80, *Standard for Fire Doors and Fire Windows*, 1992 edition.

NFPA *101*, *Life Safety Code*, 1991 edition.

NFPA 496, *Standard for Purged and Pressurized Enclosures for Electrical Equipment*, 1993 edition.

NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*, 1992 edition.

NFPA 780, *Lightning Protection Code*, 1992 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for information purposes only.

A-1-1.1

Certain “nondusting” grades of aluminum flake powder are being produced. Although they exhibit less tendency to be dispersed into a dust cloud, the same precautions described in this standard should be observed.

A-1-5 Combustible Aluminum Dust.

Any time a combustible dust is processed or handled, a potential for explosion exists. The degree of explosion hazard will vary depending on the type of combustible dust and processing methods used.

A dust explosion has three requirements, all of which must be met:

(a) The dust must be combustible.

(b) The dust particles must form a cloud at or exceeding the lower flammable limit.

(c) A source of ignition must be present.

Evaluation of a combustible dust explosion hazard and the prevention techniques employed should be determined by means of actual test data. All combustible dusts that may produce a dust explosion should be tested so as to determine the following data:

(a) Particle size distribution.

(b) Moisture content as received and dried.

(c) Minimum dust concentration to ignite.

(d) Minimum energy required for ignition (joules).

(e) Maximum rate of pressure rise at various concentrations.

(f) Layer ignition temperature.

(g) Maximum explosion pressure, at optimum concentration.

Optional Testing.

(a) Dust cloud ignition temperature.

(b) Maximum permissible oxygen content to prevent ignition.

(c) Electrical resistivity measurement.

A-2-3.7

For information on deflagration venting, see NFPA 68, *Guide for Venting of Deflagrations*.

A-2-5.1

For information on deflagration venting, see NFPA 68, *Guide for Venting of Deflagrations*.

A-2-6.1

For information on static electricity, see NFPA 77, *Recommended Practice on Static Electricity*.

A-3-1.4

Temperature-sensing elements connected to alarms or machine stop switches may be employed for locations where overheating of bearings or other elements may be anticipated.

A-3-2.2

See NFPA 77, *Recommended Practice on Static Electricity*, for information on the subject.t

A-3-2.3

Journal bearings should not be used because of the difficulty of maintaining proper lubrication to prevent overheating. Outboard bearings are used where practical because it is easier to check for overheating. In those instances where dust tends to penetrate bearings a continuous flow of inert gas ($1^1/_2$ to 5 percent oxygen) can be employed to pressurize the bearings and seals.

A-3-6

Open bin storage is not desirable. Storage bins can be sealed and they can be purged with inert gas prior to filling. Once filled, the bins can be maintained inert by a suitable gas as detailed in 4-2.4.2.

A-3-7

When aluminum is milled in the presence of a liquid that is chemically inert with respect to the metal, the air-dust explosion hazard is eliminated. When the resulting product is subsequently exposed to air, any unoxidized surfaces produced during milling will react and may generate enough heat to cause ignition. To prevent this, it is imperative that a controlled amount of oxygen be present in the milling operation and in slurries ahead of filters and blenders, so that new surfaces are oxidized as they are formed. The addition of a milling agent, such as stearic acid, does not eliminate the need for this added oxygen.

A-4-2.2

See NFPA 77, *Recommended Practice on Static Electricity*.

A-4-2.4

These minimum explosive concentrations are published in U.S. Bureau of Mines, RI 6516, "*Explosibility of Metal Powders*." Although the aluminum powder-air suspension may be held below 50 percent of the LFL in the conveying system, the suspension will necessarily pass through the flammable range in the collector at the end of the system unless the dust is collected in liquid, such as in a spray tower. Also, the powder in the conveying line from the atomizer to the collector will, of necessity, approach the lower flammable limit.

A-4-2.4.1 Aluminum and aluminum alloy powders are produced by various means. These processes, as well as certain finishing and transporting operations, tend to expose a continuously increasing area of new metal surface. Most metals immediately undergo a surface reaction with available atmospheric oxygen which forms a protective coating of metal oxide that serves as an impervious layer to inhibit further oxidation. This reaction is exothermic. If a fine or thin lightweight particle having a large surface area of "new" metal is suddenly exposed to the atmosphere, sufficient heat will be generated to raise its temperature to the ignition point.

Completely inert gas generally cannot be used as an inerting medium since the aluminum powder would eventually, at some point in the process, be exposed to the atmosphere, at which time the unreacted surfaces would be oxidized; enough heat would be produced to initiate either a fire or an explosion. To provide maximum safety, a means for the controlled oxidation of newly exposed surfaces is provided by regulating the oxygen concentration in the inert gas. The mixture serves to control the rate of oxidation, while materially reducing the fire and explosion hazard.

A completely inert gas can be used if the powder so produced will not be exposed to air.

A-4-2.4.2 Oxygen limits of 3 to 5 percent have been maintained in aluminum powder systems using a controlled flue gas. Other limits are applicable where other inert gases are used. Refer to U.S. Bureau of Mines, RI 3722, "*Inflammability and Explosibility of Metal Powders*."

A-4-2.5

Any moisture entering the system can react with the aluminum powder, generating heat and hydrogen. Hydrogen is extremely flammable and very easy to ignite. It must not be trapped in nonventilated areas of buildings, equipment, or enclosures.

A-4-2.8

Such wet collection is not always possible or desirable.

A-4-3.1

For information on explosion vents, see NFPA 68, *Guide for Venting of Deflagrations*.

A-4-4.4

Ultimately, all fans or blowers in dust collector systems accumulate sufficient powder to become a potential explosion hazard.

A-4-4.5

Fans or blowers may also be provided with vibration-indicating devices, arranged to sound an alarm or to provide shutdown, or both, in the event of blade or rotor imbalance, or bearing or drive problems.

A-5-1

A high-efficiency cyclone-type collector presents less hazard than a bag- or media-type collector and, except for extremely fine powders, will usually operate with fairly high collection efficiency. Where cyclones are used, the exhaust fan discharges to atmosphere away from other operations. It should be recognized that there will be some instances in which a centrifugal-type collector may be followed by a fabric or bag- or media-type collector or by a scrubber-type collector where particulate emissions are kept at a low level. The hazards of each collector should be recognized and protected against. In each instance, the fan will be the last element downstream in the system. Because of the extreme hazard involved with a bag- or media-type collector, consideration should be given to a multiple-series cyclone with a liquid final stage.

Industry experience has clearly demonstrated that an eventual explosion can be expected where a bag- or media-type collector is used to collect aluminum fines. Seldom, if ever, can the source of ignition be positively identified. In those unusual instances when it becomes necessary to collect very small fines for a specific commercial product, it is customary for the producer to employ a bag- or media-type collector. With the knowledge that strong explosive potential is present, the producer will locate the bag- or media-type collector a safe distance from buildings and personnel.

If a bag- or media-type collector is used, the shaking system or dust removal system can be such as to minimize sparking due to frictional contact or impact. Pneumatic or pulse-type shaking is more desirable because no mechanical moving parts are involved in the dusty atmosphere. If the bags are provided with grounding wires, they can be positively grounded through a low-resistance path to ground. Where bags are used, it is customary that the baghouse be protected by an alarm to indicate excessive pressure drop across the bags. An excess air temperature alarm is also frequently employed. A bag- or media-type collector is customarily located at least 50 ft (15.2 m) from any other building or operation. It is not customary to permit personnel to be within 50 ft (15.2 m) of the collector during operation or when shaking bags. Explosion vents are usually built into the system, as described in NFPA 68, *Guide for Venting of Deflagrations*. Care is customarily exercised in locating the vents because of the possibility of blast damage to personnel or adjacent structures.

A-5-1.4

For information on precautions for static electricity, see NFPA 77, *Recommended Practice on Static Electricity*.

A-5-4

Some collector bags or other types of media or screens have fine, noninsulated wire enmeshed into or woven with the cloth or otherwise fastened to it. These are always securely grounded. It should be pointed out that this is not a positive guarantee of static charge removal because there is no dependable force to cause the charges to move across the nonconducting area of the fabric to the grounded wires. Often, a substantial potential difference can be measured. Also, it is possible that a wire in the cloth may break in such a way that it is no longer grounded. Such a wire serves as a capacitor and may store a static charge.

A-6-2

Permanently installed vacuum cleaning systems provide the maximum safety because the dust collecting device and the exhaust blower can be located in a safe location outside the dust-producing area. The dust collector should be located outside the building, preferably more than 50 ft (15.2 m) away. If the collector is located closer than 50 ft (15.2 m), it is usually surrounded by a strong steel shield, cylindrical in shape and open at the top, or closed with a light, unfastened cover. The shield is closed at the bottom and designed to withstand a blast pressure of 200 psig (1380 kPa gauge). Such a protective barricade will direct an explosion harmlessly upward and will protect both property and personnel. All suction lines should be provided with explosion vents and anti-flashback valves.

A-6-2.2

See NFPA 77, *Recommended Practice on Static Electricity*.

A-7

Since it is almost impossible to extinguish a massive fire in dry aluminum powder, the fire problem resolves itself into the control of fires in the incipient stage. The requirements of Section 7-1 should be followed if the fire is to be controlled quickly. This is especially true with regard to the application of the extinguishing material, as even a minor dust cloud can explode violently.

A properly ringed fire will develop a hard crust of metal oxide, which will ultimately exclude enough oxygen to cause self-extinguishment. It is customary practice, after dispensing the extinguishing material, to leave the area, closing all doors leading to the area and sealing them with sand. The area should not be re-entered until combustion has stopped and the material has cooled.

A-7-2

Milling of aluminum with combustible solvents is practiced in the manufacture of aluminum flake used in pigments and powders. The material is handled as a slurry during processing. Some of the product is marketed as a paste; other portions are filtered, dried, sometimes polished, and sold as dry flake powder. The solvents employed are generally moderately high flash-point naphthas. A fire in an aluminum powder slurry is primarily a solvent fire and can be fought using Class B extinguishing agents, except for halogenated extinguishing agents.

Major producers usually employ fixed extinguishing systems of carbon dioxide or foam in this area. Some Class B portable extinguishers are provided also. Obviously, judgment should be used in determining whether Class B extinguishing agents can be safely used. If the extinguishing agent is carefully applied, it will be very evident if it accelerates the fire. If it does, its use should be discontinued and a dry inert granular material used. A fire in filter cake, a solvent-wetted but semi-dry material containing aluminum, may be a solvent fire or it may at some point exhibit the characteristic of a powder fire, at which time it should be treated as such. If the aluminum metal has ignited, it may continue to burn under a crust without flames.

A-7-2.3

Reignition may occur due to high localized heat or spontaneous heating. To avoid reignition, the residual material should be immediately smothered.

A-7-4.3

It is recommended that a practice fire drill be conducted once each year to familiarize local fire department personnel with the proper methods of fighting Class D fires.

A-8-1

Employees' health and safety in operations depend on the recognition of actual or potential hazards, controlling or eliminating these hazards, and training employees to work safely.

A-8-2.1.2.1 Attention is called to the hazardous conditions that may exist both inside and outside the plant if cutting torches are used to dismantle dust collectors or powder-producing machinery before all dust accumulations have been removed.

It is a commonly recognized practice that operators of cutting or welding torches be required to obtain a written permit from the safety or fire protection officer of the plant before using their equipment under any condition around aluminum powder plants.

A-8-2.1.2.4 Under certain circumstances, such as impact with rusted iron or steel, aluminum cannot safely be considered to be nonsparking since a minor thermite reaction can be initiated. For details, refer to "Aluminum and the Gas Ignition Risk," by H. S. Eisner and "Fire Hazards in Chemical Plants from Friction Sparks Involving the Thermite Reaction." (*See Appendix C.*)

A-8-2.1.5.3 Safety shoes meeting the following guidelines should be worn by all operating personnel except those persons who are required to work on electrical circuits or equipment.

(a) Soles should be resistant to embedding particles and to petroleum solvents, if used.

(b) Soles and heels should be attached by sewing or pegging.

(c) Nails, metal cleats, or metal plates should not be used.

(d) Safety toe caps should be completely covered with a scuff-resistant material.

(e) Soles and heels should be static conductive.

A-8-2.2 Employee Training.

(a) All employees should be carefully and thoroughly instructed by their supervisors regarding the hazards of their working environment and their behavior and procedures in case of fire or explosion.

(b) All employees should be shown the location of electrical switches and alarms, first-aid equipment, safety equipment, and fire extinguishing equipment.

(c) All employees should be taught the permissible methods for fighting incipient fires in pastes and for isolating aluminum fires.

(d) The hazards involved in causing dust clouds and the danger of applying liquids onto an incipient fire should be explained.

(e) Strict discipline and scrupulous housekeeping should be maintained at all times.

(f) Attention should be given to employee training and organizational planning to ensure safe and proper evacuation of the area.

Appendix B Electrically Conductive Floors

This Appendix is not a part of the requirements of this NFPA document, but is included for *information purposes only*.

B-1 General.

B-1.1

Electrically conductive flooring is often employed in aluminum powder plants, although it is recognized that it is difficult to maintain the conductivity of the floor over a period of time using currently available materials. Careful examination of the details of this standard will disclose the logic of the use of conductive flooring materials.

B-1.2

The surface of a conductive floor will provide a path of moderate electrical conductivity between all persons and portable equipment making contact with the floor, thus preventing the accumulation of dangerous electrostatic charges.

B-1.3

The maximum resistance of a conductive floor is usually less than 1,000,000 ohms, as measured between two electrodes placed three feet apart at any two points on the floor. The minimum resistance is usually greater than 25,000 ohms, as measured between a ground connection and an electrode placed at any location on the floor. This minimum resistance value provides protection for personnel against electrical shocks. Resistance values are checked at regular intervals, usually once each month.

B-2 Testing for Minimum and Maximum Resistance.

The following equipment and procedures are accepted practice.

B-2.1

Each electrode will weigh 5 lbs (2.27 kg) and will have a dry, flat, circular contact area 2.5 in. (6.4 cm) in diameter. The electrode will consist of a surface of aluminum foil 0.0005 in. (0.013 mm) to 0.001 in. (0.025 mm) thick, backed by a layer of rubber 0.25 in. (6.35 mm) thick and measuring 40 to 60 durometer hardness, as determined by a Shore Type A Durometer or equivalent, per ASTM D2240, *Standard Test Method for Rubber Property — Durometer Hardness*.

B-2.2

Resistance may be measured with a suitably calibrated ohmmeter that can operate on a nominal open circuit output voltage of 500 volts dc and a short-circuit current of 2.5 to 10.0 m amp.

B-2.3

Measurements may be made at five or more locations in each room and the results averaged.

B-2.4

For compliance with the maximum resistance limit, the average of all measurements should be less than 1,000,000 ohms.

B-2.5

For compliance with the minimum resistance limit, no individual measurement should be less than 10,000 ohms and the average of not less than five measurements should be greater than 25,000 ohms.

B-2.6

Where resistance to ground is measured, two measurements are customarily made at each location, with the test leads interchanged at the instruments between the two measurements. The average of the two measurements is taken as the resistance to ground at that location. Measurements are customarily taken with the electrode or electrodes more than 3 ft (0.9 m) from any ground connection or grounded object resting on the floor. If resistance changes appreciably with time during a measurement, the value observed after the voltage has been applied for about five minutes can be considered the measured value.

NFPA 654

1994 Edition

Standard for the Prevention of Fire and Dust Explosions in the

Chemical, Dye, Pharmaceutical, and Plastics Industries

1994 Edition

This edition of NFPA 654, *Standard for the Prevention of Fire and Dust Explosions in the Chemical, Dye, Pharmaceutical, and Plastics Industries*, was prepared by the Technical Committee on Fundamentals of Dust Explosion Prevention and Control and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 16–18, 1994, in San Francisco, CA. It was issued by the Standards Council on July 14, 1994, with an effective date of August 5, 1994, and supersedes all previous editions.

The 1994 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 654

NFPA 654 was initiated by the Committee on Dust Explosion Hazards in 1943 and originally applied only to the prevention of dust explosions in the plastics industry. As such, it was tentatively adopted in 1944 and officially adopted in 1945. Amendments were adopted in 1946, 1959, 1963, and 1970. The 1970 edition was reconfirmed in 1975.

In 1976, responsibility for NFPA 654 was transferred to the Technical Committee on Fundamentals of Dust Explosion Prevention and Control. The Committee, in completely revising the document, also expanded its scope to include chemical, dye, and pharmaceutical dusts, since the fire and explosion hazards of these dusts are generally the same as for plastic dusts.

The 1982 edition of this standard consisted of a complete rewrite of the 1975 edition. Due to limited technological changes in this area since 1982, the Committee voted to reconfirm the text as it appears in the 1982 version. Editorial corrections and changes to allow the document to adhere more closely to the NFPA *Manual of Style* were incorporated into the 1988 edition.

For the 1994 edition of NFPA 654, the standard was partially revised to improve its usability, adoptability, and enforceability; to update out-dated terminology; and to add the NFPA language for equivalency and retroactivity. In addition, the Technical Committee on Fundamentals of Dust Explosion Prevention and Control added new technologies for explosion prevention to be consistent with the 1992 edition of NFPA 69, *Standard on Explosion Prevention Systems*. The Committee also clarified the requirements relating to controlling hazardous accumulations of process dust.

Alternates

Committee Scope: This Committee shall have primary responsibility for documents that are generally applicable to all dusts concerning the fundamentals of dust explosion prevention. This Technical Committee also shall be responsible for documents on the prevention, control, and extinguishment of fires and explosions in dust collection equipment and in pneumatic conveying equipment.

NFPA 654
Standard for the
Prevention of Fire and Dust Explosions in the Chemical, Dye, Pharmaceutical and Plastics Industries

1994 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 8 and Appendix B.

Chapter 1 General

1-1 Scope.

1-1.1

This standard shall apply to all phases of the manufacture and processing of industrial dusts including, but not limited to, chemicals, dyes, pharmaceuticals and plastics where a fire or explosion hazard might exist due to the presence of combustible dusts.

1-1.2

This standard shall not apply to materials covered by the following:

NFPA 61A, *Standard for the Prevention of Fire and Dust Explosions in Facilities Manufacturing and Handling Starch*

NFPA 61B, *Standard for the Prevention of Fires and Explosions in Grain Elevators and*

Facilities Handling Bulk Raw Agricultural Commodities

NFPA 61C, *Standard for the Prevention of Fire and Dust Explosions in Feed Mills*

NFPA 61D, *Standard for the Prevention of Fire and Dust Explosions in the Milling of Agricultural Commodities for Human Consumption*

NFPA 65, *Standard for the Processing and Finishing of Aluminum*

NFPA 480, *Standard for the Storage, Handling and Processing of Magnesium Solids and Powders*

NFPA 481, *Standard for the Production, Processing, Handling, and Storage of Titanium*

NFPA 482, *Standard for the Production, Processing, Handling, and Storage of Zirconium*

NFPA 490, *Code for the Storage of Ammonium Nitrate*

NFPA 651, *Standard for the Manufacture of Aluminum Powder*

NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions*

NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*

NFPA 8503, *Standard for Pulverized Fuel Systems.*

1-1.3

NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials,* shall not apply to material transfer systems or dust control systems covered by this standard.

1-2 Purpose.

The purpose of this standard is to prescribe requirements for safety to life and property from fire and explosion and to minimize the resulting damage should a fire or explosion occur.

1-3 Equivalency.

Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard, provided technical documentation is submitted to the authority having jurisdiction to demonstrate equivalency and the system, method, or device is approved for the intended purpose.

1-4 Retroactivity.

This standard applies to facilities on which construction is begun subsequent to the date of publication of the standard. When major replacement or renovation of existing facilities is planned, provisions of this standard shall apply.

1-5 Definitions.

For the purpose of this standard, the following terms shall have the meanings given below.

Approved. Acceptable to the authority having jurisdiction.

NOTE: The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Chemical. A substance composed of an element or combination of elements.

Combustible Dust.* Any finely divided solid material 420 microns or smaller in diameter (material passing a U.S. No. 40 Standard Sieve) that presents a fire or explosion hazard when dispersed and ignited in air.

Detachment. In the open air or in a separate building.

Duct. Pipes, channels, or other enclosures used for the purpose of conveying air, dust, or gas. A duct shall not include short sections of flexible hose.

Dye. A solid or powdered coloring matter.

Explosion. The bursting of a building or container as a result of development of internal pressure beyond its confinement capacity.

Hybrid Mixture.* A mixture of a combustible gas with either a combustible dust or a combustible mist.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Pharmaceutical. A natural or manufactured medicinal drug composed of various ingredients.

Plastic. A generic term referring to synthetic or natural resins, with or without additives, that can be molded by heat and pressure, or both. The term also refers to the finished products.

Separation. The interposing of distance between the combustible dust process and other operations that are in the same room.

Segregation. The interposing of a physical barrier between the combustible dust process and other operations.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Plant Arrangement and Building Construction

2-1 Segregation, Separation, or Detachment of Dust Handling and Processing Areas.

2-1.1

Areas in which combustible dusts are processed or handled shall be segregated, separated, or detached in such a manner as to minimize damage to other portions of the plant should an explosion or fire occur. (*See 3-3.2.4.*)

2-1.2

If physical barriers are erected to segregate dust explosion hazards, they shall be designed for sufficient explosion resistance to preclude failure of these barriers before the explosion pressure can be safely vented to the outside.

2-1.3

Compartmentation shall be permitted to be used to limit the area considered hazardous, provided a dust collection system is installed to minimize accumulations of dust. Process equipment, including the dust collection system, shall be protected as required by Chapters 3 and 4.

2-2 Building Construction.

2-2.1

All buildings shall be of Type I or II construction, as defined in NFPA 220, *Standard on Types of Building Construction*. Where local, state, and national building codes require, modifications shall be permitted for conformance to these codes.

2-2.2*

Interior surfaces shall be as smooth as possible to facilitate cleaning and minimize combustible dust accumulation.

2-2.3

Concealed spaces shall be sealed to prevent dust accumulation.

2-2.4

Interior walls erected as fire partitions shall be designed for a minimum fire endurance of 1 hour.

2-2.5

Openings in fire walls shall be protected by automatic closing fire doors having a fire protection rating of 3 hours. Fire doors shall be installed according to NFPA 80, *Standard for Fire Doors and Fire Windows*, and shall normally be in the closed position.

2-2.6

Means of egress shall comply with NFPA *101®*, *Life Safety Code®*.

2-2.7

All penetrations of floors, walls, or partitions shall be dusttight and, where structural assemblies have a fire endurance rating, the seal shall maintain that rating.

2-2.8

Interior stairs, elevators, and manlifts shall be enclosed in dusttight shafts having a 1-hour fire resistance rating. Doors of the automatic-closing or self-closing type, having a fire protection rating of 1 hour, shall be provided at each landing.

Exception: Stairs, elevators, and manlifts serving only open-deck floors, mezzanines, and platforms need not be enclosed.

2-2.9*

Floors and load bearing walls exposed to dust explosion hazards shall be designed to preclude failure during an explosion.

2-3 Explosion Venting.

2-3.1*

If a room or building contains a dust explosion hazard external to protected equipment, such areas shall be provided with explosion venting to a safe outside location.

2-3.2*

Vent closures shall be directed toward a personnel restricted area, or the vent closure shall be restrained to minimize the missile hazard to personnel and equipment. In addition to the missile hazard, the fireball emitted from the vent opening shall not impinge upon personnel pathways.

2-3.3

Explosion vents shall be designed such that, once opened, they will remain open to prevent failure from the vacuum following the pressure wave.

Chapter 3 Process Equipment

3-1* General.

3-1.1 Equipment Explosion Protection.

In designing explosion protection for equipment, one of the following methods of protection shall be incorporated:

(a) Equipment can be designed to contain the anticipated explosion pressure in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

(b)* Explosion venting can be provided.

(c) An explosion suppression system shall be permitted to be provided and, where used, shall be designed in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

(d)* Inerting shall be permitted to be used to reduce oxygen content below the specific level for the material being handled. See NFPA 69, *Standard on Explosion Prevention Systems*.

(e) The dust shall be permitted to be rendered noncombustible through dilution with a noncombustible dust. If this method is used, test data for specific dust and diluent combinations shall be provided and shall be acceptable to the authority having jurisdiction.

3-1.2 Equipment Isolation.

Isolation devices shall be provided to prevent explosion propagation between major pieces of equipment connected by ductwork, or the design shall take into consideration the increased venting requirements from pressure piling and flame jet ignition. Isolation devices include, but are not limited to:

(a)* Chokes,

(b)* Rotary valves,

(c) Fast-acting dampers and valves,

(d) Flame front diverters,

(e) Deflagration isolation systems.

(See NFPA 69, *Standard on Explosion Prevention Systems*, for design requirements.)

3-2 Bulk Storage.

3-2.1

For the purpose of this section, bulk storage shall include such items as bins, tanks, hoppers, and silos.

3-2.2

Bulk storage containers, whether located inside or outside of buildings, shall be constructed of noncombustible material.

3-2.3

There shall be no intertank or interbin venting.

3-2.4*

Interior surfaces shall be as smooth as possible to facilitate cleaning and minimize combustible dust accumulation.

3-2.5

Access doors or openings shall be provided to permit inspection, cleaning, and maintenance. Access doors or openings shall be designed to prevent dust leaks. Access doors shall not be considered as an explosion relief area unless specifically designed for that function and vented to outside the building.

3-2.6

Bulk storage containers shall be provided with explosion protection as described in 3-1.1.

3-3 Material Transfer System.

3-3.1 Duct Systems.

3-3.1.1* Ducts handling combustible dust shall be constructed of noncombustible material, shall be of adequate strength and rigidity to meet the conditions of service and installation requirements, and shall be properly protected where subject to mechanical injury. All ducts, whether inside or outside of buildings, shall be thoroughly braced where required and substantially supported by metal hangers or brackets and shall be designed to afford strength and rigidity against disruption. All lap joints shall be made in the direction of the air flow.

Exception: Flexible hose to allow material pick-up, flexible connections for vibration isolation, and bellows for the free movement of weigh bins shall be permitted if they are conductive or the equipment is bonded and grounded.*

3-3.1.2 All ducts shall be made reasonably dusttight throughout and shall have no openings other than those required for the proper operation and maintenance of the system, i.e., clean-out panels, service access panels for explosion vents, etc.

3-3.1.3 Changes in sizes of ducts shall be by means of a taper transformation piece, the included angle of the taper being not more than 30 degrees.

3-3.1.4 The passing of ducts through a physical barrier for segregation shall be avoided.

3-3.2 Bucket Elevators.

3-3.2.1 Belt-driven bucket elevators shall be provided with explosion protection as specified in 3-1.1. Bucket elevators, wherever possible, shall be located outside buildings. Where explosion venting is provided, the bucket elevator shall be located as close as possible to exterior walls where explosion relief can be vented to the outside. If the distance between the head and boot exceeds 20 ft (6.1 m), explosion relief shall be provided at not more than 20-ft (6.1-m) intervals on the legs.

3-3.2.2 Elevator leg casings, head and boot sections, and connecting ducts shall be dusttight and shall be constructed of noncombustible materials.

3-3.2.3 Where provided, inlet and discharge hoppers shall be designed so that they are accessible for cleaning and inspection.

3-3.2.4* Belt-driven bucket elevators shall be equipped with a mechanical or electromechanical device that cuts off the power to the drive motor and sounds an alarm in the event of leg belt slowdown exceeding 20 percent. Feed to the elevator leg shall be stopped or diverted.

3-3.2.5 No bearings shall be located or exposed within the bucket elevator casing.

3-3.3 Conveyors.

3-3.3.1 All conveyors (e.g., screw, drag, pneumatic, etc.) shall be of metal construction and shall be designed to prevent escape of combustible dusts. Coverings on clean-out, inspection, and other openings shall be securely fastened.

3-3.3.2* Pneumatic systems shall be designed in accordance with NFPA 650, *Standard for Pneumatic Conveying Systems for Handling Combustible Materials*.

3-3.3.3 Conveyors shall be protected from explosion as specified in 3-1.1.

3-3.3.4 Belt-driven conveyors shall be equipped with an automechanical or an electromechanical device that cuts off the power to the drive motor and sounds an alarm in the event of a belt slowdown exceeding 20 percent. Feed to the conveyor shall be stopped or diverted.

3-3.4 Fans or Blowers.

3-3.4.1 Blowers or exhaust fans shall be installed on proper foundations and shall be secured in a substantial manner.

3-3.4.2 For fans, ample clearance shall be provided between the blades and the casing, and fans shall be designed to operate below the minimum explosible concentration of the normally expected dust and hybrid loading.

3-3.4.3* For fans on the discharge side of the dust collectors, the dust concentration in the system shall be designed to be below the minimum explosible concentration of the normally expected dust and hybrid loading.

3-3.4.4 The fan bearings shall not extend into the casings. Belt drives shall not be located inside the fan or blower housing. A clearance shall be provided between the shaft and casings.

3-3.4.5 A minimum conveying velocity shall be maintained throughout the conveying system to prevent the accumulation of dust at any point and to pick up any dust or powder that drops out during an unscheduled system stoppage.

3-4 Size Reduction.

3-4.1

Size reduction equipment shall include such items as mills, grinders, and pulverizers.

3-4.2

Before material is processed by size reduction equipment, foreign matter shall be removed as required by 5-1.1 or by the use of grates or other separation devices.

3-4.3

Size reduction equipment shall be isolated as required by 3-1.2.

3-4.4

Explosion protection shall be provided as specified in 3-1.1.

3-5* Particle Size Separation.

Screens, sieves, and similar devices shall be in dusttight enclosures. Connection ducts shall be made of metal.

Exception: Where movement of the equipment is necessary, short flexible connections shall be permitted to be used. Such connectors shall be electrically conductive and bonded. (See Section 5-3.)

3-6 Mixers and Blenders.

3-6.1*

Mixers and blenders shall be dusttight. Foreign matter shall be removed as required by 5-1.1 or by the use of grates or other separation devices.

3-6.2

Explosion protection shall be provided as specified in 3-1.1.

3-6.3

Mixers and blenders shall be made of metal or other noncombustible material.

3-7 Dryers.

3-7.1*

A dryer, within the scope of this standard, shall be any piece of processing equipment used to reduce the moisture or volatile content of the material being handled.

3-7.2*

Heating systems shall be in accordance with 5-5.1.

3-7.3

Drying media that contacts material being processed shall not be recycled to rooms or buildings. Drying media shall be permitted to be passed through a filter, dust separator, or equivalent means of dust removal and recycled to the drying process.

3-7.4

Dryers shall be isolated as required by 3-1.2.

3-7.5

Combustion controls on all heating mediums shall be provided in accordance with the following NFPA standards, as applicable:

NFPA 31, *Standard for the Installation of Oil-Burning Equipment*

NFPA 85C, *Standard for Prevention of Furnace Explosions/Implosions in Multiple Burner Boiler-Furnaces*

NFPA 86, *Standard for Ovens and Furnaces*

NFPA 8501, *Standard for Single Burner Boiler Operation.*

3-7.6

Dryers shall be constructed of noncombustible materials.

3-7.7

Interior surfaces of dryers shall be designed so that accumulations of material are minimized and cleaning is facilitated.

3-7.8

Outward opening access doors or openings shall be provided in all parts of the dryer and connecting conveyors to permit inspection, cleaning, maintenance, and the effective use of portable extinguishers or hose streams.

3-7.9

Explosion protection shall be provided as specified in 3-1.1.

3-7.10 Dryer Operation.

3-7.10.1 Operating controls shall be designed, constructed, installed, and monitored so that required conditions of safety for operation of the air heater, the dryer, and the ventilation equipment are maintained.

3-7.10.2 The drying chamber shall have an operating control arranged to maintain the temperature within the prescribed limits.

3-7.10.3 Extraneous material that would contribute to a fire hazard shall be removed from the commodity before it enters the dryer.

3-7.10.4 Operating personnel shall be fully instructed on the safe operation of the dryer, according to the manufacturer's operating instructions. Instruction shall include procedures to be followed in case of fire.

Chapter 4 Dust Control

4-1 Dust Collection.

4-1.1

Continuous suction shall be provided for processes where combustible dust is liberated in normal operation. The dust shall be conveyed to dust separators or collectors.

4-1.2 Location and Provisions for Dust Collection Systems.

4-1.2.1* Dust collectors shall be located outside of buildings.

Exception No. 1: Dust collectors shall be permitted to be located inside of buildings if they are located adjacent to an exterior wall, are vented to the outside through straight ducts not exceeding 10 ft (3 m) in length, and have explosion vents.*

Exception No. 2: Dust collectors protected with an explosion suppression system meeting the requirements of NFPA 69, Standard on Explosion Prevention Systems, shall be permitted to be located inside buildings.

4-1.2.2 Dust collection equipment shall be provided with explosion protection, as specified in 3-1.1.

4-1.3

Manifolding of dust collection ducts shall not be permitted unless arranged in accordance with 4-1.3.1 and 4-1.3.2.

4-1.3.1 Dust collection ducts from a single piece of equipment or from multiple pieces of equipment interconnected on the same process stream shall be permitted to be manifolded.

4-1.3.2 Dust collection ducts from isolated pieces of equipment shall be permitted to be manifolded if each of the ducts is equipped with an isolation device prior to manifolding.

4-1.4

Dust collectors shall be constructed of noncombustible materials. Cloth-type collectors shall be provided with dusttight metal enclosures or their equivalent.

4-1.5

Recycling of air from collectors to buildings shall be permitted if the system is designed to prevent both return of dust and transmission of energy from a fire or explosion to the building.

Exception: Recycling of air to the building shall not be permitted under any circumstances when combustible gases or vapors, hybrid mixtures, or inert gases are involved.

4-2 Housekeeping.

The requirements of 4-2.1 through 4-2.4 shall be applied retroactively.

4-2.1*

Equipment shall be designed, maintained, and operated in a manner that minimizes the escape of dust. Regular cleaning frequencies shall be established for floors and horizontal surfaces, such as ducts, pipes, hoods, ledges, and beams to minimize dust accumulations within operating areas of the facility.

4-2.2*

Surfaces shall be cleaned in a manner that minimizes the generation of dust clouds. Vigorous sweeping, blowing down with steam or compressed air produces dust clouds and shall be permitted only if the requirements of 4-2.3 are met.

4-2.3

Blowdown with steam or compressed air can be performed if the following items are complied with:

(a) Area and equipment shall be vacuumed prior to blowdown.

(b) Electrical power and other sources of ignition shall be shut down or removed from the area.

(c) Only low-pressure steam or compressed air shall be used.

4-2.4

When used, vacuum cleaners shall be listed for use in Class II hazardous locations or shall be a fixed-pipe suction system with remotely located exhauster and collector.

Exception: Where flammable vapors or combustible gases are present, vacuum cleaners shall be listed for Class I hazardous locations.

Chapter 5 Control of Ignition Sources

5-1 Friction.

5-1.1* Tramp Metal.

Magnetic separators of the permanent magnet or self-cleaning electromagnetic type or pneumatic separators shall be installed to remove metal or foreign matter capable of igniting combustible material being processed. [*See Figures A-3-1.2(a) and (b).*]

5-1.2*

Belt drives shall be designed to stall without slipping, or a safety device shall be provided to shut down the equipment if slippage occurs.

5-1.3 Bearings.

5-1.3.1 Roller or ball antifriction bearings shall be used on all processing and transfer equipment.

Lubrication shall be performed in accordance with the manufacturer's recommendations.

5-1.3.2 Wherever possible, bearings shall be located outside the combustible dust stream where they are less exposed to dust and more accessible for inspection and service.

5-1.4 Equipment.

5-1.4.1 Equipment shall be installed and maintained so that constant true alignment is maintained and adequate clearance is provided to minimize friction.

5-1.4.2 Equipment such as screw conveyors or drag conveyors shall be arranged to shut down if the discharge opening becomes plugged.

5-2 Electrical Equipment.

All electrical equipment and installations shall comply with the requirements of NFPA 70, *National Electrical Code®*, or NFPA 496, *Standard for Purged and Pressurized Enclosures for Electrical Equipment*, as applicable.

5-3* Static Electricity.

All machines and equipment, including duct work, storage bins, and permanently installed and portable vacuum cleaning systems, shall be bonded and grounded. Where belt drives are used, the belts shall be of electrically conductive material. Ionization methods shall be used to dissipate static electricity in nonconducting equipment. The utilization of flexible intermodel bulk containers shall not be permitted where flammable gases or combustible vapors are present.

5-4 Open Flames and Sparks.

The requirements of 5-4.1 through 5-4.3 shall be applied retroactively.

5-4.1

Cutting and welding shall comply with the applicable requirements of NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

5-4.2

A hot work permit system shall be used for any process resulting in sparks or using open flames in areas where combustible dust is present. Precautions shall be similar to those required in 5-4.1 for cutting and welding operations.

5-4.3

Smoking shall be permitted only in designated areas.

5-5 Heating Systems.

5-5.1 Process Heating Systems.

5-5.1.1 Process heating systems using air, steam, or heat transfer fluids shall be provided with pressure relief valves where necessary. Relief valves on systems employing combustible heat transfer media shall be vented to a safe outside location.

5-5.1.2 Heaters for heat transfer media shall be located in a separate, dust-free room or building, or outdoors.

5-5.1.3 Air for combustion shall be taken from a clean outside source.

5-5.1.4 Heat exchangers shall be located and arranged in a manner that does not allow combustible dust to accumulate on coils, fins, or other heated surfaces.

5-5.1.5 Where a system employs combustible heat transfer media, automatic sprinkler protection shall be provided in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

5-5.2 Comfort Heating.

5-5.2.1 In areas containing combustible dust, comfort heating, if provided, shall be provided by indirect means or a means suitable for the location.

5-5.2.2 If used, hot water or low-pressure steam (15 psig or less) shall be supplied by a boiler installed in accordance with 5-5.1.2.

5-5.2.3 Hot air heaters shall be installed in accordance with 5-5.1.2. Air containing combustible dust shall not be circulated back to the heater, nor shall it be recirculated to nonhazardous areas of the building.

5-5.2.4 Steam and hot water supply pipes and hot air supply ducts in areas containing combustible dust shall be fitted with properly maintained insulation having a continuous nonporous covering and having a thickness sufficient to keep the temperature of the outer surface below 80 percent of the minimum ignition temperature of the dust layer.

5-6 Hot Surfaces.

The temperature of all exposed surfaces (engines, pipes, ducts, process equipment) within an area containing a combustible dust shall be maintained below 80 percent of the minimum ignition temperature of the dust layer.

5-7 Industrial Trucks.

In areas containing a combustible dust hazard, only industrial trucks of a type suitable for the electrical classification of the area shall be used. See NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*, and Articles 500 and 502 of NFPA 70, *National Electrical Code*.

5-8 Powder-Actuated Tools.

5-8.1

Powder-actuated tools shall not be used in areas where combustible dust is present.

5-8.2

When the use of powder actuated tools becomes necessary, all dust-producing machinery in the area shall be shut down; all equipment, floors, and walls shall be cleaned carefully; and all dust accumulations shall be removed.

5-8.3

A thorough check shall be made after the work is completed to be sure that no cartridges or charges are left on the premises where they can enter equipment or be accidentally discharged after operation of the dust-producing or handling machinery is resumed.

Chapter 6* Fire Protection

6-1 Fire Extinguishers.

Portable fire extinguishers shall be provided throughout all buildings according to the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

6-2 Hose, Standpipes, and Hydrants.

6-2.1

Standpipes and hose, where provided, shall comply with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

6-2.2

Electrical-type (or equivalent) spray nozzles shall be provided in areas containing dust in order to limit the potential for generating unnecessary airborne dust during fire-fighting operations.

6-2.3

Private outside protection, including outside hydrants and hoses, where provided, shall comply with NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

6-3* Automatic Sprinklers.

Automatic sprinklers, where provided, shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

6-4 Special Fire Protection Systems.

Automatic extinguishing systems or special hazard extinguishing systems, where provided, shall be designed, installed, and maintained in accordance with the following standards as applicable. The extinguishing systems shall be designed and used to minimize the generation of dust clouds during their discharge.

(a) NFPA 11, *Standard for Low-Expansion Foam*

(b) NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

(c) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*

(d) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

(e) NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*

(f) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

(g) NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*

(h) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*

(i) NFPA 72, *National Fire Alarm Code*

6-5 Alarm Service.

Alarm service, if provided, shall comply with NFPA 72, *National Fire Alarm Code*.

Chapter 7 Training, Inspection, and Maintenance

7-1 Employee Training.

7-1.1

There shall be policies and requirements that provide for initial and continuing training for all employees. These shall include the development of operating procedures that are reviewed at least once per year and after every process change.

7-1.2

All employees shall be instructed at scheduled intervals regarding the potential hazards of their working environment and their behavior and procedures in case of equipment or process failures that can result in fire or explosion.

7-2 Periodic Inspection.

7-2.1

A systematic inspection for safe operations shall be made at regular intervals, and reports shall be submitted to plant management for review.

The inspection shall include:

(a) Fire and explosion protection and prevention equipment;

(b) Dust control equipment;

(c) Housekeeping;

(d) Potential ignition sources;

(e)* Electrical, process, and mechanical equipment, including interlocks; and

(f) Standard operating procedures and work practices.

7-2.2

Competent persons shall conduct inspections and the record of their findings and recommendations shall be recorded permanently in the principal plant office.

7-2.3*

An emergency plan shall be maintained up-to-date and shall be coordinated with existing local community emergency planning.

7-3 Maintenance.

7-3.1

A planned maintenance system shall be established to regularly lubricate, inspect, and test electrical and mechanical equipment in accordance with the manufacturer’s recommendations.

7-3.2

A recordkeeping system of repairs and planned maintenance shall be established.

Chapter 8 Referenced Publications

8-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

8-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 10, *Standard for Portable Fire Extinguishers*, 1990 edition.

NFPA 11, *Standard for Low-Expansion Foam*, 1994 edition.

NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*, 1994 edition.

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*, 1993 edition.

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*, 1992 edition.

NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*, 1990 edition.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, 1994 edition.

NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, 1993 edition.

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, 1990 edition.

NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, 1991 edition.

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*, 1994 edition.

NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*, 1992 edition.

NFPA 31, *Standard for the Installation of Oil-Burning Equipment*, 1992 edition.

NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*, 1994 edition.

NFPA 61A, *Standard for the Prevention of Fire and Dust Explosions in Facilities Manufacturing and Handling Starch*, 1989 edition.

NFPA 61B, *Standard for the Prevention of Fires and Explosions in Grain Elevators and Facilities Handling Bulk Raw Agricultural Commodities*, 1989 edition.

NFPA 61C, *Standard for the Prevention of Fire and Dust Explosions in Feed Mills*, 1989 edition.

NFPA 61D, *Standard for the Prevention of Fire and Dust Explosions in the Milling of Agricultural Commodities for Human Consumption*, 1989 edition.

NFPA 65, *Standard for the Processing and Finishing of Aluminum*, 1993 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-5 Combustible Dust.

Any time a combustible dust is processed or handled, a potential for deflagration exists. The degree of deflagration hazard will vary depending on the type of combustible dust and processing methods used.

A dust deflagration has three requirements, all of which must be met:

(a) The dust must be combustible.

(b) The dust particles must form a cloud in an oxidizing gas at or exceeding the minimum explosive concentration.

(c) A source of ignition must be present.

Evaluation of a combustible dust explosion hazard and the prevention techniques employed are determined by means of actual test data. All combustible dusts that can produce a dust explosion should be tested to determine the following data:

(a) Particle size distribution;

(b) Moisture content as received and dried;

(c) Minimum dust concentration to ignite;

(d) Minimum energy required for ignition (joules);

(e) Maximum rate of pressure rise at various concentrations;

(f) Layer ignition temperature; and

(g) Maximum explosion pressure, at optimum concentration.

Optional testing should include:

(a) Dust cloud ignition temperature.

(b) Maximum permissible oxygen content to prevent ignition.

(c) Electrical resistivity measurement.

A-1-5 Hybrid Mixtures.

The presence of flammable gases and vapors, even at concentrations less than the lower explosive limit (LEL) of the flammable gases and vapors, will add to the violence of a dust-air combustion. The resulting dust/vapor mixture is called a "hybrid mixture" and is discussed in NFPA 68, *Guide for Venting of Deflagrations*.

Hybrid mixtures can be of concern even if the dust is normally considered to be "nonexplosive." For example, polyvinyl chloride is considered to be a "nonexplosive" dust. However, tests have shown that PVC can form explosive hybrid mixtures with methane at concentrations below the lower explosive limit.

A-2-2.2

Window ledges, girders, beams, and other horizontal projections or surfaces can have the tops sharply sloped, or other provisions can be made to minimize the deposit of dust thereon. Overhead steel I-beams or similar structural shapes can be boxed with concrete or other noncombustible material to eliminate surfaces for dust accumulation.

A-2-2.9

The use of load bearing walls should be avoided to prevent structural collapse should an explosion occur.

A-2-3.1

The design of explosion venting should be based on information contained in NFPA 68, *Guide for Venting of Deflagrations*.

A-2-3.2

For further information on restraining vent closures, see NFPA 68, *Guide for Venting of Deflagrations*.

A-3-1

The following items are areas of concern during the design and installation of process equipment.

(a) The elimination of friction by use of detectors for slipping belts, temperature supervision of moving or impacted surfaces, etc.

(b) Pressure resistance or maximum pressure containment capability and pressure relieving capabilities of:

1. The machinery or process equipment,

2. The building or room.

(c) The proper classification of electrical equipment for the area and condition.

(d) Proper alignment and mounting to minimize or eliminate vibration and overheated bearings.

(e) The use of electrically conductive belting, low speed belts, and short center drives as a means of reducing static electricity accumulation. See Section 5-3.

(f) When power is transmitted to apparatus within the processing room by belt or chain, it should be encased in a practically dusttight enclosure, constructed of substantial noncombustible material that should be maintained under positive air pressure. Where power is transmitted by means of shafts, these should pass through close-fitting shaft holes in walls or partitions.

A-3-1.1(b) For explosion relief venting through ducts, consideration should be given to the thrust forces generated and the length of the ducts. The relief duct should be restricted to no more than three meters. Where explosion venting is used, its design should be based on information contained in NFPA 68, *Guide for Venting of Deflagrations*.

A-3-1.1(d) Inerting also can be done by product dilution using a noncombustible dust, such as talc or lime, to reduce the concentration of the combustible dust to below the minimum explosive concentration. This technique is used in coal mines.

A-3-1.2(a) The following diagrams illustrate two different designs of chokes.

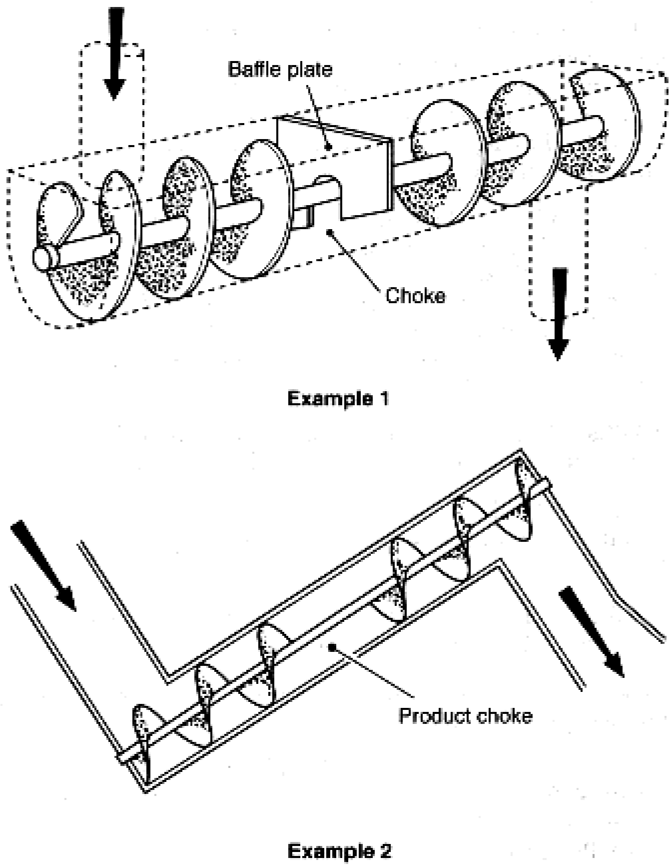

Figure A-3-1.2(a) Screw conveyor chokes.

A-3-1.2(b) When rotary valves are installed in both the inlet and outlet of equipment, care should be taken to ensure that the rotary valve on the inlet is stopped before the unit becomes overfilled. See Figure A-3-1.2(b).

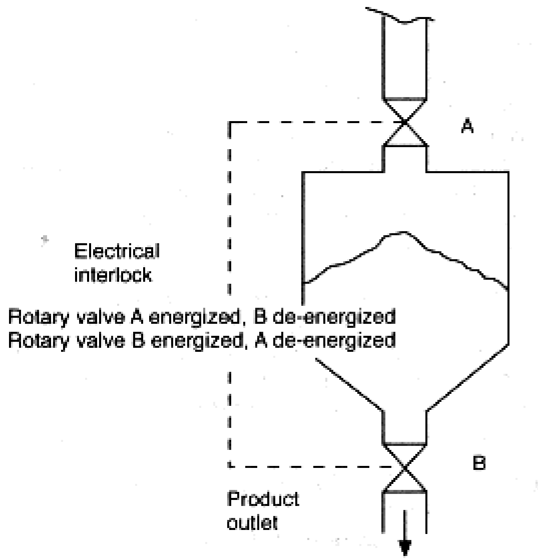

Figure A-3-1.2(b) Rotary valves.

A-3-2.4

Horizontal projections can have the tops sharply sloped to minimize the deposit of dust thereon. Efforts should be made to minimize the amount of surfaces where dust can accumulate.

A-3-3.1.1 Ducts for dust conveying systems should be as straight as possible; right angle bends should be avoided.

A-3-3.1.1 Exception For information on bonding and grounding, see NFPA 77, *Recommended Practice on Static Electricity*.

A-3-3.2.4 Where it is desired to prevent propagation of an explosion from the elevator leg to another part of the facility, an explosion blocking system should be provided at the head, boot, or at both locations.

A-3-3.3.2 Some chemical and plastic dusts release residual flammable vapors such as residual solvents, monomers, or resin additives. These vapors can be released from the material in the conveying system or in its final storage unit. Design of the system should be based on a minimum air flow sufficient to keep the concentration of the particular flammable vapor in the air stream below 25 percent of the lower explosive limit of the vapor.

Start-up and shutdown periods are the times when pneumatic conveying systems pass through the explosive range. Correct sequencing can reduce this:

Start-up: Full air first; then full load dust flow.

Shutdown: Dust stop quickly first; then run full air flow to clean.

A-3-3.4.3 Dusts should not pass through a fan or blower.

A-3-5

Explosion protection should be provided when the hazard is significant. (*See 3-1.1.*)

A-3-6.1

Mixers and blenders should, where possible, operate under slight negative pressure to avoid emitting dust to the immediate atmosphere.

A-3-7.1

Dryers commonly found in industry include tray, drum, rotary, fluidized bed, pneumatic, spray, and vacuum.

A-3-7.2

Heating by indirect means is less hazardous than by direct means and is therefore preferred. Improved protection can be provided for direct-fired dryers by providing an approved automatic spark detection and extinguishing system.

A-4-1.2.1 For information on designing explosion vents, see NFPA 68, *Guide for Venting of Deflagrations*.

A-4-2.1

A relatively small initial dust explosion will disturb and suspend in air dust that has been allowed to accumulate on the flat surfaces of a building or equipment. This dust cloud provides fuel for the secondary explosion, which usually causes the major portion of the damage. Reducing dust accumulations is, therefore, a major factor in reducing the hazard in areas where a dust hazard can exist.

Using a bulk density of 75 lb/ft^3 (1200 kg/m^3) and an assumed concentration of 0.35 oz/ft^3 (350 g/m^3), it has been calculated that a dust layer that averages $^1/_{32}$ in. (0.8 mm) thick covering the floor of a building is sufficient to produce a uniform dust cloud of optimum concentration, 10 ft (3 m) high, throughout the building. This is an idealized situation and several factors should be considered.

First, the layer will rarely be uniform or cover all surfaces and, secondly, the layer of dust will probably not be completely dispersed by the turbulence of the pressure wave from the initial explosion. However, if only 50 percent of the $^1/_{32}$ in. (0.8 mm) thick layer is suspended, this is still sufficient material to create an atmosphere within the explosive range of most dusts.

Consideration should be given to the proportion of building volume that could be filled with an explosive dust concentration. Since floor area is a measure of volume, the percentage of floor area covered can be used as a measure of the hazard. For example, a 10 ft × 10 ft (3 m × 3 m) room with a $^1/_{32}$-in. (0.8-mm) layer of dust on the floor is obviously hazardous and should be cleaned. Now consider this same 100 ft^2 (9.3 m^2) area in a 2,025 ft^2 (188 m^2) building; this also is a moderate hazard. This area represents about 5 percent of a floor area and is about as much coverage as should be allowed in any plant. To gain proper perspective, the overhead beams and ledges should also be considered. Rough calculations show that the available surface area of the bar joist is about 5 percent of the floor area. For steel beams, the equivalent surface area can be as high as 10 percent.

From the above information, the following guidelines have been established:

(a) Dust layers $^1/_{32}$ in. (0.8 mm) thick can be sufficient to warrant immediate cleaning of the area [$^1/_{32}$ in. (0.8 mm) is about the diameter of a paper clip wire or the thickness of the lead in a mechanical pencil].

(b) The dust layer is capable of creating a hazardous condition if it exceeds 5 percent of the building floor area.

(c) Dust accumulation on overhead beams and joists contributes significantly to the secondary dust cloud and is approximately equivalent to 5 percent of the floor area. Other surfaces, such as the tops of ducts and large equipment, can also contribute significantly to the dust cloud potential.

(d) The 5 percent factor should not be used if the floor area exceeds 20,000 ft^2 (1858 m^2). In such cases, a 1,000 ft^2 (93 m^2) layer of dust is the upper limit.

(e) Due consideration should be given to dust that adheres to walls, since this is easily dislodged.

(f) Attention and consideration should also be given to other projections such as light fixtures that can provide surfaces for dust accumulation.

(g) Dust collection equipment should be monitored to be certain it is operating effectively. For example, dust collectors using bags operate most effectively between limited pressure drops of 3 in. to 5 in. of water (0.74 kPa to 1.24 kPa). An excessive decrease or low drop in pressure indicates insufficient coating to trap dust.

The energy required to ignite dust in air is about 10.0 millijoules or 20 to 50 times greater than that required to ignite flammable vapors. Surface voltage of less than 5,000 volts might be considered safe except that such voltages might be indicative of higher voltages elsewhere in the system. Ungrounded metal parts having such high voltages would be hazardous because the energy stored and deliverable would be much greater. The minimum bond and ground wire size recommended is No. 8 or No. 10 AWG.

The above guidelines will serve to establish a cleaning frequency.

A-4-2.2

Vacuum cleaning systems are preferred for this purpose.

A-5-1.1

See Figures A-5-1.1(a) and (b) for examples of tramp metal removal.

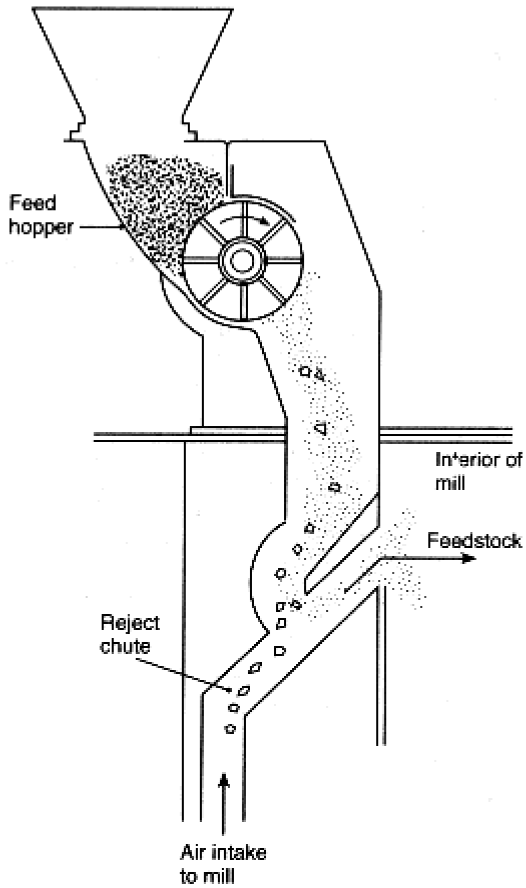

Figure A-5-1.1(a) Pneumatic separator.

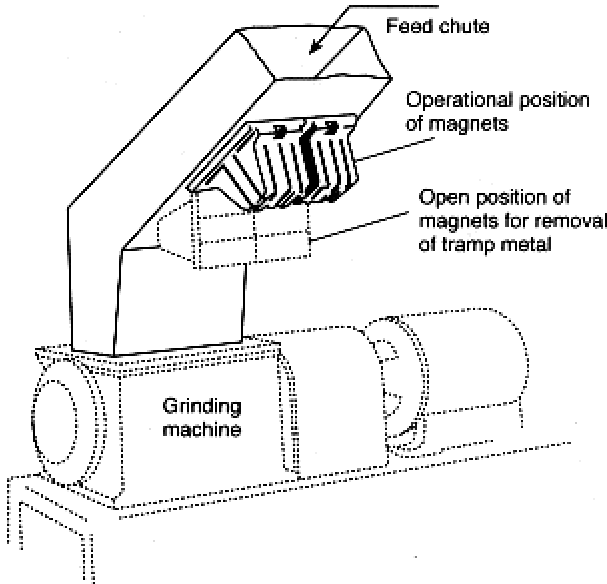

Figure A-5-1.1(b) Magnetic separator.

A-5-1.2

Transmission of power by direct drive should be used, where possible, in preference to belt or chain drivers.

A-5-3

Bonding minimizes the potential difference between metallic objects. Grounding minimizes the potential difference between objects and the ground. See NFPA 77, *Recommended Practice on Static Electricity*, for information on this subject.

A-6

Fire extinguishing equipment should be utilized in such a way to minimize the generation of dust clouds during the discharge.

A-6-3

Automatic sprinkler protection within dust collectors, silos, and bucket elevators should be considered. Considerations should include the combustibility of the equipment, the combustibility of the material, and the amount of material present. Where the combustible dust can react with water, automatic sprinkler systems should not be installed.

A-7-2.1

(e) Safety interlocks should be calibrated and tested every six months in the manner in which they are intended to operate with written test records maintained for review by management.

A-7-2.3

All plant personnel, including management, supervisors, and maintenance and operating personnel, should be trained to participate in plans for controlling plant emergencies. Trained plant fire squads or fire brigades should be maintained.

The elements of an emergency plan should:

(a) Include a signal or alarm systems.

(b) Include identification of means of egress.

(c) Minimize the effect on operating personnel and the community.

(d) Keep property and equipment losses to a minimum.

(e) Ensure interdepartmental and interplant cooperation.

(f) Ensure the cooperation of outside agencies.

(g) Promote the release of accurate information to the public.

Simulated emergency drills should be performed by process operators. Malfunctions of the process should be simulated and emergency actions undertaken. "Disaster" drills that simulate a major catastrophe situation should be undertaken periodically with the cooperation and participation of public fire, police, and other local community emergency units and nearby cooperating plants. The emergency plans should be tested annually.

Formal Interpretation

NFPA 654

Dust Explosion Prevention in Chemical, Dye, Pharmaceutical, and Plastics Industries

1994 Edition

Reference : **2-1.1**
F.I. 82-1

Question 1: Based on NFPA 654, 2-1.1, reference to "areas in which combustible dusts are processed or handled shall be segregated, separated or detached in such a manner as to minimize damage to other portions of the plant . . .," is it the Code's intent that separation be provided between such an area and another portion of the facility which also processes or handles combustible dust?

Answer: No.

Question 2: More specifically, in a deoiling processing operation a slurry of combustible dust in a hydrocarbon oil passes through a vertical process train. Four identical trains are present alongside each other in a building within fifteen to twenty feet of each other. Is it the intent of 2-1.1 that each train be considered "another portion" of the plant or another "dust explosion hazard" and thus require separation from the other trains?

Answer: No.

NFPA 655

1993 Edition

Standard for Prevention of Sulfur Fires and Explosions

1993 Edition

This edition of NFPA 655, *Standard for Prevention of Sulfur Fires and Explosions*, was prepared by the Technical Committee on Fundamentals of Dust Explosion Prevention and Control and acted on by the National Fire Protection Association, Inc. at its Annual Meeting held May 24-27, 1993, in Orlando, FL. It was issued by the Standards Council on July 23, 1993, with an effective date of August 20, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 655

This standard was first presented to the Association as a progress report in 1938 by the Committee on Dust Explosion Hazards. It was tentatively adopted in 1939. After some revision, it was officially adopted in 1940. Amendments were adopted in 1946, 1947, 1959, 1968, and 1971.

In 1976, responsibility for the document was transferred to the Technical Committee on Fundamentals of Dust Explosion Prevention and Control. The Technical Committee completely revised the 1971 edition to effect minor technical amendments and to editorially revise the document to comply with the NFPA *Manual of Style*.

Due to limited technological changes in this subject area between 1982 and 1988, the Committee reconfirmed the text as it had appeared in the 1982 version. Editorial changes and changes to allow the document to adhere more closely to the NFPA Manual of Style were incorporated into the 1988 edition.

For this 1993 edition, the Committee has made minor revisions to Chapter 2 for handling finely divided sulfur in bulk and minor revisions to the fire fighting procedures to be used when fighting fires involving sulfur, as well as editorial revisions to conform to the NFPA *Manual of Style*.

Technical Committee on Fundamentals of Dust Explosion Prevention and Control

Robert W. Nelson, *Chair*
Industrial Risk Insurers, CT
Rep. Industrial Risk Insurers

John M. Cholin, J. M. Cholin Consultants Inc., NJ

C. James Dahn, Safety Consulting Engineers, Inc., IL

David C. Kirby, Union Carbide Corp., WV

James E. Maness, Bunge Corp., AR
Rep. Grain Elevator & Processing Society

Michael E. Mowrer, Professional Loss Control Inc., TN

Gary A. Page, American Cyanamid Co., NJ

James L. Roberts, Fluor Daniel, Inc., SC

Committee Scope: This Technical Committee shall have primary responsibility for documents that are generally applicable to all dusts on the fundamentals of dust explosion prevention. This Committee shall also be responsible for documents on the prevention, control, and extinguishment of fires and explosions in dust collection equipment and in pneumatic conveying equipment.

NFPA 655

Standard for

Prevention of Sulfur Fires and Explosions

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 6 and Appendix B.

Chapter 1 General

1-1 Scope.

1-1.1*

This standard shall apply to the crushing, grinding, or pulverizing of sulfur and to the handling of sulfur.

1-1.2

This standard shall not apply to the mining or transportation of sulfur.

1-2 Purpose.

1-2.1

The purpose of this standard shall be to provide requirements to eliminate or reduce the hazards of explosion and fire inherent in the processing and handling of sulfur.

1-2.2

This standard shall not be intended to prevent the use of systems, methods, or devices that provide equivalent protection from fire and explosion, providing that suitable data is available to demonstrate equivalency.

1-3 Retroactivity.

This standard applies to facilities on which construction is begun subsequent to the date of publication of this standard. When major replacement or renovation of existing facilities is planned, provisions of this standard shall apply.

1-4 Definitions.

For the purpose of this standard, the following terms shall have the meanings given below.

Approved. Acceptable to the “authority having jurisdiction.”

NOTE: The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The “authority having jurisdiction” is the organization, office or individual responsible for “approving” equipment, an installation or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The "authority having jurisdiction" should utilize the system employed by the listing organization to identify a listed product.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Sulfur Dust.* Any finely divided solid sulfur that presents a fire or explosion hazard.

Chapter 2 Handling Finely Divided Sulfur in Bulk

2-1 General.

2-1.1

This chapter shall apply to the production, handling, and processing of finely divided sulfur.

2-1.2

For the purpose of this standard, machinery for crushing and pulverizing sulfur shall be grouped into the following categories:

(a) *Type 1.* Slow-speed primary crushers, such as jaw and roll crushers.

(b) *Type 2.* High-speed primary crushers, such as disk and hammer mills, pulverizers, and fine grinding equipment of all kinds, except Type 4, having a net internal volume of not more than 500 $in.^3$ (8193 cm^3).

(c) *Type 3.* Crushers and pulverizers of the Type 2 category, but having an internal volume of more than 500 $in.^3$ (8193 cm^3).

(d)* *Type 4.* Pulverizers that do not depend on moving parts for their disintegrating action, such as attrition mills.

2-1.3

Operation and maintenance of all crushing and pulverizing machinery shall be under supervision.

2-2 Location, Construction, and Venting of Buildings and Equipment.

2-2.1 Location of Crushing or Pulverizing Machinery and Containers.

2-2.1.1 The enclosed or semienclosed space in which the crushing or pulverizing machinery is located shall be used for no other purpose during the periods when size reduction of sulfur is in progress.

Exception: Containers shall be permitted to be filled with the ground product.

2-2.1.2* Containers shall be removed from the area as soon as possible after being filled. Containers shall not be allowed to accumulate in the area.

2-2.2 Building Construction Requirements for Housing Grinding or Pulverizing Machinery.

2-2.2.1* The enclosed or semienclosed space in which the grinding or pulverizing machinery is located shall be separated from other areas by noncombustible construction. The separating walls shall be designed to withstand the force of an explosion.

2-2.2.2 Openings through floors, walls, and ceilings for necessary pipes, shafts, and conveyors shall be tightly sealed. (*See 2-2.3.1.*)

2-2.3 Protection of Openings.

2-2.3.1 All communications between the space used for grinding and the rest of the building shall be from the outside or via indirect means as described below.

2-2.3.2* Indirect communications through separating walls by means of vestibules or stairways shall be permitted, provided the wall opening to the grinding area is protected by an automatic closing sliding fire door suitable for 3-hr openings, and the opening into the vestibule or stairway is protected by a hinged fire door suitable for 2-hr openings. The two doors shall be installed at right angles to each other. Both doors shall be installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

2-2.4*

Buildings housing operations that present a dust explosion hazard shall be designed with explosion venting.

2-2.5

All ledges and surfaces on which dust can accumulate shall be avoided in construction. Where such surfaces cannot be avoided, they shall be filled in or roofed with noncombustible material at an angle of not less than 45 degrees.

2-2.6

Explosion prevention or protection shall be provided on all equipment. One of the following methods shall be used:

(a) Equipment can be designed to contain the anticipated explosion pressure.

(b)* Appropriately designed explosion venting can be provided.

(c) An explosion suppression system meeting the requirements of NFPA 69, *Standard on Explosion Prevention Systems*, can be provided.

(d) Inert gas can be used to reduce the oxygen content within the equipment to below the level prescribed by NFPA 69, *Standard on Explosion Prevention Systems*.

2-3* Electrical Wiring and Equipment.

All electrical wiring and equipment shall comply with NFPA 70, *National Electrical Code*®. In areas where a dust explosion hazard exists, electrical wiring and equipment shall comply with Article 502 of NFPA 70.

2-4 Inert Gas.

2-4.1

Use of inert gas is not required for Type 1 machinery.

2-4.2

Type 2 machinery shall be permitted to be operated without inert gas protection if the following requirements are met:

(a) The feed and discharge shall be provided with positive chokes, such as a star feed rotary valve or a screw conveyor with the end flights removed, where directly connected to the machine.

(b) The chokes and all machinery between shall be capable of withstanding an overpressure of 100 lb per in.^{2} (690 kPa).

(c) There shall be an inspection of the machinery at least once per shift during operation to detect abnormalities in operating conditions.

2-4.3

Type 3 machinery shall not be operated without the use of an inert gas system meeting the requirements of NFPA 69, *Standard on Explosion Prevention Systems*. Where the pulverized sulfur is removed from the machinery by blower or exhaust systems, inert gas protection shall extend to all piping and collectors.

2-4.3.1 Under normal operating conditions, the reduction in oxygen content shall be to 12 percent for carbon dioxide systems and to 9.3 percent for nitrogen systems.

2-4.3.2* The inert gas system shall be equipped with sampling and recording instruments to obtain a reliable and continuous analysis of the inert atmosphere in that part or parts of the machinery where the inert atmosphere is normally weakest.

2-4.3.3 Provisions shall be made for automatically shutting down the pulverizing machinery if the oxygen content of the inert atmosphere rises above the maximum levels stated in 2-4.3.1.

2-4.4*

Type 4 machinery shall be permitted to be operated without inert gas protection if the following requirements are met:

(a) Manually operated valves shall be installed at each machine for control of feed and air lines.

(b)* The equipment shall be under supervision during operation and shall be shut down for detailed inspection and any necessary cleaning when abnormalities in operation indicate the possibility of fire within the machine.

(c) All valves shall be closed before opening the machine.

2-4.5

Auxiliary dust collectors shall be installed according to the requirements of 2-5.5.

2-5 Conveyors and Collectors.

2-5.1

Only conveyors or spouts with positive seals, such as star feed rotary valves or screw conveyors with the end flights removed, shall be permitted to pass through a fire partition separating crushing or pulverizing rooms from adjacent spaces. The chokes or seals shall be located so as to prevent flame propagation through the wall.

2-5.2

Conveyors used to feed or discharge sulfur to or from grinding machinery shall be in dusttight housings.

2-5.3

Nonferrous buckets or bucket elevators shall be used where they are housed in ferrous casings.

Exception: In cases where the above requirement is not met, steam shall be blown into the elevator boot while the elevator is in operation or an inert gas system meeting the requirements of 2-4.3 shall be used.

2-5.4

Pneumatic conveying systems shall be designed in accordance with NFPA 650, *Standard for Pneumatic Conveying Systems for Handling Combustible Materials*. Each pulverizer shall have a separate and self-contained system.

2-5.5 Dust Collection Systems.

2-5.5.1 Where dust collectors are not protected according to 2-2.6, they shall be isolated in any of the following locations:

(a) On the roof,

(b) Outside and adequately detached from buildings,

(c) In separate rooms provided with explosion venting,

(d) In separate buildings provided with explosion venting,

(e) In isolated penthouses provided with explosion venting.

2-5.5.2 Manifolding of ducts serving dust collection systems shall not be permitted.

Exception No. 1: Dust collection ducts from a single piece of equipment or from multiple pieces of equipment that are not isolated from each other need not be manifolded.
Exception No. 2: Dust collection ducts from single, isolated pieces of equipment shall be permitted to be manifolded if each duct is equipped with a suitable isolation device prior to manifolding. (See NFPA 69, Standard on Explosion Prevention Systems.)

2-5.5.3 Dust collectors shall be constructed of noncombustible materials.

Exception: Filter media need not be of noncombustible material if provided with tight metal enclosures or their equivalent.

2-5.5.4 Recycling of air from dust collectors back to buildings shall not be permitted.

2-6 Prevention of Ignition.

2-6.1*

Approved magnetic separators of the permanent magnet or self-cleaning electromagnetic types or approved pneumatic separators shall be installed ahead of all Types 2, 3, and 4 machines. The installation shall be designed to ensure removal of all ferrous material from the sulfur.

2-6.2

All machinery shall be installed and maintained in such a manner that the possibility of frictional sparks is minimized.

2-6.3

Interlocking controls shall be installed to stop the dust feed if the pulverizer stops or if the fans or blowers stop for any reason.

2-6.4*

All machinery, conveyors, housings, and collectors shall be thoroughly bonded and grounded to prevent the accumulation of static electricity.

2-6.5

All open flames, smoking, and matches shall be prohibited in enclosures containing crushers and pulverizers. Unprotected hot surfaces, such as steam lines, that can attain temperatures high enough to melt and ignite sulfur dust shall not be exposed in enclosures housing sulfur processing equipment.

Exception: Repairs involving open flames, such as cutting or welding, heat, or hand or power tools, shall be made only after all operations have ceased and all sulfur has been removed from the vicinity or protected in tight noncombustible containers. Cutting and welding procedures shall be carried out according to the requirements of NFPA 51B, Standard for Fire Prevention in Use of Cutting and Welding Processes.

2-6.6 Powder-Operated Tools.

2-6.6.1 Powder-operated tools shall not be used where combustible dust or dust clouds are present. When the use of such tools becomes necessary, all dust-producing machinery in the area shall be shut down, all equipment, floors, and walls shall be cleaned thoroughly, and all accumulations of dust removed.

2-6.6.2 After such work has been completed, a check shall be made to ensure that no cartridges or charges have been left on the premises where they could enter equipment or be accidently discharged after operation of the dust-producing or dust-handling machinery is resumed.

2-7 Housekeeping.

2-7.1*

Good housekeeping is of utmost importance. Equipment shall be designed, maintained, and operated in a manner that will minimize the escape of dust. Accumulations of escaped dust shall not be tolerated in the buildings.

2-7.2*

Bulk accumulations of fine sulfur shall be removed by soft push brooms and nonsparking scoops or shovels before vacuum cleaning equipment is used.

2-7.3

Cleaning shall be permitted to be done by vacuum sweeping devices. If vacuum apparatus is used, either stationary or portable types shall be properly grounded and checked for electrical continuity from pickup nozzle to piping system. Such equipment, if electrical, shall be of a class approved for use in atmospheres containing sulfur dust. (*See Section 2-3.*)

2-7.4

Blowing down of any surfaces by compressed air shall be prohibited.

2-8 Fire Fighting.

2-8.1*

Fog nozzles shall be used when fighting fires in finely divided sulfur.

2-8.2*

Steam and inert gases can be used as extinguishing agents for tightly closed containers provided that the sulfur dust is not disturbed.

2-8.3

In all cases, it shall be made certain that the fire is completely extinguished before disturbing the dust and that the sulfur has cooled sufficiently to prevent reignition.

2-8.4*

When grinding or other processing equipment is opened for cleaning following an ignition, the feed, discharge, and other openings shall first be closed by suitable metal valves or gates.

2-8.5*

At least two self-contained breathing apparatus shall be made available for use in case of sulfur fires. All respiratory equipment shall be inspected at regular intervals and kept in working order at all times.

Chapter 3 Handling Coarse Sizes of Sulfur in Bulk

3-1* Handling in the Open or in Semienclosed Spaces.

3-1.1*

Conveying machinery shall be bonded and grounded to prevent the accumulation of static electricity.

3-1.2

Flames, smoking, and matches shall be prohibited in such areas. Cutting and welding operations shall be permitted for repair work, provided due precautions are taken against ignition of dust. (*See NFPA 51, Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes.*)

3-2 Handling in Enclosed Spaces.

3-2.1

Handling of bulk sulfur in enclosed spaces shall be done in such a manner that the formation of dust clouds is minimized.

3-2.2*

All enclosures shall be constructed of noncombustible materials and designed so that ledges on which dust can settle are minimized. Where such surfaces are unavoidable, they shall be roofed at a steep angle.

3-2.3

Where sulfur is transferred or dumped from one container to another, dusttight housings with sufficient inward air movement to prevent escape of dust shall be provided. Where mechanical exhaust systems are used to provide this air movement, the systems shall comply with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

3-2.4* Handling Sulfur in Elevators and Conveyors.

3-2.4.1 All elevators and conveyors that agitate the sulfur being transported, such as screw conveyors and bucket elevators, shall be enclosed in dusttight casings and shall be equipped with explosion venting.

3-2.4.2 Where bucket elevators are housed in ferrous casings, the buckets or bucket conveyors shall be nonferrous.

Exception: In cases where this is impractical, steam shall be blown into the elevator boot while the elevator is in operation or the elevator shall be protected by an inert gas system.

3-2.5*

All metal parts of machinery, casings, bins, and spouts shall be bonded and grounded to prevent the accumulation of static electricity.

3-2.6

All electrical wiring and equipment installed in locations classified as Class II shall comply with Article 502 of NFPA 70, *National Electrical Code.*

3-2.7

All open flames, smoking, and matches shall be prohibited within enclosures where sulfur is handled. Heating shall be by indirect means. Exposed hot surfaces, such as steam lines, shall be avoided within the enclosure.

3-2.8

Care shall be taken to minimize static or settled dust within enclosures and semienclosures. Accumulations of static dust shall be removed promptly and in such a manner as to prevent formation of dust clouds.

3-2.9

Repairs involving the use of flames, heat, or hand or power tools shall be made only after all operations have ceased. Where practical, all sulfur shall be removed or protected in tight containers. Where this is not practical, the sulfur shall be wet down and a hose line with spray nozzle provided.

3-2.10

Powder-operated tools shall not be used unless all dust-producing machinery is shut down, and all equipment, floors, and walls have been carefully cleaned. All bulk sulfur piles or dust accumulations shall be removed or thoroughly wet down. A careful check shall be made to ensure that no cartridges or charges have been left on the premises where they could enter equipment or be accidentally discharged after operation of the dust-producing or dust-handling machinery is resumed.

3-3* Fire Fighting.

3-3.l Fires in enclosures shall be fought according to the provisions of Section 2-8. Since bulk sulfur contains only a small proportion of fines, coarser hose streams shall be permitted to be used.

3-3.2

Incipient fires in storage piles can be smothered by gently shoveling sulfur onto them.

Chapter 4 Handling of Liquid Sulfur at Normal Handling Temperatures

4-1* General.

This chapter applies to the handling of liquid sulfur in the temperature range of 246°F to 309°F (119°C to 154°C).

4-2 Detection of Unsafe Conditions.

4-2.1*

Devices for measuring the concentration of combustible gas in the atmosphere over liquid sulfur shall be designed for operation in atmospheres containing hydrogen sulfide. Instruments used for detecting explosive atmospheres shall be capable of measuring the lower explosive limit of hydrogen sulfide, since it is the primary gas evolved from sulfur that can contribute to an explosive atmosphere.

4-2.2

Operations shall be discontinued whenever instruments show a combustible gas concentration of 35 percent or more of the lower explosive limit in the gas space of liquid sulfur containers. Operations shall not be resumed until the instruments indicate a concentration of 15 percent or less of the lower explosive limit.

4-3 Operating Precautions and Equipment Design.

4-3.1

The use of open flames, electric spark-producing equipment, and smoking materials shall be prohibited in the vicinity of liquid sulfur containers.

4-3.2

Liquid sulfur storage tanks shall be designed with fill lines that extend to near the tank bottom so that the incoming sulfur enters the tank below the surface of the sulfur in the tank, thereby minimizing agitation and release of hydrogen sulfide.

4-3.3

Covered storage tanks shall be provided with heated vent systems to provide natural venting of hydrogen sulfide. Vent systems shall be maintained at a temperature above the melting temperature of sulfur.

4-3.4*

Sulfur lines and storage tanks shall be bonded and grounded to prevent accumulation of static electricity. Grounding connections shall be provided for the bonding of liquid sulfur tanks and tank cars being loaded or unloaded.

4-3.5*

In pits used for melting sulfur and in liquid storage tanks, the liquid level shall not be permitted to expose the heating coils. The liquid level shall always cover the heating coils in pits used for melting sulfur.

4-4 Fire Fighting.

4-4.1*

Covered liquid sulfur tanks shall be provided with a steam extinguishing system or an inert gas system in accordance with NFPA 86, *Standard for Ovens and Furnaces*, and NFPA 69, *Standard on Explosion Prevention Systems*.

Exception: Where liquid sulfur containers can be rapidly sealed to exclude air, the SO_2 *produced will smother the fire. In such cases, steam extinguishing systems or inert gas systems shall not be required. The system shall be allowed to cool below 309°F (154°C) before recpening.*

4-4.2*

Where a fixed inerting system is used, thin corrosion-resistant rupture discs shall be placed over the inerting nozzles so that sulfur cannot condense within the nozzle.

4-4.3

Liquid sulfur stored in open containers shall be permitted to be extinguished with a fine water spray. Use of high-pressure hose streams shall be avoided. Quantity of water used shall be kept to a minimum.

Chapter 5 Handling of Liquid Sulfur and Sulfur Vapor at Temperatures above 309°F (154°C)

5-1 General.

5-1.1

This chapter shall apply to liquid sulfur and its vapors when heated in closed containers to temperatures above 309°F (154°C).

5-1.2

The requirements of Chapter 4 shall apply.

5-2 Operating Precautions and Equipment Design.

5-2.1

Equipment shall be designed to be closed as tightly as possible to prevent escape of vapor and to exclude air from the system during operation.

5-2.2

Process equipment shall be provided with adequate explosion rupture discs. The rupture discs shall relieve into vent pipes or ducts that lead directly to the outside of the building or away from the process equipment. The vent pipes or ducts shall be heated to prevent condensation of sulfur vapor.

5-2.3

An adequate supply of a suitable inerting agent such as steam shall be available at all times for blanketing and purging equipment.

5-2.4

All buildings or enclosures for such processes shall be of noncombustible construction.

5-2.5*

All electrical wiring and equipment installed in areas handling liquid sulfur shall meet the requirements of Article 501 of NFPA 70, *National Electrical Code*.

5-2.6

Where sulfur is vaporized and subsequently condensed to sulfur dust, handling of the finely divided sulfur from the process shall comply with the requirements of Chapter 2.

Chapter 6 Referenced Publications

6-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

6-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*, 1989 edition.

NFPA 69, *Standard on Explosion Prevention Systems*, 1992 edition.

NFPA 70, *National Electrical Code*, 1993 edition.

NFPA 80, *Standard for Fire Doors and Fire Windows*, 1992 edition.

NFPA 86, *Standard for Ovens and Furnaces*, 1990 edition.

NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*, 1992 edition.

NFPA 650, *Standard for Pneumatic Conveying Systems for Handling Combustible Materials*, 1990 editiion.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA standard, but is included for information purposes only.

A-1-1.1

Sulfur differs from most other combustible dusts found in industry in that it has relatively low melting and ignition points. Depending on purity, sulfur melts at or slightly below 246°F (119°C). The ignition temperature of a dust cloud is 374°F (190°C); the ignition temperature of a dust layer is 428°F (220°C). Dilution of sulfur with inert solids is not effective in raising the ignition temperature.

Sulfur is handled and processed in the liquid and vapor states in some cases. The liquid is highly combustible and the vapor is explosive when mixed with air in the proper proportions.

The finely divided sulfur produced during crushing and pulverizing is the most hazardous from an explosion standpoint. Also, mixtures containing finely divided elemental sulfur may be just as hazardous if the sulfur is present in sufficient quantity. Some explosion and fire hazards also accompany the handling and processing of sulfur in bulk in coarse sizes due to the fine dust present.

A-1-4 Sulfur Dust

The Committee is aware of data contained in R. K. Eckhoff's book *Dust Explosions in the Process Industries*, Table A1, pg. 582, which reported positive explosion test results of a sulfur dust cloud with a median particle size of 120 microns as being explosible.

A-2-1.2 (d) The grinding in Type 4 machines is accomplished by attrition of the particles on themselves. Power for moving the particles is furnished by compressed air or other fluid suitable to the material being pulverized.

A-2-2.1.2 It is not the intent of this requirement to prohibit interim storage of bags, drums, or filled containers.

A-2-2.2.1 The grinding space should preferably be detached. Exterior walls may have to be provided with explosion venting. Steel frame construction, with light, nonbearing exterior walls and light roof, is preferable.

A-2-2.3.2 It is recommended that an emergency escapeway for personnel be provided independently.

A-2-2.4

See NFPA 68, *Guide for Venting of Deflagrations.*

A-2-2.6 (b) See NFPA 68, *Guide for Venting of Deflagrations*, for design information on the subject.

A-2-3

Although sulfur is not now included in atmospheres classified as Class II, Group G, it has been the experience of the sulfur industry that such equipment can be suitable. However, consideration should be given to the melting point of sulfur 233°F to 246°F (112°C to 119°C) in the selection of heat-producing electrical equipment.

A-2-4.3.2 Auxiliary instrumentation should be provided for sampling and recording the quality of the inert atmosphere in other parts of the system.

A-2-4.4

The large volumes and high velocities of air and the compactness of the Type 4 unit make inerting usually impractical.

A-2-4.4 (b) Flooding with inert gas or steam, combined with delayed opening to permit smothering of any residual fire, is recommended.

A-2-6.1

It must be recognized that magnetic separators will not remove nonferrous tramp material, including stones, brick, and concrete. Every care, using other means, should be taken to ensure excluding such materials from the grinding system.

A-2-6.4

See NFPA 77, *Recommended Practice on Static Electricity*, for information on the subject.

A-2-7.1

It is recommended that the interior of crushing, pulverizing, and packaging rooms or buildings be painted a color that contrasts with the color of the dust.

A-2-7.2

Push brooms should have natural bristles.

A-2-8.1

Straight streams from hoses or extinguishers should not be used, as a cloud of dust can be raised that will explode on contact with the fire.

A-2-8.2

If a container is closed tightly and the volume of oxygen enclosed is not too large, a fire will be smothered by the sulfur dioxide formed.

A-2-8.4

A period of at least 15 minutes should elapse between closing the valves or gates and opening the equipment to smother any residual fire in the equipment. As an added precaution, the equipment should be flooded with inert gas or steam, if available, prior to opening.

A-2-8.5

Gas masks approved for acid gases will not provide adequate protection in a serious sulfur fire. Self-contained breathing apparatus of the pressure demand type should be used.

A-3-1

Clouds of fine sulfur dust arising during the handling of bulk sulfur in the open or in semienclosed spaces are potentially dangerous. Arrangements should be such that they will not contact sources of ignition.

A-3-1.1

See NFPA 77, *Recommended Practice on Static Electricity*, for information on the subject.

A-3-2.2

Direct ventilation of enclosed spaces is recommended.

A-3-2.4

See NFPA 68, *Guide for Venting of Deflagrations*, for information on the subject.

A-3-2.5

See NFPA 77, *Recommended Practice on Static Electricity*, for information on the subject.

A-3-3

Automatic sprinkler protection is recommended for enclosures in which sulfur is stored or handled.

A-4-1

The normal handling temperature of liquid sulfur is 250°F to 309°F (121°C to 154°C), which is slightly above the melting point of 246°F (119°C). At this temperature, the vapor concentration above pure sulfur, free of hydrocarbons or hydrogen sulfide, is too low to form an explosive mixture in air. While the flash point of liquid sulfur varies with purity, it is always higher than the normal handling temperature. For pure sulfur, the flash point is about 370°F (188°C); for relatively impure crude sulfur, the flash point may be as low as 334°F (168°C).

The relatively low ignition temperature of sulfur and the possible presence of hydrogen sulfide are the primary fire and explosion hazards of liquid sulfur. Impure sulfur contains hydrocarbons, which react slowly with liquid sulfur to form hydrogen sulfide. Recovered sulfurs, such as those produced from hydrogen, often contain dissolved hydrogen sulfide. Hydrogen sulfide is quite soluble in liquid sulfur and will be liberated very slowly from a quiescent body of liquid sulfur. However, agitation of the sulfur can cause rapid evolution of hydrogen sulfide, which may create an explosive atmosphere within a storage tank. (In the temperature range at which liquid sulfur is normally handled, the lower explosive limit for hydrogen sulfide in air is about 3.4 percent, compared to 4.3 percent at room temperature.)

Pure sulfur will not generate an explosive atmosphere in the normal temperature range of the liquid.

A-4-2.1

The sensing elements of some explosimeters are not designed for and are adversely affected by hydrogen sulfide-containing atmospheres.

A-4-3.4

See NFPA 77, *Recommended Practice on Static Electricity*, for information on the subject.

A-4-3.5

Pyrophoric iron sulfide compounds may form from impurities in the sulfur. When heating coils are exposed to air, ignition may occur.

A-4-4.1

The inert gas must be applied rapidly enough to displace the ventilation air from the vents. Steam may be generated through the application of water through fog nozzles. Open vents should be available to prevent the buildup of steam pressure.

A-4-4.2

Sulfur flour may cause a dust explosion if it is ejected from the nozzles ahead of the inerting agent.

A-5-2.5

Due to the potential for release of dissolved hydrogen sulfide, molten sulfur handling systems require a Class I, Group C, classification for confined areas.

Appendix B Referenced Publications

B-1

The following documents or portions thereof are referenced within this standard for informational purposes only and thus should not be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

B-1.1 NFPA Publications.

NFPA 664

1993 Edition

Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities

1993 Edition

This edition of NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*, was prepared by the Technical Committee on Wood, Paper and Cellulosic Dusts and acted on by the National Fire Protection Association, Inc. at its

Annual Meeting held May 24-27, 1993, in Orlando, FL. It was issued by the Standards Council on July 23, 1993, with an effective date of August 20, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 664

NFPA activity in the field of wood dust explosion hazards dates from 1930, when work on a *Code on Wood Flour Manufacturing* (No. 662) was initiated. The first edition was adopted in 1931, and subsequent editions were issued in 1940, 1942, 1946, and 1949. A separate *Code on Woodworking Plants* (No. 663) was added in 1934, and reissued in 1952 and 1959. In 1960 these two codes were combined in a new *Code for the Prevention of Dust Explosions in Woodworking and Wood Flour Manufacturing Plants* (No. 664), and revised editions were adopted in 1962 and 1971. The 1981 edition of the standard consisted of a complete rewrite. The 1987 edition clarified the intent of numerous existing requirements. A new chapter which covered thermal oil heating systems was added as a result of increased use of these systems in industry. The format of the 1987 revision was to conform with the NFPA *Manual of Style*.

For this 1993 edition, the Committee has provided information on the characteristics of wood dust covered by the standard, clarified the dust collection requirements including the provisions for recycling exhaust air, and incorporated minor editorial revisions to comply with the NFPA *Manual of Style*.

Committee Scope: Responsible for documents for the prevention, control, and extinguishment of fires and explosions resulting from dusts produced from the handling, processing, or storage of wood and paper and other cellulosic materials.

NFPA 664
Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 12 and Appendix B.

Chapter 1 General

1-1 Scope.

1-1.1*

This standard contains the minimum requirements for the proper construction and protection of facilities that handle, store, or process wood, or wood products that produce or utilize finely divided wood particles or wood fibers.

1-1.2*

This standard shall apply to production or industrial-scale woodworking operations.

Exception: It does not apply to small-scale woodworking operations that are incidental to the principal occupancy.

1-2 Purpose.

1-2.1

The purpose of this standard is to provide a reasonable degree of protection for life and property against fire and explosion in facilities where finely divided wood dust is produced or handled.

1-2.2 Equivalency.

Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard, provided technical documentation is submitted to the authority having jurisdiction to demonstrate equivalency and the system, method, or device is approved for the intended purpose.

1-3* Retroactivity.

This standard shall apply to new facilities and to those portions of existing facilities being rebuilt or remodeled.

1-4 Definitions.

Approved.* Acceptable to the “authority having jurisdiction.”

Authority Having Jurisdiction.* The “authority having jurisdiction” is the organization, office or individual responsible for “approving” equipment, an installation or a procedure.

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed.* Equipment or materials included in a list published by an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Standard. A document containing only mandatory provisions using the word “shall” to indicate requirements. Explanatory material may be included only in the form of “fine print” notes, in footnotes, or in an appendix.

Chapter 2 Building Construction

2-1 General Requirements.

2-1.1*

The construction features of this chapter shall apply in addition to those required by state or local building codes.

2-1.2*

Precautions shall be taken to prevent the spread of fire from one section of the plant to another. These precautions shall include separation of adjacent buildings by open space or adjoining buildings by fire walls or fire partitions, as well as elimination of all unnecessary openings through floors.

2-2 Wall Construction.

2-2.1

Where walls are erected as fire walls between adjoining buildings, they shall be designed for a minimum fire endurance of four hours.

2-2.2

Interior walls erected as fire partitions between adjoining areas shall be designed for a minimum fire endurance of one hour.

2-2.3*

Interior walls erected to isolate dust explosion hazards shall be designed for sufficient explosion resistance to preclude damage to these walls before the explosion pressure can be safely vented to the outside.

2-3 Protection of Wall Openings.

2-3.1

Openings in fire partitions shall be protected by approved automatic closing fire doors having a fire endurance rating equivalent to the fire endurance rating of the fire partition. Fire doors shall be installed according to NFPA 80, *Standard for Fire Doors and Fire Windows*.

2-3.2

Openings in four-hour rated fire walls shall be protected by three-hour rated automatic closing fire doors installed on both sides of the wall.

2-3.3

All pipe openings through fire walls and fire partitions shall be tight. All duct openings through fire partitions shall be protected by approved fire dampers. No ducts shall penetrate fire walls.

2-3.4*

Openings in walls designed to be explosion resistant shall be protected by doors that provide the same degree of explosion protection as the walls. Such doors shall be kept closed at all times when not actually being used. Such doors shall not be considered as part of a means of egress to satisfy the requirements of NFPA *101*®, *Life Safety Code*®.

2-4 Stairways, Elevators, and Fire Escapes.

Exits, interior stairs, and elevators shall comply with *NFPA 101*, *Life Safety Code*.

2-5 Surfaces and Ledges in Dusty Areas.

2-5.1

Interior surfaces and ledges shall be designed to minimize dust accumulation.

2-5.2*

Surfaces not readily accessible for cleaning shall be inclined at an angle of not less than 45 degrees from the horizontal to minimize dust accumulation.

Chapter 3 Explosion Venting

3-1* General Requirements.

3-1.1*

Explosion venting, as used in this standard, is intended to encompass the design and installation of devices and systems to vent the gases and overpressure resulting from a deflagration so as to minimize structural or mechanical damage to the equipment, room, building, or other enclosure in which the explosion occurs.

3-1.2*

If a dust explosion hazard exists in equipment, rooms, buildings, or other enclosures, such areas shall be provided with explosion venting. An acceptable alternative to explosion venting is an approved explosion suppression system installed in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

Chapter 4 Housekeeping

4-1 Removal of Static Dust.

4-1.1

Provisions shall be made for systematic, thorough cleaning of the entire plant at sufficient intervals to prevent the accumulations of finely divided wood dust that might be dislodged and lead to an explosion.

4-1.2

Spills shall be cleaned up without delay.

4-1.3*

Powered cleaning apparatus, such as sweepers or vacuum cleaning equipment, used in dusty areas shall be approved for Class II, Division 1, Group G locations as defined in Article 502 of NFPA 70, *National Electrical Code®*.

4-1.4*

The use of compressed air or other similar means to remove dust accumulations from areas not readily accessible for cleaning by other methods shall be permitted only if done frequently enough to prevent hazardous concentrations of dust in suspension. Any open flame or spark-producing equipment shall not be used during blowdown.

4-2 Metal Scrap.

Provisions shall be made for separately collecting and disposing of any metal scrap, such as nails, band iron, or any wood containing metal, so that it will not enter the wood handling or processing equipment, the dust collecting system, or the scrap wood hog.

4-3* Hydraulic Fluids.

Combustible hydraulic fluid leaks, especially in press areas, shall be controlled by regular maintenance. Spilled fluid shall be cleaned up promptly.

4-4 Oil and Resin.

Buildup of residue from condensation of oil and resin volatiles shall be removed from board curing ovens at regular intervals.

4-5 Flammable Liquids.

Flammable liquids shall be handled and stored according to the requirements of NFPA 30, *Flammable and Combustible Liquids Code*.

Chapter 5 Electrical Equipment

5-1 Electrical Wiring and Equipment.

5-1.1

All electrical wiring and equipment shall comply with the requirements of NFPA 70, *National Electrical Code*.

5-1.2*

In local areas of the plant where a hazardous quantity of dust accumulates or is present in suspension in the air, all electrical equipment and installations in those local areas shall comply with Article 502 or Article 503 of NFPA 70, *National Electrical Code*, as applicable.

Chapter 6 Control of Ignition Sources

6-1 Cutting and Welding.

Cutting and welding shall comply with applicable requirements of NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

6-2 Static Electricity and Lightning Protection.

6-2.1*

Static electricity shall be prevented from accumulating on machines or equipment subject to static electricity buildup by permanent grounding and bonding wires and from moving belts by grounded metal combs or other effective means.

6-2.2

Lightning protection, where required, shall be installed in accordance with NFPA 780, *Lightning Protection Code*.

6-3 Smoking.

Smoking shall only be allowed in safe designated areas.

6-4 Propellant-Actuated Tools.

6-4.1

Propellant-actuated tools shall not be used in areas where combustible dust or dust clouds are present.

6-4.2

When the use of propellant-actuated tools becomes necessary, all dust-producing machinery in the area shall be shut down; all equipment, floors, and walls shall be carefully cleaned; and all dust accumulations removed.

6-4.3

A careful check shall be made after the work is completed to ensure that no cartridges or charges are left on the premises where they could enter equipment or be accidentally discharged after operation of the dust-producing or handling machinery is resumed.

Chapter 7 Fire Protection

7-1 Fire Extinguishers and Hose.

7-1.1

Portable fire extinguishers shall be provided throughout all buildings in accordance with the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

7-1.2*

Standpipes and hose, where provided, shall conform to NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

7-1.3

Private outside protection, including outside hydrants and hoses, where provided, shall comply with NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

7-2* Automatic Sprinklers.

Automatic sprinklers, where provided, shall comply with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

7-3 Special Fire Protection Systems.

Automatic extinguishing systems or special hazard extinguishing systems, where provided, shall be designed, installed, and maintained in accordance with the following standards, as applicable:

(a) NFPA 11, *Standard for Low Expansion Foam and Combined Agent Systems*

(b) NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

(c) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*

(d) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

(e) NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*

(f) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

(g) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*

(h) NFPA 69, *Standard on Explosion Prevention Systems*

Chapter 8 Woodworking Dust-Control Systems

8-1 Scope.

This chapter shall apply to pneumatic systems utilized to collect and convey finely divided wood particles, fibers, or shavings in the course of woodworking operations.

8-2 Conveying and Collecting Equipment.

8-2.1*

Dust collection systems shall comply with the requirements of NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

8-2.2*

Dust collectors shall be located outside of buildings.

Exception No. 1: Dust collectors shall be permitted to be located inside of buildings if they are located adjacent to an exterior wall, are vented to the outside through straight ducts not exceeding 10 ft (3 m) in length, and have explosion vents.*

Exception No. 2: Dust collectors shall be permitted to be located inside of buildings if protected by an explosion suppression system meeting the requirements of NFPA 69, Standard on Explosion Prevention Systems.

8-2.3

All cutting, shaping, planing, sanding, or other machines that produce finely divided wood dust or shavings shall be provided with a dust pickup, conveying, and collecting system.

8-2.4 Hoods and Enclosures.

8-2.4.1 Hoods or enclosures shall be so designed, located, and placed that the finely divided wood dust or shavings generated will fall, be projected, or be drawn into the hood or enclosures in the direction of the airflow and to provide the greatest possible enclosure in the zone of wood particle generation without interfering with the safe and satisfactory operation of the machine.

8-2.4.2 All hoods and enclosures shall be of noncombustible construction. If the hood or enclosure also must act as a safety guard, the construction, strength, and material specifications must be such that the machine is adequately protected.

8-2.4.3 The rate of airflow into every hood and enclosure shall be sufficient to control the wood dust or shavings and cause them to be carried into the duct system.

8-2.5 Duct System.

8-2.5.1 Every branch duct and every section of main duct shall be sized for not less than the minimum air velocity and volume required to transport the wood dust or shavings through the ducting and into the collection equipment.

8-2.5.2 The capacity of the system shall be calculated on the basis of all hoods and other openings connected to the system being open.

8-2.5.3 Dampers, gates, or orifice plates provided for the specific purpose of balancing the airflow in the system shall be fastened to prevent inadvertent manipulation.

8-2.5.4 In addition to the intakes at the individual machines, connections to the system shall be permitted at floor level in convenient locations to provide for the removal of such fine material that accumulates around the machines and be swept up.

8-2.6 Collecting Equipment.

The system shall be provided with collecting equipment of sufficient size and capacity to separate the wood dust from the air before the air is vented. The collecting equipment shall be of noncombustible construction except for filter bags, if provided.

8-2.7 Fans or Blowers.

The system shall be connected to a fan or blower that will maintain the required rate of airflow in all parts of the system and is of a type and size suitable for handling the conveyed material. Where conditions permit, the fan shall be located beyond the air cleaning equipment to handle only cleaned air.

8-2.8 Exhausting Dissimilar Matter.

Woodworking exhaust systems shall be restricted to handling wood residues and under no circumstances shall another operation generating sparks, such as from grinding wheels, be connected to a woodworking exhaust system.

8-3 Hazardous Systems.

8-3.1*

The additional requirements of this section shall apply to systems that handle finely divided wood dust with an explosion potential.

8-3.2

All hoods and enclosures shall be constructed of welded steel. Riveted construction shall not be acceptable.

8-3.3*

Ducts shall be constructed of welded steel or other noncombustible material of equivalent strength. Ducts shall be properly supported and shall be protected against corrosion.

8-3.4*

Interior ducts shall be sufficiently strong to withstand maximum explosion pressures unless protected by a listed explosion suppression system (*see Chapter 3*). Exterior ducts shall be provided with explosion venting.

8-3.5*

Cyclone collectors, if used, shall be designed and constructed entirely of noncombustible material of adequate strength and rigidity to meet conditions of both service and installation requirements. Cyclone collectors or bag filters shall be protected by explosion vents.

Exception: A listed explosion suppression system designed in accordance with NFPA 69, Standard on Explosion Prevention Systems, is an acceptable alternative to explosion venting.

8-3.6*

Wood dust collectors that discharge into storage bins or silos shall do so in a manner that will minimize the generation of dust clouds. The discharge arrangement shall be constructed to minimize dust leaks and shall contain a choke to prevent explosion propagation between the collecting equipment and the storage facilities. Bins or silos shall be provided with explosion relief where practical (*see Chapter 3*).

8-3.7*

Sander systems shall be protected by explosion venting or a listed explosion suppression system (*see Chapter 3*).

8-4 Recycling Exhaust Air.

Filtered air shall not be recycled back into the building unless one of the following arrangements 8-4.1 or 8-4.2) is provided:

8-4.1

The system shall be equipped with a listed spark detection and suppression system. The recycled air duct shall be fitted with an abort damper that would be activated by the spark detector by passing the air to atmosphere, away from the plant. The abort damper shall be provided with a manual reset, so that, after it has aborted, it can only be returned to the closed position at the damper. Automatic or remote reset shall not be allowed.

8-4.2

The system shall be equipped with a listed spark detection and suppression system. The recycled air duct shall be provided with either an automatic fast-acting valve system or flame front diverter installed in accordance with NFPA 69, *Standard on Explosion Prevention Systems.*

8-5 Wood Scrap Disposal.

8-5.1

If the scrap wood is to be processed by hogs delivering small chips and shredded product for use as fuel or for other purposes, the discharge from such processing shall be handled as required in Sections 8-2 and 8-3.

8-5.2

If the scrap wood is to be processed by mills delivering a pulverized product, the requirements of Chapter 9 shall be complied with.

8-5.3

If the finely divided wood dust is to be used as a fuel, the applicable sections of NFPA 8503, *Standard for Pulverized Fuel Systems*, shall be adhered to.

8-5.4

Where wood waste is disposed of in an incinerator, it shall be in accordance with the requirements of NFPA 82, *Standard on Incinerators, Waste, and Linen Handling Systems and Equipment*.

Chapter 9 Thermal Oil Heating Systems

9-1* Scope.

This chapter shall apply to facilities that use heat transfer fluids to provide process equipment heat via piped, indirect heating systems.

9-2 General Provisions.

The applicable portions of NFPA 30, *Flammable and Combustible Liquids Code*, shall apply to thermal oil systems and plant areas having thermal oil piping or utilization equipment.

9-3* Thermal Oil Heaters.

9-3.1 Location and Construction.

9-3.1.1 Thermal oil heater rooms or buildings shall be protected by automatic sprinklers designed to control a hot oil-spill fire.

9-3.1.2 Thermal oil heaters shall be located and arranged to minimize the hazard from a potential oil spill.

9-3.1.3 The preferred location shall be outdoors or in a separate, detached building.

9-3.1.4 Where a detached location is not practical, the heater shall be located next to an outside wall and cut off from adjacent plant areas by a fire partition having at least a two-hour fire resistance. Also, the room shall be designed to contain the largest possible oil spill using curbs, dikes, sumps, floor drains, or other suitable means.

9-3.2 Oil Leak Detection.

9-3.2.1* A means shall be provided to automatically detect a tube leak inside the oil heat exchanger and minimize damage from an ensuing oil fire.

9-3.2.2* A means shall be provided to automatically detect major oil leaks in the utilization piping and equipment, and stop the flow of oil to the equipment.

9-3.3 Fuel Burner Controls and Interlocks.

9-3.3.1 Oil- or gas-fired burners shall be designed and installed in accordance with the applicable requirements of NFPA 8501, *Standard for Single Burner Boiler Operation*.

9-3.3.2 Wood dust suspension burners shall be designed and installed in accordance with the applicable requirements of NFPA 8503, *Standard for Pulverized Fuel Systems*.

9-3.3.3* Heaters that burn wood waste in a fluidized bed or on a grate shall provide a means to prevent the accumulation of explosive concentrations of combustibles in the heater, or any stack gas utilization equipment, following a shutdown with unburned fuel in the heater.

9-3.3.4 System heaters shall be under automatic control.

9-3.3.5 The heater shall automatically shut off on low liquid level, high liquid temperature, and low circulation rate.

9-3.3.6 Where oil heater stack gas is used to heat other utilization equipment, proper purging of the heater and utilization equipment shall be accomplished by the use of isolation gates, dampers, or suitable burner control logic. The control logic shall anticipate all operating modes of the oil heater and utilization equipment, either singly or together, to ensure safe start-up, shutdown, and upset conditions.

9-4 Thermal Oil Piping — Location and Construction.

9-4.1

Piping shall be routed outside or underground where practical.

9-4.2*

Where piping must be routed indoors, spill containment features, such as curbs, dikes, floor slope, drains, etc., shall be incorporated where practical.

9-4.3

Piping that is insulated shall use closed-cell, nonabsorptive insulation. Fibrous or open-cell insulation shall not be permitted.

9-4.4*

Piping shall be securely supported and otherwise protected against mechanical damage with adequate clearance from combustible material.

9-5 Thermal Oil Utilization Equipment.

9-5.1*

Where fire extinguishing systems are provided for utilization equipment, the system shall be designed to protect the equipment from a hot oil-spill fire or from the material being processed, whichever poses the more severe fire hazard.

Chapter 10 Wood Pulverizing Operations

10-1 Scope.

This chapter shall apply to those facilities involved in the manufacturing of wood flour or the pulverizing of wood to a size smaller than 100 mesh.

10-2 Location and Construction.

10-2.1*

Pulverizing operations shall be separated from all other buildings to prevent fire or explosion propagation.

10-2.2

The pulverizing process area shall be considered a dust explosion hazard with respect to construction and the need for explosion venting (*see Chapters 2 and 3*).

10-3 Protection of Openings.

When material presenting a dust explosion hazard is delivered to or from the pulverizing operation, chokes, rotary valves, explosion suppression systems, or other approved means shall be provided to prevent flame propagation through the conveying system.

10-4 Material Handling and Process Equipment.

10-4.1*

All equipment shall be installed so that constant true alignment is maintained and so that hot bearings and friction are avoided.

10-4.2*

Ball or roller bearings shall be used wherever practical. All bearings shall be dusttight.

10-4.3

Magnetic separators of the permanent magnet or self-cleaning electromagnet-type or pneumatic separators shall be installed ahead of mills and pulverizers.

10-5 Dust Control.

All dust-producing equipment shall be dusttight or the equipment and dust-producing operations shall be provided with dusttight hoods or enclosures that comply with the requirements of Section 8-3.

Chapter 11 Composite Board Plants

11-1 Scope.

This chapter covers the storage, preparation, and forming of wood particles or fibers into board form, including dry process hardboard, particleboard, medium density fiberboard, and oriented-strand board.

11-2 Location and Construction.

The following facilities shall be located outdoors or in separate buildings detached from the rest of the plant. These facilities shall be considered dust explosion hazards with respect to the need for explosion venting (*see 2-2.2 and Chapter 3*).

(a) Raw Material Storage

Exception: Storage that does not contain hazardous quantities of combustible dust or where the moisture content of the material stored is greater than 20 percent.

(b) Size Reduction Facilities

Exception: Where moisture content of the material being pulverized is greater than 20 percent, or where effective dust control measures prevent generation and accumulation of static or airborne dust in hazardous quantities.

(c) Particle Drying Facilities.

Exception: Where effective dust control measures prevent generation and accumulation of static or airborne dust in hazardous quantities.

11-3 Process Equipment.

11-3.1

Size reduction and particle-handling equipment shall meet the requirements of Sections 10-3 and 10-4, and 10-5.1.

11-3.2

Where conveying equipment passes between buildings or rooms that are designed to be isolated from each other, a conveyor choke or other approved means shall be provided to prevent explosion propagation.

11-3.3*

Dryers and board humidifiers shall be arranged and protected in accordance with the applicable requirements of NFPA 86, *Standard for Ovens and Furnaces*. The following requirements shall also apply to dryers:

11-3.3.1 Conveying equipment shall have facilities to divert burning material from the equipment downstream from the dryer to a safe dump area in the event of a fire in the dryer.

11-3.3.2* Thermal fire detectors shall be provided downstream from the dryers, normally in the ductwork at the dryer exit. The detection system shall be arranged to accommodate normal temperature surges associated with firing up of the unloaded dryer. Detectors shall activate the fire suppression systems, if provided, sound an alarm, shut off the fuel supply, divert burning material, and shut down preparatory process equipment.

11-3.3.3 Dryer systems having a dust explosion potential shall be protected by explosion venting or an approved explosion suppression system, unless the equipment can withstand the maximum expected explosion pressures (*see Chapter 3*). Dryer exhaust systems shall be designed in accordance with *Chapter 8*.

11-3.3.4* Diesel-powered front-end loaders used to handle or reclaim raw material inside storage buildings shall comply with the requirements for DS classification as described in NFPA 505, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Maintenance, and Operation*.

Exception: If the storage building complies with 11-2(a), a nonclassified front-end loader shall be permitted to be used.

Chapter 12 Referenced Publications

12-1

The following documents or portions thereof are referenced within this document and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

12-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. 9101, Quincy, MA 02269-9101.

NFPA 8503, *Standard for Pulverized Fuel Systems*, 1992 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

A-1-1.1

Such facilities include, but are not limited to, wood flour plants, woodworking plants, lumber mills, composite board plants, and large pattern shops in foundries.

A-1-1.2

Incidental operations are those typically limited to 6 to 8 people. Small-scale operations would not have more than 1 or 2 small dust collectors.

A-1-3

It is recommended that, wherever feasible, existing installations be modified to comply with the requirements of this standard.

A-1-4 Approved.

The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

A-1-4 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The “authority having jurisdiction” should utilize the system employed by the listing organization to identify a listed product.

A-2-1.1

All buildings should be of Type I or Type II construction, as defined in NFPA 220, *Standard on Types of Building Construction*.

A-2-1.2

All conveyor, chute, and pipe openings through floors should be tight or should be protected by approved automatic closing fire doors or fire dampers having a fire endurance rating equal to the floor being penetrated.

Buildings using open space separation techniques should refer to NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*.

A-2-2.3

See NFPA 68, *Guide for Venting of Deflagrations*, for guidance on the strength of relieving and resisting walls.

A-2-3.4

Such doors should be marked “Not An Exit.” The unique requirements of doors in explosion-resistant walls preclude their use as a means of egress because NFPA *101*, *Life Safety Code*, requires exit doors from high hazard areas to swing in the direction of exit travel.

A-2-5.2

As much as a 60-degree angle of inclination might be necessary for maximum effectiveness with many types of wood dust.

A-3-1

In general, dust particles need to be below 420 μm (microns) (U.S. sieve No. 40) to create a dust explosion hazard. The degree of explosion hazard will vary depending on the type of combustible dust and processing methods used. A dust explosion has three requirements, all of which must be met:

(a) The dust must be combustible

(b) The dust particles must form a cloud at or exceeding the minimum explosion concentration

(c) A source of ignition must be present.

A-3-1.1

Refer to NFPA 68, *Guide for Venting of Deflagrations*, for sizing of explosion vents.

A-3-1.2

See "Explosion Venting as a Means of Controlling Dust Explosions," Frank, T.E., and "Explosion Venting of Industrial Air Systems," Pauli, L.E., Proceedings of the 12th Annual Particleboard Symposium, Washington State University, Pullman, WA, 1978.

A-4-1.3

Unapproved vacuum cleaning equipment can be used if the powered suction source is located in a remote, nondusty area.

A-4-1.4

It is recommended that cleaning by this method be done when the portion of the plant being cleaned is not operating. Electrical equipment suitable for Class II locations need not be de-energized during blowdown.

A-4-3

Consideration should be given to the use of fire-resistant hydraulic fluids to reduce the fire hazards of hydraulic systems in plant process equipment.

A-5-1.2

Refer to NFPA 497B, *Recommended Practice for the Classification of Class II Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*.

A-6-2.1

Grounding and bonding information can be found in NFPA 77, *Recommended Practice on Static Electricity*.

A-7-1.2

Inside $1^1/_2$-in. (3.8-cm) hose stations are recommended throughout all major woodworking facilities. Directional water spray nozzles or combination straight stream/water spray nozzles are recommended since careless use of straight hose streams can cause dust explosions by throwing hazardous quantities of dust into suspension.

A-7-2

Automatic sprinkler protection is recommended throughout all major woodworking facilities.

Press pits, press hoods, and hood ventilating fans should be protected by automatic sprinkler systems, deluge systems, or both. It is important that sprinkler and deluge heads be located so that hard-to-reach places, such as spaces between press cylinders, are properly protected.

A-8-2.1

Each system should consist of branch ducts connected to hoods or enclosures, one or more main ducts, airflow-producing equipment, a discharge duct to the out-of-doors, and a means for separating the entrained wood particles from the air flowing in the system.

A-8-2.2

Although the exceptions allow dust collectors indoors under certain conditions, the preferred location is outdoors.

A-8-2.2 Exception No. 1.

See NFPA 68, *Guide for Venting of Deflagrations*, for designing explosion venting.

A-8-3.1

Air conveying systems, such as from a hog or hammermill, can fall within the scope of this section depending on the moisture content and particle size of the dust generated.

A-8-3.3

Ducts with circular cross section are preferable to square or rectangular ducts. Welded steel of 12-gauge minimum thickness is normally strong enough to prevent failure during an explosion. This is especially true for small ducts. However, for large rectangular ducts, 12 gauge might not be adequate.

A-8-3.4

An approved spark detection and extinguishing system should be considered to quench burning material before it can be conveyed into the collecting equipment.

Also, when bag filters are used with the conveying air-flow fan located ahead of the bag filters, a high-speed abort gate activated by infrared spark detectors should be used to divert burning material before it can enter the bag filter. (*See Appendix B, Frank, T. E., "Fire and Explosion Control in Bag Filter Dust Collection Systems," NFPA Fire Journal, Vol. 75, No. 2, March 1981, p. 73.*)

It is advisable for outdoor ducts to be provided with explosion venting to help minimize the overall pressure buildup resulting from a deflagration. For information on explosion venting, see NFPA 68, *Guide for Venting of Deflagrations*.

A-8-3.5

Collecting equipment should be protected by automatic sprinklers or an approved water spray system (*see Chapter 7*). Where bag filters are used, consideration should be given to their use as primary collectors, eliminating the cyclone. Collectors and filters should be located outside the building, on independent supporting structures, and should be accessible for fire fighting. It is not advisable to locate collectors and filters on the roofs of buildings. Welded steel of 12-gauge minimum thickness is normally of sufficient strength to prevent structural failure during an explosion, if adequate explosion venting or suppression is provided.

A-8-3.6

Storage bins and silos should be protected by automatic sprinklers or an approved water spray system (*see Chapter 7*). Storage bins and silos should be located outside the building on independent supporting structures and should be accessible for fire fighting. It is not advisable to locate bins or silos on the roofs of buildings.

A-8-3.7

An infrared spark detection system should be considered to shut down the sander, stop material infeed, initiate a water spray deluge in the collecting system, and activate a fire dump in the collecting system outfeed. The exhaust system main fan should be left running to purge the system of dust and to help keep dust from dropping into suspension from dust filters.

A-9-1

Thermal oil heating systems have been used to heat lumber dry kilns, plywood veneer dryers, plywood and composite board presses, composite board furnish dryers, and also for building heat.

A-9-3

A thermal oil heating system typically consists of a central heat exchanger to heat the thermal fluid. Firing can be by conventional gas or oil burners, wood dust suspension burners, or special wood waste combustors, such as fluidized bed burners or “wet cell” burners, which partially burn and gasify wood waste on a grate using sub-stoichiometric under-fire airflow, and complete the combustion in an upper plenum using secondary air injection. The hot gases then pass through a heat exchanger to indirectly heat the thermal fluid. The heat exchanger may be a separate, stand-alone unit, or an integral part of the heater. Conventional water-tube boilers have even been used as heaters, with thermal fluid replacing the water.

The thermal fluids used are typically special oils developed for this type of application, with flash points of several hundred degrees Fahrenheit. For maximum thermal efficiency, they are usually heated above their flash points, making an oil spill especially hazardous. Also, because of the high oil temperatures, it is usually necessary to keep the oil circulating through the heat exchanger at all times to prevent oil breakdown and tube fouling. Diesel-driven pumps or emergency generators are usually provided for this purpose in case of a power outage. Oil circulation can even be needed for a period of time after burner shutdown due to the latent heat in the heater.

A-9-3.2.1 A tube rupture during heater operation would likely result in an instantaneous fire. A small leak could result in a localized oil spray fire, which could cause tube fouling from oil breakdown or tube rupture from overheating. A major leak would result in extensive damage and downtime since it is not practical to shut off the oil pumps (*see A-9-3*).

Loss of oil in the system can be detected by monitoring the oil level in the expansion tank. This in itself would not indicate a leak inside the heater. Additional flue gas instrumentation such as high temperature, combustibles, or opacity can be used to indicate a leak within the heater. These signals could then be combined to activate automatic emergency interlocks [*see Figure A-9-5.1(a)*].

Inert gas extinguishing systems (carbon dioxide, nitrogen, or steam) can be used to control fires in heaters. The feasibility of this method depends on the size and configuration of the heater. With this method, it is necessary to maintain an extinguishing concentration of inert gas inside the heater for a period of time long enough to allow hot refractory and other heater components to cool, or else re-ignition can occur.

A novel approach to minimizing fire damage is to rapidly drain all the oil from the heater. An oil drain tank is generally provided with the heater for maintenance, and it can be used, with suitable modifications, for emergency drain purposes.

Refer to Figures A-9-5.1(a) and A-9-5.1(b) for simple logic and schematic diagrams of typical protection schemes.

A-9-3.2.2 Hot oil from tube leaks outside the heater can create hazardous spills. Small leaks are of less concern and would likely be detected by personnel before a large spill occurred. A low-level alarm in the heater expansion tank should be used to detect gradual loss of oil in the system. Large spills or pipe breaks are of greater concern. Most systems utilize low-oil-pressure interlocks to start emergency oil circulation pumps. Momentary low oil pressure would be expected from a major pipe rupture. This signal, coupled with a low expansion tank level, can be used to distinguish a major pipe rupture from some other nonhazardous low-pressure condition.

To stop the flow of oil to the utilization equipment, an alternate path must be available to keep oil flowing through the heater. If no other utilization loops are provided, an emergency loop should be provided for this purpose. It may be necessary to have a dummy cooling load so as not to overheat the oil.

Refer to Figures A-9-5.1(a) and A-9-5.1(b) for simple logic and schematic diagrams of typical protection schemes.

A-9-3.3.3 Fluidized bed burners and burners that combust wood waste on a grate contain a quantity of unburned fuel during normal operation. They cannot be instantly shut off like a conventional gas, oil, or pulverized fuel suspension burner. During any emergency stop or other shutdown that does not fully combust the bed of fuel, combustibles (mostly carbon monoxide with small amounts of hydrogen) will be generated due to the latent heat in the fire box and lack of enough air for complete combustion.

Heaters that exhaust directly into a stack can usually prevent the accumulation of explosive concentrations of combustibles by natural draft means. Some facilities recover additional heat from the thermal oil heater stack gas by ducting the burner exhaust into other utilization equipment. Natural draft is unreliable in these instances, and other means, such as automatic-opening emergency vents on the burner exhaust duct, isolation dampers, or inert gas padding systems, should be used to prevent buildup of explosive concentrations of combustibles.

A-9-4.2

Concentric piping can materially lessen the spill potential as long as the annular space is monitored to detect leakage.

A-9-4.4

Proper clearance from combustibles should be determined based on the operating surface temperature of the insulated pipe. Piping should be kept free of combustible dust accumulations.

A-9-5.1

The fire hazard in process equipment such as veneer dryers, lumber dry kilns, composite panels press pits, etc., will likely be more severe than normal from a hot oil-spill fire. When this is the case, automatic sprinkler or deluge protection should be provided for the process equipment, with the system designed for the more severe hazard.

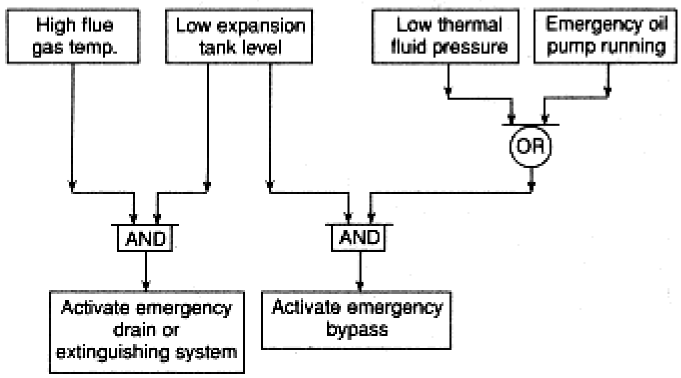

Figure A-9-5.1(a) Typical oil leak detection logic.

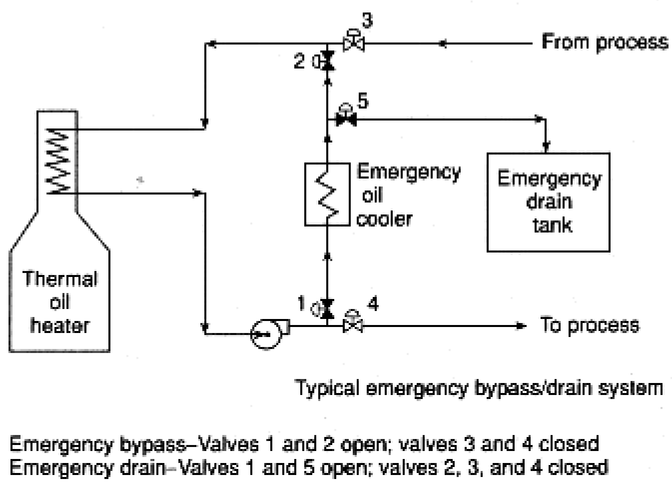

Figure A-9-5.1(b) Thermal oil heating system major leak detection/protection.

A-10-2.1

Separation can be accomplished by a physical distance of 50 ft (15 m) or by properly designed pressure-resistant barriers with directional venting.

A-10-4.1

Equipment should be installed and arranged in unit systems so that each pulverizer will deliver to a single set of scalpers and bolters. Interconnections between sets of equipment should not be permitted unless the material passing from one unit to another is conveyed through conveyors containing positive chokes.

A-10-4.2

Bearings in dusty or inaccessible locations where overheating of bearings can result in fires or explosions should be provided with approved journal alarms.

A-11-3.3

The preferable fire protection system for a hardboard humidifier, board bake oven, or tempering oven is an automatic water spray system with manual override.

A-11-3.3.2 An infrared spark detection system located downstream from the dryer should be considered, in addition to the thermal fire detection system.

A-11-3.3.4 To further reduce the hazard, fixed automatic dry chemical extinguishing systems should be provided on these vehicles.

Formal Interpretation

NFPA 664

Wood Processing and Woodworking Facilities

1993 Edition

Reference : 8-4, 8-4.1, and 8-4.2
F.I. 87-1

Question 1: Would the intent of 8-4 be met with the installation of single spark detectors which control both the suppression system and the abort dampers?

Answer: Yes.

Question 2: Is it the intent of 8-4.1 to require an approved spark detection and suppression system be installed on the inlet side of the recirculating type dust collector?

Answer: Yes.

Question 3: Is it the intent of 8-4.2 to require a separate spark detector on the recycled air duct to activate the abort damper?

Answer: No.

NFPA 701

1996 Edition

Standard Methods of Fire Tests for Flame-Resistant Textiles and Films

1996 Edition

This edition of NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, was prepared by the Technical Committee on Fire Tests and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

This edition of NFPA 701 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 701

Requirements for flameproofing of textiles were adopted by the NFPA on recommendation of the Committee on Fireproofing and Preservative Treatments in 1938. These requirements were amended in 1939, 1940, 1941, and 1951. This standard is now under the jurisdiction of the NFPA Technical Committee on Fire Tests; the 1966 edition, which was an extensive revision of the previous edition, was prepared by that committee, as were the 1968, 1969, 1975, 1976, and 1977 editions.

The 1989 edition was a complete rewrite with significant changes to the small-scale test.

The 1996 edition represents a significant departure from earlier editions, as it provides a new test for single-layer and multilayer fabric assemblies but maintains the large-scale test for multilayer assemblies involving coated fabric blackout linings. This new test was developed to address the problem presented by multilayer assemblies that could not be addressed by the current test procedures. The new Test 1 has been proven through experience to be an adequate predictor of the behavior of single-layer and multilayer assemblies.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire testing procedures when such standards are not available; for reviewing existing fire test standards and recommending appropriate action to NFPA; for recommending the application of and advising on the interpretation of acceptable test standards for fire problems of concern to NFPA technical committees and members; and for acting in a liaison capacity between NFPA and the committees of other organizations writing fire test standards. This committee does not cover fire tests that are used to evaluate extinguishing agents, devices, or systems.

NFPA 701

Standard Methods of Fire Tests for

Flame-Resistant Textiles and Films

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 15 and Appendix E.

Chapter 1 Introduction

1-1 Purpose of Test 1 and Test 2.

1-1.1

It is the purpose of these test methods to assess the propagation of flame beyond the area exposed to the ignition source.

1-1.2

These test methods do not indicate whether the material tested resists the propagation of flame under more severe exposure conditions or where used in a manner that differs substantially from the test conditions.

1-1.3

Test 1 differentiates fabrics that do not spread flame extensively from those that do burn rapidly and extensively.

1-1.4

Test 1 provides a procedure for assessing the response of fabrics both individually and in multilayer composites used as curtains, draperies, or other window treatments when exposed to a moderate flame while suspended in a vertical configuration.

1-1.5

Test 2 provides a comparison among materials using a moderate size ignition flame.

1-1.6

Flame-resistant requirements shall not be dependent on the type of treatment; however, where durability to cleaning or weathering is claimed, the fabric or material shall be tested for flame resistance as produced and after being subjected to the applicable cleaning or exposure procedures. (*See Chapter 13.*)

1-1.7

Where materials are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, the test shall be conducted and the material classified in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

1-2 Scopes.

1-2.1 Test Method 1.

1-2.1.1 This test method shall apply to fabrics (except for vinyl-coated fabric blackout linings) or other materials used in curtains, draperies, or other window treatments.

1-2.1.2 This test method shall apply to single-layer fabrics and multilayer curtain and drapery assemblies (except for vinyl-coated fabric blackout linings) in which the layers are fastened together by sewing or other means for holding portions of the assembly in intimate contact.

1-2.1.3 For the purposes of this test method, where the terms curtains, draperies, or other window treatments are used, they also shall include, but shall not be limited to, the following items:

(a) Window curtains;

(b) Stage or theater curtains;

(c) Vertical folding shades;

(d) Roll-type window shades;

(e) Hospital privacy curtains;

(f) Window draperies;

(g) Fabric vertical shades or blinds;

(h) Horizontal folding shades;

(i) Swags;

(j) Fabric horizontal shades or blinds.

1-2.1.4 This test method also shall apply to the following textile items:

(a) Table skirts;

(b) Table linens;

(c) Display booth separators;

(d) Textile wall hangings.

1-2.1.5 This test method shall not apply to fabrics or composites greater than 700 g/m^2 (21 oz/yd^2).

1-2.2 Test Method 2.

1-2.2.1 This test method shall be used for testing coated fabric blackout linings and lined draperies using a coated fabric blackout lining.

1-2.2.2 This test method shall be used for testing plastic films, with or without reinforcement or backing, where used for decorative or other purposes inside a building or as temporary or permanent enclosures for buildings under construction.

1-2.2.3 This test method shall apply to fabrics used in the assembly of awnings, tents, tarps, and similar architectural fabric structures and banners.

1-2.2.4 This test method (flat specimen configuration) shall be used for fabrics and films, with or without reinforcing or backing, that weigh in excess of 700 g/m^2 (21 oz/yd^2).

Chapter 2 Test 1

2-1 General.

2-1.1

The specimens shall be suspended from a pin bar.

2-1.2

A weighed specimen consisting of one or more layers of fabric shall be suspended vertically from a pin bar near the top rear of an open-face test cabinet. A specified gas flame shall be applied to the center of the lower edge of the specimen for 45 seconds and then withdrawn. The specimen shall be allowed to burn until the flame self-extinguishes and there is no further specimen damage. The specimen then shall be removed from the pin bar and weighed again. The percent weight loss shall be determined and used as a measure of total flamespread and specimen damage.

2-2 Conditioning Oven.

A forced draft oven, capable of maintaining a temperature of 105°C ± 3°C (220°F ± 5°F), shall be used to condition the test specimens prior to testing.

2-3 Hood.

A standard laboratory hood [minimum 820 mm (32 in.) wide by 750 mm (30 in.) high by 630 mm (25 in.) deep] or other suitable enclosure shall be used and shall provide a draft-free environment around an open-face test chamber. The hood or other enclosure shall be equipped with an exhaust fan for exhausting the smoke as provided in 5-3.2.

2-4 Test Chamber, Specimen-Mounting Pin Bar, and Gas Burner.

2-4.1

An open-face test chamber is shown in Figure 2-4.1(a). The test chamber shall be constructed in accordance with Figure 2-4.1(a) using 12-mm (0.5-in.) thick marinite mineral board. All interior surfaces of the cabinet shall be painted with a flat black paint that withstands the heating that occurs in the cabinet. Figure 2-4.1(b) shows a sketch of the cabinet with the burner and specimen in place.

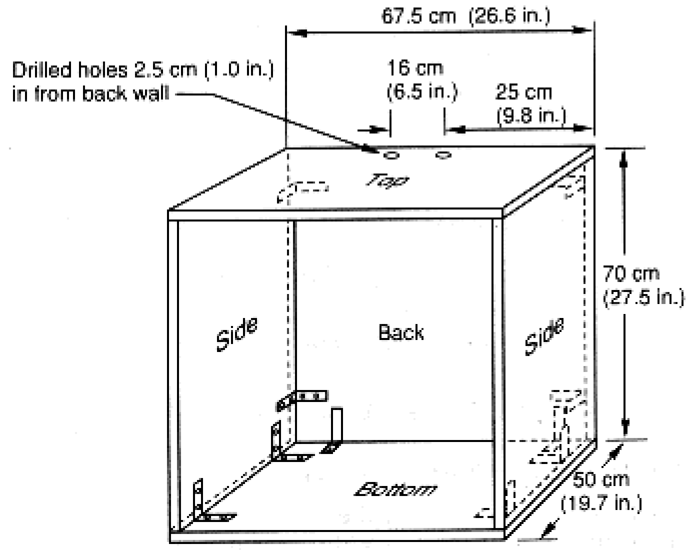

Figure 2-4.1(a) Test cabinet for Test 1.

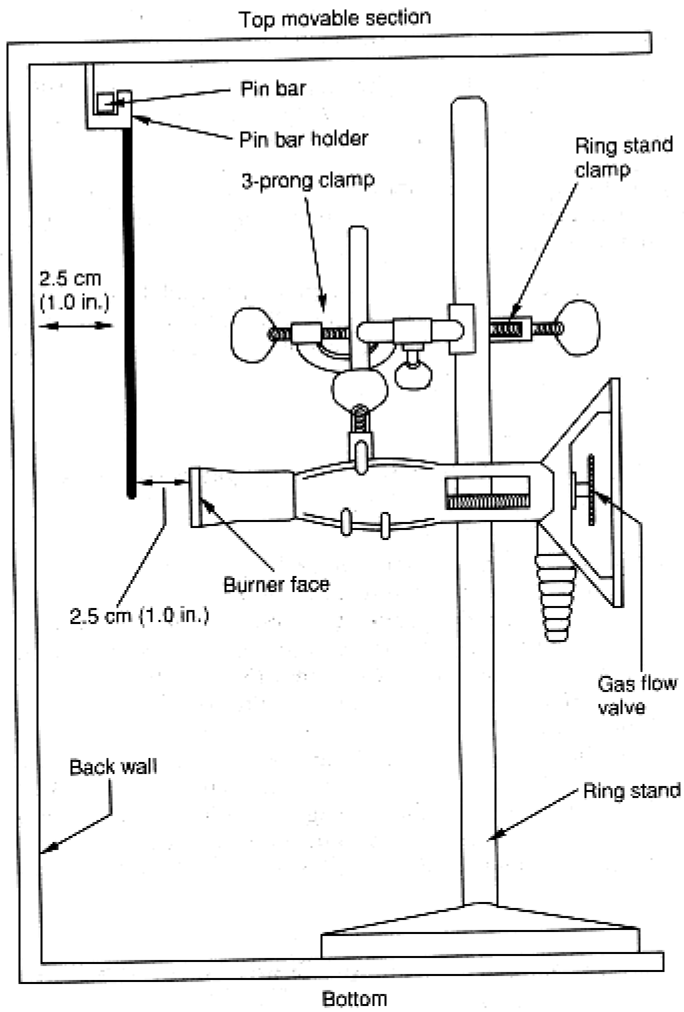

Figure 2-4.1(b) Schematic of burner and specimen placement for Test 1.

2-4.2*

The pin bar for mounting the specimen shall be a 9-mm^2 (0.36-in.^{2}) stainless steel bar, 190 mm (7.5 in.) in length, with steel pins 0.7 mm (0.027 in.) in diameter and 11 mm (0.43 in.) long, mounted at distances of 37 mm, 66 mm, 95 mm, 124 mm, and 153 mm (1.45 in., 2.60 in., 3.75 in., 4.90 in., and 6.05 in.) from each end of the bar. (*See Appendix A for information on a suitable alternate test cabinet*.)

2-4.3*

A Meeker (Fisher) burner shall be used as the ignition source.

2-5 Gas and Control System.

2-5.1*

Methane gas that is at least 97 percent pure shall be used for the burner fuel. The gas shall be contained in a cylinder equipped with a pressure-reducing valve and gauges to allow maintenance of a pressure of 17.5 kPa ± 2.0 kPa (2.5 psi ± 0.25 psi) (132 mm Hg ± 13 mm Hg) at the flow gauge.

2-5.2*

A gas flow gauge with a flow control valve shall be used to measure and control the gas flow rate.

2-5.3

The gas tank, flow gauge, control valves, and burner shall be connected as shown in Figure 2-5.3. Hose or tubing with at least a 5-mm (0.2-in.) bore shall be used. The control valve at the tank shall not be used to control the flow through the flow gauge. The flow valve at the tank shall be fully open during the test.

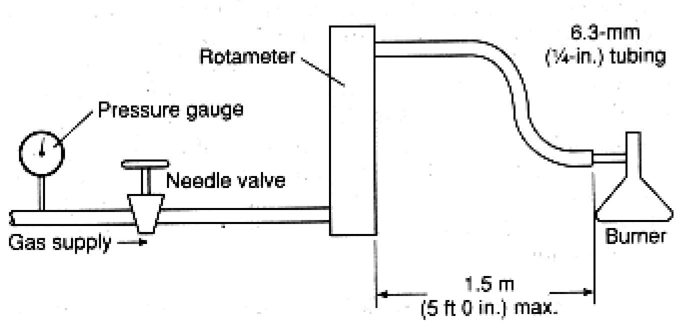

Figure 2-5.3 Gas line feed arrangement to burner.

2-6 Mounting Jig.

A mounting jig, as described in Appendix B, shall be used for mounting specimens to the pin bar in a uniform and safe manner.

2-7 Timer.

A stopwatch or other timing device shall be used to measure time to the nearest 0.2 second.

2-8 Balance.

A balance having a capacity of at least 100 g (3.53 oz) and a resolution of 0.1 g (3.5×10^{-3} oz) shall be used to weigh the specimen.

2-9 Ruler.

A ruler, marked in 1-mm ($^{1}/_{32}$-in.) increments, shall be used to measure the burner flame height and specimen dimensions.

2-10* Wire Brush.

A brush manufactured from bronze wire shall be used for removing ash and char debris from the test specimen at the conclusion of each test and before the post-test weighing.

Chapter 3 Calibration and Standardization for Test 1

3-1 General.

At the start of each series of tests, the air vents at the base of the burner shall be fully open and the gas flow set for a flow gauge scale reading of 70 ± 2 using the flow control valve on the gauge. This corresponds to an airflow of 895 ml/min ± 25 ml/min (5.26×10^{-10} ft^3/sec ± 1.47×10^{-15} ft^3/sec) and a methane flow of 1205 ml/min ± 35 ml/min (7.1×10^{-4} ft^3/sec ± 2.0×10^{-5} ft^3/sec). At the same time, the pressure gauge shall read 17.5 kPa ± 2.0 kPa (2.5 psi ± 0.25 psi) (132 mm Hg ± 13 mm Hg). This shall provide a flame height of 100 mm ± 10 mm (4.0 in. ± 0.4 in.) with the burner in a vertical position. The flow control valve on the burner shall be fully open.

Chapter 4 Specimens and Conditioning for Test 1

4-1 Test Specimens.

4-1.1

Ten individual test specimens shall be cut from a single piece of the material to be evaluated to a size of 150 mm ± 5 mm × 400 mm ± 5 mm (5.90 in. ± 0.20 in. × 15.75 in. ± 0.20 in.), with the length parallel to the lengthwise direction of the material. These 10 specimens constitute a sample. Specimens shall not be taken nearer the selvage than $^{1}/_{10}$ of the full width of the fabric.

4-1.2

For multilayer assemblies, the layers shall be sewn together as shown in Figure 4-1.2 using a plain stitch with 2.5 stitches/cm ± 0.25 stitch/cm (6.4 stitches/in. ±0.6 stitch/in.). A No. 40 polyester/cotton sewing thread shall be used. The layers of the multilayer assembly shall be sewn along all four edges at a distance of 5 mm ± 1 mm (0.2 in. ± 0.04 in.) from the edge. A fifth seam shall be sewn along the center of the assembly in the lengthwise direction. This center seam shall extend the full length of the specimen.

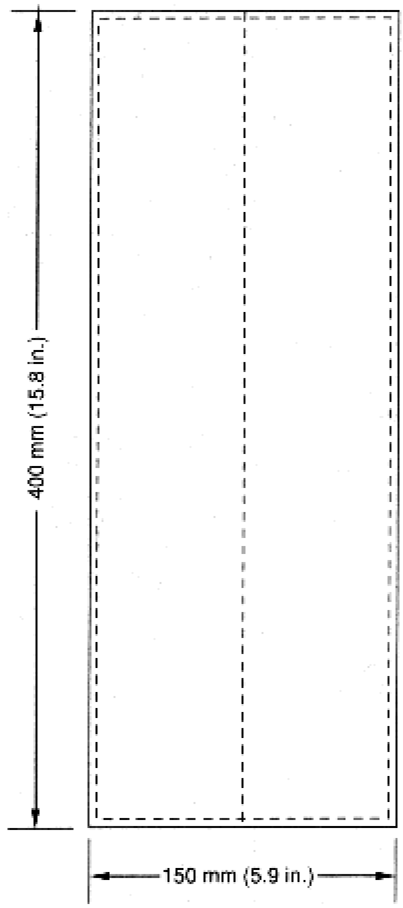

Figure 4-1.2 Multilayer specimen for Test 1.

4-1.3

Each specimen shall be numbered and weighed to the nearest 0.1 g (3.5 × 10^{-3} oz) before conditioning. The weight of each specimen shall be recorded.

4-2 Conditioning.

The specimens shall be placed in a forced draft oven to allow free circulation of air around the specimens. The specimens shall be dried for at least 30 minutes at 105°C ± 3°C (220°F ± 5°F).

Chapter 5 Test Procedure for Test 1

5-1 Mounting of Test Specimens.

5-1.1

After conditioning, the specimen shall be attached to the pin bar with the top of the specimen centered on the bar. The pins shall be 5 mm ± 1 mm (0.20 in. ± 0.04 in.) from the top edge of the specimen. The mounting jig described in Appendix B shall be used. The specimen shall be placed on the pin bar so that the face or the layer intended to face the wall or window during normal use faces the pin bar.

5-1.2

The pin bar shall be mounted on the support hanger located at the back of the ceiling of the test chamber. The face, which in normal use is intended to face the wall or window, shall face the back of the test chamber. When the pin bar and hanger are placed, the side of the specimen facing the back wall of the test chamber shall be 25 mm ± 2 mm (1.0 in. ± 0.08 in.) from the wall surface.

5-2 Burner Placement and Preparation.

5-2.1

The burner shall be placed so that it is 25 mm ± 2 mm (1.0 in. ± 0.08 in.) from the face of the specimen and with the center axis of the burner horizontal and in line with the bottom of the center seam in the specimen. Position adjustments shall be permitted to be made by moving the support base and by adjusting the height and angle of the burner.

5-2.2

The exhaust fan shall be turned on.

5-3 Conducting the Test.

5-3.1

The test shall be initiated within 2 minutes after removing the specimen from the forced draft oven. The gas shall be turned full on at the burner control valve. The gas shall be flowed for 20 sec ± 1 sec. The gas then shall be ignited. The flame shall burn for 45 sec ± 1 sec. After the 45-second exposure, the burner shall be turned on its mount so that its center axis is parallel to the plane of the specimen, and then the gas shall be turned off using the control valve on the burner. The gas flow rate shall be controlled only by the valve on the flow gauge. The valve on the burner shall be turned off completely and then turned on completely for the duration of the test exposure, and then it shall be closed completely at the end of the 45-second exposure time.

5-3.2

The exhaust fan shall remain on throughout the test procedure. The front of the hood shall be closed after the burner is turned off and pulled away from the specimen to remove the smoke produced by the burning specimen.

5-3.3

The afterflame time of the specimen (time of burning of the specimen after the gas flow is turned off) and the time of burning of material that falls to the bottom of the chamber shall be measured and recorded. Observations such as, but not limited to, the type, amount, color, density, and odor of smoke produced, the vigorousness of burning, and the dripping of molten material also shall be recorded.

5-3.4

The pin bar and specimen shall be removed from the hanger.

5-3.5

The wire brush shall be used to remove ash and char from the specimen.

5-3.6

The specimen shall be removed from the pin bar.

5-3.7

The portion of the specimen removed from the pin bar shall be weighed to the nearest 0.1 g (3.5×10^{-3}) and the weight shall be recorded. Any material that has fallen away from the specimen shall not be weighed.

Chapter 6 Calculation of Results for Test 1

6-1 Calculation of Percent Weight Loss.

6-1.1

The percent weight loss of each specimen shall be determined from the following equation:

$$\frac{\text{Weight before test} - \text{Weight after test}}{(\text{Weight before test})} \times 100 = \text{Percent weight loss}$$

The percent weight loss shall be recorded.

6-1.2

The mean percent weight loss and the standard deviation for the sample consisting of 10 specimens shall be calculated.

6-1.3

Where the percent weight loss of any individual specimen exceeds the mean value plus three standard deviations, the test shall be repeated on another sample of 10 specimens. The mean percent weight loss and standard deviation for the second set of 10 specimens shall be calculated.

Chapter 7 Flame Resistance Performance Criteria for Test 1

7-1 Performance Criteria.

7-1.1

Where fragments or residues of specimens that fall to the floor of the test chamber continue to burn for more than an average of 2 seconds per specimen for the sample of 10 specimens, the material shall be recorded as failing Test 1.

7-1.2

Where the average weight loss of the 10 specimens in a sample is greater than 40 percent, the material shall be recorded as failing this test.

7-1.3

Where the percent weight loss of any individual specimen in the second set of specimens exceeds the mean value of the second set plus three standard deviations calculated for the second set, the material shall be recorded as failing this test.

7-1.4

Where the specimens do not demonstrate performance in accordance with any of the conditions indicated in 7-1.1 through 7-1.3, the material shall be recorded as passing this test and shall be designated as flame resistant.

Chapter 8 General Requirements for Test 2

8-1 General.

8-1.1

This test method provides a comparison among materials using a moderate size igniting flame.

8-1.2

This large-scale test exposes a 1.2-m (47.25-in.) long specimen to a 280-mm ± 12 mm (11.0-in. ± 0.5 in.) igniting flame inside a three-sided test cabinet that is 305 mm^2 (12 $in.^2$) and 2.13 m (84 in.) high.

Chapter 9 Test Apparatus and Materials for Test 2

9-1 Conditioning Oven.

9-1.1

A forced draft oven shall be used to condition test specimens prior to testing.

9-1.1.1 The interior of the oven shall provide free airflow around each specimen it contains.

9-1.1.2 An oven having variable temperature control capable of maintaining its interior at a temperature of 105°C ± 3°C (220°F ± 5°F) shall be used.

9-2 Test Enclosure.

9-2.1

The test shall be conducted in a three-sided metal stack with an area of 305 mm^2 (12 $in.^2$) and a height of 2.13 m (84.0 in.) [*see Figure 9-2.1(a)*], with details as follows:

(a) The stack shall be supported 305 mm (12 in.) above the floor by legs and shall be open at the top and bottom.

(b) The stack shall have one open side to allow for free access of non-oxygen-depleted air to the exposed specimen during the test.

(c) The stack shall have a means for hanging the specimen as follows:

Top Specimen Rod. A steel rod 1.5 mm or 3.0 mm (0.06 in. or 0.12 in.) in diameter and 330 mm (13 in.) long, sharpened to a point at one end. The stack shall have holes of 4 mm on both sides aligned horizontally and located 1.19 m (46.8 in.) above the bottom edge of the cabinet for the location of the top specimen rod.

Bottom Specimen Rod. A steel rod 1.5 mm (0.06 in.) in diameter, 255 mm (10.0 in.) long, sharpened to a point at one end.

Vertical Guide Wires. Soft steel wire shall be used to make a pair of vertical guide wires on each side of the stack spaced 100 mm (4 in.) to the right and left of the vertical center of the stack [each pair separated by 200 mm (8 in.)]. The wires of each pair shall be 25 mm (1 in.) apart (front to back, in the cabinet).

The vertical guide wires shall be mounted using rods 6 mm (0.25 in.) in diameter fixed horizontally at the top and bottom of the stack. [*See Figure 9-2.1(g)*.]

(d) A glass fiber fabric baffle shall be installed in the upper portion of the test cabinet as follows:

1.* A piece of glass fiber fabric measuring 1 m × 125 mm (39.4 in. × 4.9 in.) shall be cut.

2. A 40-mm (1.6-in.) hem shall be sewn on each end of the fabric using a glass sewing thread.

3. A 3-mm × 330-mm (0.12-in. × 13-in.) rod shall be inserted through the hem at one end and through holes [4 mm (0.158 in.)] in the top middle of the two opposite sides of the cabinet. These holes shall be centered 10 mm ± 1 mm (0.4 in. ± 0.04 in.) below the top edge of the cabinet and midway between the front and back of the cabinet.

4. A 3-mm × 330-mm (0.12-in. × 13-in.) rod shall be inserted through the bottom hem of the glass fabric and also through the slotted holes that are in the opposite sides of the test cabinet centered 930 mm ± 2 mm (36.6 in. ± 0.08 in.) below the top of the cabinet. These slotted holes shall be 4 mm × 25 mm (0.16 in. × 1.0 in.), rounded at each end.

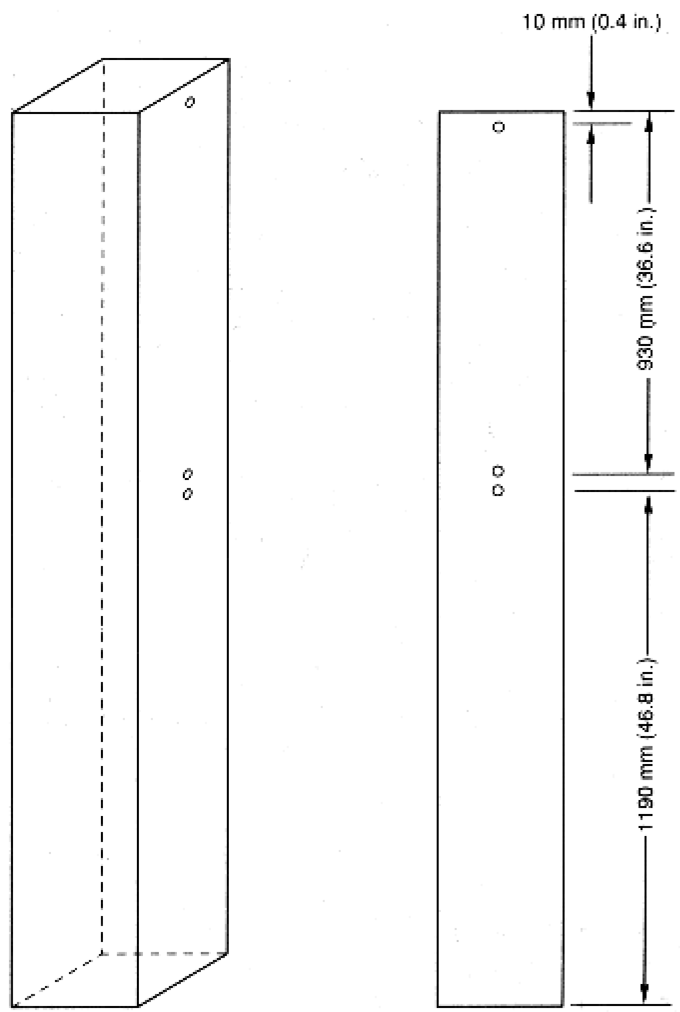

Figure 9-2.1(a) Orthographic view of test cabinet for Test 2.

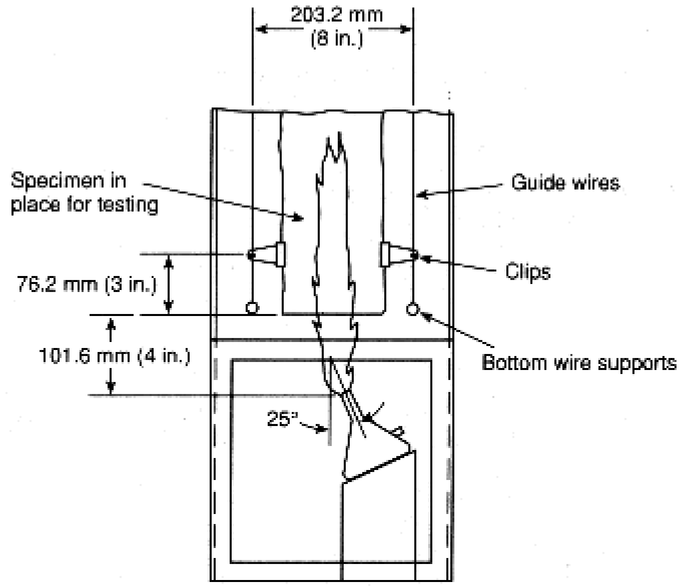

Figure 9-2.1(b) View of inside at bottom of cabinet.

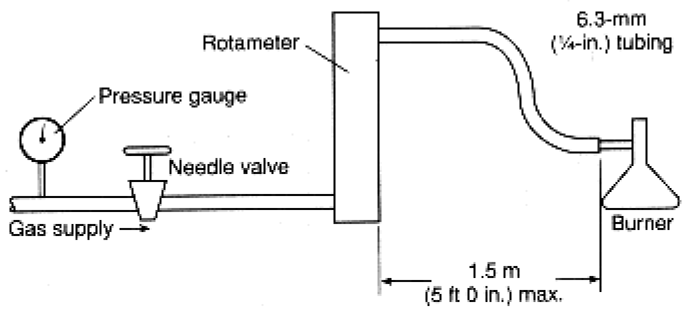

Figure 9-2.1(c) Gas line feed arrangement to burner.

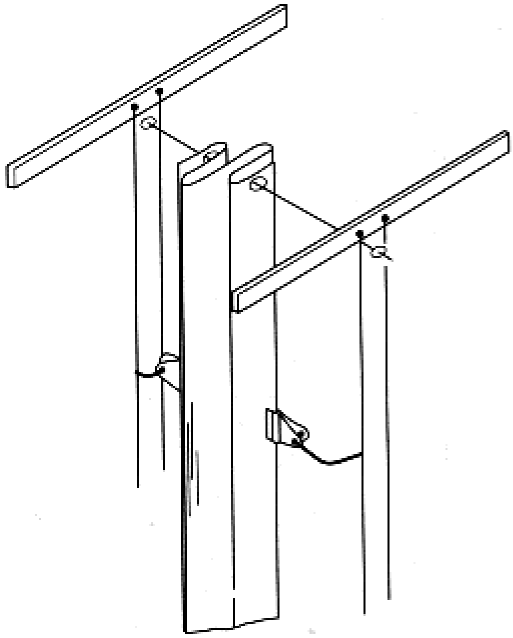

Figure 9-2.1(d) Test sample in folds.

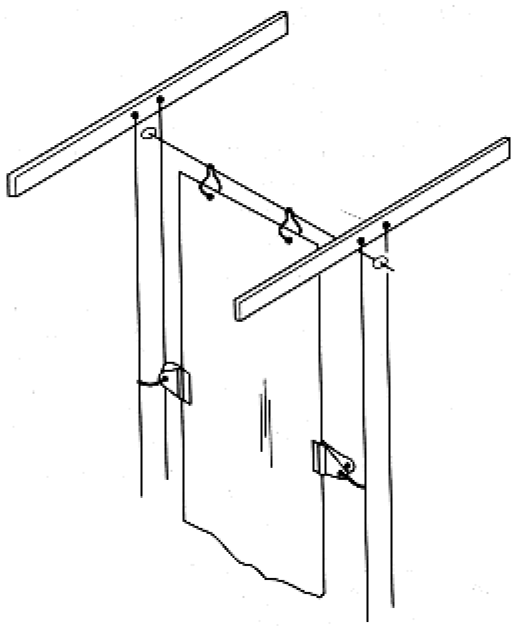

Figure 9-2.1(e) Test sample flat sheet.

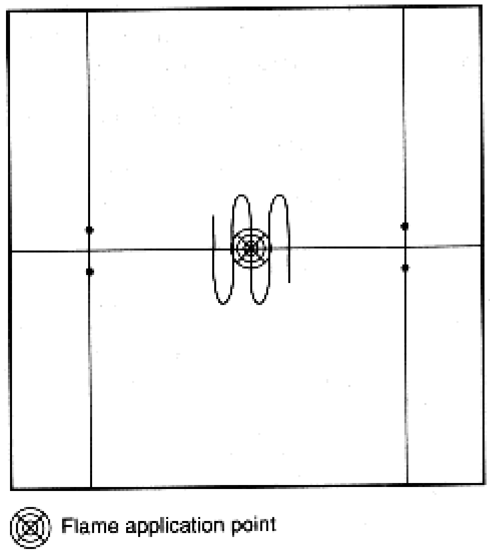

Figure 9-2.1(f) Bottom view of folded sample.

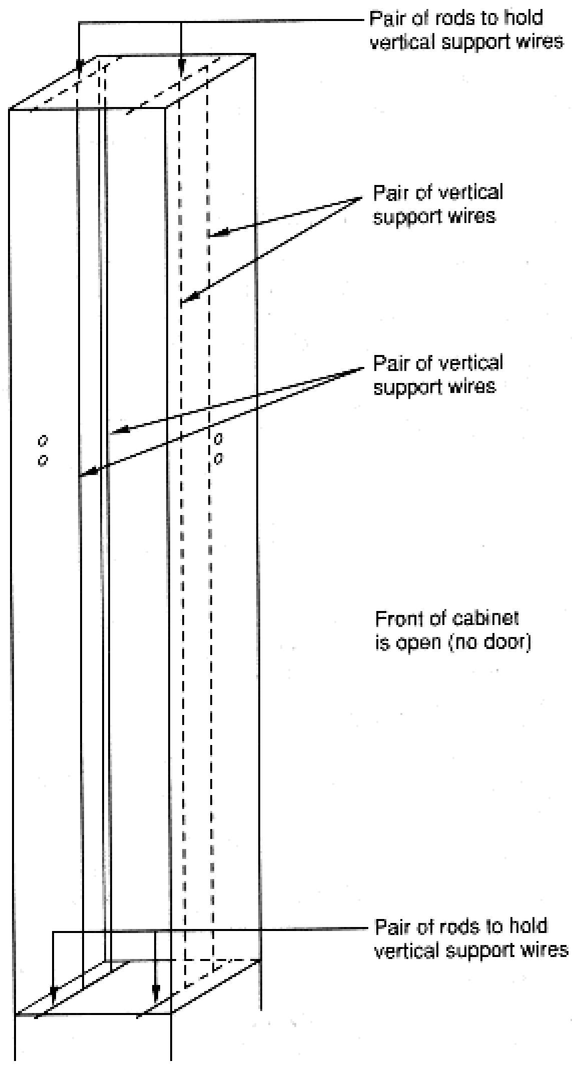

Figure 9-2.1(g) Vertical guide support.

9-2.2

The stack shall be located in a room, chamber, or hood where the temperature is 15°C ± 10°C (60°F ± 18°F) and the relative humidity does not exceed 70 percent.

9-2.3

The test chamber shall be free of drafts that affect the stability of the flame.

9-2.4

Figures 9-2.1(a) through (f) shall be used for details regarding enclosure construction and facilities for mounting both flat and folded test specimens.

9-3 Restraining Clamps.

See 11-2.3.

9-4* Gas Burner.

A bunsen burner of 9.5-mm (0.375-in.) tube diameter shall be used for the ignition source. If the burner is equipped with a gas flow controlling valve, the valve shall be open fully in order to prevent restriction of gas flow. The art vents shall be kept closed and sealed.

9-4.1

The burner shall be fixed in a position so that the barrel is at a 25-degree angle with the vertical, with the upper tip of the burner located 100 mm (4 in.) below the bottom edge of the test specimen.

9-4.2

The gas supply to the burner shall be at least 97 percent pure methane or manufactured or natural gas having a heat value of 25×10^6 J/m^3 to 31×10^6 J/m^3 (800 Btu/ft^3 to 1000 Btu/ft^3).

9-4.3

A needle valve for gas flow control shall be used followed by a rotameter in the gas line leading to the burner. The upper limit of the rotameter shall be 150 L/hr to 300 L/hr (1.47×10^{-3} ft^3/sec to 2.9×10^{-3} ft^3/sec). A pressure gauge shall be located between the gas supply and the needle valve used for controlling the gas flow. The gas lines from the needle valve to the rotameter and from the rotameter to the burner shall have a bore of at least 6 mm (0.24 in.) and shall not exceed a total length of 1.5 m (60 in.). [*See Figure 9-2.1(c).*]

9-5 Timer.

A stopwatch or other timing device that measures to an accuracy of 0.5 second shall be used for determining afterflame of burning specimens and the flame time of portions of residues that break away or drip from the test specimen and continue to flame after reaching the floor of the test chamber.

9-6 Ruler.

A ruler marked in 1-mm ($^1/_{32}$-in.) increments shall be used to measure the burner flame height and specimen dimensions.

Chapter 10 Specimens and Conditioning for Test 2

10-1 Test Specimens.

10-1.1

Selvages shall be removed from the material to be evaluated before cutting and conditioning specimens. The test specimens shall be taken from widely separated and symmetrically located sections over the entire area of the material. The specimens shall be cut on their long dimension in the lengthwise direction of the material.

10-1.2

For conducting flame tests of flat sheet materials, at least 10 specimens, 125 mm × 1.20 m ± 25 mm (4.9 in. × 47.25 in. ± 1.0 in.) shall be used. Only those specimens that cannot be folded shall be tested in the flat configuration.

10-1.3

For conducting flame tests of materials hung in folds, at least four specimens, 610 mm ± 25 mm × 1.20 m ± 25 mm (24.0 in. ± 1.0 in. × 47.25 in. ± 1.0 in.), shall be used. Each specimen shall be folded longitudinally to form four folds so that the segment of material on each side of a fold uniformly measures 125 mm ± 20 mm (4.9 in. ± 0.8 in.) in width over the length of the specimen. [*See Figures 9-2.1(d) and (f).*]

10-1.4

For multilayer assemblies (either flat or folded), the layers shall be sewn together as shown in Figure 10-1.4 using a plain stitch with 2.5 stitches/cm ± 0.25 stitch/cm (6.4 stitches/in. ± 0.6 stitch/in.). A No. 40 polyester/cotton sewing thread shall be used. The layers of the multilayer assembly shall be sewn along all four edges at a distance of 5 mm ± 1 mm (0.2 in. ± 0.04 in.) from the edge. A fifth seam shall be sewn along the center of the assembly in the lengthwise direction. This center seam shall extend the full length of the specimen. The seam shall be within 10 mm (0.4 in.) of the center of the specimen and shall continue for a distance within 300 mm (12 in.) of the lower end of the specimen.

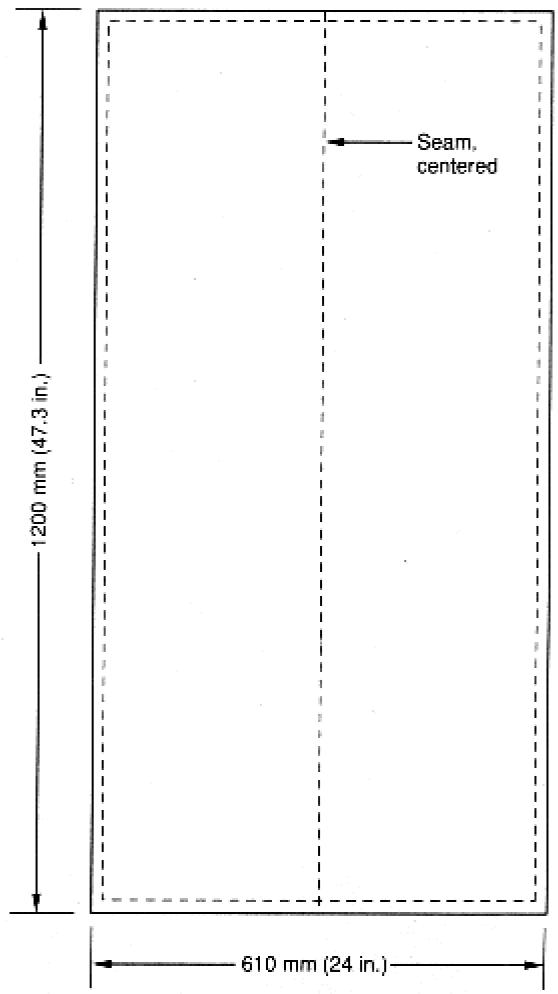

Figure 10-1.4 Multilayer specimen for Test 2.

10-2 Conditioning of Test Specimens.

10-2.1

The test specimens shall be conditioned in an oven at a temperature of 105°C ± 3°C (220°F ± 5°F) for not less than 1 hour nor more than 3 hours before testing.

10-2.2

Each specimen shall be removed from the oven no earlier than 2 minutes before igniting the gas burner.

Chapter 11 Flame Test Procedures for Test 2

11-1 Mounting of Test Specimens.

11-1.1

The 330-mm (13-in.) steel mounting rod shall be threaded through the specimen so that the folded or flat configuration, as appropriate, is maintained. The rod shall be threaded through the specimen 15 mm ± 5 mm (0.6 in. ± 0.2 in.) below the top edge of the test specimen.

11-1.1.1 The folded specimens shall be suspended vertically with the edges of the two center folds facing the front of the stack. The folds shall be spread 12 mm ± 3 mm (0.5 in. ± 0.12 in.) apart by means of the top support rod and the 1.5-mm × 255-mm (0.06-in. × 10-in.) sharpened rod shall be installed halfway down the length of the specimen to hold the folds in place. The bottom of the center portion of the section between the two middle folds shall be 100 mm ± 10 mm (4.0 in. ± 0.4 in.) above the bunsen burner.

11-1.1.2 The flat specimens shall be suspended vertically in the stack with their full width facing the front of the stack so that the center of the bottom of the specimen is located 100 mm ± 10 mm (4.0 in. ± 0.4 in.) above the bunsen burner.

11-1.2

Test specimens shall be restrained laterally at the midpoint of their length and within 75 mm (3 in.) of the bottom edge by bulldog clips and lightweight chains attached to the vertical guide wires.

11-1.3

Figures 9-2.1(d) through (f) shall be used for details for mounting test specimens.

11-2 Conducting the Flame Test.

11-2.1

The gas burner shall be ignited. The gas pressure shall be 17.5 kPa ± 2.0 kPa (2.5 psi ± 0.25 psi) with a flow rate of 113 L/hr ± 3 L/hr (1.1 × 10^{-3} ft^3/sec ± 2.9 × 10^{-5} ft^3/sec).

11-2.2

The burner air inlets shall be sealed with vinyl electrical adhesive tape to prevent the entrance of air, and the gas shall be adjusted to produce a 280-mm ± 12 mm (11-in. ± 0.5 in.) flame.

11-2.3

The position of the specimen relative to the test flame shall be maintained by using bulldog clips attached to the edges of the specimen and the vertical guide wires with lightweight chains. These clips shall be attached to the edges of the specimen at the midpoint of the specimen's length.

11-2.4

The test flame shall be applied to the specimen for 2 minutes and then shall be withdrawn.

The flame shall be applied at an angle of 25 degrees from the vertical with the burner opening 100 mm (4 in.) below the edge of the specimen and within 20 mm (0.8 in.) of the middle of the width of the lower edge of the specimen in a single sheet, or at the middle segment of folded specimens. [*See Figure 9-2.1(f).*]

11-2.5

The duration of flaming combustion of material that drops to the floor of the test chamber shall be measured to the nearest 0.5 second and recorded.

11-2.6

The duration of burning of the specimen after the igniting flame has been removed shall be measured to the nearest 0.5 second and recorded.

11-2.7

After all flaming has ceased, the test cabinet and room shall be purged prior to the next test.

11-3 Measurement of Length of Char.

The length of the char after all flaming and afterglow on the specimen has ceased shall be determined. The length of char shall be defined as the original length of the specimen minus the distance from the top edge of the specimen to the horizontal line above which all material is intact.

Chapter 12 Flame Resistance Performance Criteria for Test 2

12-1 Performance Criteria.

12-1.1

Where any specimen continues flaming for more than 2 seconds after the test flame is removed from contact with the specimen, the material shall be recorded as failing the test. (*See Section 12-2.*)

12-1.2

Where the length of char of any individual folded specimen exceeds 1050 mm (41.34 in.), the material shall be recorded as failing the test. (*See Section 12-2.*)

12-1.3

Where the char length of any single flat specimen exceeds 435 mm (40.76 in.), the material shall be recorded as failing the test. (*See Section 12-2.*)

12-1.4

Where at any time during or after the application of the test flame any portions or residues of the material being tested break or drip from the specimen and fall to the floor of the test apparatus and continue burning for more than 2 seconds after reaching the floor of the test apparatus, the material shall be recorded as failing the test. (*See Section 12-2.*)

12-2 Retest.

12-2.1

In the event that only one of the four folded specimens meets the criteria of Section 12-1, two new specimens cut in the same direction as those that failed shall be tested. If both of the new specimens fail to meet the criteria, the material shall be recorded as passing this test and shall be designated as flame resistant.

12-2.2

In the event that only one of the 10 flat specimens meets the above criteria, five new specimens cut in the same direction as the one that failed shall be tested. If all five of the new specimens fail to meet the criteria, the material shall be recorded as passing this test and shall be designated as flame resistant.

Chapter 13 Cleaning Procedures

13-1 General.

Where a manufacturer claims that the material tested in accordance with this method retains its flame resistance after cleaning or weathering, the material also shall be tested after it has been subjected to the exposure conditions specified in this section of the test method.

13-2 Application.

Each fabric shall be subjected to those exposure conditions that are applicable to its intended use (dry cleaning, laundering, or other exposure to water). Each material or assembly shall meet the flame resistance requirements of Chapters 7 and 12 after passing through the appropriate exposure cycles.

13-3 Accelerated Dry Cleaning.

13-3.1

Where the material to be tested is intended to be refurbished by dry cleaning, the material shall be subjected to three full cycles of one of the following dry-cleaning procedures:

(a) A dry-cleaning procedure specified by the manufacturer or finisher for the routine care of the material. If such care instructions are provided by the manufacturer, they shall be used; or

(b) Conventional commercial dry cleaning using either perchloroethylene or Stoddard solvent as the cleaning medium.

13-3.2

Test specimens shall be cut from the dry-cleaned material for testing.

13-3.3

The specimens shall be conditioned before testing.

13-4 Accelerated Laundering.

13-4.1

Where the material to be tested is intended to be refurbished by laundering, the material shall be subjected to five full cycles of one of the following laundering procedures:

(a) A laundering procedure specified by the manufacturer or finisher for the routine care of the material;

(b) Conventional commercial laundering; or

(c) The home laundering procedure specified in the AATCC Technical Manual, *Standard Laboratory Practice for Home Laundering Fabrics Prior to Flammability Testing to Differentiate Between Durable and Non-Durable Finishes*.

13-4.2

Test specimens cut from laundered material shall be used for testing.

13-4.3

The specimens shall be conditioned before testing.

13-5 Accelerated Water Leaching.

13-5.1

Where the material is expected to be suitable for use outdoors, the material shall be immersed totally in a vessel containing tap water at room temperature (20°C ± 5°C) (68°F ± 9°F) for not less than 72 hours. A vessel with a capacity of at least 15.1 L (4 gal) shall be used.

13-5.2

The water shall be drained from the vessel at 24-hour intervals during the immersion period. After all water has drained from the vessel, it shall be refilled as done initially.

13-5.3

At the conclusion of the immersion period, the sample shall be removed from the vessel and dried at room temperature.

13-5.4

Test specimens cut from leached material shall be used for testing.

13-5.5

The specimens shall be conditioned before testing.

13-5.6

Where the material is subjected to the accelerated laundering prescribed in Section 13-4, this leaching procedure shall not be required.

13-6 Accelerated Weathering.

13-6.1

Where limitations imposed by the weathering equipment make it possible to expose only the specimen for Test 1, the following procedure then shall be performed:

(a) The specimens for Test 1 shall be cut before the accelerated weathering procedure is performed.

(b) The specimens shall be exposed for 100 hours using the apparatus and procedure specified in AATCC Test Method 111A, *Weather Resistance: Sunshine Arc Lamp Exposure with Wetting*.

(c) The specimens shall be conditioned before testing.

Chapter 14 Reporting

14-1 General.

The recorded results shall be reported along with the description of the materials tested, test conditions, and the accelerated refurbishing or weathering treatments used (if any).

14-2 Material Description.

14-2.1

The composition and form of the material that was tested shall be described. The description shall include the manner in which the material was assembled. Where flame retardants have been added, they shall be described along with the method of application. The weight and construction of the material in the description shall be included.

14-2.2

The intended application of the material or assembly shall be included, where known.

14-3 Test Conditions.

The test used and the test conditions shall be described.

14-4 Refurbishing or Weathering Conditions.

Where any refurbishing or accelerated weathering procedures were applied to the sample, the procedures shall be described along with the number of cycles used.

14-5 Test Results.

The results from individual specimens as well as the sample average for the following measurements and observations shall be reported:

(a) The time of burning for any material that falls to the bottom of the test chamber to the nearest 0.5 second;

(b) The mass of each specimen (to the nearest g) before and after exposure to the ignition flame (Test 1);

(c) The char length to the nearest 3 mm (0.12 in.) (Test 2);

(d) The afterflame time to the nearest 0.5 second (Test 2);

(e) Any unusual behavior of specimens and other observations.

14-6 Final Conclusion.

The report shall specify whether the material passes or fails the test based on the test results and the criteria of Chapter 7 or 12, whichever is appropriate. If the material passes the test, the report shall specify that the material is flame resistant.

Chapter 15 Referenced Publications

15-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

15-1.1 NFPA Publication.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, 1996 edition.

15-1.2 Other Publications.

15-1.2.1 AATCC Publications. American Association of Textile Chemists and Colorists, P.O. Box 12215, Research Triangle Park, NC 27709.

AATCC Test Method 111A, *Weather Resistance: Sunshine Arc Lamp Exposure with Wetting*, 1990.

AATCC Technical Manual, *Standard Laboratory Practice for Home Laundering Fabrics Prior to Flammability Testing to Differentiate Between Durable and Non-Durable Finishes*, 1994.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-2-4.2

A suitable alternate test cabinet that does not require a separate hood, equipped with a pin bar, burner-mounting system, gas control system, and timers is available as Model HVUL from Atlas Electric Devices, 4114 North Ravenswood Ave., Chicago, IL 60613; telephone (312) 327-4250.

A-2-4.3

A suitable burner is available as Catalog No. 03-902 from Fisher Scientific Co., 711 Forbes Ave., Pittsburgh, PA 15219-4785; telephone (412) 562-8300.

A-2-5.1

A suitable pressure gauge is available as Catalog No. 11-281B (0-300 mm Hg) from Fisher Scientific Co., 711 Forbes Ave., Pittsburgh, PA 15219-4785; telephone (412) 562-8300.

A-2-5.2

A suitable gas flow gauge for maintaining and monitoring the gas flow rate is available as Catalog No.N 03229-19 from Cole-Parmer Instrument Co., 7425 North Oak Park Ave., Chicago, IL 66048-9930; telephone (800) 323-4340.

A-2-10

A suitable brush can be obtained as Catalog No. 03-685 from Fisher Scientific Co., 711 Forbes Ave., Pittsburgh, PA 15219-4785; telephone (412) 562-8300.

A-9-2.1(d)1 A suitable glass fabric is Style 2116, available from Clark Schwebel Fiber Glass Corp., P.O. Box 2627, Anderson, SC 29622.

A-9-4

A suitable burner is available as Catalog No. 03-917 from Fisher Scientific Co., 711 Forbes Ave., Pittsburgh, PA 15219-4785; telephone (412) 562-8300.

Appendix B Test 1 Information

This Appendix is not a part of the requirements of this NFPA document but is included for *informational purposes only.*

B-1 Specimen Mounting Jig for Test 1.

B-1.1

Figure B-1.1 shows the construction details for a mounting jig, which makes it quicker, easier, and safer to mount the specimens for Test 1 onto the pin bar correctly.

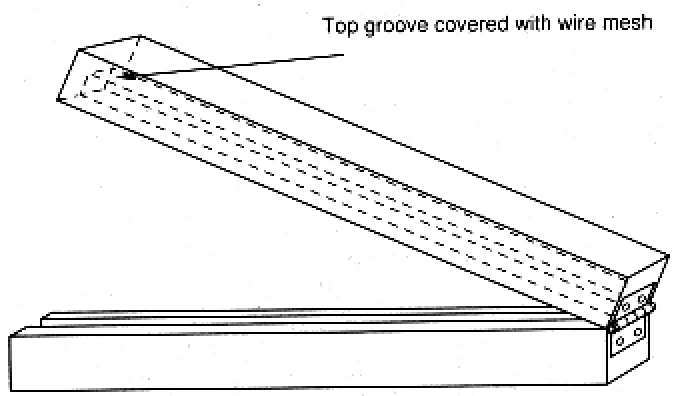

Figure B-1.1 Mounting jig for Test 1 specimens.

B-1.2

With the pin bar placed in the slot of the long arm of the jig, the specimen should be held so that the top seam of composite specimens [or an imaginary line 5 mm (0.196 in.) below the top edge of single-layer specimens] is aligned with the pins on the pin bar. The short arm of the jig then should be lowered over the pins and gently pushed downward. This secures the specimen to the pin bar. The short arm then should be raised and the pin bar, with the specimen attached, should be removed from the jig and mounted on the pin bar holder that is attached to the upper back panel of the test chamber. When in place, the pins of the pin bar should face the open side of the chamber (i.e., toward the operator).

B-2 History and Background.

B-2.1

In the past, curtain and drapery fabrics have been evaluated for their flammability characteristics primarily using the NFPA 701 test (1977 and 1989 editions), which has demonstrated a failure common to all similar tests that include a small-scale test using a mounting frame for the specimen. This failure occurs when thermoplastic products are tested. Thermoplastic tends to melt and pull away from the flame. Frequently, the thermoplastic melts and spills over and onto the frame, carrying some residual flame with it. When the test material and flame reach the frame, the frame acts as a wick and allows the material to continue burning for an extended time. Sometimes the flame self-extinguishes shortly after reaching the frame. At other times, the frame acts as a candle wick and allows the flame to continue to consume test material. In any event, thermoplastics frequently fail the afterflame criterion and sometimes the char length criterion as well.

B-2.2

In the past, NFPA 701 did permit the operator to test such thermoplastic materials using the large-scale test, which does not involve any sort of frame. In most cases, thermoplastic materials that failed the small-scale test using a frame would pass the large-scale test. This caused a problem because:

(a) More testing was needed for thermoplastic materials;

(b) Much more material was needed for the large-scale test; and

(c) The large-scale test is much more expensive to perform.

Furthermore, some regulatory jurisdictions required that materials pass both tests.

B-2.3

During the 1980s considerable effort was expended to modify the NFPA 701 tests and to arrive at pass/fail criteria for the small-scale test that would agree more closely with the results obtained with the large-scale test. During this time, a series of tests involving multilayer composites was performed at Southwest Research Institute by Belles and Beitel.

B-2.4

The tests by Belles and Beitel primarily involved combinations of materials, each of which passed the NFPA 701 small-scale test. The tests were performed on full-scale draperies hung close to a gypsum board wall, which was set up to be freestanding in a very large test room. A gypsum board ceiling extended out over the draperies for a distance of about 1 m (3.28 ft). The ignition source was a 280-mm (11-in.) flame from a bunsen burner. In order to ensure the validity of the test, the ignition flame was allowed to burn for 5 minutes.

B-2.5

These tests demonstrated, in general, that draperies consisting of face and lining materials made from the same type of fiber were less likely to propagate flame extensively. Also, draperies consisting of face and lining fabrics made from dissimilar materials were very likely to propagate flame extensively and to be destroyed almost totally in less than 2 minutes. The only exception to these results were draperies consisting of face and lining materials made from cotton with nondurable, flame-resistant treatments. In these cases, the fabric tended to resist the flame for 2 minutes to 3 minutes and then to ignite and burn intensely. Since NFPA 701 is intended to evaluate fabrics for relatively short exposures to the flame, such fabrics generally pass NFPA 701 tests.

B-2.6

In any event, these tests demonstrated a serious weakness in the NFPA 701 test, since the same combinations of fabrics that propagated the flames extensively in the SwRI tests performed well in both the NFPA 701 large- and small-scale tests. This led the fiber and textile industry trade associations to work closely with NFPA, ASTM, and the Center for Fire Research at the National Institute for Science and Technology to implement a program to develop a new test that would evaluate both single-layer fabrics as well as multilayer composites, such as draperies for flame resistance, in a small-scale test that adequately predicts the results obtained at SwRI.

B-2.7

The first phase of work at NIST confirmed the results of the SwRI tests and also showed that existing small-scale tests did not predict the SwRI results.

B-2.8

The second phase resulted in the Test 1 method. Subsequent to the work at NIST, there has been some refinement of the test method as well as much verification testing. The Test 1 method, as presented here, does not reproduce the SwRI results precisely, since combinations that burned nearly completely (at least 95 percent destruction) in the SwRI tests showed a weight loss of approximately only 80 percent in this test. Nevertheless, the “good” performers at SwRI showed a weight loss of less than 40 percent in this test and the “bad” performers at SwRI showed a weight loss of greater than 40 percent. The one exception is vinyl-coated fabric blackout linings, which behave in a very inconsistent manner. Consequently, these linings and lined draperies containing such materials should be tested using Test 2, the large-scale test.

B-2.9

During the development of the Test 1 method, another test method was tried and eventually abandoned because of the cost of the apparatus and potential operator safety problems. This alternative test method was based on an analysis of the differences between the room-scale test and the NFPA 701 test. It was observed in the room-scale tests that flames usually propagated more rapidly on the portion of the specimen that faced the wall. This suggested that the radiant energy reflected back to the specimen by the wall was critical. In order to simulate this situation in a test cabinet such as the one used in the NFPA 701 test, it seemed appropriate to heat the back wall of the cabinet so that it would radiate heat to the back surface of the specimen. Consequently, a cabinet was equipped with electrical strip heaters mounted on a 1-cm (0.39-in.) aluminum plate that, in turn, was attached to the back of the cabinet. The remainder of the test was identical to ASTM D 3659, *Standard Test Method for Flammability of Apparel Fabrics by Semi-Resistant Method*. Back surface temperatures in excess of 240°C (465°F) were needed to duplicate the SwRI results. The quoted cost of a test chamber modified for ASTM D 3659 is $3000. The additional modification for heating the back wall surface was estimated at an additional $3000 for a total cost for the test chamber of approximately $6000. This cost would prevent many laboratories from participating in the interlaboratory test required to validate the test. For this reason, as well as the possibility of operators sustaining burns when placing and removing specimens, this alternative method was abandoned.

B-2.10

The present test method eliminates the need for heating the back surface by placing the specimen very close to the back surface. This tends to form a chimney that funnels the heat between the wall and the specimen. This heats the back wall, which, in turn, reradiates some of the heat onto the back surface of the specimen.

Appendix C Textile Considerations

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

C-1 General Considerations.

C-1.1

While it is not possible to make combustible textiles and films completely resistant to charring and decomposition when exposed to flame or high temperature, a degree of flame resistance can be achieved. Most natural and synthetic fiber textiles can be treated chemically to increase their flame resistance. Such treatments might be fugitive and, hence, not durable to laundering, dry cleaning, or water leaching, while other treatments are very durable and can withstand many cycles of laundering, dry cleaning, or water leaching. Furthermore, some synthetic fibers are made from polymers that contain flame retardants in their basic structure. Both approaches could be necessary to impart flame resistance to materials in which different types of fibers are blended. It should be noted, however, that combinations of flame-resistant (FR) fibers with relatively small percentages of non-flame-resistant fibers can interfere with the flame-resistant effect of the FR fibers.

C-1.2

The hazards introduced by combustible textiles might, of course, be avoided entirely where the use of such noncombustible fibers as glass is practical.

C-1.3

Many flame-resistant synthetic materials soften and melt when exposed to heat and fire. They also can be subject to twisting, shrinking, dripping, and elongation when subjected to fire conditions.

C-2 Applications of Flame-Resistant Fabrics.

C-2.1

Standards for theater scenery, curtains, and furnishings in high risk or assembly occupancies are commonly set by law.

Flame-resistant fabrics are used in hotels, hospitals, and similar occupancies in the interest of the preservation of lives and property from fire.

C-2.2

Flame-resistant fabrics also are used as work clothing in industries where exposure to heat, open flames, and flash fire is a possibility.

C-2.3

Fabrics treated for flame and weather resistance are used for tents, tarpaulins, and other outdoor protective covering.

C-2.4

Reinforced plastic films with flame-resistant qualities are used in membrane structures.

C-2.5

Transparent plastic films often are used as a temporary enclosure for greenhouses and for construction work.

C-3 Flame-Retardant Treatments.

C-3.1

An increasing range of flame-retardant treatments for natural and synthetic fiber materials is becoming available. The selection of a particular treatment is governed by the intended use of the treated fabric.

C-3.2

Topical treatments based on water-soluble chemicals are generally the least expensive and most easily applied; however, they are subject to removal by the leaching action of water in laundering, scrubbing, or exposure to weather.

C-3.3

Some treatments can be impaired by the action of the solvents used in dry cleaning, and some gradually can lose their effectiveness under conditions of storage and usage not involving leaching.

C-3.4

Relatively temporary treatments are suitable only where proper treatment renewal can be ensured or for decorations and other items that are used briefly and then discarded.

C-3.5

Situations where retreatment is uncertain or not feasible indicate the choice of one of the durable treatments that is suitable for clothing and decorative fabrics. A number of these treatments can withstand extensive laundering and dry cleaning, although they are higher in cost and should be applied professionally.

C-3.6

For outdoor use, treatments have been developed that can be expected to remain effective for the useful life of the fabric under normal conditions of weather exposure.

C-3.7

It should be noted that painting or coating a treated or flame-resistant fabric or film could impair its flame-resistant qualities unless the coating itself is flame-resistant.

C-4 Physical Properties of Treated Fabrics.

C-4.1

A number of factors, which vary in importance depending on the end use of the fabric, should be considered in selecting a flame-retardant treatment.

C-4.2

The effect on the appearance, texture, and flexibility of the fabric often is of primary concern.

Appendix D Bibliography

Appendix E Referenced Publications

E-1

The following document or portions thereof is referenced within this standard for informational purposes only and thus is not considered part of the requirements of this document. The edition indicated for the reference is the current edition as of the date of the NFPA issuance of this document.

E-1.1 ASTM Publication.

American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

ASTM D 3659, *Standard Test Method for Flammability of Apparel Fabrics by Semi-Resistant Method*, 1993.

Tentative Interim Amendment

NFPA 701 Figure B-1.1

Standard Methods of Fire Tests for Flame-Resistant Textiles and Films

1996 Edition

Reference: 1-1.7, A-1-1.7(New)
TIA 96-1 (NFPA 701)

Pursuant to Section 4 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, 1996 edition. The TIA was processed by the Technical Committee on Fire Tests, and was issued by the Standards Council on January 12, 1996, with an effective date of February 1, 1996.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automatically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

1. Revise 1-1.7 to read as follows:

1-1.7*

Where materials are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, they shall be tested in accordance with the appropriate test method for that particular interior finish application.

2. Add an appendix note to read as follows:

A-1-1.7

Other tests used to evaluate interior finishes include NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, and NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings*. Additional information on interior finishes can be found in Section 6-5, NFPA 101®, *Life Safety Code*®.

NFPA 701

Standard Methods of Fire Tests for Flame-Resistant Textiles and Films

1996 Edition

Reference: A-2-4.2
TIA 96-2 (NFPA 701)

Pursuant to Section 4 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, 1996 edition. The TIA was processed by the Fire Tests Committee, and was issued with revision by the Standards Council on January 15, 1997, with an effective date of February 4, 1997.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automatically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

1. Delete paragraph A-2-4.2 and the last parenthetical sentence in 2-4.2.

NFPA 703

1995 Edition

Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials

1995 Edition

This edition of NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*, was prepared by the Technical Committee on Building Construction and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 703 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 703

In 1957, the Committee on Flameproofing and Preservative Treatments began to develop a standard for flameproofing of wood. It soon became clear to the committee that the fire retardant coating industry was expanding considerably, and that fire retardant admixtures of plastics and other building materials required coverage in the standard. Thus, in its many subsequent meetings, the Committee reexamined its approach and expanded the standard to cover all fire retardant treatments.

The standard was tentatively adopted at the 1960 Annual Meeting and was submitted for final adoption at the 1961 Annual Meeting.

The 1979 edition of NFPA 703, *Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*, superseded the previous 1961 edition. The change in title was necessary to more adequately cover the subjects included in the text of the standard. The principal changes in the 1979 edition included improved definitions for fire retardant coatings.

The 1985 edition included the addition of a new Chapter 4 that listed referenced publications whose use is mandated within this standard.

In the 1992 edition, the Committee provided clarification in several areas defining fire resistance. The 1995 edition was reconfirmed with some editorial changes.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the design, installation and maintenance of building construction features not covered by other NFPA committees. (This Committee does not cover building code requirements, exits, protection at openings, vaults, air conditioning, blower systems, etc., which are handled by other committees.)

NFPA 703
Standard for
Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 4 and Appendix B.

Chapter 1 General

1-1* Scope.

This standard provides criteria for defining and identifying fire retardant impregnated wood and fire retardant coated building materials.

1-2 Definitions.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Chapter 2 Fire Retardant Impregnated Wood

2-1 Application.

These requirements shall apply to pressure impregnation treatments that reduce certain burning characteristics of wood. Pressure impregnated lumber and plywood shall be treated for fire retardance in accordance with the requirements of the American Wood Preservers' Association Standard C1, *All Timber Product-Preservative Treatment by Pressure Process*, as modified herein. Other approved methods of impregnation of wood products providing at least equal performance shall also be considered acceptable.

2-2 Results of Treatment — All Species.

2-2.1 Conditions of Material.

2-2.1.1 Moisture Content. Subsequent to treatment, fire retardant treated lumber and plywood shall be air-dried or kiln-dried to an average moisture content of 19 percent or less for lumber and 15 percent or less for plywood in accordance with end-use requirements.

2-2.1.1.1 Air-Drying. Where material is air dried it shall not be exposed to conditions that could cause chemicals to leach out.

2-2.1.1.2 Kiln-Drying. During kiln-drying the dry bulb temperature of the kiln shall not exceed 16°F until the average moisture content of the wood has dropped to 25 percent or less.

2-2.2 Performance Rating.

2-2.2.1 Fire Hazard Classification. Material shall have a flame spread index of 25 or less with no evidence of significant progressive combustions when tested for 30 minutes by the test listed in Section 2-3. In addition, the flame front shall not progress more than 10.5 ft beyond the center line of the burner at any time during the test.

2-2.2.2 Interior Type A. Where experience demonstrates a specific need for the use of materials with low hygroscopicity, material shall have an equilibrium moisture content of not more than 28 percent when tested in accordance with the procedures in ASTM D3201, *Standard Test Method for Hygroscopic Properties of Fire-Retardant Wood and Wood-Base Products*, at 92 ± 2 percent relative humidity.

2-2.2.3 Interior Type B. Where experience demonstrates no specific need for the use of material with low hygroscopicity, the material shall have an equilibrium moisture content of not more than 28 percent when tested in accordance with the procedures in ASTM D3201, *Standard Test Method for Hygroscopic Properties of Fire-Retardant Wood and Wood-Base Products*, at 78 ± 2 percent relative humidity.

2-2.2.4 Exterior Type. Where material is to be used outdoors and subjected to rainfall or sustained humidity of 80 percent or more, the material shall show no increase in flame spread index when subjected to the standard rain test described in ASTM D2898, *Standard Methods for Accelerated Weathering of Fire Retardant-Treated Wood for Fire Testing* – Method A.

2-3* Tests.

Fire retardant treated wood shall be tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials.*

2-4 Inspection and Identification.

Inspection shall be required by an independent and qualified test agency that establishes the requirements for treatment relative to the preceding requirements. All fire retardant treated wood products shall be labeled by the testing agency certifying such ratings.

2-5 Exposure.

Design criteria for fire retardant impregnated wood shall take into consideration the temperature and humidity conditions to which the material will be exposed.

Chapter 3 Fire Retardant Coatings for Building Materials

3-1 Application.

These requirements shall apply to fire retardant coatings such as paints and other surface coatings used to reduce certain burning characteristics of building materials.

3-2 Definitions.

Fire Retardant Coating. A coating that reduces the flame spread of Douglas Fir, and all other tested combustible surfaces to which it is applied, by at least 50 percent or to a flame spread classification value of 75 or less, whichever is the lesser value, and has a smoke developed rating not exceeding 200.

Class A Fire Retardant Coating. As applied to building materials, shall reduce the flame spread to 25 or less, and have a smoke developed rating not exceeding 200.

Class B Fire Retardant Coating. As applied to building materials, shall reduce the flame spread to greater than 25 but not more than 75, and have a smoke developed rating not exceeding 200.

3-3 General.

3-3.1

Fire retardant coatings shall remain stable and adhere to the material under all atmospheric conditions the material is exposed to.

3-3.2

A fire retardant coating shall not be used for unprotected outdoor installations unless labeled for such installations.

3-3.3

The classification of fire retardant coatings is applicable only when the coating is applied at the rates of coverage and to the type or kind of surfaces indicated on the test report when the coating is applied in accordance with the manufacturer's directions supplied with the container.

3-3.4

These coatings shall be applied in accordance with the manufacturer's direction.

3-3.5

The authority having jurisdiction might require that the application be certified by the applicator as being in conformance with the manufacturer's direction for application.

3-3.6

A fire retardant coating shall not be overcoated with any material unless both the fire retardant coating and the overcoat have been tested as a system and are found to meet the requirements of a fire retardant coating.

3-4 Tests.

3-4.1*

Fire retardant coatings shall be tested by NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

3-4.2

Where fire retardant coatings are to be subjected to sustained humidity of 80 percent or more or exposure to the weather, certification by a testing laboratory must indicate that there is no increase in listed classification when subjected to the "Standard Rain Test" described in ASTM D2898, *Standard Methods for Accelerated Weathering of Fire Retardant-Treated Wood for Fire Testing.*

3-5 Maintenance of Protection.

Fire retardant coatings shall possess the desired degree of permanency and shall be maintained to retain the effectiveness of the treatment under the service conditions encountered in actual use.

3-6 Identification.

Each container of fire retardant coating material shall be labeled to indicate conformance with the preceding requirements and shall include the manufacturer's instructions for application.

Chapter 4 Referenced Publications

4-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

4-1.1 NFPA Publication.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, 1990 edition.

4-1.2 Other Publications.

4-1.2.1 ASTM Publications. American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

ASTM D2898, *Standard Methods for Accelerated Weathering of Fire Retardant-Treated Wood for Fire Testing*, 1981.

ASTM D3201, *Standard Test Method for Hygroscopic Properties of Fire-Retardant Wood and Wood-Base Products*, 1986.

4-1.2.2 AWPA Publication. American Wood Preservers Association, P.O. Box 286, Woodstock, MD 21163-0286.

C-1, *All Timber Product-Preservative Treatment by Pressure Process*, 1991.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1

Fire resistance ratings measured on an hourly basis are not covered in this standard. To establish such ratings, tests should be made in accordance with NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

A-1-2 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

A-2-3

Test methods similar to NFPA 255, *Test for Surface Burning Characteristics of Building Materials*, include UL 723, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, and ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials.* Under the criteria of NFPA 255, the flame spread rating is expressed numerically on a scale for which the zero point is fixed by the performance of inorganic-reinforced cement board and the 100 point (approximately) is fixed by the performance of untreated red oak flooring.

A-3-4.1

The flame spread rating is expressed numerically on a scale for which the zero point is fixed by the performance of inorganic-reinforced cement board and the 100 point (approximately) is fixed by the performance of red oak flooring.

Appendix B Referenced Publications

NFPA 704

1996 Edition

Standard System for the Identification of the Hazards of

1996 Edition

This edition of NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, was prepared by the Technical Committee on Classification and Properties of Hazardous Chemical Data and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 20-23, 1996, in Boston, MA. It was issued by the Standards Council on July 18, 1996, with an effective date of August 9, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 704 was approved as an American National Standard on July 26, 1996.

Origin and Development of NFPA 704

Work on this standard originated in 1957 with a great deal of the development work having been done by the NFPA Sectional Committee on Classification, Labeling and Properties of Flammable Liquids starting in 1952. Background data was published by the Association in its Quarterly magazine in July 1954, 1956, and 1958. The material in its present form was first Tentatively Adopted in 1960. Official Adoption was secured in 1961 and revisions adopted in 1964, 1966, 1969, 1975, 1980, and 1985. In the 1987 and 1990 editions, the Committee on Fire Hazards of Materials introduced quantitative guidelines for assigning the Health Hazard and Reactivity Hazard Ratings. This 1996 edition contains additional quantitative guidelines and amended definitions for the Reactivity (Instability) Hazard Ratings.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the classification of the relative hazards of all chemical solids, liquids and gases and to compile data on the hazard properties of these hazardous chemicals.

NFPA 704
Standard System for the Identification of the Hazards of Materials for Emergency Response

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Appendix E.

Foreword

The Committee has been working on the material in this standard since early 1957. A great deal of preliminary work was developed as a manual by the Sectional Committee on Classification, Labeling and Properties of Flammable Liquids of the NFPA Committee on Flammable Liquids starting in 1952. Progress reports were given on this activity at NFPA Annual Meetings and reported in the NFPA *Quarterly* in July issues of 1954, 1956, and 1958. The material was tentatively adopted as a guide in 1960, adopted in 1961, and further amended in 1964, 1966, 1969, 1975, and 1980.

As originally conceived, the purpose of the standard is to safeguard the lives of those individuals who respond to emergencies occurring in an industrial plant or storage location where the hazards of materials are not readily apparent.

Chapter 1 General

1-1 Scope.

1-1.1

This standard shall address the health, flammability, instability, and related hazards that are presented by short-term, acute exposure to a material under conditions of fire, spill, or similar emergencies.

1-1.2

This standard provides a simple, readily recognized and easily understood system of markings that provides a general idea of the hazards of a material and the severity of these hazards as they relate to emergency response. The objectives of the system are:

(a) To provide an appropriate signal or alert and on-the-spot information to safeguard the lives of both public and private emergency response personnel;

(b) To assist in planning for effective fire and emergency control operations, including clean-up;

(c) To assist all designated personnel, engineers, plant and safety personnel in evaluating hazards.

1-1.3

It is recognized that local conditions will have a bearing on evaluation of hazards; therefore, discussion shall be kept in general terms.

1-2 Applicability.

1-2.1

This standard is applicable to industrial, commercial, and institutional facilities that manufacture, process, use, or store hazardous materials.

1-2.2

This standard is not applicable to transportation or use by the general public.

1-2.3*

This standard is not intended to address:

(a) Occupational exposure;

(b) Explosive and blasting agents, including commercial explosive material as defined in NFPA 495, *Explosive Materials Code*;

(c) Chemicals whose only hazard is one of chronic health hazards;

(d) Teratogens, mutagens, oncogens, etiologic agents, and other similar hazards.

1-3 Purpose.

This system is intended to provide basic information to fire fighting, emergency, and other personnel, enabling them to easily decide whether to evacuate the area or to commence emergency control procedures. It is also intended to provide them with information to assist in selecting fire-fighting tactics and emergency procedures.

1-4 Description.

1-4.1

This system identifies the hazards of a material in terms of three principal categories: "health," "flammability," and "instability." The system indicates the degree of severity by a numerical rating that ranges from four (4), indicating severe hazard, to zero (0), indicating minimal hazard.

1-4.2

The information is presented by a spatial arrangement of numerical ratings with the health rating always at the nine o'clock position; the flammability rating always at the twelve o'clock position; and the instability rating always at the three o'clock position. Each rating is located in a square-on-point field, each of which is assigned a color: blue for health hazard; red for flammability hazard; yellow for instability hazard. Alternately, the square-on-point field shall be permitted to be any convenient contrasting color and the numbers themselves shall be permitted to be colored. See Figures 6-1 through 6-3 for examples of the spatial arrangements.

1-4.3

The fourth space, at the six o'clock position, is reserved for indicating any unusual reactivity with water. The standard symbol for indicating unusual reactivity with water is the letter "W" with a line through the center: W̶. No special color is associated with this symbol.

1-4.3.1 This space shall be permitted to be used to indicate other unusual hazards, but only if not needed to indicate reactivity with water. Approved symbols will be designated in Chapter 5 of this standard.

1-5 Assignment of Ratings.

1-5.1

While the system is basically simple in application, the hazard evaluation required to determine the correct numerical ratings for a specific material shall be performed by persons who are technically competent and experienced in the interpretation of the hazard criteria set forth in this standard. Assignment of ratings shall be based on factors that encompass a knowledge of the inherent hazards of the material, including the extent of change in behavior to be anticipated under conditions of exposure to fire or fire control procedures. For additional information, see NFPA 49, *Hazardous Chemicals Data*, and NFPA 325, *Guide to Fire Hazard Properties of Flammable Liquids, Gases, and Volatile Solids*.

1-5.2

The system is based on relative rather than absolute values. Therefore, it is anticipated that conditions of storage and use can result in different ratings being assigned to the same material by different persons. Furthermore, the guidance presented in the following chapters is necessarily limited. For example, flash point is the primary criterion for assigning the flammability rating, but other criteria might be of equal importance. For example, autoignition temperature, flammability limits, and susceptibility of a container to failure due to fire exposure also shall be considered. For instability, emphasis has been placed on the ease by which an energy-releasing reaction is triggered. For health, consideration shall be given not only to inherent hazards but also to protective measures that shall be taken to minimize effects of short-term exposure.

1-5.3

In some situations, such as warehouses, storage rooms or buildings, laboratory facilities, etc., a variety of materials can be present in one localized area. In such cases considerable judgment might be needed to properly assign ratings to the area.

1-5.4

Based upon professional judgment it shall be permitted to either increase or decrease the hazard rating to more accurately assess the likely degree of hazard that will be encountered.

Chapter 2 Health Hazards

2-1 General.

2-1.1

This chapter shall address the capability of a material to cause personal injury due to contact with or entry into the body via inhalation, ingestion, skin contact, or eye contact. Only the hazards that arise from an inherent toxic property of the material or its products of decomposition or combustion shall be considered. Injury resulting from the heat of a fire or from the force of an explosion shall not be considered.

2-1.2

In general, the health hazard that results from a fire or other emergency condition is one of acute (single) short-term exposure to a concentration of a hazardous material. This exposure can vary from a few seconds to as long as one hour. The physical exertion demanded by fire-fighting or other emergency activity can be expected to intensify the effects of any exposure. In addition, the hazard under ambient conditions will likely be exaggerated at elevated temperatures. Health hazards that can result from chronic or repeated long-term exposure to low concentrations of a hazardous material shall not be considered.

2-1.3

The oral route of exposure, i.e., ingestion, is highly unlikely under the conditions anticipated by this standard. If situations are encountered, however, where the oral toxicity values indicate a significantly different health hazard rating than from other, more likely routes of exposure, or where the oral toxicity values would tend to either exaggerate or minimize the hazards likely to be encountered, then professional judgment shall be exercised in assigning the health hazard rating. In such cases, other routes of entry shall be considered to be more appropriate in assessing the hazard. Similarly, inhalation of dusts and mists is unlikely under the conditions anticipated by this standard. In such cases, the health hazard ratings shall also be based on data for the more likely routes of exposure.

2-1.4*

For purposes of assigning the health hazard rating, only the inherent physical and toxic properties of the material shall be considered, unless the combustion or decomposition products present a significantly greater degree of risk.

2-1.5

The degree of hazard shall indicate to fire fighting and emergency response personnel one of the following: that they can work safely only with specialized protective equipment; that they can work safely with suitable respiratory protective equipment; or that they can work safely in the area with ordinary clothing.

2-2 Definitions.

Health Hazard. The likelihood of a material to cause, either directly or indirectly, temporary or permanent injury or incapacitation due to an acute exposure by contact, inhalation, or ingestion.

2-3 Degrees of Hazard.

2-3.1*

The degrees of health hazard shall be ranked according to the probable severity of the effects of exposure to emergency response personnel. For each degree of hazard the criteria are listed in a priority order based upon the likelihood of exposure. Data from all routes of exposure shall be considered when applying professional judgment to assign a health hazard rating.

4 Materials that, under emergency conditions, can be lethal. The following criteria shall be considered when rating materials:

Gases whose LC_{50} for acute inhalation toxicity is less than or equal to 1000 parts per million (ppm);

Any liquid whose saturated vapor concentration at 68°F (20°C) is equal to or greater than ten times its LC_{50} for acute inhalation toxicity, if its LC_{50} is less than or equal to 1000 parts per million (ppm);

Dusts and mists whose LC_{50} for acute inhalation toxicity is less than or equal to 0.5 milligrams per liter (mg/L);

Materials whose LD_{50} for acute dermal toxicity is less than or equal to 40 milligrams per kilogram (mg/kg);

Materials whose LD_{50} for acute oral toxicity is less than or equal to 5 milligrams per kilogram (mg/kg).

3 Materials that, under emergency conditions, can cause serious or permanent injury. The following criteria shall be considered when rating materials:

Gases whose LC_{50} for acute inhalation toxicity is greater than 1000 parts per million (ppm), but less than or equal to 3000 parts per million (ppm);

Any liquid whose saturated vapor concentration at 68°F (20°C) is equal to or greater than its LC_{50} for acute inhalation toxicity, if its LC_{50} is less than or equal to 3000 parts per million (ppm) and that does not meet the criteria for degree of hazard 4;

Dusts and mist whose LC_{50} for acute inhalation toxicity is greater than 0.5 milligrams per liter (mg/L), but less than or equal to 2 milligrams per liter (mg/L);

Materials whose LD_{50} for acute dermal toxicity is greater than 40 milligrams per kilogram (mg/kg), but less than or equal to 200 milligrams per kilogram (mg/kg);

Materials that are corrosive to the respiratory tract;

Materials that are corrosive to the eye or cause irreversible corneal opacity;

Materials that are severely irritating and/or corrosive to skin;

Materials whose LD_{50} for acute oral toxicity is greater than 5 milligrams per kilogram (mg/kg), but less than or equal to 50 milligrams per kilogram (mg/kg).

2 Materials that, under emergency conditions, can cause temporary incapacitation or residual injury. The following criteria shall be considered when rating materials:

Gases whose LC_{50} for acute inhalation toxicity is greater than 3000 parts per million (ppm), but less than or equal to 5000 parts per million (ppm);

Any liquid whose saturated vapor concentration at 68°F (20°C) is equal to or greater than one-fifth ($^1/_5$) its LC_{50} for acute inhalation toxicity, if its LC_{50} is less than or equal to 5000 parts per million (ppm) and that does not meet the criteria for either degree of hazard 3 or degree of hazard 4;

Dusts and mists whose LC_{50} for acute inhalation toxicity is greater than 2 milligrams per liter (mg/L), but less than or equal to 10 milligrams per liter (mg/L);

Materials whose LD_{50} for acute dermal toxicity is greater than 200 milligrams per kilogram (mg/kg), but less than or equal to 1000 milligrams per kilogram (mg/kg);

Materials that are respiratory irritants;

Materials that cause irritating but reversible injury to the eyes;

Materials that are primary skin irritants or sensitizers;

Materials whose LD_{50} for acute oral toxicity is greater than 50 milligrams per kilogram, but less than or equal to 500 milligrams per kilogram (mg/kg).

1 Materials that, under emergency conditions, can cause significant irritation. The following criteria shall be considered when rating materials:

Gases and vapors whose LC_{50} for acute inhalation toxicity is greater than 5000 parts per million (ppm), but less than or equal to 10,000 parts per million (ppm);

Dusts and mists whose LC_{50} for acute inhalation toxicity is greater than 10 milligrams per liter (mg/L), but less than or equal to 200 milligrams per liter (mg/L);

Materials whose LD_{50} for acute dermal toxicity is greater than 1000 milligrams per kilogram (mg/kg), but less than or equal to 2000 milligrams per kilogram (mg/kg);

Materials that are slightly irritating to the respiratory tract, eyes, and skin;

Materials whose LD_{50} for acute oral toxicity is greater than 500 milligrams per kilogram (mg/kg), but less than or equal to 2000 milligrams per kilogram (mg/kg).

0 Materials that, under emergency conditions, would offer no hazard beyond that of ordinary combustible materials. The following criteria shall be considered when rating materials:

Gases and vapors whose LC_{50} for acute inhalation toxicity is greater than 10,000 parts per million (ppm);

Dusts and mists whose LC_{50} for acute inhalation toxicity is greater than 200 milligrams per liter (mg/L);

Materials whose LD_{50} for acute dermal toxicity is greater than 2000 milligrams per kilogram (mg/kg);

Materials whose LD_{50} for acute oral toxicity is greater than 2000 milligrams per kilogram (mg/kg);

Essentially nonirritating to the respiratory tract, eyes, and skin.

Chapter 3 Flammability Hazards

3-1 General.

3-1.1

This chapter shall address the degree of susceptibility of materials to burning. Since many materials will burn under one set of conditions but will not burn under others, the form or condition of the material shall be considered, along with its inherent properties. The definitions for liquid classification are found in NFPA 30, *Flammable and Combustible Liquids Code*.

3-2 Degrees of Hazard.

3-2.1*

The degrees of hazard shall be ranked according to the susceptibility of materials to burning as follows:

4 Materials that will rapidly or completely vaporize at atmospheric pressure and normal ambient temperature or that are readily dispersed in air, and which will burn readily. This includes:

Flammable gases;

Flammable cryogenic materials;

Any liquid or gaseous material that is liquid while under pressure and has a flash point below 73°F (22.8°C) and a boiling point below 100°F (37.8°C) (i.e., Class IA liquids);

Materials that ignite spontaneously when exposed to air.

3 Liquids and solids that can be ignited under almost all ambient temperature conditions. Materials in this degree produce hazardous atmospheres with air under almost all ambient temperatures or, though unaffected by ambient temperatures, are readily ignited under almost all conditions. This includes:

Liquids having a flash point below 73°F (22.8°C) and having a boiling point at or above 100°F (37.8°C) and those liquids having a flash point at or above 73°F (22.8°C) and below 100°F (37.8°C) (i.e., Class IB and Class IC liquids);

Materials that on account of their physical form or environmental conditions can form explosive mixtures with air and that are readily dispersed in air;

Materials that burn with extreme rapidity, usually by reason of self-contained oxygen (e.g., dry nitrocellulose and many organic peroxides).

2 Materials that must be moderately heated or exposed to relatively high ambient temperatures before ignition can occur. Materials in this degree would not under normal conditions form hazardous atmospheres with air, but under high ambient temperatures or under moderate heating might release vapor in sufficient quantities to produce hazardous atmospheres with air. This includes:

Liquids having a flash point at or above 100°F (37.8°C) and below 200°F (93.4°C) (i.e., Class II and Class IIIA liquids);

Solid materials in the form of coarse dusts that burn rapidly but that generally do not form explosive atmospheres with air;

Solid materials in a fibrous or shredded form that burn rapidly and create flash fire hazards, such as cotton, sisal, and hemp;

Solids and semisolids that readily give off flammable vapors.

1 Materials that must be preheated before ignition can occur. Materials in this degree require considerable preheating, under all ambient temperature conditions, before ignition and combustion can occur. This includes:

Materials that will burn in air when exposed to a temperature of 1500°F (815.5°C) for a period of 5 min or less;

Liquids, solids, and semisolids having a flash point at or above 200°F (93.4°C) (i.e., Class IIIB liquids);

Liquids with a flash point greater than 95°F (35°C) that do not sustain combustion when tested using the *Method of Testing for Sustained Combustibility*, per 49 CFR Part 173 Appendix H, or the UN *Recommendations on the Transport of Dangerous Goods*, 8th Revised Edition.

Liquids with a flash point greater than 95°F (35°C) in a water-miscible solution or dispersion with a water noncombustible liquid/solid content of more than 85 percent by weight.

Liquids that have no fire point when tested by ASTM D 92, *Standard Test Method for Flash Point and Fire Point by Cleveland Open Cup*, up to the boiling point of the liquid or up to a temperature at which the sample being tested shows an obvious physical change;

Most ordinary combustible materials.

0 Materials that will not burn. This includes any material that will not burn in air when exposed to a temperature of 1500°F (815.5°C) for a period of 5 min.

Chapter 4 Instability Hazards

4-1 General.

4-1.1

This chapter shall address the degree of susceptibility of materials to release energy. Some materials are capable of rapid release of energy by themselves, through self-reaction or polymerization, or can undergo violent explosive reaction through contact with water or other extinguishing agents or with certain other materials.

4-1.2

The violence of a reaction or decomposition of materials can be increased by heat or pressure, or by mixture with certain other materials to form fuel-oxidizer combinations, or by contact with incompatible substances, sensitizing contaminants, or catalysts.

4-1.3

Because of the wide variations of accidental combinations possible in fire or other emergencies, these extraneous hazard factors (except for the effect of water) cannot be applied to a general numerical rating of hazards. Such extraneous factors must be considered individually in order to establish appropriate safety factors, such as separation or segregation. Such individual consideration is particularly important where significant amounts of materials are to be stored or handled. Guidance for this consideration is provided in NFPA 49, *Hazardous Chemicals Data*.

4-1.4

The degree of instability hazard shall indicate to fire fighting and emergency personnel whether the area shall be evacuated, whether a fire shall be fought from a protected location, whether caution shall be used in approaching a spill or fire to apply extinguishing agents, or whether a fire can be fought using normal procedures.

4-2 Definitions.

4-2.1

For the purposes of this standard, an unstable material is one that can enter into a violent chemical reaction with water. Guidelines for determination of water instability hazard ratings can be found in Appendix D. Reactions with other materials can also result in violent release of energy but are beyond the scope of this standard.

4-2.2

For the purposes of this standard, an unstable material is one that, in the pure state or as commercially produced, will vigorously polymerize, decompose or condense, become self-reactive, or otherwise undergo a violent chemical change under conditions of shock, pressure, or temperature. This calculation is not applicable for the evaluation/classification of organic peroxides. Refer to NFPA 43B, *Code for the Storage of Organic Peroxide Formulations*, for more specific information regarding the instability hazard rating of organic peroxides. Guidelines for determining thermal stability ratings can be found in Appendix D.

4-2.3

Stable materials are those that normally have the capacity to resist changes in their chemical composition, despite exposure to air, water, and heat as encountered in fire emergencies.

4-3 Degrees of Hazard.

4-3.1

The degrees of hazard shall be ranked according to ease, rate, and quantity of energy release as follows:

4 Materials that in themselves are readily capable of detonation or explosive decomposition or explosive reaction at normal temperatures and pressures. This includes materials that are sensitive to localized thermal or mechanical shock at normal temperatures and pressures.

Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) of 1000 W/mL or greater.

3 Materials that in themselves are capable of detonation or explosive decomposition or explosive reaction, but that require a strong initiating source or that must be heated under confinement before initiation. This includes:

Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 100 W/mL and below 1000 W/mL;

Materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures;

Materials that react explosively with water without requiring heat or confinement.

2 Materials that readily undergo violent chemical change at elevated temperatures and pressures. This includes:

Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 10 W/mL and below 100 W/mL;

Materials that react violently with water or form potentially explosive mixtures with water.

1 Materials that in themselves are normally stable, but that can become unstable at elevated temperatures and pressures. This includes:

Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) at or above 0.01 W/mL and below 10 W/mL;

Materials that react vigorously with water, but not violently;

Materials that change or decompose on exposure to air, light, or moisture.

0 Materials that in themselves are normally stable, even under fire conditions. This includes:

Materials that have an instantaneous power density (product of heat of reaction and reaction rate) at 482°F (250°C) below 0.01 W/mL;

Materials that do not react with water;

Materials that do not exhibit an exotherm at temperature less than or equal to 932°F (500°C) when tested by differential scanning calorimetry.

Chapter 5 Special Hazards

5-1 General.

5-1.1

This chapter shall address the other properties of the material that cause special problems or require special fire-fighting techniques.

5-1.2

Special hazards symbols shall be shown in the fourth space of the diagram or immediately above or below the entire symbol.

5-2 Symbols.

5-2.1

Materials that demonstrate unusual reactivity with water shall be identified by the letter W with a horizontal line through the center (~~W~~).

5-2.2

Materials that possess oxidizing properties shall be identified by the letters OX.

Chapter 6 Identification of Materials by Hazard Rating System

6-1

One of the systems delineated in the following illustrations shall be used for the implementation of this standard.

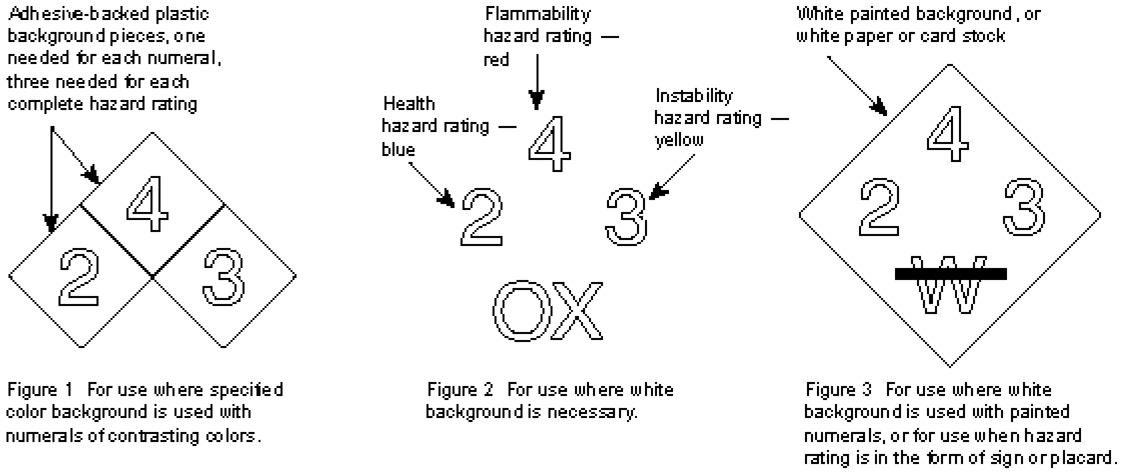

Figure 6-1 Alternate arrangements for display of NFPA 704 Hazard Identification System.

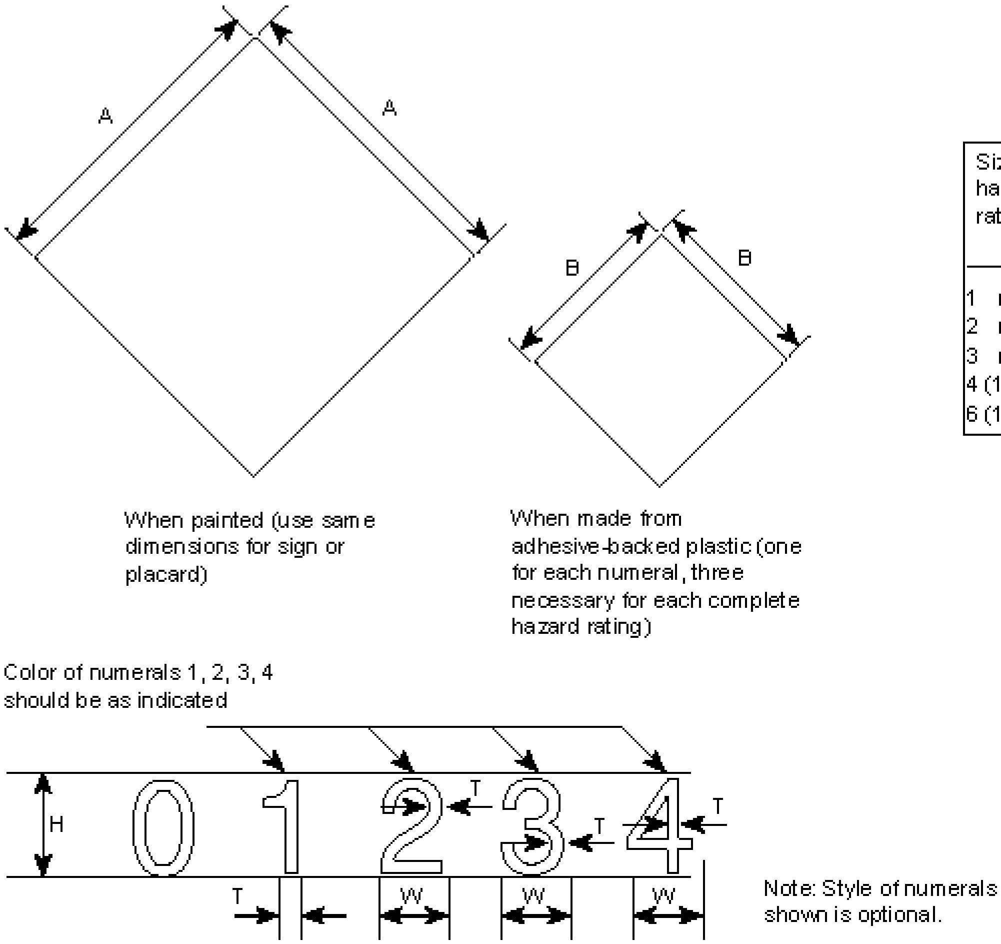

Minimum dimensions of whit
background for hazard rating
(white background is optiona

Size of hazard ratings H	W	T	A
1 (2.54)	0.7 (1.8)	5/32 (0.4)	2 ½ (6.35
2 (5.08)	1.4 (3.6)	5/16 (0.79)	5 (12.7)
3 (7.62)	2.1 (5.3)	15/32 (1.19)	7 ½ (19.05

Arrangement and order of hazard ratings—
optional form of application

Distance at which hazard ratings must be legible	Minimum size of hazard ratings required
50 ft (15.24 m)	1 in. (2.54 cm)
75 ft (22.86 m)	2 in. (5.08 cm)
100 ft (30.48 m)	3 in. (7.62 cm)
200 ft (60.96 m)	4 in. (10.16 cm)
300 ft (91.44 m)	6 in. (15.24 cm)

Note: This shows the correct spatial arrangement and order of hazard ratings used for identification of materials by hazard.

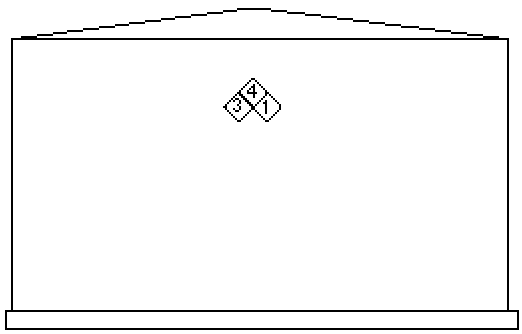

Figure 6-3 Minimum size of numerals for legibility at distance.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-2.3 The Committee recognizes that the potential exists for certain materials to cause a carcinogenic or teratogenic effect from acute exposure(s). However, there is not sufficient data available to this Committee to allow for the development of numerical ratings based upon carcinogenic or teratogenic potential.

A-2-1.4 Some materials have products of combustion or decomposition that present a significantly greater degree of hazard than the inherent physical and toxic properties of the original material. The degree of hazard is dependent on the conditions at the time of the incident. NFPA 49, *Hazardous Chemicals Data*, provides information on products of combustion when available.

A-2-3.1 Certain materials upon release can cause frostbite. Frostbite, as a health hazard, should be related to the skin/eye component of the health hazard rating criteria.

A-3-2.1 For water-miscible solutions and liquids that do not sustain combustion in accordance with the hazard rating "1" criteria, the individual performing the hazard evaluation should recognize that in large vapor spaces evaporation of volatile components of the mixture can create a flammable mixture in the vapor space which could increase the fire or explosion hazard. This could occur even though the bulk material meets the aforementioned criteria.

Appendix B

Health Hazard Rating

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

In developing this edition of NFPA 704, the Committee on Classification and Properties of Hazardous Chemicals Data determined that the standard should provide quantitative guidelines for determining the numerical health hazard rating of a material. In addition, the Committee agreed that a "4" or a "3" health hazard rating should be assigned to any material classified as a "Poison-Inhalation Hazard" by the U.S. Department of Transportation (DOT). This classification, "Poison-Inhalation Hazard," was adopted by DOT from the United Nations (UN) criteria detailed in the UN publication, *Recommendations on the Transport of Dangerous Goods*, 4th Edition - Revised, 1986. (See also "Notice of Proposed Rulemaking," Federal Register, Vol. 50, p. 5270 et seq., February 7, 1985, and "Notice of Final Rule," Federal Register, Vol. 50, p. 41092 et seq., October 8, 1985.)

The UN criteria for inhalation toxicity are based upon the LC_{50} and saturated vapor concentration of the material. Furthermore, in addition to inhalation toxicity, the UN has established criteria for oral and dermal toxicity, as well as corrosivity. Based upon these criteria, the UN assigns a given material to categories called Packing Groups I, II, or III. Packing Group I materials represent a severe hazard in transport, Group II materials a serious hazard, and Group III materials a low hazard.

The Committee decided to adopt the UN criteria for toxicity and corrosivity, and correlate Packing Groups I, II, and III with the health hazard ratings "4," "3," and "2," respectively. Adoption of the UN system has several advantages. First, it addresses hazards in transportation, which are similar to the type of emergencies likely to be encountered by fire fighting personnel and emergency responders. Most other hazard ranking systems have been developed for occupational exposures.

Secondly, the UN system is well established, and it is presumed that a large number of chemical manufacturers have already classified (or can easily classify) materials into the appropriate Packing Groups. Finally, users of chemicals can assign "4," "3," or "2" health hazard ratings by establishing whether chemicals have been assigned to UN Packing Groups due to toxicity or corrosivity.

In order to establish "1" and "0" health hazard rankings, the Committee utilized criteria for the "1" and "0" ratings contained in the Hazardous Materials Identification System (HMIS) developed by the National Paint & Coatings Association (NPCA) (*Hazardous Materials Identification System Revised, Implementation Manual*, 1981). Although the NPCA criteria were developed for occupational exposure, the "1" and "0" criteria are on the low end of the hazard spectrum and are fairly consistent with, and complementary to, the "4," "3," and "2" ratings based upon the UN criteria. No UN criteria were established for eye irritation, and the Committee adopted NPCA "3," "2," and "1," and "0" criteria as health hazard ratings for eye irritation.

The Committee made a number of revisions to the proposed hazard rating system to provide conformity with existing industrial practice and to recognize limitations and availability of corrosivity and eye irritation into a single "skin/eye contact" category and utilize descriptive terms for the health hazard ratings. Minor changes were made to the "2," "1," and "0" criteria for oral toxicity and to the "1" and "0" criteria for dermal toxicity. Specifically, the distinction between solids and liquids in the oral toxicity criteria was eliminated, and the cutoff between "1" and "0" rankings for oral and dermal toxicity was lowered from 5000 to 2000 mg/kg.

In summary, the "4," "3," and "2" health hazard rankings for oral, dermal, and inhalation toxicity are based primarily on UN criteria. The "1" and "0" health hazard rankings for oral, dermal, inhalation toxicity, and all of the "skin/eye contact" rankings are based primarily on NPCA criteria.

For the assistance of the user of this standard, the following definitions are quoted from Section 6.5 of *Recommendations on the Transport of Dangerous Goods*, 4th Revised Edition, 1986, published by the United Nations, New York, NY.

"LD_{50} for acute oral toxicity:

That dose of the substance administered which is most likely to cause death within 14 days in one half of both male and female young adult albino rats. The number of animals tested shall be sufficient to give a statistically significant result and be in conformity with good pharmacological practice. The result is expressed in milligrams per kilogram of body weight.

LD_{50} for acute dermal toxicity:

That dose of the substance which, administered by continuous contact for 24 hours with the bare skin of albino rabbits, is most likely to cause death within 14 days in one half of the animals tested. The number of animals tested shall be sufficient to give a statistically significant result and be in conformity with good pharmacological practice. The result is expressed in milligrams per kilogram of body weight.

LC_{50} for acute toxicity on inhalation:

That concentration of vapor, mist or dust which, administered by continuous inhalation to both male and female young adult albino rats for one hour, is most likely to cause death within 14 days in one half of the animals tested. If the substance is administered to the animals as dust or mist, more than 90 percent of the particles available for inhalation in the test must have a diameter of 10 microns or less, provided that it is reasonably foreseeable that such concentrations could be encountered by man during transport. The result is expressed in milligrams per liter of air for dusts and mists or in milliliters per cubic meter of air (parts per million) for vapors."

The following information quoted from Section 6.4 of the above-cited *Recommendations* also applies:

"The criteria for inhalation toxicity of dusts and mists are based on LC_{50} data relating to 1 hour exposures and where such information is available it should be used. However, where only LC_{50} data relating to 4 hour exposures to dusts and mists are available, such figures can be multiplied by four and the product substituted in the above criteria, i.e., LC_{50} (4 hour) × 4 is considered equivalent of LC_{50} (1 hour).

The criteria for inhalation toxicity of vapors are based on LC_{50} data relating to 1 hour exposures, and where such information is available it should be used. However, where only LC_{50} data relating to 4 hour exposures to dusts and mists are available, such figures can be multiplied by two and the product substituted in the above criteria, i.e., LC_{50} (4 hour) × 2 is considered equivalent of LC_{50} (1 hour)."

Appendix C Flammability

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

The selection of the flash point breaks for the assigning of ratings within the Flammability category has been based upon the recommendations of the Technical Committee on Classification and Properties of Flammable Liquids of the NFPA Committee on Flammable Liquids. This Technical Committee initiated the study that led to the development of this standard. Close cooperation between the Technical Committee and the Committee on Fire Hazards of Materials has continued.

Flash point indicates several things. One, if the liquid has no flash point, it is not a flammable liquid. Two, if the liquid has a flash point, it must be considered flammable or combustible. Three, the flash point is normally an indication of susceptibility to ignition.

The flash point test can give results that would indicate if a liquid is nonflammable or if it should be rated 1 or 2 as a mixture containing, for example, carbon tetrachloride. As a specific example, sufficient carbon tetrachloride can be added to gasoline so that the mixture has no flash point. However, on standing in an open container, the carbon tetrachloride will evaporate more rapidly than the gasoline. Over a period of time, the residual liquid will first show a high flash point, then a progressively lower one until the flash point of the final 10 percent of the original sample will approximate that of the heavier fractions of the gasoline. In order to evaluate the fire hazard of such liquid mixtures, fractional evaporation tests can be conducted at room temperature in open vessels. After evaporation of appropriate fractions, such as 10, 20, 40, 60, and 90 percent of the original sample, flash point tests can be conducted on the residue. The results of such tests indicate the grouping into which the liquid should be placed if the conditions of use are such as to make it likely that appreciable evaporation will take place. For open system conditions, such as in open dip tanks, the open-cup test method will give a more reliable indication of the flammability hazard.

In the interest of reproducible results, it is recommended that:

The flash point of liquids having a viscosity less than 45 SUS (Saybolt Universal Seconds) at 100°F (37.8°C) and a flash point below 200°F (93.4°C) can be determined in accordance with ASTM D 56, *Standard Method of Test for Flash Point by the Tag Closed Tester*. (In those countries that use the Abel or Abel-Pensky closed cup tests as an official standard, these tests will be equally acceptable to the Tag Closed Cup Method.)

The flash point of aviation turbine fuels can be determined in accordance with ASTM D 3828, *Test Method for Flash Point by Setaflash Closed Tester*.

For liquids having flash points in the range of 32°F (0°C) to 230°F (110°C) the determination may be made in accordance with ASTM D 3278, *Flash Point of Liquids by Setaflash Closed*

Tester.

For viscous and solid chemicals the determination may be made in accordance with ASTM E 502, *Flash Point of Chemicals by Closed Cup Methods*.

The flash point of liquids having a viscosity of 45 SUS (Saybolt Universal Seconds) or more at 100°F (37.8°C) or a flash point of 200°F (93.4°C) or higher may be determined in accordance with ASTM D 93, *Test Methods for Flash Point by the Pensky-Martens Closed Tester*.

Appendix D Instability, Thermal Hazard Evaluation Techniques

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

D-1 Water Reactivity.

Heat of mixing tests between a chemical and water can provide a measure of how vigorous the reaction with water will be in a fire fighting scenario. There are two scenarios to be considered: a material that rapidly releases heat on contact with water, and a material that rapidly releases heat and gas on contact with water. These guidelines apply only to the first scenario, i.e., a chemical that reacts exothermically to release heat on contact with water but does not produce gaseous or low boiling [<212°F (<100°C)] by-products or azeotropes.

INSTABILITY RATING	HEAT OF MIXING	DESCRIPTOR
4		Reactivity with water not considered for rating of 4
3	600 cal/gm or greater	Explosive
2	At or above 100 cal/gm and below 600 cal/gm	Violent
1	At or above 30 cal/gm and below 100 cal/gm	Vigorous
0	Below 30 cal/gm	Nonreactive

The heat of mixing should be determined using a Two Drop Mixing Calorimeter (Hofelich, 1994) or equivalent technique using a 1:1 ratio of chemical to water.

D-2 Thermal Stability.

Thermal stability for hazard evaluation purposes can be done by a number of methods. Frequently used techniques include DTA (Differential Thermal Analysis), DSC (Differential Scanning Calorimetry), and ARC (Accelerating Rate Calorimetry). These tests should be performed in a manner meeting or exceeding the requirements outlined in ASTM E 537, *Standard Test Method for Assessing the Thermal Stability of Chemicals by Methods of Differential Thermal Analysis* (for DTA or DSC) or ASTM E XXX, *Standard Test Method for*

Assessing the Thermal Stability of Chemicals by Methods of Accelerating Rate Calorimetry (in development for ARC).

D-3 Instantaneous Power Density.

Instantaneous power density (IPD) is calculated as the product of the enthalpy of decomposition/reaction and the initial rate of reaction, determined at 482°F (250°C). This quantity represents the amount of heat energy per unit time per unit volume (W/mL) that a material will initially give at 482°F (250°C). The values that make up the power density can be obtained from thermodynamic tables, calculations and experimental measurements. The values are most easily obtained from appropriate measurements using differential scanning calorimetry (ASTM E 698, *Standard Test Method for Arrhenius Kinetic Constants for Thermally Unstable Materials*) or adiabatic runaway calorimetry (Townsend, 1980). In a typical calculation, the rates of reaction as a function of temperature are obtained and expressed in terms of an Arrhenius expression and an overall, initial-rate expression (Laidler, 1965). This rate expression represents the initial rate of decomposition where the decrease in concentration of the material as a result of the decomposition/reaction has not progressed to a significant (< 5%) level. This allows one to use the initial concentration of the material in the simplified rate expression. (*See Appendix E for the references*.)

INSTABILITY RATING	INSTANTANEOUS POWER DENSITY AT 250°C
4	1000 W/mL or greater
3	At or above 100 W/mL and below 1000 W/mL
2	At or above 10 W/mL and below 100 W/mL
1	At or above 0.01 W/mL and below 10 W/mL
0	Below 0.01 W/mL

In order to clarify the calculation of instantaneous power density, a sample calculation is provided.

Differential scanning calorimetry was carried out and the following parameters were obtained for a material of interest:

Enthalpy of decomposition (ΔH): -80.5 cal/g

Arrhenius Activation Energy (E_a): 36.4 kcal/mol

Arrhenius Pre-exponential (^{A}PRE): $1.60 \times 10^{+15}\ s^{-1}$

Reaction Order (n) 1

Initial concentration of material, or density of pure material (Conc.): 0.80 g/mL

The initial rate of decomposition of the material at 482°F (250°C) can be calculated using the following Arrhenius expression, where R is the universal gas whose value is taken as 1.987 cal/(mol°C):

$$\text{Rate} = \text{Conc}^{\text{Order}} \times A_{\text{PRE}} \times e^{-E_a/RT}$$

UNITS:

$$\frac{g}{mL \times s} = \left(\frac{g}{mL}\right)^{\text{Order}} \times \left(\frac{g}{mL \times s}\right)^{1-\text{Order}} \times e^{-\frac{cal/mol}{cal/(mol\,x\,K)\,K}}$$

$$\text{Rate} = 0.80^{+1} \times 1.60 \times 10^{+15} \times e^{-\frac{36400}{1.987 \times (273 + 250)}}$$

$$\text{Rate} = 0.79\,\frac{g}{mL \times s}$$

$$\text{Rate} = 0.80^{+1} \times 1.60 \times 10^{+15} \times e^{-\frac{36400}{1039}}$$

The power density is given as the product of this decomposition and the enthalpy of decomposition (the value of 4.184 W/cal/s allows the use of units W/mL):

$$\text{IPD} = -\Delta H \times \text{Rate}$$

$$\text{UNITS}: \frac{W}{mL} = \frac{cal}{g} \times \frac{g}{mL \times s} \times 4.184\,\frac{W}{cal/s}$$

$$\text{IPD} = -(-80.5) \times 0.79 \times 4.184\,\frac{W}{cal/s}$$

$$\text{IPD} = 63\,\frac{cal}{s \times mL} \times 4.184\,\frac{W}{cal/s}$$

$$\text{IPD} = 270\,\frac{W}{mL}$$

The instantaneous power density (IPD) is used as a positive value: the greater the power density, the greater the rate of energy release per volume. Therefore, the exothermic enthalpy of reaction, thermodynamically taken with a negative sign to show release of heat to the surroundings, is taken as a negative so as to rectify the sign of IPD.

This material, having an IPD = 270 W/mL, would be rated a 3 per the table.

NFPA 705

1993 Edition

Recommended Practice for a Field Flame Test for Textiles and

1993 Edition

This edition of NFPA 705, *Recommended Practice for a Field Flame Test for Textiles and Films*, was prepared by the Technical Committee on Fire Tests and acted on by the National Fire Protection Association, Inc. at its Fall Meeting held November 16-18, 1992, in Dallas, TX. It was issued by the Standards Council on January 15, 1993, with an effective date of February 12, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Origin and Development of NFPA 705

The new NFPA 705 is a complete revision of NFPA 701, Chapter 10, Field Test: Match Flame Test. Due to the lack of data demonstrating a relationship between the field match test and NFPA 701, small- or large-scale testing, the committee determined it would be appropriate to create this document so as not to perpetuate any application of a correlation. The field match test does not incorporate the more rigorous laboratory testing methods incorporated into the small- and large-scale testing such as conditioning of specimen, reproducibility, and repeatability. The revisions to NFPA 705 incorporate an increase in safety precautions during the testing procedure, type of ignition source, and removal of sample prior to testing.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: To develop standards for fire testing procedures when such standards are not available; review existing fire test standards and recommend appropriate action to NFPA; recommend the application of and advise on the interpretation of acceptable test standards for fire problems of concern to NFPA technical committees and members; act in a liaison capacity between NFPA and the committees of other organizations writing fire test standards. The

Committee is not responsible for fire tests that are used to evaluate extinguishing agents, devices or systems.

NFPA 705
Recommended Practice for a Field Flame Test for Textiles and Films

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 5.

Chapter 1 Introduction

1-1 Scope.

1-1.1

This recommended practice provides guidance to enforcement officials for the field application of an open flame to textiles and films (1) that have been in use in the field or (2) for which reliable laboratory data are not available.

1-1.2

There is no known correlation between this recommended practice and NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, or full-scale fire behavior.

1-1.3

These recommendations apply to materials used in the interior of buildings, for protective outdoor coverings, such as tarpaulins and tents, and plastic films (with or without reinforcing or backing) used for decorative or other purposes inside buildings or as temporary or permanent enclosures for buildings under construction.

1-1.4

Materials applied to surfaces of buildings or backing materials as interior finishes in buildings should be tested and classified in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

1-2 Purpose.

The purpose of this recommended practice is to provide authorities having jurisdiction with a field means of determining the tendency of textiles and films to sustain burning subsequent to the application of a relatively small, open flame. The methods described herein and the results do not correlate with any known test method; and factors relating to reproducibility and correlation have not been determined; therefore, they should not be relied upon when more definitive test data are available.

1-3 Definitions.

Film. A flat section of a thermoplastic resin, a regenerated cellulose derivative, or other material that is extremely thin in comparison to its length and breadth and has a nominal maximum thickness of 0.01 in. (0.25 mm).

Kitchen Match. A piece of wood with a combustible mixture at its tip that bursts into flame through friction, with an approximate length of $2^{7}/_{16}$ in. (61.9 mm) and an approximate weight of 1 oz (29 g) per hundred.

Textile. A material made of natural or man-made fibers and used for the manufacture of items such as curtains, clothing, and furniture fittings.

Chapter 2 General

2-1 Application/Specific Limitations.

2-1.1*

The field test method may be useful to regulatory officials as an indicator of whether a material being used or installed burns very easily or may be flame resistant as indicated by (a) cessation of burning when the igniting flame is removed, (b) failure to burn at all, or (c) continuing to burn nonaggressively after the igniting flame is removed. The field test method has utility only when the authority having jurisdiction has no reliable data and, therefore, is forced to rely solely on the field test findings.

2-1.2

There are only two types of materials for which the field test method can be deemed to provide foolproof and totally adequate results: those made entirely of noncombustible inorganic material and those that ignite and burn readily on exposure to a small flame. For example, with only limited experience, an inspector will have no difficulty in identifying an all-mineral fiber fabric by employing a small, open flame, and no other procedure is necessary. The only effect of a small fire exposure on a mineral fiber fabric is to burn off the surface coloring, if any, leaving the threads themselves virtually undamaged. This result is not obtained with any other type of decorative fabric and, therefore, is readily recognized. At the other extreme, if a material ignites and burns readily from the application of a small, open flame from a source such as a kitchen match, showing no semblance of flame resistance, no other procedure is necessary, since the material obviously is not acceptable.

2-1.3

Between these two extremes, the field test method has a limited and a varying degree of reliability. Within this large group, comprising the great majority of materials the enforcement official is likely to encounter in the field, the most reliable results are obtained in the testing of cellulose-based materials (cotton, rayon, and paper) flame-retardant treated with the common inorganic salt formulations. These materials retain their shape reasonably during testing, and the results are not greatly affected by differences in sample size or severity of fire exposure. However, the least reliable results are obtained with chemically treated fabrics of synthetic fibers or flexible plastic films and laminates. These materials are subject to a variety of physical changes when exposed to fire, such as shrinking, curling, melting, elongating, and similar distortions, making the examination of small samples quite difficult and the results ambiguous. Furthermore, some of these thermoplastic materials are apt to appear flame resistant with small flame exposures but ignite and burn fiercely with longer exposures to larger ignition sources.

Chapter 3 Procedure

3-1* Materials.

3-1.1

Specimens should be samples removed from the existing material.

3-1.2

Specimens should be dry and should be a minimum of $^{1}/_{2}$ in. × 4 in. (12.7 mm × 101.6 mm).

3-2 Open Flame.

The fire exposure should be from a common wood kitchen match or source with equivalent flame properties and should be applied for 12 seconds.

3-3* Method.

3-3.1

The test should be performed in a draft-free and safe location free of other combustibles.

3-3.2

The sample should be suspended (preferably by means of a spring clip, tongs, or similar device) with the long axis vertical, the flame supplied to the center of the bottom edge, and the bottom edge $^{1}/_{2}$ in. (12.7 mm) above the bottom of the flame.

3-3.3

After 12 seconds of exposure, the match is to be removed gently away from the sample.

3-4 Requirements.

During the exposure, flaming should not spread over the complete length of the sample or in excess of 4 in. (101.6 mm) from the bottom of the sample (for larger size samples). There should be not more than two seconds of afterflame. Materials that break or drip flaming particles should be rejected if the materials continue to burn after they reach the floor.

Chapter 4 Summary

4-1 Limitations.

The deficiencies and limitations of the field test method can lead to misleading or erroneous results, and the error can be in both directions. It is quite possible to have a too-small sample show several seconds of afterflaming, causing the material to be rejected. It is equally possible for improper or inadequate field procedures to indicate satisfactory flame resistance. This can result in dangerous errors.

4-2 Precautions.

Field procedures are useful, but they must be used with good judgment and their limitations recognized. Field tests should not be relied on as the sole means for ensuring adequate flame resistance of decorative materials but are useful in augmenting a comprehensive regulatory program.

Chapter 5 Referenced Publications

5-1

The following documents or portions thereof are referenced within this recommended practice and should be considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

5-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, 1990 edition

NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, 1989 edition

Appendix A

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

A-2-1.1

By far, the greatest benefit can be derived from the field test method when the inspector has had the opportunity to practice and experiment on a variety of decorative materials and particularly to make comparisons between the results of laboratory tests performed in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, and the less precise field test method. Experience is the best teacher, and it is strongly recommended that inspectors who may be involved in this activity familiarize themselves with a wide variety of treated and inherently flame-resistant fabrics of many types and their typical behavior under a variety of test conditions. With this background, the inspector possesses a greater capability for properly interpreting field test results.

A-3-1

A difficult and controversial question concerns the minimum number of specimens that should be tested. The answer can be dictated by a number of factors. A good general rule is the more specimens, the better; but, in all cases, the inspector should exercise good judgment. The variety of circumstances that can be encountered can be illustrated by some specific examples:

(a) A dance in a school gymnasium, decorated by students with a profusion of paper banners, crepe paper streamers, figures made of pieces of tissue paper stuffed in chicken wire molds, hay and straw, painted fabrics, dry palm fronds, and similar products, all alleged to be flame resistant: In this situation, the inspector has neither reason nor excuse to be inhibited in taking samples for tests. The materials are inexpensive, are likely not intended to be reused, and taking samples for tests will cause little if any change to the decorative effect.

(b) A large assembly tent made of supposedly treated canvas but with no identifying marks and no confirming evidence of such treatment: The life hazard is acute, tent canvas can readily be patched, and, therefore, the situation warrents nothing less than sufficient samples from all sections of canvas for the inspector to be satisfied that the quality and uniformity of the treatment are acceptable.

(c) A nightclub with very expensive draperies known to be adequately flame-retardant treated when installed two years previously: The only way to be certain that the quality of flame resistance remains acceptable is to take a sample, but in the interest of maintaining good public relations, the inspector should be diplomatic and persuasive. Usually, a place can be found where a small but adequate sample can be extracted without causing any visible damage. Often this is the most the inspector can expect to get.

A-3-3

There can be complications of a technical nature. Decorative fabrics sometimes are installed overhead, in or near a horizontal position. Some plastic films or fabrics woven of thermoplastic synthetic fibers will successfully resist continued burning in the normal vertical position of test, but will exhibit continued burning if exposed in a horizontal position. Fabrics or films installed horizontally may be a serious threat to safety in a fire situation, and, therefore, the inspector is justified in testing the material in a horizontal position.

A somewhat similar problem can exist with some of the new and increasingly popular decorative fabrics with one or more types of fibers in the threads along the length (warp) and different fibers in the threads along the widths (fill). This can result in a different burning behavior in the two directions of the fabric to the extent that, where a flame-retardant treatment has been applied, tests for flame resistance in one direction may be acceptable, but the fabric could show continued burning in the other direction. Where visual examination of the fabric indicates this condition might exist, the inspector should test samples cut with the long dimension paralleling both the length and width of the fabric.

NFPA 750

1996 Edition

Standard on Water Mist Fire Protection Systems

1996 Edition

This edition of NFPA 750, *Standard on Water Mist Protection Systems,* was prepared by the

Technical Committee on Water Mist Fire Suppression Systems and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 20-23, 1996, in Boston, MA. It was issued by the Standards Council on July 18, 1996, with an effective date of August 9, 1996.

This edition of NFPA 750 was approved as an American National Standard on July 26, 1996.

Origin and Development of NFPA 750

In 1993, representatives from the research and engineering communities, water mist system manufacturers, the insurance industry, enforcement authorities, and industrial users met and organized the NFPA Technical Committee on Water Mist Fire Suppression Systems. The committee started work on developing a new NFPA document that would begin to standardize water mist technology and provide for reliable design and installation of these systems.

Water mist systems were introduced in the 1940s and were utilized for specific applications such as on passenger ferries. The renewed interest in water systems is due partially to the phasing out of Halon and their potential as a fire safety system for spaces where the amount of water that can be stored or that can be discharged is limited. In addition, their application and effectiveness for residential occupancies, flammable liquids storage facilities, and electrical equipment spaces continues to be investigated with encouraging results.

NFPA 750 will contain elements which are similar to other types of fire protection systems such as automatic sprinklers, fixed water spray, carbon dioxide, and Halon. In many ways, water mist can be thought of as a hybrid of these systems. Overall, water mist systems utilize water as the extinguishing, suppression, or control medium, but do so in a nontraditional manner. In developing this new standard, the committee addressed system components and hardware, system types, installation requirements, design objectives, hazard classifications, calculations, water supplies, atomizing media, plans, documentation, acceptance criteria, and maintenance considerations.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the design, installation, and maintenance of systems which use a water mist for the control, suppression, or extinguishment of fire.

NFPA 750
Standard on
Water Mist Fire Protection Systems

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 12 and Appendix C.

Chapter 1 General Information

1-1* Scope.

This standard contains the minimum requirements for the design, installation, maintenance, and testing of water mist fire protection systems. This standard does not provide definitive fire performance criteria nor does it offer specific guidance on how to design a system to control, suppress, or extinguish a fire. Reliance is placed on the procurement and installation of listed water mist equipment or systems which have demonstrated performance in fire tests as part of a listing process.

1-2 Purpose.

The purpose of this standard is to provide a reasonable degree of protection for life and property from fire through the standardization of design, installation, maintenance, and testing requirements for water-based fire suppression systems that use a specific spray (mist) that absorbs heat, displaces oxygen, or blocks radiant heat to control, suppress, or extinguish fires as required by the application. This standard endeavors to establish minimum requirements for water mist technology based on sound engineering principles, test data, and field experience. Nothing in this standard is intended to restrict new technologies or alternate arrangements, provided the level of safety prescribed by this standard is not lowered. Materials or devices not specifically designated by this standard shall be utilized in accordance with all conditions, requirements, and limitations of their listings.

NOTE 1: Water mist systems are specialized fire protection systems. Design and installation of these systems necessitates specialized training, knowledge, and experience.

NOTE 2: Water mist systems offer potential benefits for many specialized applications, particularly where available water supplies are limited or where the application of water needs to be restricted. Potential benefits also might exist for applications previously protected by gaseous and other fire suppressant agents.

1-3 Retroactivity Clause.

The provisions of this document are considered necessary to provide a reasonable level of protection from loss of life and property from fire. They reflect situations and the state of the art at the time the standard was issued.

Unless otherwise noted, it is not intended that the provisions of this document be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of this document.

Exception: In those cases where it is determined by the authority having jurisdiction that the existing situation involves a distinct hazard to life or property, this standard shall apply.

1-4 Definitions and Units.

1-4.1 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Atomizing Media. Compressed air or other gases that produce water mist by mechanical mixing with water.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Deluge System. A water mist system using open nozzles attached to a piping system which is connected to a water supply through a valve that is opened by means of a detection system installed in the same area as the mist nozzles. When the valve opens, water flows into the piping system and discharges through all nozzles attached to the system.

Dry Pipe System. A water mist system using automatic nozzles attached to a piping system containing air, nitrogen, or inert gas under pressure, the release of which (as from an opening of an automatic nozzle) allows the water pressure to open a dry pipe valve. The water then flows into the piping system and out through any open nozzles.

Dv_f. A drop diameter such that the cumulative volume, from zero diameter to this respective diameter, is the fraction, f, of the corresponding sum of the total distribution.

NOTE: $Dv_{0.50}$ is the volume median diameter; that is, 50 percent of the total volume of liquid is in drops of smaller diameter and 50 percent is in drops of larger diameter.

Enclosure. The case, housing, partition, or walls that will substantially contain water mist in the vicinity of the hazard for a sufficient length of time to achieve the fire protection objectives.

Engineered Systems. Those systems that need individual calculation and design to determine the flow rates, nozzle pressures, pipe size, area, or volume protected by each nozzle, discharge density of water mist, the number and types of nozzles, and the nozzle placement in a specific system.

Fire Control. The limitation of the growth of a fire by prewetting adjacent combustibles and controlling ceiling gas temperatures to prevent structural damage.

Fire Extinguishment. The complete suppression of a fire until there are no burning combustibles.

Fire Suppression. The sharp reduction of the rate of heat release of a fire and the prevention of regrowth.

High Pressure System. A water mist system where the distribution system piping is exposed to pressures of 500 psi (34.5 bars) or greater.

Intermediate Pressure System. A water mist system where the distribution system piping is exposed to pressures greater than 175 psi (12.1 bars) but less than 500 psi (34.5 bars).

Listed.* Equipment, materials, or services included in a list published by an organization acceptable to the authority having jurisdiction and concerned with evaluation of products or services that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services and whose listing states either that the equipment, material, or service meets identified standards or has been tested and found suitable for a specified purpose.

Local Application System. A water mist system arranged to discharge directly on an object or hazard in an enclosed, unenclosed, or open outdoor condition.

Low Pressure System. A water mist system where the distribution piping is exposed to pressures of 175 psi (12.1 bars) or less.

Preaction System. A water mist system using automatic nozzles attached to a piping system containing air that might or might not be under pressure, with a supplemental detection system installed in the same areas as the mist nozzles. The actuation of the detection system opens a valve that allows water to flow into the piping system and discharges through all opened nozzles in the system.

Pre-engineered Systems. Those systems having predetermined flow rates, nozzle pressures, and volumes and spray flux densities of water mist. These systems have the specific pipe size, maximum and minimum pipe lengths, flexible hose specifications, number of fittings, and number and types of nozzles prescribed by a testing laboratory. Systems are provided with either a self-contained or external water supply. Based on actual test fires, the hazards protected by these systems are specifically limited as to type and size by a testing laboratory. Limitations on hazards that are allowed to be protected by these systems are contained in the manufacturer's installation manual, which is referenced as part of the listing.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Single Fluid System. A water mist system utilizing a single piping system to supply each nozzle.

Standard. A document, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements, which is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions shall be located in an Appendix, footnote, or fine-print note and are not to be considered a part of the requirements of a standard.

Total Compartment Application System. A system designed to discharge water mist to protect all hazards in an enclosure.

Twin Fluid System. A water mist system in which water and atomizing media are separately supplied to and mixed at the water mist nozzle.

Valves.

Automatic (Activation) Valve. The valve controlling water flow into the mist system, including the alarm, dry pipe, deluge, zone, and group valves.

Control Valve. Any automatic or manually operated valve that controls the flow of water or air to any part of the system in the air or water supply. Control valves include gate and ball valves.

Ventilation-limited. An enclosure in which, under normal operating conditions, all doors, hatches, and service openings in the enclosure are closed and in which activation of the water mist system automatically stops the ventilation system supplying or exhausting air from the enclosure.

Water Mist.* A water spray for which the $Dv_{0.99}$, as measured at the coarsest part of the spray in a plane 3.3 ft (1 m) from the nozzle, at its minimum design operating pressure, is less than 1000 microns.

Water Mist Nozzle. A special purpose device containing one or more orifices designed to produce and deliver water mist.

Automatic Nozzles. Automatic nozzles shall operate independently of other nozzles by means of a detection/activation device built into the nozzle.

Nonautomatic Nozzles (Open). Nonautomatic nozzles shall operate as an entire system or grouping of nozzles. These nozzles contain open orifices and the water flow to the nozzles shall be activated by an independent detection system.

Hybrid Nozzles. A hybrid nozzle shall operate using a combination of the two methods described previously (automatic or nonautomatic means, or both). These nozzles contain a built-in detection/activation device that also can be activated by an independent detection system.

Water Mist System. A distribution system connected to a water supply or water and atomizing media supplies and equipped with one or more nozzles capable of delivering water mist intended to control, suppress, or extinguish fires and that has been demonstrated to meet the performance requirements of its listing and this standard.

Wet Pipe System. A water mist system using automatic nozzles attached to a piping system containing water and connected to a water supply so that water discharges immediately from nozzles operated by the heat from a fire.

Zoned Application System. A system designed to protect hazards in a predetermined portion of an enclosure.

1-4.2 Units.

1-4.2.1 Metric units of measurement in this standard are in accordance with the modernized metric system known as the International System of Units (SI). Liter and bar units are outside of but recognized by SI and are commonly used in international fire protection. These units are provided with their conversion factors in Table 1-4.2.2.

1-4.2.2 If a value for a measurement provided in this standard is followed by an equivalent value in other units, the first stated value shall be regarded as the requirement. A given equivalent value shall be considered an approximate value.

Table 1-4.2.2 Metric Conversion Factors

Name of Unit	Unit Symbol	Conversion Factor
Millimeter	mm	1 in. = 25.4 mm
Square meter	m^2	1 ft^2 = 0.0929 m^2
Liter	L	1 gal = 3.785 L
Cubic decimeter	dm^3	1 gal = 3.785 dm^3
Cubic meter	m^3	1 ft^3 = 0.028317 m^3

Kilogram	kg	1 lb = 0.4536 kg
Kilograms per cubic meter	kg/m^3	1 lb/ft^3 = 16.0183 kg/m^3
Pascal	Pa	1 psi = 6895 Pa
Bar	bar	1 psi = 0.0689 bars
Bar	bar	1 bar = 10^5 Pa
Liter per minute per square meter	$L/min/m^2$	1 gpm = 40.746 $L/min/m^2$
Micron	µ	1 mm = 1000µ (1000 microns)

NOTE 1: For additional conversions and information, see ASTM E 380, *Standard Practice for Use of the International System of Units (SI) (the Modernized Metric System).*

NOTE 2: In Canada, refer to CSA CAN3-A234.1, *Canadian Metric Practice Guide*.

NOTE 3: The abbreviation "gal" indicates the U.S. gallon measure.

1-5* General.

1-5.1

A water mist system is a fire protection system using very fine water sprays (i.e., water mist). The very small water droplets allow the water mist to control or extinguish fires by cooling of the flame and fire plume, oxygen displacement by water vapor, and radiant heat attenuation.

1-5.2 Use and Limitations.

1-5.2.1 Water mist systems are used for a wide range of performance objectives, including the following:

(a) Fire extinguishment;

(b) Fire suppression;

(c) Fire control;

(d) Temperature control; and

(e) Exposure protection.

1-5.2.2* Water mist systems shall not be used for direct application to materials that react with water to produce violent reactions or significant amounts of hazardous products. These materials include:

(a) Reactive metals, such as lithium, sodium, potassium, magnesium, titanium, zirconium, uranium and plutonium;

(b) Metal alkoxides, such as sodium methoxide;

(c) Metal amides, such as sodium amide;

(d) Carbides, such as calcium carbide;

(e) Halides, such as benzoyl chloride and aluminum chloride;

(f) Hydrides, such as lithium aluminum hydride;

(g) Oxyhalides, such as phosphorus oxybromide;

(h) Silanes, such as trichloromethylsilane;

(i) Sulfides, such as phosphorus pentasulfide; and

(j) Cyanates, such as methylisocyanate.

1-5.2.3 Water mist systems shall not be used for direct application to liquefied gases at cryogenic temperatures (such as liquefied natural gas), which boil violently when heated by water.

1-6 Safety.

1-6.1* Hazards to Personnel.

For fire situations, suitable safeguards shall be provided to ensure prompt evacuation of and to prevent entry into hazardous atmospheres and also to provide means for prompt rescue of any trapped personnel. Safety items such as personnel training, warning signs, discharge alarms, self-contained breathing apparatus, evacuation plans, and fire drills shall be considered.

1-6.2 Electrical Clearances.

NOTE: As used in this standard, "clearance" is the air distance between water mist system equipment, including piping and nozzles, and unenclosed or uninsulated live electrical components at other than ground potential. The minimum clearances provided are for the purpose of electrical clearance under normal conditions; they are not intended for use as "safe" distances during water mist system operation.

1-6.2.1* All system components shall be located to maintain minimum clearances from unenclosed and uninsulated energized electrical components in accordance with NFPA 70, *National Electrical Code*®.

1-6.2.2 Where the design basic insulation level (BIL) is not available and where nominal voltage is used for the design criteria, the highest minimum clearance specified for this group shall be used.

1-6.2.3 The selected clearance to ground shall satisfy the greater of the switching surges or BIL duty, rather than being based on nominal voltage.

1-6.2.4 The clearance between uninsulated energized parts of the electrical system equipment and any portion of the water mist system shall not be less than the minimum clearance provided elsewhere for electrical system insulation on any individual component.

1-7 Environmental Factors.

When selecting water mist to protect a hazard area, the effects of water runoff on the environment shall be considered. Particular attention shall be given to any water additives or any chemicals that can be carried out of the hazard area by the water.

Chapter 2 System Components and Hardware

2-1 General.

This chapter provides requirements for the correct use of water mist system components.

2-1.1

All components shall be listed for their intended use.

Exception No. 1: Where approval of system components is specifically permitted to be substituted for listing.

Exception No. 2: Where components are part of a listed, pre-engineered system.

2-1.2

System components shall be rated for the maximum working pressure to which they are exposed but not less than 175 psi (12.1 bar).

Exception: Where components are part of a listed, pre-engineered system with a self-contained water supply.

2-1.3 Corrosion Resistance.

Where components are subjected to severe corrosive atmospheres, corrosion protection such as special corrosion-resistive materials or coating shall be required.

2-2 Gas and Water Containers.

2-2.1 Capacity.

Gas and water containers, if provided, shall be sized to supply quantities of gas and water as required by Chapter 7.

2-2.2 Design.

2-2.2.1* Gas and water containers shall be designed for secure installation according to the manufacturer's installation manual, including provision for attachment of seismic restraint.

2-2.2.2* Gas and water containers shall be designed to meet the requirements of the U.S. Department of Transportation or of Transport Canada, if used as shipping containers. If not shipping containers, they shall be designed, fabricated, inspected, certified, and stamped in accordance with Section VIII of the ASME *Boiler and Pressure Vessel Code*. The design pressure shall be suitable for the maximum pressure developed by the water mist system at 130°F (54°C).

2-2.2.3 Each pressurized container shall be provided with a safety device to release excess pressure.

2-2.2.4 Each water container shall have a permanent nameplate or other permanent marking specifying the liquid held in the container (including additives) and the nominal water volume and pressurization level (where applicable) of the container.

Exception: Marking shall not be required on each water container if the information is provided on a nameplate or placard permanently installed on the system at a location convenient for servicing or content measuring.

2-2.2.5 External sight glasses on water containers shall be protected against mechanical damage.

2-2.2.6 Each gas container shall have a permanent nameplate or other permanent marking specifying the type of gas, weight of gas, weight of container, nominal gas volume, and pressurization level of the container.

Exception: Marking shall not be required on each gas container if the information is provided *on a nameplate or placard permanently installed on the system at a location convenient for servicing or content measuring.*

2-2.2.7 A reliable means shall be provided to indicate the pressure in refillable, pressurized gas containers.

2-2.3 Multiple Container Systems.

All containers supplying the same manifold outlet shall be interchangeable and of the same size and charge.

2-3 Piping and Tube.

2-3.1*

All piping from the system strainer to the nozzle shall have corrosion resistance at least equivalent to piping specified in Table 2-3.3.1. Wherever the word "pipe" is used, it shall be understood also to mean "tube."

2-3.2

Other types of pipe or tube investigated for suitability in water mist system installations and listed for this service shall be permitted where installed in accordance with their listing limitations, including installation instructions. Bending of the pipe shall be permitted as provided by the listing. Pipe or tube shall not be listed for portions of an occupancy classification.

2-3.3 Low Pressure Systems.

2-3.3.1 Pipe or tube used in low pressure water mist systems shall meet or exceed one of the standards in Table 2-3.3.1 or shall be in accordance with 2-3.2. The chemical properties, physical properties, and dimensions of the materials given in Table 2-3.3.1 shall conform at a minimum to the standards cited in the table. Pipe and tube used in water mist systems shall be designed to withstand a working pressure of not less than 175 psi (12.1 bar).

Table 2-3.3.1 Pipe or Tube Standards

Materials and Dimensions	Standard
Copper Tube (Drawn, Seamless)	
Standard Specification for Solder Metal [95-5 (Tin-Antimony-Grade 95TA)]	ASTM B 32
Standard Specification for Seamless Copper Tube[1]	ASTM B 75
Standard Specification for Seamless Copper Water Tube[1]	

	ASTM B 88
Standard Specification for General Requirements for Wrought Seamless Copper and Copper-Alloy Tube	ASTM B 251
Standard Specification for Liquid and Paste Fluxes for Soldering Applications of Copper and Copper-Alloy Tube	ASTM B 813
Specification for Filler Metals for Brazing and Braze Welding (Classification BCuP-3 or BCuP-4)	AWS A5.8
Stainless Steel	
Standard Specification for Seamless and Welded Austenitic Stainless Steel Tubing for General Service	ASTM A 269
Standard Specification for Seamless and Welded Austenitic Stainless Steel Tubing (Small-Diameter) for General Service	ASTM A 632
Standard Specification for Welded, Unannealed Austenitic Stainless Steel Tubular Products	ASTM A 778
Standard Specification for Seamless and Welded Ferritic/ Austenitic Stainless Steel Tubing for General Service	ASTM A 789/A 789M

[1]Denotes pipe or tube suitable for bending (*see 2-3.6*) according to ASTM standards.

2-3.3.2 Copper tube as specified in the standards referenced in Table 2-3.3.1 shall have a wall thickness of Type K, L, or M where used in water mist systems.

2-3.4 Intermediate and High Pressure Systems.

2-3.4.1 Pipe or tube shall be of noncombustible material having physical and chemical characteristics such that its deterioration under stress can be predicted with reliability. The piping shall be in accordance with ANSI B31.1, *Power Piping Code*. The internal pressure used for calculation of pipe wall thickness shall be the maximum operating pressure of the water mist systems at a pipe temperature of 130°F (54°C).

2-3.4.2* Flexible piping, tubing, or hoses (including connections) shall be listed for their intended use.

2-3.5 Pipe or Tube Identification.

2-3.5.1 All pipe or tube, including specially listed pipe or tube, shall be marked continuously along its length by the manufacturer in such a way as to identify the type of pipe or tube properly. This identification shall include the manufacturer's name, model designation, or schedule.

2-3.5.2 Pipe or tube marking shall not be painted, concealed, or removed prior to approval by the authority having jurisdiction.

2-3.6 Pipe or Tube Bending.

Bending of Type K and Type L copper tube shall be permitted where bends are made with no kinks, ripples, distortions, reductions in diameter, or any noticeable deviations from a round shape. The minimum radius of a bend shall be six pipe diameters for pipe sizes of 2 in. (51 mm) and smaller and five pipe diameters for pipe sizes larger than 2 in. (51 mm).

2-4 Fittings.

2-4.1* General.

All fittings used on piping described in 2-3.1 shall have a corrosion resistance at least equivalent to wrought copper fittings conforming to ANSI B16.22, *Wrought Copper and Copper Alloy Solder Joint Pressure Fittings*.

2-4.2 Low Pressure Systems.

2-4.2.1 Fittings used in water mist systems shall meet or exceed the standards in Table 2-4.2.1 or shall be in accordance with 2-4.2.2.

Table 2-4.2.1 Fitting Standards

Materials and Dimensions	Standard
Copper	
Cast Copper Alloy Solder Joint Pressure Fittings	ANSI B16.18
Wrought Copper and Copper Alloy Solder Joint Pressure Fittings	ANSI B16.22
Stainless Steel	
Standard Specification for Castings, Austenitic, Austenitic-Ferritic (Duplex) for Pressure-Containing Parts	ASTM A 351/A 351M
Standard Specification for Wrought Austenitic Stainless Steel Piping Fittings	ASTM A 403/A 403M
Standard Specification for As-Welded Wrought Austenitic Stainless Steel Fittings for General Corrosive Service at Low and Moderate Temperatures	ASTM A 774/A 774M
Standard Specification for Wrought Ferritic, Ferritic/Austenitic, and Martensitic Stainless Steel Piping Fittings	ASTM A 815/A 815M

2-4.2.2* Other types of fittings investigated for suitability in water mist installations and listed for this service shall be permitted where installed in accordance with their listing limitations, including installation instructions.

2-4.2.3 Screwed unions shall not be used on pipe larger than 2 in. (51 mm). Couplings and unions of other than the screwed type shall be listed for the intended use.

2-4.2.4 A one-piece reducing fitting shall be used wherever a change is made in the size of pipe.

Exception: Hexagonal or face bushings shall be permitted in reducing the size of openings of fittings where standard fittings of the required size are not available.

2-4.2.5 All threads used in joints and fittings shall conform to ANSI B1.20.1, *Pipe Threads, General Purpose (Inch)*. Joint compound, tape, or thread lubricant shall be applied only to the male threads of the joint.

2-4.2.6 Soldering fluxes shall be in accordance with Table 2-3.3.1. Brazing fluxes, if used, shall not be of a highly corrosive type.

2-4.2.7 Welding shall be performed in accordance with AWS D10.9, *Specification for Qualification of Welding Procedures and Welders for Piping and Tubing*, Level AR-3.

2-4.3 Intermediate and High Pressure Systems.

2-4.3.1 Fittings shall have a minimum-rated working pressure equal to or greater than the maximum operating pressure of the water mist systems at 130°F (54°C). For systems that employ the use of a pressure regulating device in the distribution piping, the fittings downstream of the device shall have a minimum-rated working pressure equal to or greater than the maximum anticipated pressure in the downstream piping.

2-4.3.2 All threads used in joints and fittings shall conform to ANSI B1.20.1, *Pipe Threads, General Purpose (Inch)*. Joint compound, tape, or thread lubricant shall be applied only to the male threads of the joint.

2-4.3.3 Welding and brazing alloys shall have a melting point above 1000°F (538°C).

2-4.3.4 Welding and brazing shall be performed in accordance with Section IX of the ASME *Boiler and Pressure Vessel Code*.

2-4.3.5 Where copper, stainless steel, or other suitable tubing is joined with compression-type fittings, the manufacturer's pressure temperature ratings for the fitting shall not be exceeded.

2-5 Hangers.

2-5.1

Hangers shall be listed for use with the pipe or tube involved.

Exception: Hangers certified by a registered professional engineer to include the following shall be permitted where:

(a) Hangers are designed to support five times the weight of the pipe or tube when filled with gas or water, as appropriate, plus 250 lb (114 kg) at each point of piping support;

(b) These points of support are adequate to support the water mist system; and

(c) Hanger components are ferrous.

Detailed calculations shall be submitted, where required by the authority having jurisdiction, showing the stresses developed both in the hangers and the piping and the safety factors provided.

2-5.2

Hanger components shall be ferrous.

Exception: Nonferrous components that have been proven by fire tests to be adequate for the hazard application, that are listed for this purpose, and that are in compliance with the other requirements of this section shall be permitted.

2-5.3

The components of hanger assemblies that attach directly to the pipe or to the building structure shall be listed. Threaded portions of hangers shall not be bent.

Exception: Mild steel rods that connect pipe and building attachment components shall be permitted to be of an approved type.

2-5.4

The use of listed inserts set in concrete to support hangers shall be permitted.

2-5.5

Power-driven fasteners shall not be used to attach hangers to the building structure where systems are required to be protected against earthquakes.

Exception: Power-driven fasteners shall be permitted where they are specifically listed for service in seismic areas.

2-6 Nozzles.

2-6.1*

Nozzles shall be listed either individually or as a part of a pre-engineered system. Listing information shall include:

(a) Specific hazards and protection objectives;

(b) Volumetric flow rate characteristics of water discharge for each nozzle;

(c) Maximum height of protected space;

(d) Minimum distance between nozzle tip or diffuser, as applicable, and plane of protection;

(e) Maximum spacing between nozzles;

(f) Maximum coverage area per nozzle;

(g) Minimum spacing between nozzles;

(h) Maximum height between ceiling and nozzle diffuser or tip, as applicable;

(i) Nozzle obstruction spacing criteria;

(j) Maximum spacing of nozzles from walls;

(k) Minimum- and maximum-rated operating pressures of nozzles;

(l) Allowable range of nozzle orientation angle from vertically down;

(m) Classification of automatic nozzle thermal response characteristics as fast, special, or standard response;

(n) Maximum compartment volume, if applicable; and

(o) The maximum time delay for water mist delivery to the most remote nozzle.

2-6.2

Only new nozzles shall be installed in water mist systems.

2-6.3

Nozzles shall be permanently marked to identify the manufacturer, type, and size of the orifice(s) or part number.

2-6.4

Additional corrosion protection, such as special corrosion-resistant materials or coatings, shall be required in severely corrosive atmospheres. Where protective coatings are used to meet the requirements of 2-1.3, the coatings shall be applied by the nozzle manufacturer and the coated nozzle shall be listed.

2-6.5

Where clogging by external, foreign materials is likely, discharge nozzles shall be provided with frangible discs, blow-off caps, or other suitable devices. These devices shall provide an unobstructed opening upon system operation and shall be located so they cannot injure personnel.

2-6.6

The standard temperature ratings of individual, thermally activated nozzles are shown in Table 2-6.6. Individual, thermally activated nozzles shall be colored in accordance with the color code designated in Table 2-6.6.

Table 2-6.6 Temperature Ratings, Classifications, and Color Coding of Individual, Thermally Activated Nozzles

Maximum Ambient Temperature		Nozzle Temperature Rating		Temperature	Color	Glass Bulb
(°F)	(°C)	(°F)	(°C)	Classification	Code	Colors
100	38	135 to 170	57 to 77	Ordinary	Uncolored or black	Orange or red
150	66	175 to 225	79 to 107	Intermediate	White	Yellow or green
225	107	250 to 300	121 to 149	High	Blue	Blue
300	149	325 to 375	163 to 191	Extra high	Red	Purple
375	191	400 to 475	204 to 246	Very extra high	Green	Black
475	246	500 to 575	260 to 302	Ultra high	Orange	Black
625	329	650	343	Ultra high	Orange	Black

2-6.7

The stock of spare, individual, thermally activated nozzles shall include all types and ratings installed and shall be as follows:

(a) For systems having fewer than 50 nozzles, not fewer than 3 nozzles;

(b) For systems having 50 to 300 nozzles, not fewer than 6 nozzles;

(c) For systems having 301 to 1000 nozzles, not fewer than 12 nozzles; and

(d) For systems having over 1000 nozzles, not fewer than 24 nozzles.

2-7 Valves.

2-7.1

All valves shall be listed for their intended use.

Exception: Valves used only for drains or test connections shall be permitted to be approved.

2-7.2

All gaskets, O-rings, sealants, and other valve components shall be constructed of materials that are compatible with the gas or water and any additives contained in the water.

2-7.3 Identification of Valves.

All control, drain, and test connection valves shall be provided with permanently marked, weatherproof, metal or rigid plastic identification signs. The sign shall be secured with corrosion-resistant wire, chain or other approved means.

2-8 Strainers and Filters.

2-8.1

Pipeline strainers and filters shall be listed for use in water supply connections.

2-8.2

The strainer or filter shall be capable of continued operation without serious increase in head loss for a period that is estimated to be ample, taking into account the type of protection provided, the condition of the water, and similar local circumstances.

2-8.3

Pipeline strainer and filter designs shall incorporate a flush-out connection.

2-8.4

Pipeline strainers and filters shall be sized in accordance with 7-5.1.2 and 7-5.1.4.

2-8.5

Individual strainers or filters for water mist nozzles, where required by the manufacturer, shall be listed as a part of a nozzle.

2-8.6

A stock of spare pipeline and individual nozzle strainers and filters for water mist nozzles shall be provided and shall include all types and sizes installed. Sufficient spare strainers and filters shall be provided to service the nozzles for the largest single hazard or group of hazards to be protected simultaneously.

2-9 Pumps.

2-9.1 Materials.

2-9.1.1 Pumps shall be designed with capacities in accordance with 7-5.2.

2-9.1.2 Pumps capable of overpressurizing the system shall be provided with adequate means of pressure relief from the discharge to the supply side of the pump to prevent excessive pressure and temperature. Overpressure shall not exceed the working pressure of the piping system.

2-9.1.3 Pumps shall start automatically upon system actuation.

2-9.1.4 Provisions shall be made for automatic shutoff of the pump after the water supply is exhausted.

2-9.1.5 Pumps shall not take suction under a static lift condition.

2-9.2 Power Supply.

2-9.2.1 The power supply for pump drivers shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and NFPA 70, *National Electrical Code*.

Exception: Power supplies shall not be required to be fed by an independent service feed.

2-9.2.2 Power supplies shall be arranged so that disconnecting power to the protected facility during a fire shall not disconnect the power supply to the pump feeder circuit.

2-9.3 Controllers.

2-9.3.1 Controllers for pumps shall be listed as follows:

(a) Electric drive pumps greater than 30 horsepower, use listed fire pump controller;

(b) Electric drive pumps greater than 15 horsepower but not exceeding 30 horsepower, use listed fire pump controller or use listed limited service controller;

(c) Electric drive pumps less than 15 horsepower, use listed limited service controller; and

(d) Diesel engine drive pumps, use listed fire pump controller.

2-9.3.2 A service-disconnecting means in the feeder circuit to limited service controllers shall be permitted where acceptable to the authority having jurisdiction, provided the disconnecting means is supervised for the proper position. Supervision for proper position shall be by one of the following methods:

(a) Central station, proprietary, or remote station signaling electrical supervision service; or

(b) Local electrical supervision through use of a signaling service that causes the sounding of an audible signal at a constantly attended location; or

(c) Locking of the disconnecting means in the proper position, with monthly recorded inspections.

2-10 Detection, Actuation, Alarm, and Control Systems.

2-10.1 General.

2-10.1.1 Detection, actuation, alarm, and control systems shall be installed, tested, and maintained in accordance with appropriate, protective, signaling systems standards as follows:

NFPA 70, *National Electrical Code*;

NFPA 72, *National Fire Alarm Code*;

CAN/ULC S524-M86, *Standard for the Installation of Fire Alarm Systems (in Canada)*; and

CAN/ULC S529-M87, *Smoke Detectors for Fire Alarm Systems (in Canada)*.

2-10.1.2 Where a detection system is used to actuate the water mist system, detection and actuation shall be automatic.

Exception: Manual-only actuation shall be permitted if approved by the authority having jurisdiction.

2-10.2 Automatic Detection.

2-10.2.1* Automatic detection shall be by listed equipment installed in accordance with NFPA 72, *National Fire Alarm Code*.

2-10.2.2 Adequate and reliable primary and 24-hour minimum standby sources of energy shall be used to provide for operation of the detection, signaling, control, and actuation requirements of the systems.

2-10.2.3 If an existing detection system is used in a new water mist system, the detection system shall comply with the requirements of this standard.

2-10.3 Operating Devices.

2-10.3.1 Operating devices shall include water mist releasing devices or valves, discharge controls, and shutdown equipment necessary for successful performance of the system.

2-10.3.2 Operation shall be by listed mechanical, electrical, or pneumatic equipment. An adequate and reliable source of energy shall be used.

2-10.3.3 Devices shall be designed for the service they are to encounter and shall not readily be rendered inoperative or susceptible to accidental operation. Devices shall be designed to function properly from –20°F to 130°F (–29°C to 54°C) or shall be marked to indicate temperature limitations.

2-10.3.4 An emergency release of the system that can be achieved by a single manual operation shall be provided. This shall be accomplished by a mechanical manual release or by an electrical, manual release when the control equipment that monitors the battery voltage level of the standby battery supply indicates a low battery signal. The release shall cause simultaneous operation of automatically operated valves that control agent release and distribution. The battery shall be sized to accomplish all functions.

Exception: Dry and wet pipe systems utilizing individual, thermally activated nozzles.

2-10.3.5 The normal manual control(s) for actuation shall be located for easy accessibility at all times, including at the time of a fire. The manual control(s) shall be of distinct appearance and clearly recognizable for the purpose intended. Operation of any manual control shall cause the complete system to operate in its normal fashion.

2-10.3.6 Manual controls shall not require a force of more than 40 lbf (178 N) nor a movement of more than 14 in. (356 mm) to secure operation. At least one manual control for activation shall be located not more that 4 ft (1.2 m) above the floor.

2-10.3.7 All devices for shutting down supplementary equipment shall be considered integral parts of the system and shall function with the system in operation.

2-10.3.8 All manual devices shall be identified as to the hazard they protect.

2-10.4 Control Equipment.

2-10.4.1 Electrical Control Equipment. Automatic control equipment shall be listed and installed in accordance with NFPA 72, *National Fire Alarm Code*.

2-10.4.2 The control unit shall be listed for release device service.

2-10.4.3 Pneumatic Control Equipment.

2-10.4.3.1 Pneumatic control lines shall be protected against crimping and mechanical damage. Where installations could be exposed to conditions that could lead to loss of integrity of the pneumatic lines, special precautions shall be taken to ensure that no loss of integrity occurs. Pneumatic control lines used as part of the system actuation shall be supervised.

Exception No. 1: Pneumatically operated control lines immediately adjacent to the pressurizing source are not required to be supervised.

Exception No. 2: Pneumatic control lines from master to slave cylinders which are located in close proximity to one another are not required to be supervised.

2-10.4.3.2 The control equipment shall be specifically listed for the number and type of actuating devices utilized, and their compatibility shall have been listed.

2-11 Unwanted System Operation.

Care shall be taken to thoroughly evaluate and correct any factors that could result in unwanted system discharge.

2-12 Compatibility.

All components of pneumatic, hydraulic, or electrical systems shall be compatible.

Chapter 3 System Requirements

3-1 General.

Water mist systems shall be described by the following four parameters:

(a) System application;

(b) Nozzle type;

(c) System operation method; and

(d) System media type.

3-2 System Applications.

System applications shall consist of the following three categories:

(a) Local application systems;

(b) Total compartment application systems; or

(c) Zoned application systems.

3-2.1 Local Application Systems.

Local application systems are designed and installed to provide complete distribution of mist around the hazard or object to be protected.

3-2.1.1 Local application systems shall be designed to protect an object or a hazard in an enclosed, unenclosed, or open outdoor condition.

3-2.1.2 Local application systems shall be actuated by automatic nozzles or by an independent detection system.

3-2.2 Total Compartment Application Systems.

Total compartment application systems are designed and installed to provide complete protection of an enclosure or space.

3-2.2.1* The complete protection of an enclosure or space shall be achieved by the simultaneous operation of all nozzles in the space by manual or automatic means.

3-2.3 Zoned Application Systems.

Zoned application systems are a subset of the compartment system and are designed to protect a predetermined portion of the compartment by the activation of a selected group of nozzles.

3-2.3.1 Zoned application systems shall be designed and installed to provide complete mist distribution throughout a predetermined portion of an enclosure or space. This shall be achieved by simultaneous operation of a selected group of nozzles in a predetermined portion of the space by manual or automatic means.

3-2.3.2 Zoned application systems shall be actuated by automatic nozzles or by an independent detection system.

3-3 Nozzle Types.

Water mist nozzles shall be classified as one of the following three types:

(a) Automatic;

(b) Nonautomatic; and

(c) Hybrid.

3-4 System Operation Methods.

Water mist systems shall operate by means of one of the following methods:

(a) Deluge;

(b) Wet pipe;

(c) Preaction; and

(d) Dry pipe.

3-4.1 Deluge Systems.

Deluge systems shall employ nonautomatic nozzles (open) attached to a piping network connected to the fluid supply(ies) through a valve controlled by an independent detection system installed in the same area as the mist nozzles. When the valve(s) is activated, the fluid shall flow into the piping network and discharge from all nozzles attached thereto.

3-4.2 Wet Pipe Systems.

Wet pipe systems shall employ automatic nozzles attached to a piping network pressurized with water up to the nozzles.

3-4.3 Preaction Systems.

Preaction systems shall employ automatic nozzles attached to a piping network containing a pressurized gas with a supplemental, independent detection system installed in the same area as the nozzles. Operation of the detection system shall actuate a tripping device that opens the valve, pressurizing the pipe network with water to the nozzles.

3-4.4 Dry Pipe Systems.

Dry pipe systems shall employ automatic nozzles attached to a piping network containing a pressurized gas. The loss of pressure in the piping network shall activate a control valve, which causes water to flow into the piping network and out through the activated nozzles.

3-5* Media System Types.

Water mist systems shall be classified by two media system types:

(a) Single fluid; or

(b) Twin fluid.

3-5.1

Twin fluid media systems produce water mist (droplet production) by exposing a slow-moving liquid to a higher velocity atomizing fluid stream. The process shall occur in or near the discharge nozzle.

Chapter 4 Installation Requirements

4-1 General.

This chapter provides requirements for the correct installation of water mist system components.

4-1.1

All listed materials and devices shall be installed in accordance with their listing. All other materials and devices shall be installed in accordance with the system design manual. Systems installed in corrosive environments shall comply with 2-1.3.

4-1.2

System components shall be located, installed, or suitably protected so they are not subject to mechanical, chemical, or other damage that could render them inoperative.

4-2 Nozzles.

4-2.1 General.

Nozzles shall be installed in accordance with the manufacturer's listing.

4-2.2 Nozzle Height Limitations.

The minimum and maximum heights shall be in accordance with the manufacturer's listing.

4-2.3 Nozzle Spacing Limitations.

The minimum and maximum distances between nozzles shall be in accordance with the manufacturer's listing.

4-2.4 Distance from Walls.

The minimum and maximum distance from nozzles to walls or partitions shall be in accordance with the manufacturer's listing.

4-2.5 Obstructions to Nozzle Discharge.

The location of nozzles with respect to obstructions shall be in accordance with the manufacturer's listing.

4-2.6 Distance Below Ceilings.

The distance between the nozzle and the ceiling shall be in accordance with the range (minimum and maximum) identified in the manufacturer's listing.

4-2.7 Spacing under Pitched or Curved Surfaces.

The distance between nozzles in or under a pitched or curved surface shall be in accordance with the manufacturer's listing.

4-2.8 Nozzle Protection.

Nozzles subject to mechanical damage shall be protected with listed guards. Guards shall not significantly reduce the effectiveness of the nozzle.

4-2.9 Escutcheon Plates.

4-2.9.1 Escutcheon plates used in a recessed or flush-type nozzle installation shall be a part of a listed nozzle assembly.

4-2.9.2 Nonmetallic escutcheon plates shall be listed.

4-2.10 Thermally Activated Nozzle Temperature Ratings.

4-2.10.1 Ordinary temperature-rated nozzles shall be used unless otherwise specified.

4-2.10.2 The following practices shall be observed where providing automatic nozzles of other than ordinary temperature classification unless other temperatures are determined or unless high temperature nozzles are used throughout.

(a) Automatic and hybrid nozzles installed in a heater zone shall be of the high temperature classification, and nozzles in the danger zone shall be of the intermediate temperature classification.

(b) Automatic and hybrid nozzles located within 12 in. (305 mm) to one side of or 30 in. (762 mm) above an uncovered steam main, heating coil, or radiator shall be of the intermediate temperature classification.

(c) Automatic and hybrid nozzles within 7 ft (2.1 m) of a low pressure blow-off valve that discharges freely in a larger room shall be of the high temperature classification.

(d) Automatic and hybrid nozzles installed under glass or plastic skylights exposed to the direct rays of the sun shall be of the intermediate temperature classification.

(e) Automatic and hybrid nozzles installed in an unventilated, concealed space, under an insulated roof, or in an unventilated attic shall be of the intermediate temperature classification.

(f) Automatic and hybrid nozzles installed in unventilated areas having high-powered electric lights near the ceiling shall be of the intermediate temperature classification.

(g) Automatic and hybrid nozzles protecting commercial-type cooking equipment and ventilation systems shall be of the high or extra-high temperature classification as determined by use of a temperature measuring device.

4-3 Pipe and Tubing.

4-3.1

Piping and tubing for water mist systems shall be installed in accordance with the manufacturer's installation manual.

4-3.1.1 All water and atomizing media piping and tubing for water mist systems shall be installed in accordance with ANSI B31.1, *Power Piping Code*.

Exception No. 1: Piping in low pressure systems installed in accordance with NFPA 13, Standard for the Installation of Sprinkler Systems. This exception does not apply to piping conveying atomizing media.

Exception No. 2: Piping installed in accordance with a water mist system listing where the listing provides installation criteria different from ANSI B31.1, Power Piping Code.

4-3.1.2 All system piping, tubing, and hoses shall be rated for the maximum working pressure to which they are exposed.

4-3.1.3 Any flexible piping, tubing, hoses, or combination thereof shall be constructed and installed in accordance with the manufacturer's listing.

4-3.2

The system piping shall be supported by structural elements that are independent of the ceiling sheathing to prevent lateral and horizontal movement upon system actuation.

4-3.3

All system piping and fittings shall be installed so that the entire system can be drained.

4-3.4 Location of Hangers and Supports.

Hangers and supports shall be located in accordance with the system's design manual.

Exception: For low pressure and intermediate systems, steel pipe and copper tubing shall be supported in accordance with NFPA 13, Standard for the Installation of Sprinkler Systems.

4-3.4.1 The length of an unsupported arm over to a nozzle shall not exceed 2 ft (0.6 m) for steel pipe or 1 ft (0.3 m) for steel tubing.

4-3.5 Protection of System Components against Damage where Subject to Earthquakes.

Water mist systems shall be protected to prevent pipe breakage where subject to earthquakes in accordance with 4-14.4.3 of NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-4 Fittings.

4-4.1

All system fittings shall be installed in accordance with the manufacturer's listing.

Exception: All fittings installed in low pressure water mist systems shall conform to NFPA 13, Standard for the Installation of Sprinkler Systems.

4-4.2

All fittings shall be rated for the maximum working pressure to which they are exposed.

4-5 Gas and Water Storage Containers.

4-5.1

Storage containers shall be installed, mounted, and braced in accordance with the manufacturer's listing.

4-5.2

Storage containers and accessories shall be installed so that inspection, testing, recharging, and other maintenance are facilitated and interruption to protection is held to a minimum.

4-5.3*

Storage containers shall be located as close as possible to the hazard or within the hazards they protect, and shall not be exposed to fire or mechanical damage in a manner to affect performance.

4-5.4

Storage containers shall be protected from severe weather conditions and from mechanical, chemical, or other damage.

4-5.4.1 Where excessive climatic or mechanical exposures are expected, guards or enclosures shall be provided.

4-5.5 High Pressure Storage Containers.

4-5.5.1 High pressure containers or cylinders shall be constructed, tested, and marked in accordance with recognized, international standards, such as the U.S. Department of Transportation, Title 49, *Code of Federal Regulations*, Parts 171 to 190, Sections 178.36 and 178.37, specifications (in effect upon date of manufacture and test) for DOT-3A, 3AA-1800, or higher, seamless steel cylinders. Charged cylinders shall be tested for tightness before shipment in accordance with an approved procedure.

4-5.5.2 Where manifolded, cylinders shall be adequately mounted and suitably supported in a rack provided for this purpose, including facilities for convenient, individual servicing or weighing of contents. When any cylinder is removed for maintenance, automatic means shall be provided to prevent leakage from the manifold if the system is operated.

4-5.5.3 Storage temperatures shall be maintained within the range specified in the manufacturer's listing. External heating or cooling shall be an acceptable method to keep the temperature of the storage container within desired ranges.

4-5.5.4 Containers shall be secured with manufacturer listed supports to prevent container movement and possible physical damage.

4-5.6 Low Pressure Storage Cylinders.

4-5.6.1 The pressure container shall be made, tested, approved, equipped, and marked in accordance with recognized, international standards, such as the current specifications of the ASME *Boiler and Pressure Vessel Code*, Section VIII, or the requirements of U.S. Department of Transportation, Title 49, *Code of Federal Regulations*, Parts 171 to 190, Sections 178.36 and 178.37, or both. The design working pressure shall be in accordance with the manufacturer's listing.

Exception: Pressure containers for heated water mist systems shall be in accordance with the manufacturer's listing.

4-5.6.2 Each pressure container shall be equipped with a liquid level gauge, a pressure gauge, and a high/low pressure supervisory alarm set at the values identified in the manufacturer's listing.

Exception: Media storage containers that become pressurized only during system activation shall not require high/low pressure supervisory alarms.

4-5.7

Storage temperatures shall be maintained within the range specified in the manufacturer's listing. External heating or cooling shall be an acceptable method to keep the temperature of the storage container within desired ranges.

4-5.7.1 Containers shall be secured with manufacturer-listed supports to prevent container movement and possible physical damage.

4-6 Pumps and Pump Controllers.

4-6.1*

Pumps shall be sized to provide 120 percent of the required system water flow rate, at the minimum system operating pressure, as determined by hydraulic calculations.

4-6.2

Pumps shall start automatically and shall supply water to the water mist system until manually shut off or automatically shut off in accordance with the manufacturer's listing.

4-6.3

Power supplies for system pumps shall meet the requirements specified in NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, or shall be in accordance with the manufacturer's listing.

4-6.4

Pumps shall be provided with supervisory service from a listed central station, proprietary, or remote station system or equivalent.

Exception: Pumps for single family dwellings.

4-7 Strainers and Filters.

4-7.1

Strainers and filters shall be provided at all water supply connections in accordance with Chapter 7. Filters and strainers shall be installed to minimize potential head loss due to accumulation of particulates.

4-8 Valves and Pressure Gauges.

4-8.1 General.

4-8.1.1 All valves shall be installed in accordance with the manufacturer's listing.

4-8.1.2 Valves having components that extend beyond the valve body shall be installed in a manner that does not interfere with the operation of any system components.

4-8.1.3 All valves shall be listed for their particular application and installation.

4-8.1.4 All control, drain, and test connection valves shall be provided with permanently marked, weatherproof, metal or rigid plastic identification signs. The sign shall be secured by corrosion-resistant wire or chain or by other approved means.

4-8.1.5 System valves and gauges shall be installed such that they are accessible for operation, inspection, and maintenance.

4-8.1.6 At least one listed indicating valve shall be installed in each source of water supply.

Exception: Systems with a single water supply source composed of a self-contained system (cylinders, containers).

4-8.1.7 Valves on connections to water supplies, sectional control valves, and other valves in supply pipes to nozzles shall be locked open or equipped with tamper-monitoring devices.

Exception: Normally closed, automatic water control valves.*

4-8.2 Control/Activation Valves.

4-8.2.1 Control/activation valves shall include any device or valve that automatically opens to supply water to the nozzles after the detection of a fire.

4-8.2.2 Control/activation valves shall operate by a listed mechanical, electrical, or pneumatic means. An adequate and reliable source of energy shall be used.

4-8.2.3 Control/activation valves shall be installed such that they are not subject to mechanical, chemical, or other damage that would render them inoperative.

4-8.3 Pressure Regulating and Pressure Relief Valves.

4-8.3.1 Water Pressure Regulating Valves.

4-8.3.1.1 Pressure regulating valves shall be installed in any portion of the system where the potential exists for the system pressure to exceed the maximum-rated working pressure of the system or system components, or both. These valves shall open when the system pressure reaches 95 percent of the system-rated pressure.

4-8.3.1.2 A relief valve of not less than $^1/_2$ in. (13 mm) shall be provided on the discharge side of the pressure regulating valve that is set to operate at a pressure not exceeding the system-rated pressure.

4-8.3.1.3 A listed indicating valve shall be provided on the inlet side of each pressure reducing valve.

Exception: A listed indicating valve shall not be required where the pressure regulating valve meets the listing requirements for use as an indicating valve.

4-8.3.1.4 A water flow test valve that is sized to produce the designed flow of the pressure reducing valve shall be installed on the downstream side of the pressure reducing valve.

4-8.3.1.5 A sign indicating the correct discharge pressure for static and residual pressures shall be attached to the pressure reducing valve.

4-8.3.2 Compressed Gas Pressure Regulating Valves (PRVs).

4-8.3.2.1 PRVs shall be installed in accordance with the manufacturer's listing.

4-8.3.2.2 PRVs shall be installed when the supply pressure is higher than the design operating pressure of the water mist system.

4-8.3.2.3 PRVs shall be capable of providing a stable regulating output at the rated flow capacity and design set point over the full range of input pressures that will be experienced over the course of the discharge period.

4-8.3.2.4 Downstream pressure drift under no-flow conditions shall not exceed the lesser of the downstream components pressure rating or the pressure relief valve set point, if provided.

4-8.3.2.5 Pressure set, point-adjusting mechanisms on the PRVs shall be tamper resistant, and the adjustment shall be indicated by a permanent marking. A means to indicate evidence of tampering shall be provided.

4-8.3.2.6 The PRVs set point shall be set by the manufacturer.

4-8.3.2.7 Permanent markings shall indicate the inlet and outlet connections of the PRVs.

4-8.4 Check Valves and Backflow Preventers.

4-8.4.1 Check valves shall be installed in accordance with the manufacturer's listing.

4-8.4.2 A check valve shall be installed between the system and the point of permanent connection to a potable water supply.

Exception: Where additives are used in the water mist system, either by injection into flowing lines or by premixing into stored water sources, a backflow preventer shall be installed between the system control valve or stored water supply and a permanent connection to a potable water supply.

4-8.4.3 Check valves shall be installed in the main feed lines, near the control valves of both the water and pneumatic system piping of a twin fluid system, to prevent the backflow of water or atomizing fluid into the companion piping.

4-8.5 Pressure Gauges.

4-8.5.1 Pressure gauges shall be installed in the following locations:

(a) On both sides of a pressure regulating valve;

(b) On the pressurized side of all supply connections;

(c) On the pressurized side of all system control valves;

(d) On all pressurized storage containers; and

(e) On all air supplies for dry pipe and preaction systems.

4-8.5.2 The required pressure gauges shall be compatible with their intended use and shall have an operating range not less than twice the normal working pressure of the system.

4-9 Electrical Systems.

4-9.1 Electrical Equipment.

4-9.1.1 Water mist systems shall be installed in accordance with the requirements of NFPA 70, *National Electrical Code.*

4-9.1.2* All signaling system circuits and wiring shall be installed in accordance with NFPA 72, *National Fire Alarm Code.*

4-9.2 Control Equipment.

4-9.2.1 Electrical fire detection and control equipment used to activate water mist systems shall be installed in accordance with NFPA 70, *National Electrical Code;* NFPA 72, *National Fire Alarm Code* or equivalent; or the manufacturers' recommendations, as appropriate.

4-9.2.2 All circuitry that is monitoring or controlling the water mist system shall be electrically supervised in accordance with NFPA 72, *National Fire Alarm Code*.

4-9.2.3 Adequate and reliable primary and 24-hour minimum standby sources of energy shall be used to provide for operation of the detection, signaling, control, and actuation requirements of the system.

4-9.2.4 Alarms shall be provided to indicate system activation or system trouble conditions, or both. Trouble and supervisory signals shall include power failure, operation (closing) of monitored valving, and electrical faults in the detection/activation of pump power control systems. These alarms shall be both visible and audible inside the protected space, at the location of the primary system components (e.g., pumps, storage tanks), and in a continuously attended location. The system activation alarm shall be distinctly different from the system trouble signal to prevent confusion.

4-9.3 Fire Detection.

4-9.3.1* When electrically operated automatic fire detection systems are used, the installation shall be in accordance with NFPA 72, *National Fire Alarm Code*.

4-9.3.2 Adequate and reliable primary and 24-hour minimum standby sources of energy shall be used to provide for operation of the detection, signaling, control, and actuation requirements of the system.

4-9.3.3 Where a new water mist system is installed in a space that has an existing detection system, an analysis shall be made of the detection devices to ensure that the detection system meets the requirements of the water mist system listing and that the detection system is in good operating condition.

4-9.4 Automatic and Manual Activation.

4-9.4.1 A means of automatic operation of the water mist system shall be provided. This shall be accomplished by means of automatic nozzles (independently thermally activated), automatic group control valves, or an independent automatic fire detection system, coupled with a listed system activation panel.

Exception: Manual-only actuation shall be permitted if approved by the authority having jurisdiction.

4-9.4.2 A means of manual release of the system shall be installed and arranged in accordance with 2-10.3.

Chapter 5 Design Objectives and Hazard Classifications

5-1 General. Currently, no general design method is recognized for water mist protection systems. Water mist protection systems shall be designed and installed in accordance with their listing for the specific hazards and protection objectives specified in the listing. The characteristics of the specific application (compartment variables and hazard classification) shall be consistent with the listing of the system. The compartment geometry, fire hazard, and system variables described in this chapter shall be considered adequate to ensure that the system design and installation are consistent with the system listing.

5-1.1

The fire-fighting performance objectives of a water mist system shall be described using the following three terms:

(a) Control;

(b) Suppression; and

(c) Extinguishment.

5-1.1.1 Fire Control. Fire control can be measured using three basic approaches:

(a) A reduction in the thermal exposure to the structure, where the primary objective is to maintain the structural integrity of the building (e.g., prevent flashover);

(b) A reduction in the threat to occupants, where the primary objective is to minimize the loss of life; and

(c) A reduction in a fire-related characteristic, such as heat release rate, fire growth rate, or spread to adjacent objects.

5-1.1.2 Fire Suppression. Fire suppression is the sharp reduction in the heat release rate of a fire and the prevention of its regrowth by a sufficient application of water mist.

5-1.1.3 Fire Extinguishment. Fire extinguishment is the complete suppression of a fire until there are no burning combustibles.

5-2 Application Parameters. Design considerations shall address both compartment variables and fire hazard classification.

5-2.1 Compartment Variables. Compartment variables shall include both the geometry of the compartment and the ventilation conditions in the compartment.

5-2.1.1 Compartment Geometry. The compartment geometry (floor area, compartment volume, ceiling height, and aspect ratio) shall be considered when designing such parameters as nozzle locations, system flow rate, and total water use needs of the system.

5-2.1.2 Ventilation. Ventilation considerations shall include both natural and forced ventilation parameters.

5-2.1.2.1* Natural Ventilation. The number, size, and location of the openings in the space (e.g., door, windows) shall be addressed in the design and installation of the system. In some cases, special precautions are necessary to minimize the effects of these openings. These precautions include, but are not limited to, automatic door closures and water mist curtains.

5-2.1.2.2 Forced Ventilation. The magnitude of the forced ventilation in the compartment shall be addressed in the design and installation of the water mist system. In some cases, consideration shall be given to shutting down the forced ventilation prior to mist system activation.

5-2.2 Fire Hazard Classification. The fire hazard shall be classified by both the combustible loading and fuel type.

5-2.2.1 Combustible Loading. A fire hazard analysis shall be conducted to determine both the design parameters of the water mist system and the type of detection/activation scheme employed by the system. The system shall be based on the fuel type, combustible loading, and anticipated fire growth rate as well as the desired fire-fighting performance objectives.

5-2.2.2 Fuel Type. Overall fire hazard is directly related to the type and quantity of the fuel present in a space. The ease of ignition/reignition of the fuel, the fire growth rate, and the difficulty of achieving control, suppression, extinguishment, or any combination thereof, shall be considered when selecting or designing a water mist system.

5-2.2.2.1 Class A Fires. Fuel loading and configuration shall be considered when selecting/designing a system to protect a space or area containing Class A materials. If fire extinguishment is desired, consideration shall be given to the potential for deep-seated fires as well as to the potential for smoldering fires.

5-2.2.2.2 Class B Fires. The hazard associated with Class B fires is related primarily to the fuel loading, fuel configuration, flashpoint, and burning rate of the fuel. Preburn time also affects the overall characteristics of the fire. Class B fires are grouped into two categories: two-dimensional pool fires and three-dimensional spray and running fuel fires. The parameters associated with each category are as follows:

(a) Class B two-dimensional fires:

1. Fuel loading and configuration;
2. Fuel flashpoint; and
3. Preburn time pool/spill size.

(b) Class B three-dimensional fires:

1. Fuel loading and configuration;
2. Fuel flashpoint;

3. Preburn time;

4. Cascade/running fuel fires;

5. Fuel flow rate;

6. Fire configuration;

7. Spray fires;

8. Fuel line pressure;

9. Fuel spray angle;

10. Fuel spray orientation; and

11. Reignition sources.

When designing and installing water mist systems to protect Class B hazards, the parameters specified in 5-2.2.2.2(a) and (b) shall be considered.

5-2.2.2.3 Class C Fires. Electrical conductivity of water and water mist shall be addressed when considering applications where the primary fire is a Class C fire.

5-2.2.2.4 Combination Fires. Combinations in fuel loadings and hazards shall be addressed.

5-2.3 Fire Location.

The location of the fuel in the space shall be considered when selecting/designing a water mist system. Some of the locations of concern include:

(a) Fuel located at higher elevations in the space;

(b) Fuel located in close proximity to vent openings;

(c) Fuel located in the corners of the space; and

(d) Fuel stacked against walls.

5-2.4 Obstructions and Shielding.

Water mist nozzles shall be positioned to distribute mist to all locations in the area or around the object being protected. The presence of obstructions and the potential for shielding of misting spray patterns shall be evaluated to ensure that the system performance is not affected.

5-3 Listing Testing.

Tests shall be conducted as part of the nozzle or system listing to address the compartment geometry, fire hazard, and performance objectives of the application specified in the listing.

5-3.1 Applicability.

Tests shall be designed to replicate most or all of the application parameters associated with a given installation. Any variations in these parameters shall be substituted using the worst case conditions. The listing of the system hardware shall be consistent with the intended system application.

5-3.2 Adequacy of Testing.

Tests shall be designed and conducted to stress the system in order to determine the working limits and parameters of the system and to incorporate adequate severity to minimize the effects of test parameter variations.

5-3.3* Results.

The results documented in the listing testing shall identify the working limits and parameters of the system, the fire hazard, and the range of compartment parameters.

Chapter 6 Calculations

6-1 General.

System flow calculation procedures for water mist systems shall be in accordance with Section 6-2.

Exception No. 1: Hydraulic calculations for systems with no additives and with working pressures not exceeding 175 psi (12 bars) shall be permitted to be performed using the method provided in Section 6-3.

Exception No. 2: Calculations for piping carrying atomizing media in twin fluid systems shall be performed in accordance with Section 6-4.

6-1.1*

Where any modification is made that alters the system flow characteristics of an existing, engineered water mist system, system flow calculations shall be furnished indicating the previous design, volume, and pressure at points of connection, and adequate calculations also shall be provided to indicate the effect on existing systems.

6-1.2

Pre-engineered systems shall not be modified outside the limits of the listing.

6-2* Darcy-Weisbach Calculation Method for Intermediate and High Pressure, Single Fluid, Single Liquid Phase Systems.

6-2.1

Pipe friction losses shall be determined using the formulae in Table 6-2.1.

Table 6-2.1. Darcy-Weisbach and Associated Equations for Pressure Loss in Intermediate and High Pressure Systems.

English Units	SI Units
Darcy-Weisbach Equation:	
$\Delta p = 0.000216 \frac{fL\rho Q^2}{d^5}$	$\Delta p_m = 2.252 \frac{fL\rho Q^2}{d^5}$
Reynolds Number:	

$$Re = 506\frac{Q\rho}{d\mu}$$

$$Re = 21.22\frac{Q\rho}{d\mu}$$

Relative roughness:

$$\text{relative roughness} = \frac{\varepsilon}{D}$$

$$\text{relative roughness} = \frac{\varepsilon}{d}$$

Δp = friction loss, psi gauge
L = length of pipe, ft
f = friction factor, psi/ft
Q = flow, gpm
d = internal pipe diameter, in.
D = internal pipe diameter, ft
ε = pipe wall roughness, ft
ρ = weight density of fluid, lb/ft^3
μ = absolute (dynamic) viscosity, in centipoise (cP)

Δp_m = friction loss, bars gauge
L = length of pipe, m
f = friction factor, bars/m
Q = flow, L/min
d = internal pipe diameter, mm
ε = pipe wall roughness, mm
ρ = weight density of fluid, kg/m^3
μ = absolute (dynamic) viscosity, in centipoise (cP)

6-2.2

Figure 6-2.2 (Moody Diagram) shall be used to determine the value of the friction factor, f, in the Darcy-Weisbach equation, where the Reynolds number and relative roughness are calculated as shown in Table 6-2.1, using coefficients provided in Tables 6-2.2(a) and 6-2.2(b).

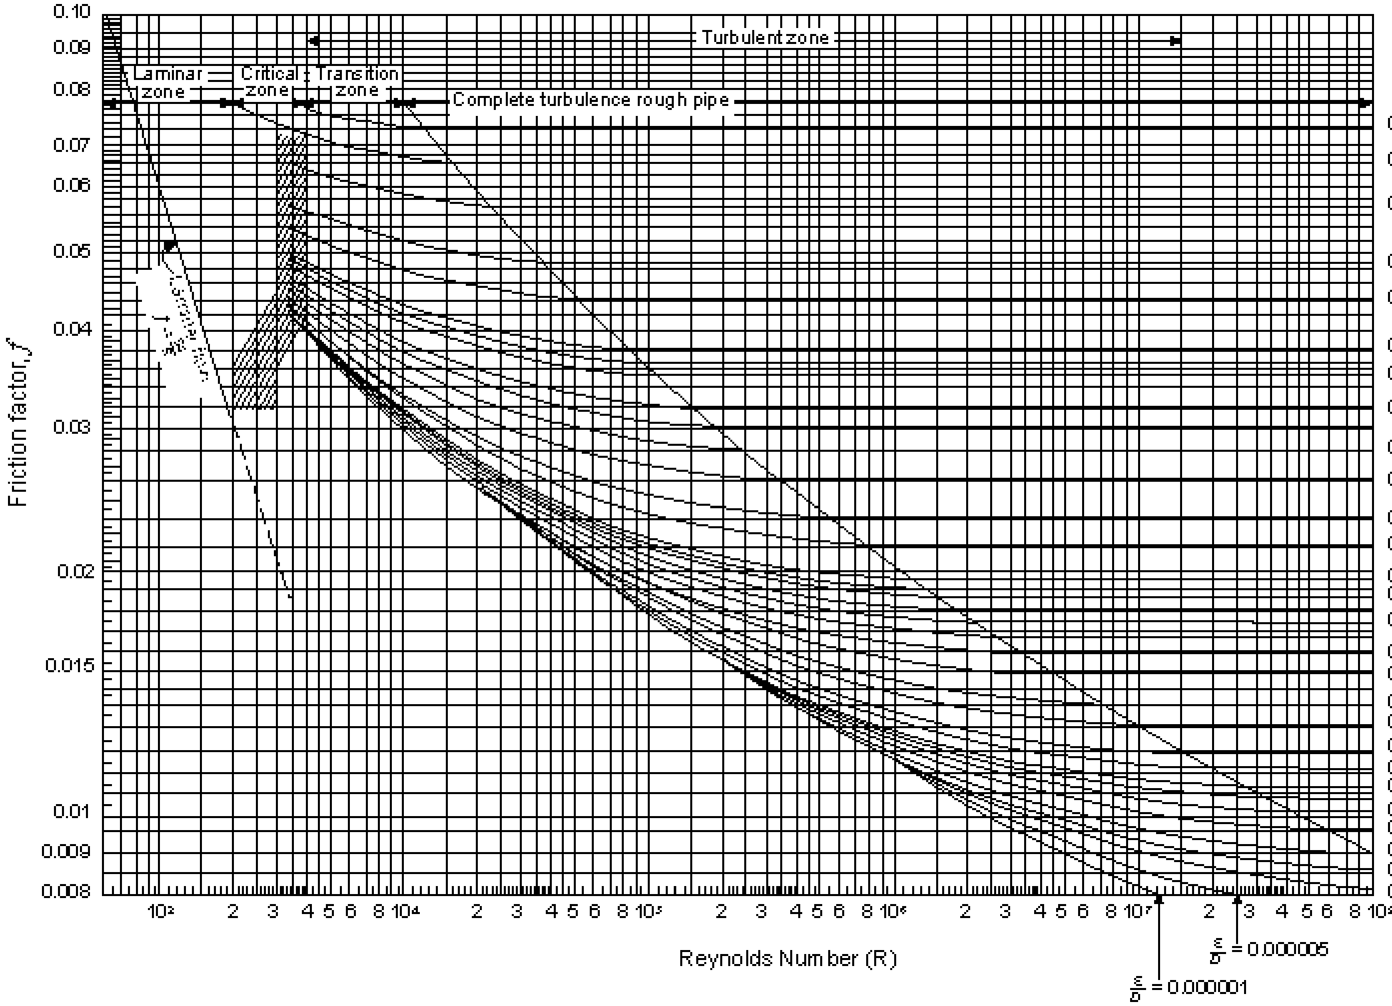

Figure 6-2.2 Moody diagram.

Table 6-2.2(a) Recommended Values of Absolute Roughness or Effective Height of Pipe Wall Irregularities, for Use in Darcy-Weisbach Equation

	Design Value of ε,	
Pipe Material (New)	**(ft)**	**(mm)**
Copper, copper nickel, drawn tubing	0.000 005	0.0015
Stainless steel	0.000 15	0.045

Table 6-2.2(b) Approximate Values of μ, Absolute (Dynamic) Viscosity, and ρ for Clean Water, over the Temperature Range 40°F to 100°F (4.4°C to 37.8°C)

Temperature °F	Temperature °C	Weight Density of Water, lb/ft^3	Weight Density of Water, kg/m^3	Absolute (Dynamic) Viscosity, μ, in Centipoise
40	4.4	62.42	999.9	1.5
50	10.0	62.38	999.7	1.3
60	15.6	62.34	998.8	1.1
70	21.1	62.27	998.0	0.95
80	26.7	62.19	996.6	0.85
90	32.2	62.11	995.4	0.74
100	37.8	62.00	993.6	0.66

6-2.3

Minimum and maximum operating pressure at each nozzle shall be within the listed operating range.

6-2.4

System piping shall be hydraulically designed to deliver the water flow requirements in accordance with the manufacturer's listing and the provisions of Chapter 5.

6-3* Hazen-Williams Calculation Method (Low Pressure Systems).

6-3.1

Hydraulic calculations for water mist systems with working pressures not exceeding 175 psi (12 bars) shall be permitted to be performed using the Hazen-Williams calculation method.

6-3.2 Friction Loss Formula.

Friction losses for water-filled pipe shall be determined on the basis of the Hazen-Williams

$$P_f = \frac{4.52 Q^{1.85}}{C^{1.85} d^{4.87}}$$

where:

P_f = Frictional resistance (psi/ft of pipe)

Q = Flow (gpm)

d = Actual internal diameter of pipe (in.)

C = Friction loss coefficient.

For SI units:

$$P_m = 6.05 \frac{Q_m^{1.85}}{C^{1.85} d_m^{4.87}} \times 10^5$$

where:

P_m = Frictional resistance (bars/m of pipe)

Q_m = Flow (L/min)

d_m = Actual internal diameter of pipe (mm)

C = Friction loss coefficient.

6-3.3 Velocity Pressure Formula.

Velocity pressure for water-filled pipe shall be determined on the basis of the following formula:

$$P_V = \frac{0.001123\, Q^2}{D^4}$$

where:

P_v = Velocity pressure (psi)

Q = Flow (gpm)

D = Inside diameter (in.).

For SI units:

$$P_V = 5.61(10)^{-7} \frac{Q^2}{D^4}$$

where:

P_v = Velocity pressure (bars)

Q = Flow (L/min)

D = Inside diameter (mm).

6-3.4 Normal Pressure Formula.

Normal pressure, P_n, shall be determined on the basis of the following formula:

$$P_n = P_t - P_v$$

where:

P_n = Normal pressure

P_t = Total pressure [psi (bars)]

P_v = Velocity pressure [psi (bars)].

6-3.5 Hydraulic Junction Points.

Pressures at hydraulic junction points shall balance within 0.5 psi (0.03 bar). The highest pressure at the junction point, and the total flows as adjusted, shall be used in the calculations.

6-3.6 Equivalent Pipe Lengths of Valves and Fittings.

6-3.6.1 Table 6-3.6.1 shall be used to determine the equivalent length of pipe for fittings and devices, unless the manufacturer's test data indicate that other factors are appropriate. For saddle-type fittings having friction loss greater than that shown in Table 6-3.6.1, the increased friction loss shall be included in hydraulic calculations. For internal pipe diameters that differ from copper tubing, the equivalent feet shown in Table 6-3.6.1 shall be multiplied by a factor derived from the following formula:

$$\left[\text{Actual inside diameter}/\text{Type K copper tube I.D.}\right]^{4.87} = \text{Factor}$$

The factor thus obtained shall be modified further in accordance with Table 6-3.6.2.

Table 6-3.6.1 Equivalent Length of Pipe for Copper Fittings and Values

Nominal or Standard Size		Fittings: Standard Ell 90°		Standard Ell 45°		90° Tee Side Branch		90° Tee Straight Run		Coupling		Valves: Ball		Gate	
(in.)	(mm)	(ft)	(m)	(ft)	(m)	(ft)	(m)	(ft)	(m)	(ft)	(m)	(ft)	(m)	(ft)	(m)
3/8	9.53	0.5	0.15			1.5	0.46								
1/2	12.7	1	0.31	0.5	0.15	2	0.61

NOTES: Allowances are for streamlined, soldered fittings and recessed threaded fittings. For threaded fittings, double the allowances shown. The equivalent lengths presented above are based upon a C factor of 150 in the Hazen-Williams friction loss formula. The lengths shown are rounded to the nearest half foot.

6-3.6.2 Table 6-3.6.1 shall be used with Hazen-Williams only where C=150. For other values of C, the values in Table 6-3.6.1 shall be multiplied by the factors in Table 6-3.6.2.

Table 6-3.6.2 C Value Multiplier

Value of C	100	120	130	140
Multiplying Factor	0.472	0.662	0.767	0.880

NOTE: The multiplying factor is based upon the friction loss through the fitting being independent of the C factor available to the piping.

6-3.6.3 Specific friction loss values or equivalent pipe lengths for special valves, strainers, and other devices shall be made available to the authority having jurisdiction.

6-3.6.4 Pipe friction loss shall be calculated in accordance with the Hazen-Williams formula C values from Table 6-3.6.4.

Table 6-3.6.4 Hazen-Williams C Values

Pipe or Tube	C Value[1]
Plastic (listed per 2-3.2 or 2-3.4.2) all types	150
Copper tube or stainless steel	150

[1]The authority having jurisdiction is permitted to consider other C values.

6-4 Pneumatic Calculation Procedures for Atomizing Media in Twin Fluid Systems.

6-4.1

Calculations shall be performed to determine the maximum and minimum pneumatic pressures and flow rates (at standard temperature and pressure) at the atomizing media inlet of each twin-fluid nozzle in multi-nozzle system. Maximum and minimum pressures at each nozzle shall be within the performance tolerances for the nozzle, as provided by the nozzle manufacturer. The following iterative procedure is described as one approach.

6-4.2

A pneumatic calculation procedure shall be based on standard engineering methods for sizing of compressed air piping systems. Air flow at each nozzle is dependent on water pressure at the same nozzle. To start the calculation, the air pressure and air flow rate at the hydraulically most remote nozzle shall be set at the optimum air pressure and flow rate for the corresponding water pressure and water flow rate at that nozzle.

6-4.3

The initial water pressure condition at the most remote nozzle shall be taken from hydraulic calculations performed independently (i.e., treating the water piping as a single fluid system), using assumed nozzle discharges. Once the water pressure and flow rate at each nozzle are determined, the corresponding required air pressure and flow rate to allow the assumed water flow rate can be estimated from information provided by the nozzle manufacturer.

6-4.4

Having determined the nominal air pressure and flow requirements at each nozzle, the pneumatic piping system shall be calculated independently, to verify that the pipe sizes are adequate to provide the required pressure and flow at each nozzle location. Using the calculated pressures at each nozzle, the effect on the water discharge rate must be checked. If the water flow rate at the calculated air pressure is within 10 percent of the assumed flow rate in 6-4.3, no correction is required. If not, the nozzle discharge shall be adjusted, and the hydraulic calculation of 6-4.3 shall be repeated. This procedure is iterative, and must be repeated until calculated air and water pressures are within the desired range and ratio.

6-4.5

The ratio of the air pressure to water pressure at each nozzle shall be maintained within 10 percent of the manufacturer's recommended operating ratio as provided by the nozzle manufacturer.

6-4.6

The results of the hydraulic and pneumatic calculations shall indicate the total water demand as a flow rate and pressure at the system supply point, and the total air flow rate (in SCFM) and initial air pressure at the atomizing media supply point.

Chapter 7 Water Supplies and Atomizing Media

7-1 General.

Unless otherwise specified, the following requirements shall apply to the water supplies, the atomizing media, and any additives necessary for fire-extinguishing performance.

7-1.1

Every water mist system shall have at least one automatic water supply.

7-1.2*

Compressed gas or other atomizing medium, where used as part of a twin fluid water mist system, shall be automatically supplied in concurrence with the water.

7-2* Quantity.

The quantities of water, water additives in listed concentrations (if used), and of atomizing media (if used) shall be at least sufficient for the largest single hazard or group of hazards to be protected simultaneously.

7-3* Duration.

Automatic supplies of water and of atomizing media (if used) shall be adequate to supply the system for a minimum of 30 minutes.

Exception No. 1: For pre-engineered systems, the minimum duration shall be sufficient for two complete discharges, as required by the listing and by Chapter 5.

Exception No. 2: Where the hazard has been evaluated by a fire protection engineer using standard methods of fire hazard analysis, the water supply duration shall be determined by the specified performance characteristics of the water mist system. It shall be permitted for this method to result in water supply duration requirements greater than or less than those specified in Section 7-3.

7-4 Reserve Supplies.

7-4.1*

A reserve supply shall be provided where the extinguishing agent cannot otherwise be replaced within 24 hours following system operation.

7-4.2

Where a reserve supply is provided, it shall be connected to the system piping at all times. If a manual changeover is necessary, the mechanism shall be readily accessible from outside of the protected space.

7-4.3

Means shall be provided to prevent discharge of reserve supplies from open manifold connections when supplies are removed for servicing.

7-5 Water Supplies.

7-5.1* Water Quality.

7-5.1.1 The water supply for a water mist system shall be taken from a source that is equivalent in quality to a potable source with respect to particulate and dissolved solids, or from a source of natural seawater.

Exception No. 1: In areas which are normally occupied, liquid or dissolved chemicals are permitted to be added to the water supplies in accordance with the listing, provided they are used at concentrations for which the manufacturer can demonstrate to the satisfaction of the U.S. Environmental Protection Agency that no adverse toxilogical or physiological effects have been observed.

Exception No. 2: For systems which protect normally unoccupied areas, liquid or dissolved chemicals are permitted to be added to the water supplies in accordance with the listing.

7-5.1.2 A filter or strainer shall be provided at the supply side of each nozzle.

Exception: Nozzles with multiple orifices and with minimum waterway dimensions greater than 800 µm per opening shall not be required to be provided with a strainer or filter at each nozzle.

7-5.1.3 A filter or a strainer shall be provided at each water supply connection or system riser. The filter or strainer shall be installed downstream (on the system side) of all piping that is not corrosion resistant. Such strainers shall be provided with a cleanout port and shall be arranged to facilitate inspection, maintenance, and replacement.

7-5.1.4 The maximum filter rating or strainer mesh opening shall be 80 percent of the minimum nozzle waterway dimension.

7-5.1.5 Systems which utilize nozzles with a minimum nozzle waterway dimension less than 51 µm shall be supplied with de-mineralized water.

7-5.2 Pumps.

7-5.2.1 Centrifugal pumps shall be sized to supply the greatest demand at not more than 140 percent of rated flow capacity.

7-5.2.2 Other pumps shall be sized to supply 110 percent of system demand at the design pressure.

7-5.2.3 Pumps supplying water mist systems shall be automatically controlled and shall be of sufficient capacity to meet the system demand.

7-5.2.4 Supervision. Pumps supplying water mist systems shall be supervised for the conditions specified in 7-5.2.4.1 and 7-5.2.4.2.

7-5.2.4.1 Electric Pumps.

(a) Pump running;

(b) Loss of power; and

(c) Phase reversal.

7-5.2.4.2 Diesel-Driven Pumps.

(a) Pump running;

(b) Power failure;

(c) Controller not in automatic position;

(d) Low oil pressure;

(e) High water temperature;

(f) Failure to start/overcrank;

(g) Overspeed; and

(h) Fuel level (set at 75 percent capacity).

7-5.3 Tanks.

7-5.3.1 Water tanks shall be arranged in accordance with NFPA 22, *Standard for Water Tanks for Private Fire Protection*.

7-5.3.2 Water tanks shall be supervised for the following conditions:

(a) Water level;

(b) Water temperature (for tanks located in unheated areas); and

(c) Air pressure (for pressure tanks).

7-5.4 Storage Containers.

7-5.4.1 Storage containers and accessories shall be located and arranged to facilitate inspection, testing, recharging, and other maintenance. Interruption to protection shall be held to a minimum.

7-5.4.2 Storage containers shall not be located where they are likely to be subject to severe weather conditions or to mechanical, chemical, or other damage.

7-5.4.3 Where excessive climatic or mechanical exposures are expected, suitable safeguards or enclosures shall be provided.

7-5.4.4 Storage containers shall be mounted securely in accordance with the manufacturer's installation manual. This shall include mounting the container on the appropriate mounting surface.

7-5.4.5 Each pressurized container or cylinder shall be provided with a safety device to release excess pressure.

7-5.4.6 A reliable means shall be provided to indicate the pressure and level in all storage containers.

7-5.5* Fire Department Connection.

A fire department connection shall be provided on the discharge side of the pressure source components. The connection to the system shall be made on the upstream (supply) side of the system strainer or filter.

Exception No. 1: For systems with operating pressures in excess of 175 psi (12 bars), the connection shall be made on the suction side of the pressure source components.

Exception No. 2: Fire department connections shall not be required for systems protecting less than 2000 ft^2 *(200* m^2*).*

Exception No. 3: Fire department connections shall not be required for systems with operating pressures in excess of 175 psi (12 bars) and supplied only by storage cylinders.

Exception No. 4: Fire department connections shall not be required for systems where the atomizing medium is essential for fire suppression.

7-6 Atomizing Media for Twin Fluid Systems.

7-6.1 General.

7-6.1.1 Atomizing media essential to the production of water mist shall be taken from a dedicated source.

Exception: Where the facility has an air supply that meets or exceeds the requirements of a dedicated main and reserve air supply, both meeting the quality, quantity, pressure, and reliability requirements of the listing and the approval of the authority having jurisdiction. Plant air used as an atomizing medium for a water mist system shall be monitored by the fire control panel, with the low air alarm set at a point at least 50 percent above the availability of two full system discharge requirements.

7-6.1.2 Atomizing media shall be supervised for high and low pressure.

7-6.1.3 Moisture content in the atomizing medium shall not exceed 25 ppm.

7-6.1.4 Regulators controlling the supply of water for the atomizing medium shall be listed for the intended purpose.

7-6.1.5 A check valve or other means shall be installed in the piping at the supply point to prevent the entrance of water into the atomizing medium.

7-6.1.6 Filters or other means to protect nozzles from obstructions shall be provided in accordance with 7-5.1.2.

7-6.2 Air Compressors.

7-6.2.1 Air compressors used as a dedicated source shall be listed for use on fire protection systems.

7-6.2.2 Compressors used as a dedicated supply shall be connected to a backup power supply.

7-7 Pressure Gauges.

A pressure gauge shall be provided for each water supply and each atomizing medium.

Chapter 8 Plans and Documentation

8-1 Working Plans.

8-1.1

Working plans shall be submitted for approval to the authority having jurisdiction before any equipment is installed or remodeled. Deviation from approved plans shall require permission of the authority having jurisdiction.

8-1.2

Working plans shall be drawn to specified scale on sheets of uniform size. Special symbols shall be defined and used to identify components of the water mist system clearly. The plans shall provide the following information that pertains to the design of the system:

(a) Name of owner and occupant;

(b) Location, including street address;

(c) Point of compass and symbol legend;

(d) Location and construction of protected enclosure walls and partitions;

(e) Location of fire walls;

(f) Enclosure cross section, with full height or schematic diagram, including location and construction of building floor/ceiling assemblies above and below, raised access floor, and suspended ceiling;

(g) Description of occupancies and hazards being protected, designating whether or not the enclosure is normally occupied;

(h) Description of exposures surrounding the enclosure;

(i) Description of water and gas storage containers used including make, internal volume, storage pressure, and nominal capacity expressed in units of mass or volume at standard conditions of temperature and pressure;

(j) Description of nozzles used including manufacturer, size, orifice port configuration, and orifice size or part number;

(k) Description of pipe and fittings used including material specifications, grade, and pressure rating;

(l) Description of wire or cable used including classification, gauge (AWG), shielding, number of strands in conductor, conductor material, and color coding schedule. The segregation requirements of various system conductors shall be clearly indicated. The required method of making wire terminations shall be detailed;

(m) Description of the method of detector mounting;

(n) Equipment schedule or bill of materials for each piece of equipment or device indicating device name, manufacturer, model or part number, quantity, and description;

(o) Plan view of the protected area showing enclosure partitions (full and partial height); water distribution system including storage containers or pumps; gas distribution system including gas storage containers; piping; nozzles; type of pipe hangers and rigid pipe supports; detection, alarm, and control system including all devices; end-of-line device locations; location of controlled devices such as dampers and shutters; and location of instructional signage;

(p) Isometric view of the water mist distribution system showing the length and diameter of each pipe segment; node reference numbers relating to the flow calculations; fittings including reducers and strainers; orientation of tees; and nozzles including size, orifice port configuration, and flow rate;

(q) Seismic building joints, if any, showing where water mist distribution or supply piping crosses the joint; expected movement of the seismic joint; details of the piping arrangement; and flexible connectors used to accommodate seismic movement;

(r) The calculation of seismic loads if seismic restraint is required by the authority having jurisdiction;

(s) Scale drawing showing the layout of the annunciator panel graphics if required by the authority having jurisdiction;

(t) Details of each unique rigid pipe support configuration showing method of securement to the pipe and to the structure;

(u) Details of the method of container securement showing method of securement to the container and to the structure;

(v) Complete step-by-step description of the system sequence of operations including functioning of abort and maintenance switches, delay timers, and emergency power shutdown;

(w) Schematic diagrams and point-to-point wiring diagrams showing all circuit connections to the system control panels, detectors, system devices, controlled devices, external and add-on relays, and graphic annunciator panels;

(x) Schematic diagrams and point-to-point wiring diagrams of the system control panels;

(y) Complete calculations to determine enclosure volume for the application of water mist; and

(z) Complete calculations to determine the size of backup batteries; the method used to determine the number and location of audible and visual indicating devices; and number and location of detectors.

8-2 Hydraulic Calculation Documentation.

8-2.1

Hydraulic calculations shall be prepared on form sheets that include a summary sheet, detailed work sheets, and a graph sheet.

Exception: Pre-engineered systems.

8-2.2 Summary Sheet.

The summary sheet shall contain the following information:

(a) Date;

(b) Location;

(c) Name of owner and occupant;

(d) Building number or other identification;

(e) Description of hazard;

(f) Name and address of contractor or designer;

(g) Name of approving agency;

(h) System design requirements, including:

1. Design area of water application or volume of space protected;
2. Minimum rate of water application (density); and
3. Area per nozzle.

(i) Total water requirements as calculated; and

(j) Limitations (dimension, flow, and pressure) resulting from the use of automatic sprinkler systems or other water fire suppression systems.

8-2.3 Detailed Work Sheets.

The detailed work sheets or computer printouts shall contain the following information:

(a) Sheet number;

(b) Nozzle description;

(c) Hydraulic reference points;

(d) Flow in gpm (L/min);

(e) Pipe size;

(f) Pipe lengths, center to center of fittings;

(g) Equivalent pipe lengths for fittings and devices;

(h) Friction loss in psi/ft (bars/m) of pipe;

(i) Total friction loss between reference points;

(j) Elevation head in psi (bars) between reference points;

(k) Required pressure in psi (bars) at each reference point;

(l) Velocity pressure and normal pressure if included in calculations;

(m) System flushing locations;

(n) Notes to indicate starting points, reference other sheets, or clarify data shown;

(o) Diagram to accompany gridded system calculations to indicate flow quantities and directions for lines with water mist nozzles operating in the remote area; and

(p) Other calculations necessary for design of the water mist system.

8-2.4 Graph Sheet.

A graphic representation of the complete hydraulic calculation shall be plotted on semilogarithmic ($Q^{1.85}$) graph paper and shall include the following:

(a) Water supply curve; and

(b) Water mist system demand.

8-3 Pneumatic Calculation Documentation.

8-3.1

Pneumatic calculations shall be prepared on form sheets that include a summary sheet and detailed work sheets.

Exception: Pre-engineered systems.

8-3.2 Summary Sheet.

The summary sheet shall contain the following information:

(a) Date;

(b) Location;

(c) Name of owner and occupant;

(d) Building number or other identification;

(e) Description of hazard;

(f) Name and address of contractor or designer; and

(g) Total gas volume required.

8-3.3 Detailed Work Sheets (for pneumatic calculations).

The detailed work sheets or computer printouts shall contain the following information:

(a) Sheet number;

(b) Nozzle description;

(c) Pneumatic reference points;

(d) Atomizing media flow rate (in SCFM) and pressure at each nozzle;

(e) The air pressure to water pressure ratio at each nozzle;

(f) Pipe size;

(g) Pipe lengths;

(h) Total pressure loss between reference points;

(i) Required pressure in psi (bars) at each reference point; and

(j) Notes to indicate starting points, reference other sheets, or clarify data shown.

8-4 Detection, Actuation, and Control Systems Documentation.

After successful completion of acceptance tests satisfactory to the authority having jurisdiction, as-built installation documentation shall be prepared and provided to the system owner or the owner's designated representative, including as-built installation drawings, operation and maintenance manuals, a written sequence of operation, and reports.

8-4.1 As-Built Installation Drawings.

A set of as-built installation drawings, reproducible and drawn to a scale specified on sheets of uniform size, shall provide the as-built configuration of detection, actuation, and control systems and shall include:

(a) The name of owner and occupant;

(b) The location, including street address;

(c) The plan view of the protected area showing all detector locations; end-of-line device locations; location of detector indicating lights if separate from the detectors; location of audible and visual indicating devices; location of control panels; location of manual release and abort switches; location of controlled devices such as dampers and shutters; location of maintenance and emergency power shutdown switches; and location of the annunciator panel;

(d) An equipment schedule or bill of materials for each piece of equipment or device indicating the device name, manufacturer, model or part number, quantity, and description;

(e) A description of wire or cable used including classification, gauge (AWG), shielding, number of strands in conductor, conductor material, and color coding schedule. The segregation requirements of various system conductors shall be clearly indicated. The as-built method of making wire terminations shall be detailed;

(f) A scale drawing showing the graphics layout of all annunciator panels;

(g) Schematic diagrams and point-to-point wiring diagrams showing all circuit connections to the system control panels, detectors, system devices, controlled devices, external and add-on relays, and graphic annunciator panels;

(h) Schematic diagrams and point-to-point wiring diagrams of the system control panels;

(i) The size and type of backup batteries; and

(j) The details of any special features.

8-4.2 Operation and Maintenance Manuals.

Operation and maintenance manuals shall include operation and maintenance instructions for each piece of equipment or device of the as-built system.

8-4.3 Written Sequence of Operation.

The written sequence of operation of the as-built system shall include a complete step-by-step description of the functioning of abort and maintenance switches, delay timers, and emergency power shutdown features.

8-4.4 Reports.

Reports shall include inspection, testing, and maintenance reports.

Chapter 9 System Acceptance

9-1 Approval of Water Mist Systems.

The completed system shall be reviewed and tested by qualified personnel to meet the approval of the authority having jurisdiction. These personnel shall confirm that listed equipment and devices have been used in the system where required by this standard. To determine that the system has been properly installed and functions as specified, the installing contractor shall:

(a) Notify the authority having jurisdiction and the owner's representative of the time and date testing is to be performed; and

(b) Perform all required acceptance tests.

9-2* Acceptance Requirements.

9-2.1 Flushing or Cleaning of Piping.

9-2.1.1 Water Supply Connection. Where systems are connected to municipal or private water supplies, underground mains and lead-in connections to water mist system piping shall be flushed completely before connection is made to water mist piping. The flushing operation shall be continued for a sufficient time to ensure thorough cleaning. The minimum rate of flow shall be one of the following, whichever is greater:

(a) The hydraulically calculated water demand rate of the system; or

(b) The maximum flow rate available to the system under fire conditions.

9-2.1.2 System Pipe or Tube. Each pipe or tube section shall be cleaned internally after preparation and before assembly in accordance with the manufacturer's installation manual. The piping network shall be free of particulate matter and oil residue before installation of nozzles or discharge devices.

9-2.2 Hydrostatic Tests.

9-2.2.1 General.

9-2.2.1.1 The test pressure shall be read from a gauge located at the low elevation point of the system or portion being tested.

9-2.2.1.2 Water used for testing shall be filtered or strained to remove all solids of a size sufficient to obstruct the water mist nozzles.

9-2.2.1.3 Additives, corrosive chemicals such as sodium silicate or derivatives of sodium silicate, brine, or other chemicals shall not be used while hydrostatically testing systems or for stopping leaks.

9-2.2.1.4 Test blanks shall have painted lugs protruding in such a way as to clearly indicate their presence. The test blanks shall be numbered, and the installing contractor shall have a recordkeeping method to ensure their removal after work is completed.

9-2.2.2 Low Pressure System. All interior piping and attached appurtenances subjected to system working pressure shall be hydrostatically tested at 200 psi (13.8 bars) and shall maintain that pressure without loss for 2 hours. Loss shall be determined by a drop in gauge pressure or visible leakage.

Exception No. 1: Portions of systems normally subjected to working pressures in excess of 150 psi (10.4 bars) shall be tested as described above at a pressure of 50 psi (3.5 bars) in excess of normal working pressure.

Exception No. 2: Where cold weather does not allow testing with water, an interim air test shall be conducted as described in 9-2.3.

9-2.2.3 Intermediate and High Pressure Systems. All interior piping and attached appurtenances subjected to system pressure shall be hydrostatically tested to 150 percent of the normal working pressure, and they shall maintain that pressure without loss for 2 hours. Loss shall be determined by a drop in gauge pressure or visible leakage.

9-2.3 Air Tests.

For dry and preaction systems, an air pressure leakage test at 40 psi (2.8 bars) shall be conducted for 24 hours in addition to the standard hydrostatic test. Any leakage that results in a loss of pressure in excess of $1^1/_2$ psi (0.1 bars) during the 24 hours shall be corrected.

> CAUTION: Pneumatic pressure testing creates a potential risk of injury to personnel in the area as a result of airborne projectiles if rupture of the piping system occurs. Prior to the pneumatic pressure test being conducted, the area shall be evacuated and appropriate safeguards shall be provided for test personnel.

9-2.4 Review of Components.

9-2.4.1 Review of Mechanical Components.

9-2.4.1.1 The piping system shall be inspected to determine that it is in compliance with the design and installation documents and hydraulic calculations.

9-2.4.1.2 Nozzles and pipe size shall be in accordance with system drawings. The means of pipe size reduction and the attitudes of tees shall be checked for conformance to the design.

9-2.4.1.3 Piping joints, discharge nozzles, and piping supports shall be fastened securely to prevent unacceptable vertical or lateral movement during discharge. Discharge nozzles shall be installed in such a manner that piping cannot become detached during discharge.

9-2.4.1.4 The discharge nozzle shall be oriented in such a manner that optimum water mist application can be effected.

9-2.4.1.5 The discharge nozzles, piping, and mounting brackets shall be installed in such a manner that they do not potentially cause injury to personnel.

9-2.4.1.6 All water and gas storage containers shall be located properly in accordance with an approved set of system drawings.

9-2.4.1.7 All containers and mounting brackets shall be fastened securely in accordance with the manufacturer's requirements.

9-2.4.2 Review of Electrical Components.

9-2.4.2.1 All wiring systems shall be checked for proper installation in conduit and in compliance with the approved drawings. It shall be confirmed that ac wiring and dc wiring are not combined in a common conduit or raceway unless properly shielded and grounded.

9-2.4.2.2 All field circuits shall be confirmed to be free of ground faults and short circuits. Where measuring field circuitry, all electronic components, such as smoke and flame detectors or special electronic equipment for other detectors or their mounting bases, shall be removed, and jumpers shall be installed properly to prevent the possibility of damage within these devices. Components shall be replaced after measuring.

9-2.4.2.3 The detection devices shall be checked for proper type and location as specified on the system drawings.

9-2.4.2.4 The detectors shall be installed in a professional manner and in accordance with technical data regarding their installation. NFPA 72, *National Fire Alarm Code*, shall be referenced for installation requirements. In Canada, CAN/ULC S524-M86, *Standard for the Installation of Fire Alarm Systems*, and CAN/ULC S529-M87, *Smoke Detectors for Fire Alarm Systems*, shall be referenced.

9-2.4.2.5 Manual pull stations shall be confirmed as readily accessible, accurately identified, and properly protected to prevent damage.

9-2.4.2.6 For systems using abort switches, the switches shall be confirmed to be of the deadman type that necessitates constant manual pressure, properly installed, readily accessible within the hazard area, and clearly identified. Switches that remain in the abort position when released shall not be permitted for this purpose. Verification that normal and manual emergency control overrides the abort function shall be made.

9-2.4.2.7 Polarity shall have been observed on all polarized alarm devices and auxiliary relays.

9-2.4.2.8 All end-of-line resistors shall have been installed across the detection and alarm bell circuits where required.

9-2.4.2.9 The control unit shall be checked for proper installation and ready accessibility.

9-2.4.2.10* All wiring systems shall be checked for proper grounding and shielding. It shall be verified that the water mist system branch piping has not been used as an electrical ground.

9-2.5 Preliminary Functional Tests.

9-2.5.1 If the system is connected to an alarm receiving office, the alarm receiving office shall be notified that the fire system test is to be conducted and that an emergency response by the fire department is not desired. All concerned personnel at the end-user's facility shall be notified that a test is to be conducted and shall be instructed as to the sequence of operation.

9-2.5.2 Each water mist release mechanism shall be disabled so that activation of the release circuit does not release water mist. The release circuit shall be reconnected with a functional device in lieu of each water mist release mechanism. For electrically actuated release mechanisms, these devices can include 24-volt lamps, flash bulbs, or circuit breakers. For pneumatically actuated release mechanisms, these devices can include pressure gauges. The manufacturer's installation manual shall be referenced for recommended procedures and test methods.

9-2.5.3 Each detector shall be checked for proper response.

9-2.5.4 All auxiliary functions such as alarm sounding or displaying devices, remote annunciators, air-handling shutdown, and power shutdown shall be checked for proper operation in accordance with system requirements and design specifications.

9-2.5.5 Manual pull stations shall be checked to confirm that they override abort switches.

9-2.5.6 All supervised circuits shall be checked for proper trouble response.

9-2.6 System Operational Tests.

9-2.6.1 Where practicable, full flow tests of the system piping using water shall be made as a means of checking the nozzle layout, discharge pattern, and any obstructions, determining the relationship between design criteria and actual performance, and ensuring against the clogging of the smaller piping and nozzles by foreign matter carried by the water.

9-2.6.2 Where practicable, the maximum number of systems that are expected to operate in case of fire shall be in full operation simultaneously when checking the adequacy and condition of the water supply.

9-2.6.3 All operating parts of the system shall be tested fully to ensure that they function as intended. It shall be verified that all devices function properly and that they are properly sequenced.

9-2.6.4 After flow testing, all filters and strainers shall be inspected, and cleaned or replaced, as necessary.

Chapter 10 System Maintenance

10-1 Responsibility of the Owner or Occupant.

10-1.1

The responsibility for properly maintaining a water mist fire protection system shall be the obligation of the property owner. By means of periodic inspection, tests, and maintenance, the equipment shall be shown to be either in good operating condition or that defects or impairments exist.

10-1.2

Inspection, testing, and maintenance activities shall be implemented in accordance with procedures meeting or exceeding those established in this document and in accordance with the manufacturer's instructions. These tasks shall be performed by personnel who have developed competence through training and experience.

10-1.3

The owner or occupant shall notify the authority having jurisdiction, the fire department (if required), and the alarm receiving facility before shutting down a system or its supply. The notification shall include the purpose for the shutdown, the system or component involved, and the estimated time needed. The authority having jurisdiction, the fire department, and the alarm receiving facility shall be notified when the system, supply, or component is returned to service.

10-1.4

The owner or occupant shall promptly correct or repair deficiencies, damaged parts, or impairments found while performing the inspection, test, and maintenance requirements of this standard. Corrections and repairs shall be performed by qualified maintenance personnel or a qualified contractor.

10-1.5

The owner or occupant shall give special attention to factors that might alter the requirements for a continued satisfactory or acceptable installation. Such factors shall include, but shall not be limited to:

(a) Occupancy changes;

(b) Process or material changes;

(c) Structural revisions such as relocated walls, added horizontal or vertical obstructions, or ventilation changes; and

(d) Removal of heating systems in spaces with piping subject to freezing.

10-1.6

Where changes in the occupancy, hazard, water supply, storage arrangement, structural modification, or other condition that affects the installation criteria of the system are identified, the owner or occupant shall promptly take steps to evaluate the adequacy of the installed system to protect the hazard in question, such as contacting a qualified contractor, consultant, or engineer. Where the evaluation reveals a deficiency, the owner shall notify the insurance underwriter, the authority having jurisdiction, and the local fire department.

10-1.7

Where a water mist system is returned to service following an impairment, it shall be verified that it is working properly. Chapter 9 shall be referenced to provide guidance on the type of inspection or test, or both, that is required.

10-2 Inspection and Testing.

All components and systems shall be inspected and tested to verify that they function as intended. The frequency of inspections and tests shall be in accordance with Tables 10-2(a) and (b) or as specified in the manufacturer's listing, whichever is more frequent. Following tests of components or portions of water mist systems that require valves to be opened or closed, the system shall be returned to service, with verification that all valves are restored to their normal operating position. Plugs or caps for auxiliary drains or test valves shall be replaced.

10-2.1

Test results shall be compared with those of the original acceptance test (if available) and with the most recent test results.

10-2.2

Inspection and testing requirements for each component are provided in Tables 10-2(a) and (b).

10-2.3

Specialized equipment required for testing shall be in accordance with the manufacturer's specifications.

Table 10-2(a) Inspection Frequencies

Item	Activity	Frequency
Water tank (unsupervised)	Check water level	Weekly
Air receiver (unsupervised)	Check air pressure	Weekly
Dedicated air compressor (unsupervised)	Check air pressure	Weekly
Water tank (supervised)	Check water level	Monthly
Air receiver (supervised)	Check air pressure	Monthly
Dedicated air compressor (supervised)	Check air pressure	Monthly
Air pressure cylinders (unsupervised)	Check pressure and indicator disk	Monthly
System operating components, including control valves (locked/unsupervised)	Inspect	Monthly
Air pressure cylinders (supervised)	Check pressure and indicator disk	Quarterly
System operating components, including control valves	Inspect	Quarterly
Waterflow alarm and supervisory devices	Inspect	Quarterly
Initiating devices and detectors	Inspect	Semiannually
Batteries, control panel, interface equipment	Inspect	Semiannually
System strainers and filters	Inspect	Annually
Control equipment, fiber optic cable connections	Inspect	Annually
Piping, fittings, hangers, nozzles, flexible tubing	Inspect	Annually

Table 10-2(b) Testing Frequencies

Item	Activity	Frequency
Pumps	Operation test (no flow)	Weekly
Compressor (dedicated)	Start	Monthly
Control equipment (functions, fuses, interfaces, primary power, remote alarm) (unsupervised)	Test	Quarterly
System main drain	Drain test	Quarterly
Remote alarm annunciation	Test	Annually
Pumps	Function test (full flow)	Annually
Batteries	Test	Semiannually
Pressure relief valve	Manually operate	Semiannually
Control equipment (functions, fuses, interfaces, primary power, remote alarm) (supervised)	Test	Annually
Water level switch	Test	Annually
Detectors (other than single use or self-testing)	Test	Annually
Release mechanisms (manual and automatic)	Test	Annually
Control unit/programmable logic control	Test	Annually
Section valve	Function test	Annually
Water	Analysis of contents	Annually
Pressure cylinders (normally at atmospheric pressure)	Pressurize cylinder (discharge if possible)	Annually
System	Flow test	Annually
Pressure cylinders	Hydrostatic test	5-12 years
Automatic nozzles	Test (random sample)	20 years

10-2.4

High pressure cylinders used in water mist systems shall not be recharged without a hydrostatic test (and remarking) if more than 5 years have elapsed from the date of the last test. Cylinders that have been in continuous service without discharging shall be permitted to be retained in service for a maximum of 12 years, after which they shall be discharged and retested before being returned to service.

10-3 Maintenance.

10-3.1

Maintenance shall be performed to keep the system equipment operable or to make repairs. As-built system installation drawings, original acceptance test records, and device manufacturer's maintenance bulletins shall be retained to assist in the proper care of the system and its components.

10-3.2

Preventive maintenance includes, but is not limited to, lubricating control valve stems, adjusting packing glands on valves and pumps, bleeding moisture and condensation from air compressors and air lines, and cleaning strainers. Scheduled maintenance shall be performed as outlined in Table 10-3.2.

Table 10-3.2 Maintenance Frequencies

Item	Activity	Frequency
Water tank	Drain and refill	Annually
System	Flushing	Annually
Strainers and filters	Clean or replace as required	After system operation

10-3.3

Corrective maintenance includes, but is not limited to, replacing loaded, corroded, or painted nozzles, replacing missing or loose pipe hangers, cleaning clogged fire pumps, replacing valve seats and gaskets, and restoring heat in areas subject to freezing temperatures where water-filled piping is installed.

10-3.4

Emergency maintenance includes, but is not limited to, repairs due to piping failures caused by freezing or impact damage, repairs to broken water mains, and replacing frozen or fused nozzles, defective electric power, or alarm and detection system wiring.

10-3.5

Specific maintenance activities, where applicable to the type of water mist system, shall be performed in accordance with the schedules in Table 10-3.2.

10-3.6

Replacement components shall be in accordance with the manufacturer's specifications and the original system design. Spare components shall be readily accessible and shall be stored in a manner to prevent damage or contamination.

10-3.7*

After each system operation, a representative sample of operated water mist nozzles in the activated zone shall be inspected.

10-3.8

After each system operation due to fire, the system filters and strainers shall be cleaned or replaced.

10-4 Training.

All persons who might be expected to inspect, test, maintain, or operate water mist systems shall be trained thoroughly in the functions they are expected to perform. Refresher training shall be provided as recommended by the manufacturer or by the authority having jurisdiction.

Chapter 11 Marine Systems

11-1 General.

This chapter outlines the deletions, modifications, and additions that are necessary for marine applications. All other requirements of NFPA 750, *Standard on Water Mist Fire Protection Systems*, shall apply to shipboard systems except as modified by this chapter.

11-1.1

The following definitions shall be applicable to this chapter.

Flammable Liquid Hazards Systems. Systems protecting spaces where the predominant hazard consists of flammable and combustible liquids. Examples include machinery spaces, flammable liquid store rooms, cargo pump rooms and paint lockers.

Sprinkler Equivalent Systems. Systems protecting spaces where the predominant hazard consists of Class A combustibles. Examples include accommodation spaces, public spaces, galleys, and store rooms.

11-1.2*

The efficacy and reliability of all marine water mist system arrangements and their components shall be tested in accordance with standards developed by the International Maritime Organization (IMO).

11-1.2.1 Sprinkler equivalent systems shall comply with the fire suppression and component manufacturing tests of IMO Assembly Resolution A.800(19).

11-1.2.2 Flammable liquid hazard systems shall comply with fire suppression and components manufacturing tests contained in IMO *Maritime Safety Committee Circular* 668, as amended by IMO FP40/WP.9 Annex 3, *Report of the 40th Session of the Subcommittee on Fire Protection.*.

11-1.3

All marine water mist systems and their components shall be listed or approved.

11-1.4

The system and equipment shall be suitably designed to withstand ambient temperature changes, vibrations, humidity, shock, impact, clogging, and corrosion normally encountered in ships.

11-1.5*

Equipment and piping systems mounting and hanging practices shall be in accordance with internationally recognized standards for marine applications.

11-1.6*

The required water mist pumps shall be arranged such that with the largest pump out of service, the greatest system demand can still be satisfied.

11-1.7 Controls and Alarms.

11-1.7.1 Pump systems shall have the following:

(a) Automatic pump start-up; and

(b) Manual pump start and annunciation at the following locations:

1. Near the pump;
2. Engine control room; and
3. Central control station where provided.

11-1.7.2 Annunciation shall include (as applicable):

(a) Power available/power failure;

(b) Water flow and location;

(c) Pump run; and

(d) Diesel driver oil pressure.

11-1.7.3 Any flow condition shall sound an alarm on the bridge or at a constantly manned control station.

11-1.7.4 On the bridge and in the engine control room there shall be a pressure monitor consisting of one of the following:

(a) Pressure gauge;

(b) Transducer system; or

(c) High/low/OK pressure switch.

11-2 Sprinkler Equivalent Systems.

11-2.1

The system shall be automatic.

11-2.2

The water mist system shall be adequate to supply the system with fresh water for a period of at least 30 minutes. The vessel's potable water supply shall be permitted to constitute an acceptable source to satisfy the 30-minute demand period.

11-2.3

A pressure tank system shall be provided to meet the functional requirements for Safety of Life at Sea (SOLAS) Regulation II-2/12.4.1.

11-2.4*

After 30 minutes of system activation, manual intervention shall be permitted for continued operation.

11-2.5

The system shall be fitted with a permanent sea inlet and be capable of continuous operation using sea water for a period of at least 120 minutes.

11-2.6

Strainers and filters shall be provided and sized for the worst case water quality conditions expected.

11-2.7*

The system shall be of the wet pipe type.

Exception: Where environmental conditions dictate, small sections are permitted to be of another approved type.

11-2.8

The system shall be provided with main and emergency sources of power.

11-2.9

Pumps and alternate supply components shall be sized to be capable of maintaining the required flow.

11-2.10

The water supply shall be sufficient to meet the flow and pressure requirements as determined by the listing of all nozzles in the hydraulically most remote design area determined in accordance with 11-2.10.1 and 11-2.10.2.

11-2.10.1 In ordinary hazard public spaces, the design area shall be 3014 ft^2 (280 m^2).

11-2.10.2 In light hazard public spaces and accommodation spaces, the design area shall be 1507 ft^2 (140 m^2).

Exception: The water supply requirements for nozzles only shall be based upon the room that creates the greatest demand. The density selected shall be in accordance with the listing. To utilize this method, all rooms shall be enclosed with walls having a fire resistance rating equivalent to an A-15 or B-15 rating.

Minimum protection of opening shall be as follows:

Light hazard. Automatic or self-closing doors.

Exception: Where opening is not protected, calculations shall include the nozzle in the room plus two nozzles in the communication space nearest each such unprotected opening unless the communication space has only one nozzle, in which case calculations shall be extended to the operation of that nozzle. The selection of the room and communication space nozzles to be calculated shall be that which produces the greatest hydraulic demand.

Ordinary and extra hazard. Automatic or self-closing doors with appropriate fire resistance ratings for the enclosure.

11-2.11

The water supply shall be sufficient to meet the total flow and pressure requirements of all nozzles in the hydraulically most remote design area determined in conformance with 11-2.11.1

and 11-2.11.2.

11-2.11.1 In ordinary hazard public spaces, the design area shall be 3014 ft^2 (280 m^2).

11-2.11.2 In light hazard public spaces and accommodation spaces, the design area shall be 1507 ft^2 (140 m^2), plus 3 nozzles in the corridor outside the compartment.

Exception: In accommodation spaces consisting of small compartments and an adjacent corridor, the design area shall include all nozzles in the largest compartment plus 3 nozzles in the corridor outside the compartment, provided that the compartment boundaries (floors, walls, ceilings) meet the following conditions:

(a) Open to the weather; or

(b) Have a fire resistance rating of not less than 15 minutes; and

(c) Doors opening into adjacent spaces or onto the corridor have a fire resistance rating of not less than 15 minutes and are equipped with automatic self-closing devices designed to close the doors on receipt of signal from the fire alarm system or upon actuation of the water mist system.

11-2.12

Spaces shall be permitted to be protected with alternate, approved fire suppression systems when such areas are separated from mist protected areas with a 1-hour rated assembly.

11-2.13

Water mist supply components shall be located outside Category A machinery spaces. This shall apply to pumps, pressure tanks, cylinder tanks, emergency power cables, and controllers.

11-3 Flammable Liquids.

11-3.1

This section applies to flammable liquid hazard systems.

11-3.2

Flammable liquid hazard systems shall be shown by test to be capable of extinguishing a variety of fires that can occur in spaces where the predominate hazard consists of flammable liquids.

11-3.2.1 Systems for machinery spaces and cargo pump rooms shall be capable of fire extinguishment as demonstrated by testing in accordance with IMO Fire Test Procedures. Systems for flammable liquid store rooms, paint lockers, and other flammable liquid hazards shall be based on tests acceptable to the authority having jurisdiction. Nozzle locations, types of nozzles, and spray characteristics shall be within the limits tested.

11-3.3*

The system shall be capable of manual actuation allowing water to discharge into the protected space without the necessity of further human intervention.

11-3.3.1* After 30 minutes of system activation, manual intervention shall be permitted for continued operation.

11-3.4*

Where time delays are provided, audible and visual signals shall be provide throughout the protected space.

11-3.5 Water Supply.

11-3.5.1 The system's water supply shall be available for immediate use.

11-3.5.2 The water supply shall be based on complete protection of the space demanding the greatest quantity of water.

11-3.5.3 Pressure tank(s) shall be provided to immediately supply the system at the design flow and pressure for not less than 60 seconds.

11-3.5.4 The water supply shall be adequate to supply the system with fresh water for a period of at least 30 minutes. The vessel's potable water supply shall be permitted to constitute an acceptable source to satisfy the 30-minute demand period.

11-3.5.4.1 The fresh water supply shall meet the water quality requirements of 7-5.1.

11-3.5.5 Where the water mist system is designed for uniform cycling, the maximum-reduced discharge period is 60 seconds.

11-3.5.6* The minimum quantity of water used in uniform cycling systems shall be the maximum system flow for a 15-minute constant duration.

11-3.5.7* The system shall be fitted with a permanent sea inlet and be capable of continuous operation using sea water.

11-3.6* Power Supplies.

The system shall be provided with both main and emergency sources of power and shall be provided with automatic change over. One of those sources of power shall be wholly provided from outside the protected space.

11-3.7

Pressure source components of the system shall be located outside the protected space.

11-3.8

A means to allow for periodic testing of the operation of the system for assuring the required pressure and flow shall be provided.

11-4* Human Factors.

Human factors shall be considered to the extent practicable during the design of water mist systems on marine vessels.

Chapter 12 Referenced Publications

Appendix A Explanatory Material

This Appendix is not part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1 Other NFPA standards should be referenced for additional requirements relating to underground or lead-in connections to water mist systems from municipal or private water supplies.

A-1-4.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4.1 Authority Having Jurisdiction. The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4.1 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-1-4.1 Water Mist. This standard addresses the use of fine water sprays for the efficient control or extinguishment of fires using limited volumes of water. Properly designed water mist systems can be effective on both liquid fuel (Class B) and solid fuel (Class A) fires. Research indicates that droplets smaller than 400 microns are essential for extinguishment of Class B fires, while larger drop sizes are effective for Class A combustibles, which benefit from extinguishment by fuel wetting. For this reason the definition of water mist in this standard includes sprays with $Dv_{0.99}$ of up to 1000 microns.

This standard's definition of "water mist" includes some water sprays used in NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, some sprays produced by standard sprinklers operating at high pressure, as well as light mists suitable for greenhouse misting and HVAC humidification systems. This range is so broad that some important differences in the performance of sprays with finer distributions are not distinguished.

As a means of allowing distinctions to be made between "coarser" and "finer" sprays across the 1000-micron spectrum of this standard's definition of water mist, it is useful to subdivide mist into Class 1, 2, or 3 water mist, according to the drop size distribution. The defining boundaries for the three classifications are illustrated in Figure A-1-4.1.

Class 1 Water Mist. The cumulative percent volume distribution curve lies entirely to the left of a line connecting $Dv_{0.1}$ = 100 microns and $Dv_{0.9}$ = 200 microns. This represents the "finest" water mist. Many commercially available water mist nozzles produce Class 1 mists.

Class 2 Water Mist. A portion of the cumulative percent volume distribution curve lies beyond the limits of a Class 1 spray, but entirely to the left of the line connecting $Dv_{0.1}$ = 200 microns and $Dv_{0.9}$ = 400 microns. Such sprays can be generated by pressure jet nozzles, twin-fluid nozzles, and many impingement nozzles. Due to the presence of larger drops, higher mass flow rates are easier to achieve with Class 2 sprays than with Class 1 sprays. The larger drops are not too large to be effective on liquid fuel fires, however. Considerable surface wetting occurs with sprays in this range, so a Class 2 mist is also likely to be effective on fires involving ordinary combustibles.

Class 3 Water Mist. The $Dv_{0.9}$ is greater than 400 microns, or for which any portion of the curve extends to the right of the Class 2 cut-off line (but the $Dv_{0.99}$ is less than 1000 microns). Such sprays are typically generated by intermediate pressure, small orifice sprinklers, impingement nozzles of various sorts, and fire hose fog-nozzles. High mass flow rates are possible. They are suitable for Class A combustibles, and under some circumstances provide fire control or fire extinguishment for Class B fires.

The relationship between drop size distribution and extinguishing capacity of a water mist is complex. In general, Class 1 and Class 2 sprays are successful at extinguishing liquid fuel pool fires and spray fires without agitation of liquid pool surfaces. Given an appropriate geometry, Class 3 sprays are reported to have extinguished pool fires, however. Also in general, it is difficult to extinguish Class A combustibles with Class 1 sprays, which may not achieve the fuel wetting necessary to penetrate the char layer. However, Class A fires can be extinguished with Class 1 mists, particularly if the velocity is high, the burning is superficial, or enclosure effects enhance the degree of oxygen reduction. This evidence confirms that drop size distribution alone does not determine the ability of a spray to extinguish a given fire. Factors such as fuel properties, enclosure effects, spray flux density, and spray velocity (momentum) are all involved in determining whether a fire will be extinguished.

The drop size distribution of a spray does not uniquely define its suitability for a given application. It is inseparable from the spray direction relative to the fire plume, its velocity and flux density. The "momentum" of an element of spray is the product of its velocity (which includes direction as well as speed) and the mass of dispersed water droplets. Therefore, all three variables, drop size distribution, flux density and momentum, are involved in determining the ability to extinguish a fire in a given scenario. The classification system allows a designer to distinguish between the fine and coarse end of the spectrum of sprays encompassed by the definition.

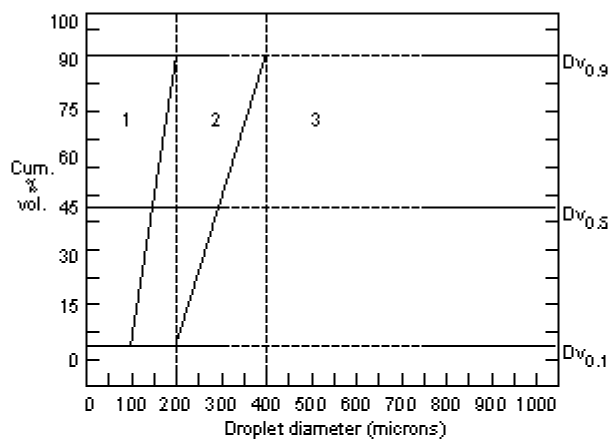

Figure A-1-4.1 Classification of water mist according to drop size distribution.

A-1-5 Applications of Water Mist Systems. Water mist systems have been proven effective in controlling, suppressing, or extinguishing many types of fires. Potential applications include:

(a) Gas jet fires;

(b) Flammable and combustible liquids;

(c) Hazardous solids, including fires involving plastic foam furnishings;

(d) Protection of aircraft occupants from an external pool fire long enough to provide time to escape;

(e) Ordinary (Class A) combustible fires such as paper, wood, and textiles;

(f) Electrical hazards, such as transformers, switches, circuit breakers, and rotating equipment; and

(g) Electronic equipment, including telecommunications equipment.

A-1-5.2.2 Water Reactive Materials. In special cases, where adequate safeguards have been provided, water mist systems for the protection of structures, equipment, or personnel in the presence of such materials as described in 1-5.2.2 may be permitted.

A-1-6.1 Water mist is unlikely to present any significant hazard to personnel in most applications; however, direct impingement of the water mist could present an eye hazard. Noise during operation of the water mist systems could be a hazard to hearing. Water mist can reduce visibility and increase the time and difficulty in egress from an affected compartment. Additionally, whipping or swinging of broken piping, tubing, and hoses could be a hazard, particularly for intermediate and high pressure systems.

A-1-6.2.1 Electrical Clearances. All system components should be located so as to maintain minimum clearances from live parts, as shown in Table A-1-6.2.1.

As used in this standard, "clearance" is the air distance between water mist equipment, including piping and nozzles, and unenclosed or uninsulated live electrical components at other than ground potential.

The clearances in Table A-1-6.2.1 are for altitudes of 3300 ft (1000 m). The clearance should be increased at the rate of 1 percent for each 330 ft (100 m) increase in altitude above 3300 ft (1000 m).

Table A-1-6.2.1 Clearance from Water Mist Equipment Live Uninsulated Electrical Components[1]

	Nominal System Voltage (kV)	Maximum System Voltage (kV)	Design BIL2 (kV)	Minimum[1] Clearance (in.)	Minimum[1] Clearance (mm)
To	13.8	14.5	110	7	178
	23	24.3	150	10	254
	34.5	36.5	200	13	330
	46	48.5	250	17	432

69	72.5	350	25	635
115	121	550	42	1067
138	145	650	50	1270
161	169	750	58	1473
230	242	900 1050	76 84	1930 2134
345	362	1050 1300	84 104	2134 2642
500	550	1500 1800	124 144	3150 3658
765	800	2050	167	4242

[1]For voltages up to 161 kV, the clearances are taken from NFPA 70, *National Electrical Code*. For voltages 230 kV and above, the clearances are taken from Table 124 of ANSI C2, *National Electrical Safety Code*.

[2]BIL values are expressed as kilovolts (kV), the number being the crest value of the full wave impulse test that the electrical equipment is designed to withstand. For BIL values that are not listed in the table, clearances may be found by interpolation.

A-2-2.2.1 Local building codes specify minimum requirements for seismic restraint or bracing.

A-2-2.2.2 Independent inspection and certification is recommended for gas and water containers.

A-2-3.1 It is important to select pipe or tube for water mist systems that exhibits minimal corrosion because of the potential for the clogging of water mist nozzles.

A-2-3.4.2 Listed flexible connections may be permitted. Flexible connections for water mist installations should be kept as short as possible and should be protected against mechanical injury.

A-2-4.1 It is important to select fittings for water mist systems that exhibit minimal corrosion because of the potential for the clogging of water mist nozzles.

A-2-4.2.2 Rubber-gasketed pipe fittings and couplings should not be installed where ambient temperatures can be expected to exceed 150°F (66°C) unless listed for such service. If the manufacturer further limits a given gasket compound, those recommendations should be followed.

A-2-6.1 In recognition of the future value of scientifically based fire protection system engineering or design methods but in consideration of the fact that the present water mist technology base is likely incomplete for general system design purposes, it is recommended that the nozzle-listing agencies collect and report to the manufacturer the following data for possible future use as required listing information:

(a) Cumulative volumetric distribution of water droplets to be measured at the centers on nine 1-ft × 1-ft (0.305-m × 0.305-m) areas projecting outward from the central axis of the nozzle for a total of 3 ft × 3 ft (0.914 m × 0.914 m), in a quadrant, with the plane of the measurements to be oriented perpendicular to the central axis of the nozzle and positioned 39.4 in. (1.0 m) below the nozzle. The measurements are to be made at the minimum- and maximum-rated operating pressures of the nozzle, in accordance with ASTM E 799, *Standard Practice for Determining*

Data Criteria and Processing for Liquid Drop Size Analysis.

(b) Water discharge distribution in a plane 3.3 ft (1.0 m) below and perpendicular to the central axis of the nozzle using 1-ft × 1-ft (0.305-m × 0.305-m) collection pans. The water distribution measurements are to be made at the minimum- and maximum-rated operating pressures of the nozzle and over an area sufficient to collect at least 90 percent of the water discharge.

(c) Profile of the nozzle spray envelope encompassing at least 90 percent of the water discharge, measured from the tip of the nozzle and extending over the effective range determined from the listing investigation. The profile of the nozzle spray envelope is to be provided at the minimum- and maximum-rated operating pressures of the nozzle as well as over the intended range of orientation angles, if in other than the vertically down orientation.

(d) Spray thrust force as measured in a plane perpendicular to the central axis of the nozzle, at a distance of 1 ft (0.305 m) below the nozzle and over an area sufficient to capture at least 90 percent of the water discharge. The measurements are to be made at the minimum- and maximum-rated operating pressures of the nozzle.

For fire test purposes, the maximum distance from test fires should be considered as:

(a) The manufacturer's maximum spacing of nozzles from walls or one half of the manufacturer's recommended maximum spacing between nozzles, whichever is greater; or

(b) The manufacturer's recommended placement of nozzles with regard to local hazard protection.

A-2-10.2.1 Detectors installed at the maximum spacing as listed or approved for fire alarm use could result in excessive delay in water mist system actuation, especially where more than one detection device is required to be in alarm before automatic actuation results.

A-3-2.2.1 The simultaneous operation of all nozzles in the space should be achieved by the use of pilot activation nozzles, automatic nozzles, or by an independent detection system.

A-3-5 Single fluid and twin fluid systems can be operated in the low, intermediate, or high pressure range.

Single Fluid Media Systems. A single fluid media system requires one set of distribution piping to transport the fluid to each nozzle.

Single fluid media systems shall produce water mist (droplet production) by one of the means specified below.

Liquid shall be discharged at a high velocity with respect to the surrounding air. The difference in velocities between the liquid and surrounding air shall shear the liquid into small droplets.

A liquid stream is impinged upon a fixed surface. The impact of the liquid on the surface breaks the liquid stream into small droplets.

Two liquid streams of similar composition collide upon one another. The collision of the two streams breaks the individual streams into small droplets.

Liquid is either vibrated or electrically broken into small droplets (ultrasonic and electrostatic atomizers).

Liquid is heated above its boiling point in a pressurized container and released suddenly to atmospheric pressure (flashing liquid sprays).

Twin Fluid Media Systems. Twin fluid media systems produce water mist (droplet production) by impingement of two fluids delivered from separate piping systems. One set of piping provides a liquid (water) to the nozzle, with the second piping network providing an atomizing fluid/media.

A-4-5.3 When the storage container(s) is placed in the hazard area being protected, provisions shall be made to ensure that the system operation is not adversely affected by its location.

A-4-6.1 Sizing pumps at 120 percent is arbitrary, but it is one way to ensure that the pump curve lies above the system operating point. It could be 110 percent or 150 percent, depending on the degree of conservatism desired. If the system strainer is likely to become partially clogged during operation, the overage should be increased.

A-4-8.1.7 Exception. Sectional control valves and group control valves that are intended to be normally closed, and to be automatically opened by an electrical or pneumatic or hydraulic signal from the system control center, do not have to be locked open. Such control valves should be tested as integral parts of the system and described in the listing literature. The tests for listing of systems incorporating normally closed, remotely activated sectional valves should address concerns about reliability of function.

A-4-9.1.2 In order to prevent system impairment from two or more ground faults or a single open circuit condition, Class A circuits should be considered.

A-4-9.3.1 Detectors installed at the maximum spacing as listed or approved for fire alarm use can result in excessive delay in agent release, especially where more than one detection device is required to be in alarm before automatic actuation results.

A-5-2.1.2.1 Natural ventilation/openings in the compartment allow the hot gases layer (ceiling jet) to exhaust mist from the compartment, decreasing the extinguishing potential. The flow of gases into and out of the compartment also alters the mixing characteristics of the system, which, in turn, might require the additional momentum of the mist in order to overcome this alteration. Forced ventilation also significantly reduces the amount of mist in the compartment as well as affects the mixing characteristics of the system.

Prior to or concurrent with the operation of the water mist system, consideration should be given to automatic closing of doors and dampers, shutdown of electrical equipment, and shutdown of HVAC equipment.

A-5-3.3 Results. The results of the listing testing should identify the following:

(a) System Flow Rate (minimum and maximum).

1. Flow rate per unit area (if applicable); and
2. Flow rate per unit volume (if applicable).

(b) System Operating Pressure (minimum and maximum).

1. Nozzle operating pressure range;
2. Pump/cylinder operating pressure range; and
3. Pump inlet and outlet pressure and flow rate requirements.

(c) General Water Requirements.

1. Quantity/duration;
2. Quality; and
3. Temperature.

(d) Nozzle Characteristics.

1. Type(s)/model numbers;
2. Flow rate (minimum and maximum); and
3. Operating pressure (minimum and maximum).

(e) Nozzle Spray Characteristics.

1. Spray angle;
2. Drop size distribution; and
3. Momentum/velocity.

(f) Nozzle Installation Parameters.

1. Distance above floor (minimum and maximum);
2. Distance below ceiling (minimum and maximum);
3. Distance above hazard (minimum and maximum);
4. Nozzle spacing (minimum and maximum);
5. Orientation;
6. Minimum distance from walls; and
7. Minimum distance from obstructions.

(g) Activation Device.

1. Type/model number;
2. Activation, temperature; and
3. Activation, smoke obscuration.

(h) General Design Parameters.

1. Pipe Requirements.
   a. Size; and
   b. Operating pressures/wall thicknesses.
2. Fittings.
   a. Type; and
   b. Operating pressure.

3. Pumps.

a. Valves, fittings, and filters;

b. Power requirements;

c. Operating pressure and flow rates; and

d. Water requirements.

4. Cylinders.

a. Valves and fittings;

b. Capacity; and

c. Operating pressures.

A-6-1.1 The addition of piping and nozzles to an existing water mist system can render the system ineffective if it leads to reduced pressure and flow. The existing piping does not have to be increased in size to compensate for additional nozzles, provided that the new work is calculated and the calculations include that portion of the existing system that is necessary to carry water or atomizing medium (if used) to the new work.

A-6-2 The Hazen-Williams (H-W) equation cannot be corrected for flow velocity, water temperature, viscosity, or pipe-wall roughness factors, all of which significantly affect the degree of turbulence, hence the pressure losses in piping. Water mist systems in general, and intermediate and high pressure systems in particular [>175 psi to 4000 psi (>12 bar to 270 bar)], are likely to create conditions where there could be higher velocities, different water properties, or smaller diameter pipe than are used in low-pressure systems. (As pipe diameters decrease, the relative effect of wall roughness increases). Because it allows for input of actual fluid properties, the Darcy-Weisbach (D-W) equation should be used instead of the H-W equation for intermediate and high pressure systems.

A-6-3 Many low pressure water mist systems will be similar to standard fire protection systems, such as sprinklers (NFPA 13, *Standard for the Installation of Sprinkler Systems*) and water spray systems (NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*). It is expected that piping materials, fittings, valves, and pipe sizes will be selected in accordance with those standards. These expectations imply that velocities in the piping will be in the same range as in sprinkler piping. This assumed similarity to sprinkler piping is the reason this standard accepts the use of the H-W equation for low pressure water mist systems.

Not all low pressure water mist system piping will necessarily be similar to sprinkler piping, however. The designer may choose to use small diameter piping in order to reduce system weight, or, to live with high friction losses in piping in order to be able to install piping in a restricted space, as in an aircraft cargo compartment. Use of small diameter piping will put the velocities higher than is "normal" in sprinkler piping, which introduces the probability that the H-W equation will not be accurate. Values of the friction loss coefficient, C, which is used in the H-W equation, are accurate only if the flow velocity is close to that at which the value of "C" was measured. It is a matter of judgement as to what velocity is "too high" for the H-W equation. American Water Works Association (AWWA) data lists C factors measured at a velocity of 3 ft/sec (0.9 m/s), yet it is accepted practice in sprinkler calculations to have velocities in sprinkler piping between 10 ft/sec and 30 ft/sec (3.05 m/s and 9.1 m/s). Similarly, the tables of equivalent lengths for fittings and valves, used by sprinkler system designers, are based on fittings and valve types typical of sprinkler system. Water mist systems may incorporate different types of fittings and valves, for which the H-W-based equivalent length values will be incorrect. In the interest of "good practice," the water mist system designer should use the D-W equation for low pressure system calculations when pipe sizes or other system features, such as the use of solenoid valves, differ significantly from normal sprinkler practices.

It is also important to note that the H-W equation contains no terms that account for the temperature. Hence, density and viscosity of the liquid also are not taken into account. It assumes that the water contains no additives and is close to 60°F (15.6°C). If viscosity or water temperature depart significantly from typical sprinkler system water supply conditions, the D-W equation should be used instead, regardless of the pressure regime or flow velocities.

A-7-1.2 Although some water discharge might continue after the atomizing medium has been exhausted, it is not effective for fire suppression.

A-7-2 Some water mist systems protect single hazards or areas. Other system designs are based on multiple zones with overlapping protection at the zone boundaries. It is also possible for one water mist system to provide local application protection for several individual hazards. Quantities of water and of atomizing media should be based on the most demanding location for the fire. For example, if a fire could start at the intersection of four zones, the water supply and the atomizing medium (if used) should be able to supply all four zones simultaneously. If a water mist system protects several individual hazards that are located in close proximity, it might be necessary to design for simultaneous operation of multiple local application zones.

A-7-3 The 30-minute water supply requirement applies to water supply capacity and does not require that the system actually discharge for 30 minutes. This minimum duration should be provided for all water mist systems that are installed for life safety purposes or for structural protection. For water mist systems designed to protect equipment or other special hazards in unoccupied areas, Exception No. 1 allows the water supply duration to be determined in accordance with Chapter 5. Exception No. 2 provides for performance-based design of water mist systems by qualified fire protection engineers. It should be noted that, currently, there is no generally accepted method for performance-based design of a water mist system.

A-7-4.1 An extra supply (connected reserve) of extinguishing agent (including additives and atomizing medium, if used) piped to feed into the automatic system should be considered on all installations. The reserve supply is normally actuated by manual operation of the main/reserve switch on either electrically operated or pneumatically operated systems. A connected reserve is desirable for the following reasons:

(a) Provides improved reliability for systems used for protection of life safety;

(b) Provides protection should a reflash occur;

(c) Provides reliability should the main bank malfunction; and

(d) Provides protection of other hazards, if selector valves are involved and multiple hazards are protected by the same set of cylinders.

A-7-5.1 Algae and bacteriological growth in stored water can clog the system by blocking the filters or strainers. Annual sampling or replacement of stored water is required by Table 10-2(b).

A-7-5.5 It is the intention of this section to require a fire department connection wherever it would be of benefit. Exception No. 2 provides for local area protection where the fire department could effectively respond with small hose streams or portable fire extinguishers. Exception No. 3 provides for systems where the pressures available from fire department pumpers would not be adequate to supply the water mist system. Exception No. 4 exempts systems where the atomizing medium is essential for fire suppression, and water alone would be of no benefit.

A-9-2 Acceptance Test Recommendations.

(a) All tests should be made by the contractor in the presence of an authorized inspector. When an inspector is not available, tests may be permitted to be witnessed by the owner or owner's representative.

(b) Before asking for final approval of the protective equipment, installing companies should furnish a written statement to the effect that the work covered by its contract has been completed, and all specified flushing of underground, lead-in, and system piping has been completed, successfully, together with specified hydrostatic pressure tests.

A-9-2.4.2.10 Proper shielding and grounding is particularly important if ac and dc wiring are combined in a common conduit or raceway.

A-10-3.7 The representative sample should include 10 percent of the water mist nozzles in the activated zone. If contamination of filters or strainers is found on inspection, it is recommended that all nozzles within the activated zone also be inspected.

A-11-1.2 Reference is made to standards developed by the International Maritime Organization.

A-11-1.5 Refer to ASTM F 1547, *Standard Guide Listing Relevant Standards and Publications for Commercial Shipbuilding*, 1994, and ASME *Power Piping Code*.

A-11-1.6 Consideration should be given to physically separating the pumping units. It is recommended that not less than 40 percent of the maximum system's flow demand be provided from any single pumping location. Consideration shall be given to using designs incorporating looped systems or arrangements that allow a section to be taken out of service for maintenance. When pumps from another onboard fire protection system, such as fire main pumps, are used to satisfy this requirement, they should be sized to simultaneously supply both systems.

A-11-2.4 An example of an acceptable arrangement is manual operation of a sea chest valve (outside the protected space) to allow continued operation using seawater following the 30-minute stored fresh water operation.

A-11-2.7 Deluge or antifreeze systems may be needed where protected areas are subject to freezing. Piping subject to freezing may be subject to clogging by ice.

A-11-3.3 It is assumed that water mist systems for flammable liquid hazards and compartments require the simultaneous release of water mist from all nozzles in groups of nozzles in the manner of total flooding systems. If systems that operate using individually thermally actuated nozzles are shown by test to have the capability of extinguishing the variety of fires of the machinery space fire test protocol, then manual actuation should cause sufficient nozzles to operate to achieve protection not less effective than that demonstrated in the test protocol.

A-11-3.3.1 An example of an acceptable arrangement is manual operation of a sea chest valve (outside the protected space) to allow continued operation on sea water following the 30-minute stored fresh water discharge.

A-11-3.4 Time delays are optional on water mist systems.

A-11-3.5.6 For systems that cycle, the 15-minute requirement represents 15 minutes at the maximum flow rate, as if the duty cycle was 100 percent for 15 minutes.

Examples include:

Constant. Such as supplied by a pump;

Decaying. Occurs when a pressure cylinder discharges;

Uniform cycling. When a timing device is used to periodically change the pressure or the flow rate; and

Nonuniform cycling. Such as when a heat detector cycles a system on and off.

A-11-3.5.7 Following the depletion of the 30-minute fresh water supply, if continuous sea water operation is provided at a pressure other than that used to successfully perform the machinery space fire tests of 11-3.2.1, the nozzle spray characteristics should be capable of maintaining the cooling of the compartment. Flow rates need not equal those of Safety of Life at Sea (SOLAS) Resolution 10 fixed pressure water spray systems.

A-11-3.6 It is recommended that on passenger ships designed to carry more than 36 persons and on all tank vessels, both the main and emergency sources of power should be from outside the protected space.

A-11-4 The ship's crew will be called upon to inspect, test, maintain, react to, and use some or all parts of the water mist fire suppression system. Therefore, the crew is an integral part of the system. Historically, the crew is the part of the system that system designers and installers have little or no control over. Much of the system will be designed to maintain readiness and operate without human intervention. However, system readiness and operation during an emergency will always involve human interaction with the system. Systems should include design and component features incorporating human factors so as to maximize readiness and utility during a fire.

Appendix B Research Summary

This Appendix is not part of the requirements of this NFPA document but is included for informational purposes only.

Water Mist Droplet Size Characterization and Measurement.

A key mechanism in the successful use of water mist fire protection systems is the increased surface area per unit water volume afforded with the generation and application of small droplets. The increased surface area dramatically increases the rate of heat transfer from the fire to the water mist droplet, cooling the combustion reaction and diluting the oxygen concentration with the generation of water vapor in the vicinity of the fire. It is important to characterize the droplet size distribution produced in listed nozzles for use in the future design and application of water mist systems. It will be valuable in assessing the ability of water mist droplets to control, suppress, and extinguish fires of all types and sizes.

Presently, there are three basic techniques used for the characterization of droplet sizes in a nozzle spray: optical imaging; diffraction; and Doppler refraction. The first technique uses optical technology to photograph or electronically image the droplets in a small volume of the mist. The image is then analyzed to determine the size distribution of droplets on the image.

The second technique uses a collimated light source passed through the water mist. The water droplets diffract the light into a series of detectors. The angle of diffraction is a function of the size of the droplets in the light beam. By measuring the relative light intensities on the detectors, the distribution of droplet sizes can be determined.

The third technique uses a pair of crossed laser beams to generate a small sample volume through which the water droplets pass. The laser light is refracted inside the droplets and detected off-axis. The detector signal is processed to define the droplet size and velocity distributions.

All three techniques are automated in most commercially available measuring instruments, sampling tens of thousands of droplets for the determination of a droplet size distribution. The instruments typically divide the sizes into categories, or "bind," defined by a range of diameters assigned to each bin. Results are then reported as the number of droplets in each bin or as a fractional distribution of number count or total volume in each bin.

Most commercially available measuring instruments also present additional measurements of size distribution significant to the characterization of a water mist. One of these is the Sauter Mean Diameter (SMD), defined as the total volume of the measured droplet population divided by the total surface area of the population. SMD is often used as characteristic dimension when mass transfer (including phase change) is the key process. Another important measurement is the maximum diameter at which a specified fraction of the total volume is accumulated. For example, $Dv_{0.10}$ represents the diameter at which 10 percent of the total volume of the water mist is contained in droplets at or less than the specified diameter. By this definition, $Dv_{0.10}$ represents the volumetric median diameter, that is 50 percent of the total volume of the total water mist is contained in droplets equal to or less than this diameter and 50 percent is contained in droplets of greater diameter.

NFPA 780

1995 Edition

Standard for the Installation of Lightning Protection Systems

1995 Edition

This edition of NFPA 780, *Standard for the Installation of Lightning Protection Systems*, was prepared by the Technical Committee on Lightning Protection and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council with modifications to the document's scope and title, on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 780 was approved as an American National Standard on August 18, 1995.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 780

The National Fire Protection Association first adopted *Specifications for Protection of Buildings Against Lightning* in 1904. Revised standards were adopted in 1905, 1906, 1925, 1932, and 1937. In 1945, the NFPA Committee and the parallel ASA Committee on Protection Against Lightning were reorganized and combined under the sponsorship of the NFPA, the National Bureau of Standards, and the American Institute of Electrical Engineers (now the IEEE). In 1946, the NFPA acted to adopt Part III and in 1947 published a revised edition incorporating this part. Further revisions, recommended by the Committee, were adopted by the NFPA in 1949, 1950, 1951, 1952, 1957, 1959, 1963, 1965, 1968, 1975, 1977, 1980, 1983, 1986, 1989, and 1992.

Commencing with the 1992 edition of the *Lightning Protection Code*, the NFPA numerical designation of the document was changed from NFPA 78 to NFPA 780.

Commencing with the current edition, the name of the document has been changed from *Lightning Protection Code* to *Standard for the Installation of Lightning Protection Systems*. This change was directed by the Standards Council on issuance of the document in order to make the title more accurately reflect the document's content. In addition, the Council directed certain changes to the scope of the document in order to clarify that the document does not cover lightning protection installation requirements for early streamer emission systems or lightning dissipator array systems.

In issuing this document, the Standards Council has noted that lightning is a stochastic, if not capricious, natural process. Its behavior is not yet completely understood. This standard is intended to provide requirements, within the limits of the current state of knowledge, for the installation of those lightning protection systems covered by the standard.

Notice

Following the issuance of this edition of NFPA 780, *Standard for the Installation of Lightining Protection Systems*, by the NFPA Standards Council, an appeal was filed with the NFPA Board of Directors. At the time of printing, this appeal was pending.

The appeal requests that the Board of Directors reverse the Standards Council decision to issue the 1995 edition of NFPA 780.

NFPA will announce the disposition of the appeal when it has been determined. Anyone wishing to receive the disposition of the appeal should notify in writing the Secretary, Standards Council, NFPA, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the protection from lightning of buildings and structures, recreation and sports areas, and any other situations involving danger from lightning to people or property, except those concepts utilizing early streamer emission air terminals. The protection of electric generating, transmission, and distribution systems is not within the scope of this Committee.

NFPA 780
Standard for the Installation of Lightning Protection Systems

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Appendix M.

Chapter 1 Introduction

1-1 Scope.

1-1.1

This document covers lightning protection system installation requirements for:

(a) ordinary structures;

(b) miscellaneous structures and special occupancies;

(c) heavy duty stacks;

(d) watercraft; or

(e) structures containing flammable vapors, flammable gases, or liquids that can give off flammable vapors.

1-1.2*

This document does not cover lightning protection installation requirements for:

(a) explosives manufacturing buildings and magazines; or

(b) electric generating, transmission, and distribution systems.

1-1.3

This document does not cover lightning protection installation requirements for early streamer emission systems or lightning dissipator array systems.

1-2 Purpose.

The purpose of this standard is the practical safeguarding of persons and property from hazards arising from exposure to lightning.

1-3 Listed, Labeled, or Approved Components.

Where fittings, devices, or other components required by this standard are available as Listed or Labeled, such components shall be used. Otherwise, such components shall be approved by the authority having jurisdiction.

1-4 Mechanical Execution of Work.

Lightning protection systems shall be installed in a neat and workmanlike manner.

Chapter 2 Terms and Definitions

2-1 General Terminology.

General terms commonly used in describing lightning protection methods and devices are defined or redefined to conform to recent trends:

Lightning Protection System. This term refers to systems as described and detailed in this standard. A lightning protection system is a complete system of air terminals, conductors, ground terminals, interconnecting conductors, surge suppression devices, and other connectors or fittings required to complete the system.

2-2* Definitions.

Air Terminal. An air terminal is that component of a lightning protection system that is intended to intercept lightning flashes. [*See Figure A-2-2(a).*]

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Bonding. An electrical connection between an electrically conductive object and a component of a lightning protection system that is intended to significantly reduce potential differences created by lightning currents. [*See Figure A-2-2(b).*]

Cable. A conductor formed of a number of wires stranded together. [*See Figure A-2-2(c) and Tables 3-4 and 3-5.*]

Chimney. A smoke or vent stack having a flue with a cross-sectional area less than 500 $in.^2$ (0.3 m^2) and a total height less than 75 ft (23 m). [*See Figure A-2-2(d).*]

Class I Materials. Lightning conductors, air terminals, ground terminals, and associated fittings required by this standard for the protection of structures not exceeding 75 ft (23 m) in height. [*See Figure A-2-2(e) and Table 3-4.*]

Class II Materials. Lightning conductors, air terminals, ground terminals, and associated fittings required by this standard for the protection of structures exceeding 75 ft (23 m) in height. [*See Figure A-2-2(e) and Table 3-5.*]

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C).

Combustible liquids shall be subdivided as follows:

Class II liquids shall include those having flash points at or above 100°F (37.8°C) and below 140°F (60°C).

Class IIIA liquids shall include those having flash points at or above 140°F (60°C) and below 200°F (93°C).

Class IIIB liquids shall include those having flash points at or above 200°F (93°C).

Conductor, Bonding. A conductor intended to be used for potential equalization between grounded metal bodies and the lightning protection system.

Conductor, Main. A conductor intended to be used to carry lightning currents between air terminations and ground terminals.

Copper-clad Steel. Steel with a coating of copper bonded to it.

Explosive Materials. These include explosives, blasting agents, and detonators as authorized for transportation by the Department of Transportation or the Department of Defense.

Fastener. An attachment to secure the conductor to the structure.

Flame Protection. Self-closing gauge hatches, vapor seals, pressure-vacuum breather valves, flame arresters, or other reasonably effective means to minimize the possibility of flame entering the vapor space of a tank.

Flammable Air-Vapor Mixtures. When flammable vapors are mixed with air in certain proportions, the mixture will burn rapidly when ignited. The combustion range for ordinary petroleum products, such as gasoline, is from about $1^1/_2$ to $7^1/_2$ percent of vapor by volume, the remainder being air.

Flammable Liquid. A liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psia (275 kPa) at 100°F (37.8°C) shall be known as a Class I liquid.

Class I liquids shall be subdivided as follows:

Class IA shall include those having flash points below 73°F (22.8°C) and having a boiling point below 100°F (37.8°C).

Class IB shall include those having flash points below 73°F (22.8°C) and having a boiling point at or above 100°F (37.8°C).

Class IC shall include those having flash points at or above 73°F (22.8°C) and below 100°F (37.8°C).

Flammable Vapors. The vapors given off from a flammable or combustible liquid at or above its flash point.

Flash Point. The minimum temperature at which a liquid gives off vapor in sufficient concentration to form an ignitable mixture with air near the surface of the liquid within the vessel, as specified by appropriate test procedure and apparatus.

Gastight. Structures so constructed that gas or air can neither enter nor leave the structure except through vents or piping provided for the purpose.

Ground Terminal. The portion of a lightning protection system such as a ground rod, ground plate, or ground conductor that is installed for the purpose of providing electrical contact with the earth. [*See Figure A-2-2(f).*]

Grounded. Connected to earth or to some conducting body that is connected to earth.

High-Rise Building. For the purposes of this standard a high-rise building is a structure exceeding 75 ft (23 m) in height.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Loop Conductor. A conductor encircling a structure that is used to interconnect ground terminals, main conductors, or other grounded bodies.

Metal-clad Structure. A structure with sides or roof, or both, covered with metal.

Metal-framed Structure. A structure with electrically continuous structural members of sufficient size to provide an electrical path equivalent to that of the lightning conductors covered in this standard.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Sideflash. An electrical spark, caused by differences of potential, occurring between conductive metal bodies or between such metal bodies and a component of the lightning protection system or ground. [*See Figure A-2-2(g).*]

Spark Gap. As used in this standard, the term spark gap means any short air space between two conductors electrically insulated from or remotely electrically connected to each other.

Stack, Heavy-duty. A smoke or vent stack is classified as heavy-duty if the cross-sectional area of the flue is greater than 500 in.^{2} (0.3 m^2) or the height is greater than 75 ft (23 m).

Striking Distance. The distance over which the final breakdown of the initial stroke occurs.

Surge Arrester. A protective device for limiting surge voltages by discharging or bypassing surge current. It also prevents continued flow of follow current while remaining capable of repeating these functions.

Vapor Openings. Openings through a tank shell or roof above the surface of the stored liquid. Such openings might be provided for tank breathing, tank gauging, fire fighting, or other operating purposes.

Watercraft. For the purpose of this document, watercraft is defined as all forms of boats and vessels up to 300 gross tons (272 metric tons) used for pleasure or commercial purposes, but excluding seaplanes, hovercraft, vessels with a cargo of flammable liquids, and submersible vessels.

Zone of Protection. The zone of protection is that space adjacent to a lightning protection system that is substantially immune to direct lightning flashes.

2-3 Metric Units of Measurement.

Metric units of measurement in this standard are in accordance with the modernized metric system known as the International System of Units (SI). If a value for measurement as given in this standard is followed by an equivalent value in other units, the first stated is to be regarded as the requirement. A given equivalent value might be approximate.

Chapter 3 Protection for Ordinary Structures

3-1 General.

An ordinary structure is one that is used for ordinary purposes whether commercial, industrial, farm, institutional, or residential. Ordinary structures not exceeding 75 ft (23 m) in height shall be protected with Class I materials as shown in Table 3-4. Ordinary structures greater than 75 ft (23 m) in height shall be protected with Class II materials as shown in Table 3-5.

3-1.1 Roof Types and Pitch.

For the purpose of this standard, roof types and pitches are as shown in Figures 3-1.1(a) and 3-1.1(b).

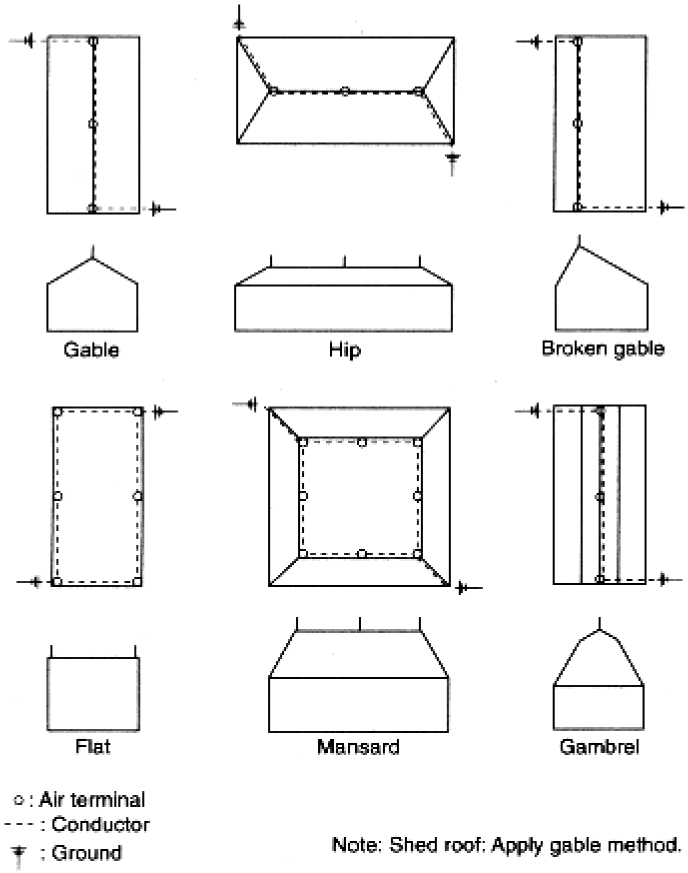

Figure 3-1.1(a) Roof types: protection methods (drawings are top and end views of each roof type).

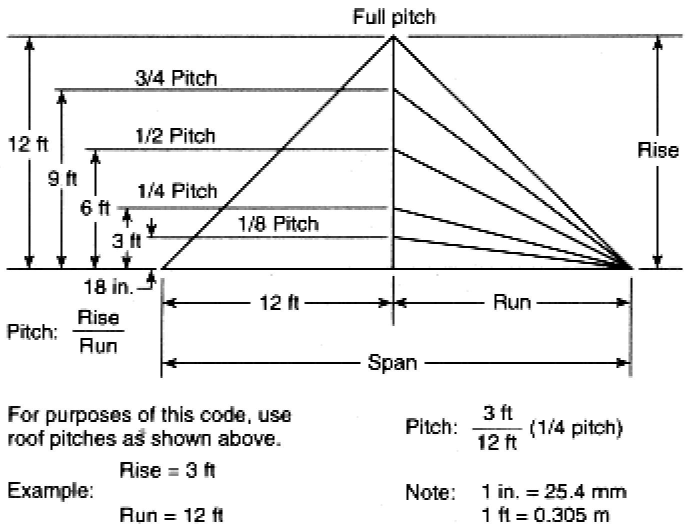

Figure 3-1.1(b) Roof pitch.

3-2 Materials.

The materials protection systems are made of shall be resistant to corrosion or shall be acceptably protected against corrosion. No combination of materials shall be used that forms an electrolytic couple of such nature that in the presence of moisture corrosion is accelerated. One or more of the following materials shall be used:

(a) *Copper*. Where copper is used it shall be of the grade ordinarily required for commercial electrical work, generally designated as being of 95-percent conductivity when annealed.

(b) *Copper Alloys*. Where alloys of copper are used they shall be substantially as resistant to corrosion as copper under similar conditions.

(c) *Aluminum*. Where aluminum is used, care shall be taken not to use it in contact with the earth or elsewhere where it will rapidly deteriorate. Conductors shall be of electrical grade aluminum.

(d) Copper lightning protection materials shall not be installed on aluminum roofing, siding, or other aluminum surfaces.

(e) Aluminum lightning protection materials shall not be installed on copper surfaces.

3-3 Form and Size.

Air terminals shall be made of solid or tubular rods. Conductors shall be in the form of multiple strand cables, single wires or rods, or flat strips, sized as shown in Tables 3-4 and 3-5. Ground terminals shall be made of rods, plates, or stranded cables.

3-4 Materials, Class I.

Table 3-4 gives minimum sizes and weights for air terminals and conductors for use on ordinary buildings and structures not exceeding 75 ft (23 m) in height.

Table 3-4 Class I Material Requirements

Type of Conductor		Copper		Aluminum	
		Standard	Metric	Standard	Metric
Air Terminal, Solid	Min. Diameter	⅜ in.	9.5 mm	½ in.	12.7 mm
Air Terminal, Tubular	Min. Diameter Min. Wall Thickness	⅝ in. 0.033 in.	15.9 mm 0.8 mm	⅝ in. 0.064 in.	15.9 mm 1.6 mm
Main Conductor, Cable	Min. Size ea. Strand Wgt. per Length Cross Sect. Area	17 AWG 187 lb/1000 ft 57,400 CM	 278 g/m 29 mm^2	14 AWG 95 lb/1000 ft 98,600 CM	 141 g/m 50 mm^2
Main Conductor, Solid Strip	Thickness Width	0.051 in. 1 in.	1.30 mm 25.4 mm	0.064 in. 1 in.	1.63 mm 25.4 mm
Bonding Conductor, Cable (solid or stranded)	Min. Size ea. Strand Cross Sect. Area	17 AWG 26,240 CM		14 AWG 41,100 CM	
Bonding Conductor, Solid Strip	Thickness Width	0.051 in. ½ in.	1.30 mm 12.7 mm	0.064 in. ½ in.	1.63 mm 12.7 mm

3-5 Materials, Class II.

Table 3-5 gives minimum sizes and weights for air terminals and conductors for use on ordinary buildings and structures exceeding 75 ft (23 m) in height. If part of a structure is over 75 ft (23 m) in height (as a steeple), and the remaining portion is less than 75 ft (23 m) in height, the requirements for Class II air terminals and conductors shall apply only to that portion over 75 ft (23 m) in height. Class II conductors from the higher portion shall be extended to ground and shall be interconnected with the balance of the system.

Table 3-5 Class II Material Requirements

Type of Conductor		Copper		Aluminum	
		Standard	Metric	Standard	Metric
Air Terminal, Solid	Min. Diameter	½ in.	12.7 mm	⅝ in.	15.9 mm
Main Conductor, Cable	Min. Size ea. Strand Wgt. per Length Cross Sect. Area	15 AWG 375 lb/1000 ft 115,000 CM	 558 g/m 58 mm^2	13 AWG 190 lb/1000 ft 192,000 CM	 283 g/m 97 mm^2
Bonding Conductor, Cable (solid or stranded)	Min. Size ea. Strand Cross Sect. Area	17 AWG 26,240 CM		14 AWG 41,100 CM	
Bonding Conductor, Solid Strip	Thickness Width	0.051 in. ½ in.	1.30 mm 12.7 mm	0.064 in. ½ in.	1.63 mm 12.7 mm

3-6 Corrosion Protection.

Precautions shall be taken to provide the necessary protection against any tendency towards deterioration of any lightning protection component due to local conditions. Copper components installed within 24 in. (600 mm) of the top of a chimney or vent emitting corrosive gases shall be protected by a hot-dipped lead coating or equivalent.

3-7 Mechanical Damage or Displacement.

Any part of a lightning protection system that is subject to mechanical damage or displacement shall be protected with a protective molding or covering. If metal pipe or tubing is used around the conductor, the conductor shall be electrically connected to the pipe or tubing at both ends.

3-8 Use of Aluminum.

Aluminum systems shall be installed in accordance with other applicable sections and with the following:

(a) Aluminum lightning protection equipment shall not be installed on copper-roofing materials or other copper surfaces, or where exposed to the runoff from copper surfaces.

(b) Aluminum materials shall not be used where they come into direct contact with earth. Fittings used for the connection of aluminum-down conductors to copper or copper-clad grounding equipment shall be of the bimetallic type. Bimetallic connectors shall be installed not less than 18 in. (457 mm) above earth level.

(c) Connectors and fittings shall be suitable for use with the conductor and the surfaces on which they are installed. Bimetallic connectors and fittings shall be used for splicing or bonding dissimilar metals.

(d) An aluminum conductor shall not be attached to a surface coated with alkaline-base paint, embedded in concrete or masonry, or installed in a location subject to excessive moisture.

3-9 Air Terminals.

Air terminals shall be provided for all parts of a structure that are likely to be damaged by direct lightning flashes. Metal parts of a structure that are exposed to direct lightning flashes and that have a metal thickness of $^{3}/_{16}$ in. (4.8 mm) or greater only require connection to the lightning protection system. Such connections shall provide a two-way path to ground as is required for air terminals. Air terminals shall not be required for those parts of a structure located within a zone of protection.

3-9.1 Height.

The tip of an air terminal shall be not less than 10 in. (254 mm) above the object or area it is to protect, except as permitted by Section 3-11. (*See Figure 3-9.1.*)

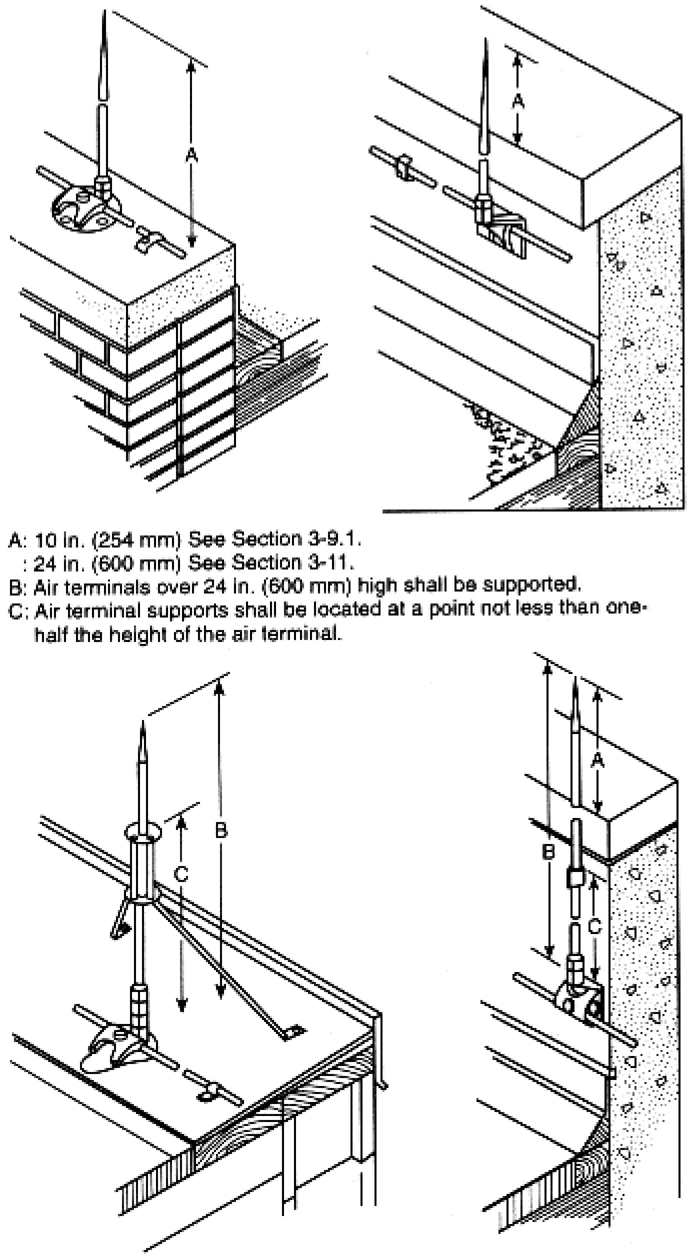

Figure 3-9.1 Air terminal height.

3-9.2 Support.

Air terminals shall be secured against overturning either by attachment to the object to be protected or by means of braces that shall be permanently and rigidly attached to the building. An air terminal exceeding 24 in. (600 mm) in height shall be supported at a point not less than one-half its height.

3-9.3 Ornaments.

An ornament or decoration on a freestanding, unbraced air terminal shall not present, in any plane, a wind-resistance area in excess of 20 in.^{2} (0.01 m^2). This permits the use of an ornamental ball 5 in. (127 mm) in diameter.

3-10 Zones of Protection.

To determine the zone of protection, the geometry of the structure shall be considered. The zone of protection is described in 3-10.1 through 3-10.3.

3-10.1

For flat or gently sloping roofs, dormers, domed roofs, and roofs with ridges, wells, chimneys, or vents, the zone of protection includes the roof and appurtenances where protected in accordance with Section 3-11.

3-10.2

For structures with multiple level roofs no more than 50 ft (15 m) in height, the zone of protection includes areas as identified in 3-10.2.1 and 3-10.2.2. The zone of protection forms a cone having an apex at the highest point of the air terminal, with walls forming approximately a 45- or 63-degree angle from the vertical.

3-10.2.1 Structures that do not exceed 25 ft (7.6 m) above earth are considered to protect lower portions of a structure located in a one-to-two zone of protection as shown in Figures 3-10.2.1(a) and 3-10.2.1(b).

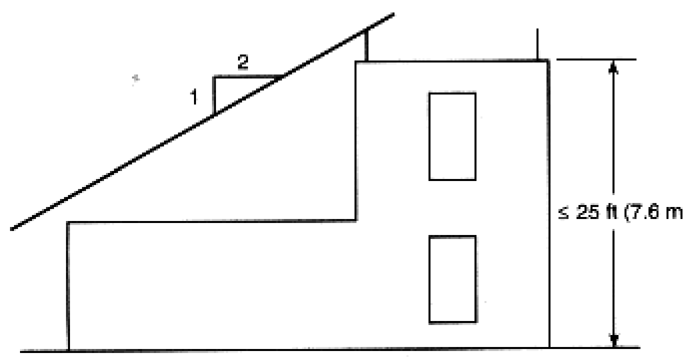

Figure 3-10.2.1(a) Lower roof protection for flat roof buildings 25 ft (7.6 m) or less in height.

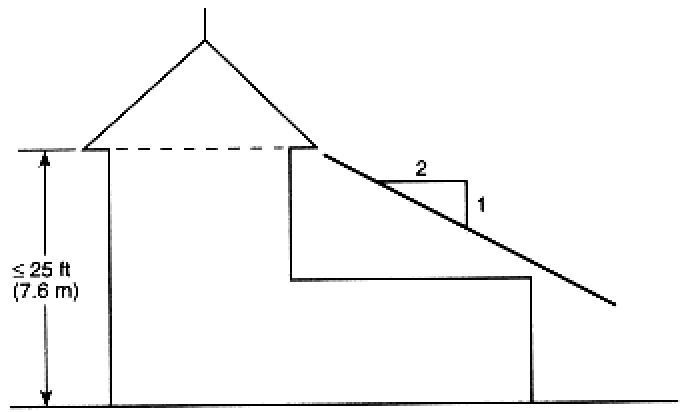

Figure 3-10.2.1(b) Lower roof protection provided by pitched roof buildings 25 ft (7.6 m) or less in height.

3-10.2.2 Structures that do not exceed 50 ft (15 m) above earth are considered to protect lower portions of a structure located within a one-to-one zone of protection as shown in Figures 3-10.2.2(a) and 3-10.2.2(b).

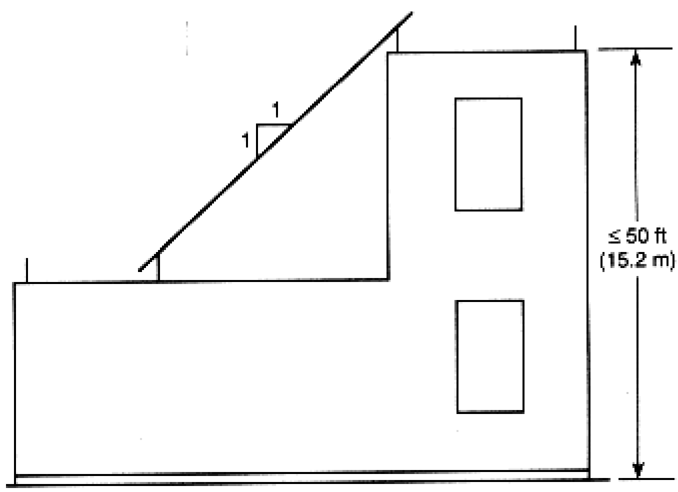

Figure 3-10.2.2(a) Lower roof protection for buildings 50 ft (15.24 m) or less in height.

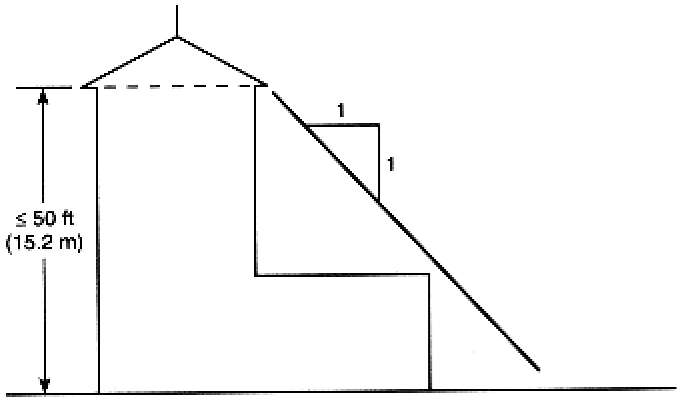

Figure 3-10.2.2(b) Lower roof protection provided by pitched roof buildings 50 ft (15.24 m) or less in height.

3-10.3 Rolling Sphere Concept.

3-10.3.1 The zone of protection includes the space not intruded by a rolling sphere having a radius of 150 ft (46 m). When tangent to earth and resting against a lightning protection air terminal, all space between the two points of contact and under the sphere are in the zone of protection. A zone of protection is also formed when such a sphere is resting on two or more air terminals and includes the space under the sphere between those terminals, as shown in Figure 3-10.3.1. All possible placements of the sphere must be considered when determining the zone of protection using the rolling sphere concept.

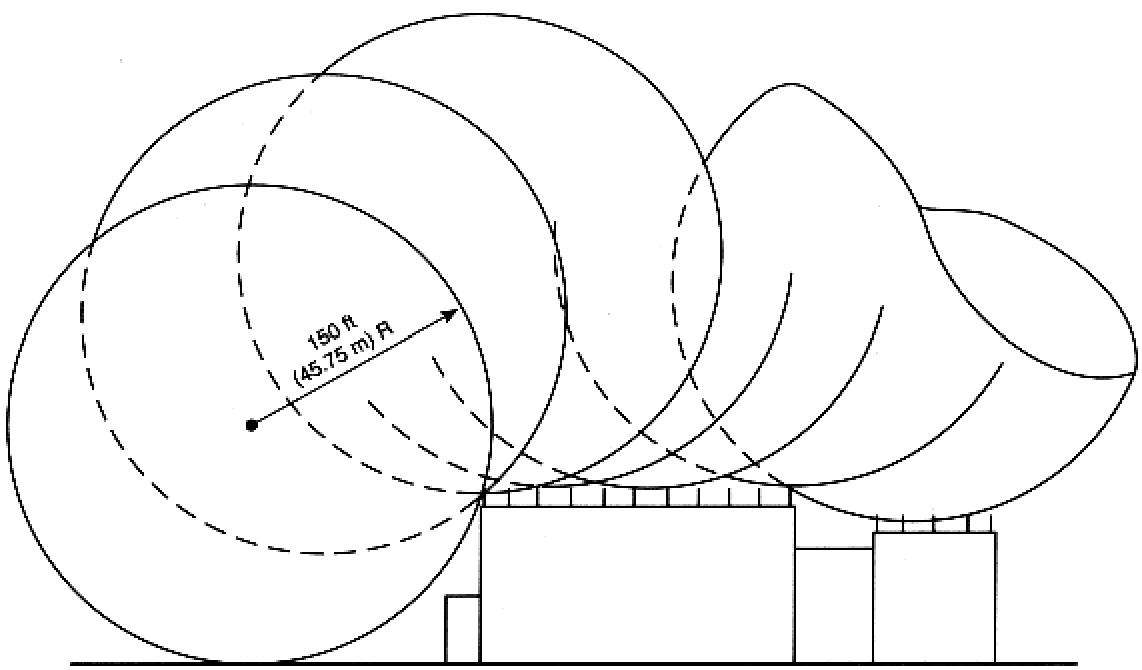

Figure 3-10.3.1.

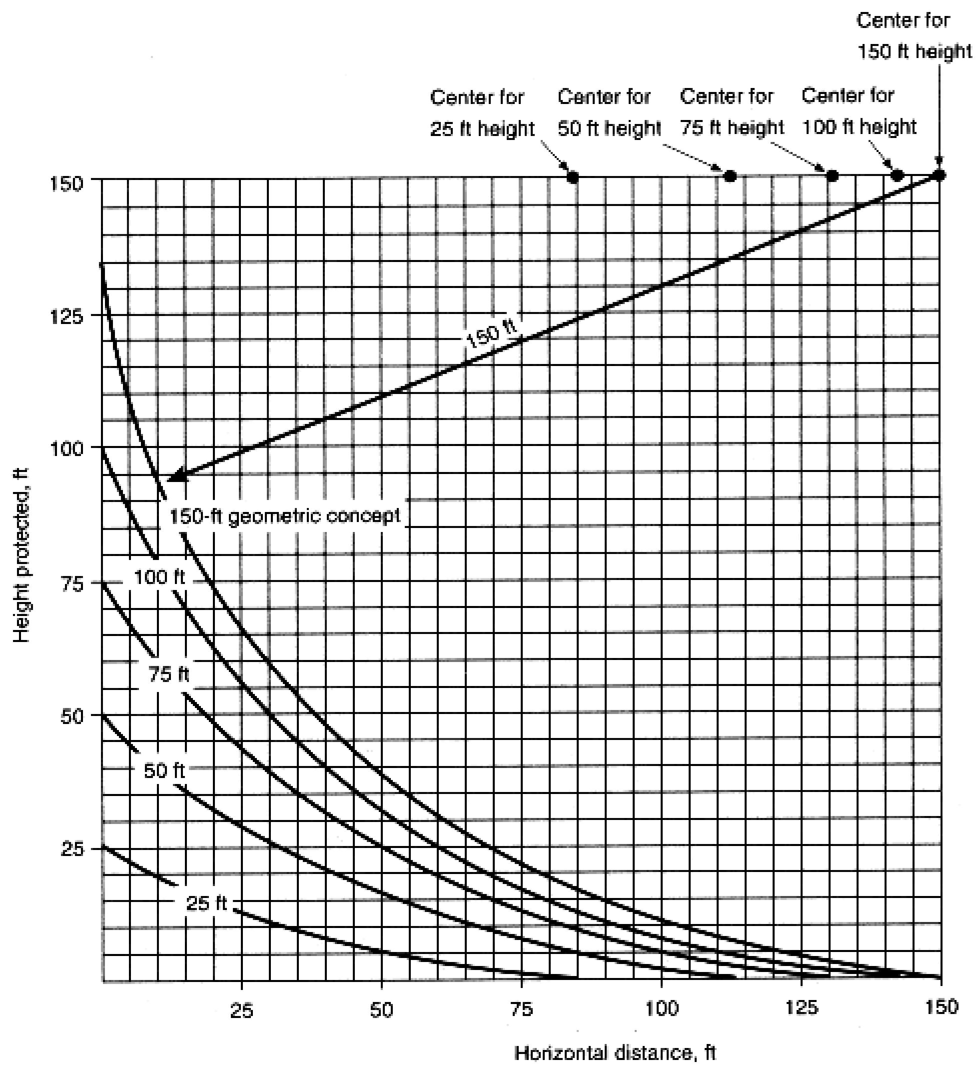
3-10.3.2 For structure heights exceeding 150 ft (46 m) above earth or above a lower air terminal, the zone of protection is considered to be the space between the points of contact and under the sphere, when it is resting against a vertical surface of the structure and the lower air terminal or earth. The zone of protection is limited to the space above the horizontal plane of the lowest terminal unless it can be extended by further analysis, such as in rolling the sphere to be tangent to earth.

3-10.3.3 Figure 3-10.3.3 provides a graphic representation of the 150-ft (46-m) geometric concept for structures of selected heights up to 150 ft (46 m). Based on the height of the air terminal on a protected structure being 25 ft (7.6 m), 50 ft (15 m), 75 ft (23 m), 100 ft (30 m), or 150 ft (46 m) above ground, reference to the appropriate curve shows the anticipated zone of protection for objects and roofs at lower elevations. The graph shows the protected distance ("horizontal distance") as measured radially from the protected structure. The horizontal distance thus determined applies only at the horizontal plane of the "height protected."



Note: 1 ft = 0.305 m

Figure 3-10.3.3 Zone of protection.

3-10.3.4 Under the rolling sphere concept, the horizontal protected distance found geometrically by Figure 3-10.3.3 ("horizontal distance, ft") can also be calculated using the formula:

$$d = \sqrt{h_1 (300 - h_1)} - \sqrt{h_2 (300 - h_2)}$$

Where:

d = horizontal distance, ft

h_1 = height of the higher roof, ft

h_2 = height of the lower roof (top of the object), ft

Use of this formula is based on a 150 ft (46 m) striking distance.

For the formula to be valid, the sphere must be tangent to either the lower roof or in contact with the earth, and in contact with the vertical side of the higher portion of the structure. In addition, the difference in heights between the upper and lower roofs or earth must be 150 ft (46 m) or less.

3-11 Air Terminals on Roofs.

Air terminals shall be placed on ridges of pitched roofs and around the perimeter of flat or gently sloping roofs at intervals not exceeding 20 ft (6 m). Air terminals of 24 in. (600 mm) above the object or area to be protected are permitted to be placed at intervals not exceeding 25 ft (7.6 m). Air terminals shall be placed at or within 2 ft (0.6 m) of the ends of ridges on pitched roof buildings, or at edges and outside corners of flat or gently sloping roofs. [*See Figures 3-11, 3-11.1(a) and (b)*]. In the case of tall structures having a pitched roof with eaves height of 50 ft (15 m) or less above grade, only the ridge requires protection provided the roof pitch is $^1/_4$ or greater and there is no horizontal portion of the building that extends beyond the eaves, other than a gutter. For pitched roof buildings with an eaves height over 50 ft (15 m), the 150-ft (46-m) geometric concept shall be used to calculate air terminal locations. [*See Figures 3-10.3.1, 3-11, 3-11.1(a) and (b)*].

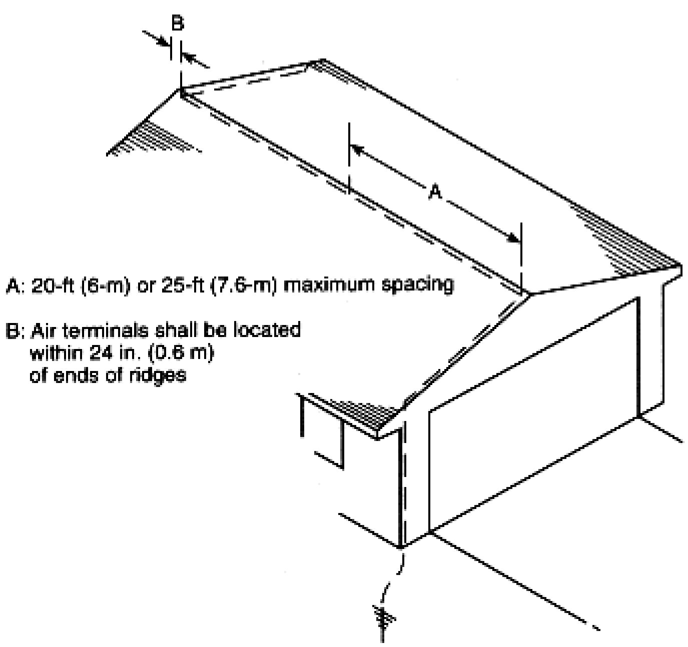


Figure 3-11 Air terminals on peaked roof.

3-11.1 Flat or Gently Sloping Roofs.

Flat or gently sloping roofs that exceed 50 ft (15 m) in width or length shall have additional air terminals located at intervals not to exceed 50 ft (15 m) on the flat or gently sloping areas.

Gently sloping roofs are defined as: (1) those roofs having a span of 40 ft (12 m) or less and a pitch of less than $^1/_8$; and (2) those roofs having a span of more than 40 ft (12 m) and a pitch of less than $^1/_4$. [*See Figures 3-11.1(a) and 3-11.1(b).*]

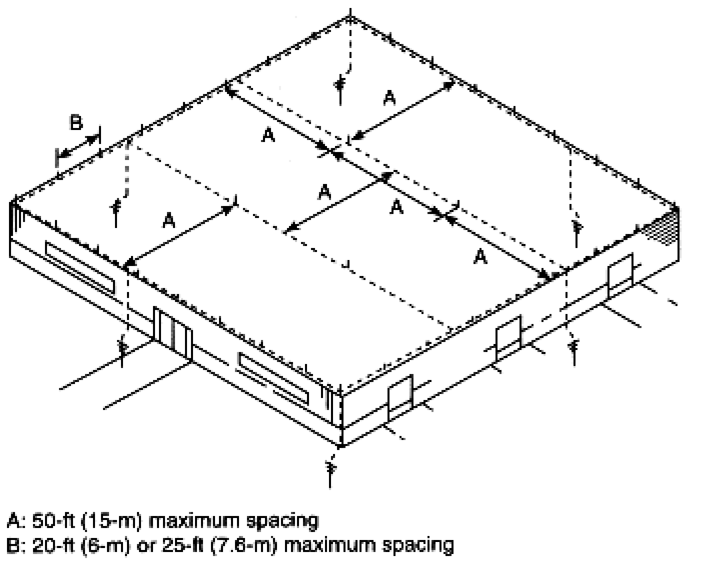

Figure 3-11.1(a) Air terminals on flat roof.

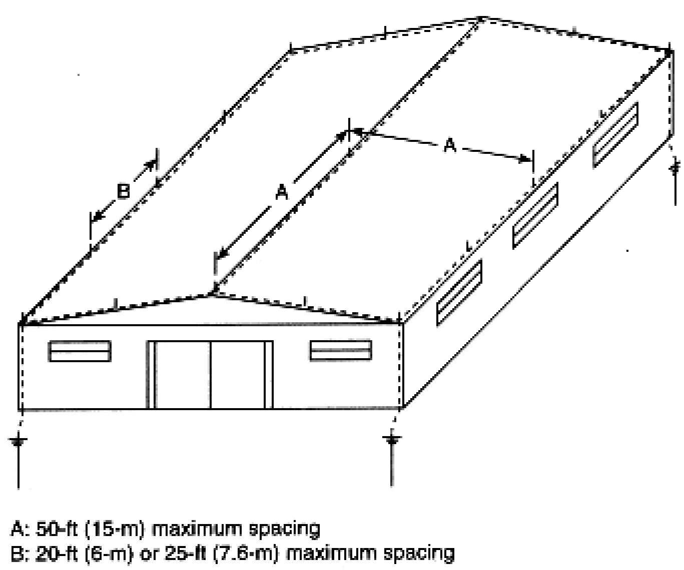

Figure 3-11.1(b) Air terminals on gently sloping roof.

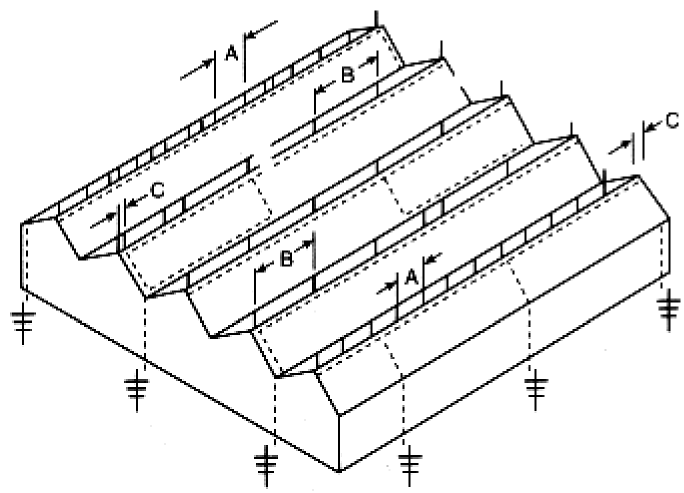
3-11.2* Dormers.

Dormers as high or higher than the main roof shall be protected with air terminals, cable, down conductors, and grounds as normally specified. Dormers and projections below the main ridge require protection only on those areas extending outside a zone of protection.

3-11.3 Roofs with Intermediate Ridges.

Air terminals shall be located along the outermost ridges of buildings that have a series of intermediate ridges at the same intervals as required by Section 3-11. Air terminals shall be located on the intermediate ridges in accordance with the requirements for the spacing of air terminals on flat or gently sloping roofs. If any intermediate ridge is higher than the outermost ridges, it shall be treated as a main ridge and protected according to Section 3-11. (*See Figure 3-11.3.*)



Maximum spacings:

A: 20 ft (6 m) or 25 ft (7.6 m)
B: 50 ft (15 m)
C: 2 ft (610 mm)

Figure 3-11.3 Air terminals on intermediate ridges.

3-11.4 Flat or Gently Sloping Roofs with Irregular Perimeters.

Structures that have exterior wall designs that result in irregular roof perimeters shall be treated on an individual basis. In many cases the outermost projections form an “imaginary” roof edge that is used to locate the terminals in accordance with Section 3-11. In all cases, however, air terminals shall be located in accordance with Section 3-11 through 3-11.7. [*See Figure 3-11.4(a).*]

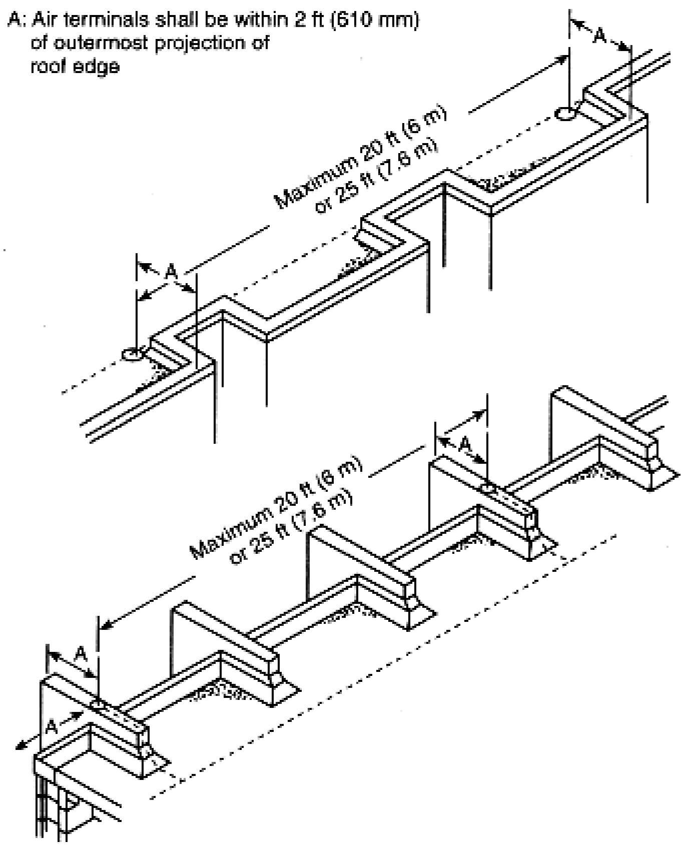


Figure 3-11.4(a) Flat or gently sloping roof with irregular perimeter.

Air terminals installed on vertical roof members shall be permitted to use a single sized cable to a main roof conductor. The main roof conductor shall be run adjacent to the vertical roof members so that the single cable from the air terminal is as short as possible and, in any case, no longer than 16 ft (4.9 m). The connection of the single cable to the down conductor shall be made with a tee splice. [*See Figure 3-11.4(b).*]

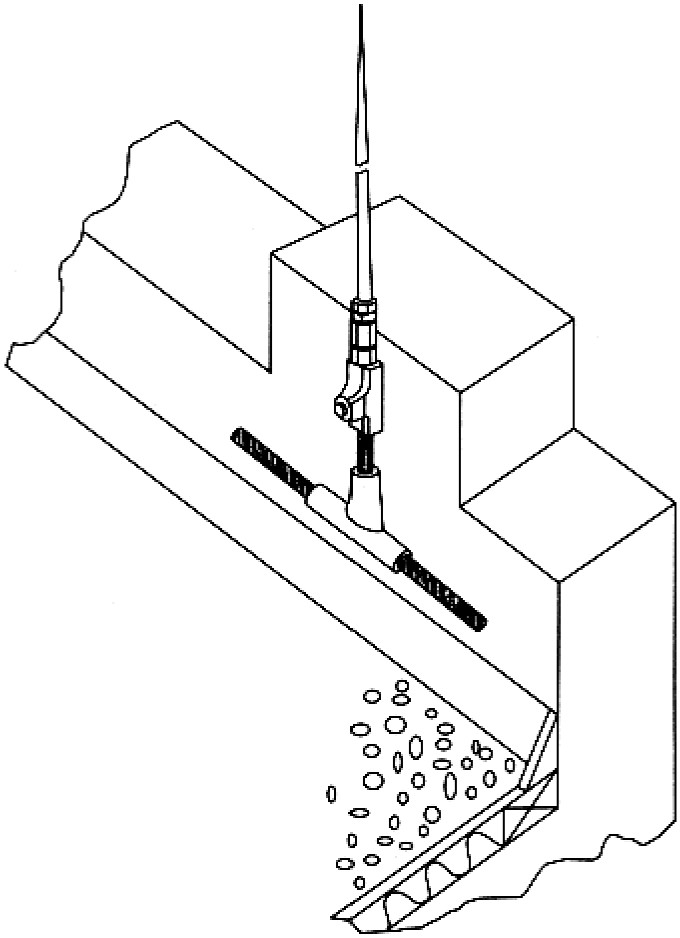

Figure 3-11.4(b) Irregular roof perimeter.

3-11.5 Open Areas in Flat Roofs.

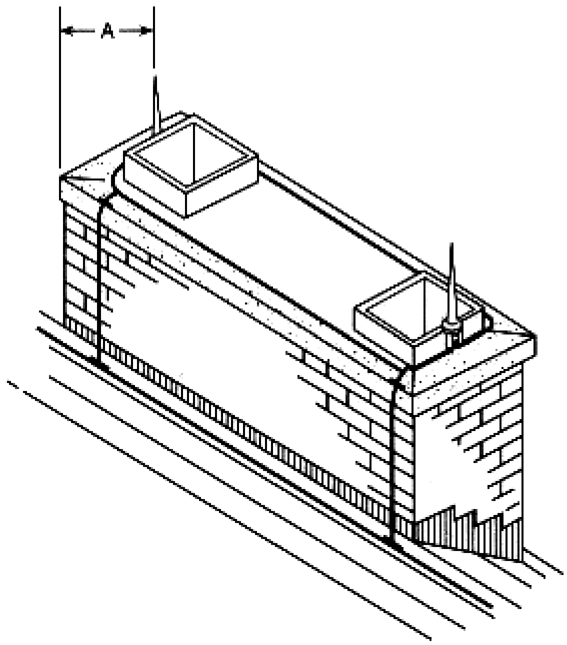
The perimeter of open areas, such as light or mechanical wells, that are located in large flat-roofed structures shall be protected if their perimeter exceeds 300 ft (92 m) provided both rectangular dimensions exceed 50 ft (15 m).

3-11.6 Domed or Rounded Roofs.

Air terminals shall be located as required so that no portion of the structure is located outside a zone of protection, based on a striking distance of 150 ft (45 m), as set forth in Section 3-11.

3-11.7 Chimneys and Vents.

Air terminals are required on all chimneys and vents, including metal chimneys having a metal thickness of less than $^{3}/_{16}$ in. (4.8 mm), where such chimneys or vents are not located within a zone of protection. If the metal thickness is $^{3}/_{16}$ in. (4.8 mm) or more, only a connection to the lightning protection system is required. Such a connection shall be made using a main size lightning conductor, a bonding device having a surface contact area of not less than 3 in.^{2} (1940 mm2), and shall provide a two-way path to ground as is required for air terminals. Required air terminals shall be installed on chimneys and vents so that the distance from an air terminal to an outside corner or the distance perpendicular to an outside edge shall be not greater than 2 ft (0.6 m). (*See Figure 3-11.7.*) Where only one air terminal is required on a chimney or vent, at least one main sized conductor shall connect the air terminal to a main conductor at the location where the chimney or vent meets the roof surface and provides a two-way path to ground from that location in accordance with Section 3-12 and 3-12.2.



A: 2 ft (0.6 m) maximum

Figure 3-11.7 Air terminals on chimney.

3-12 Conductors.

Conductors shall interconnect all air terminals and shall form a two-way path from each air terminal horizontally, downward, or rising at a rate not exceeding 3 in. per ft (76.2 mm) to connections with ground terminals, except as permitted by 3-12.1 and 3-12.2.

3-12.1 One-Way Path.

Air terminals on a lower roof level that are interconnected by a conductor run from a higher roof level only require one horizontal or downward path to ground provided the lower level roof conductor run does not exceed 40 ft (12 m).

3-12.2 Dead Ends.

Air terminals shall be permitted to be “dead ended” with only one path to a main conductor on roofs below the main protected level provided the conductor run from the air terminal to a main conductor is not more than 16 ft (4.9 m) in total length and maintains a horizontal or downward coursing. (*See Figure 3-12.2.*)

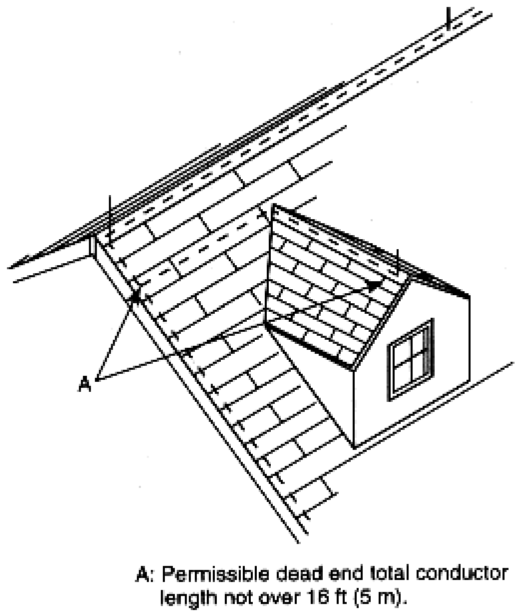


Figure 3-12.2 Dead end.

3-12.3 Substitution of Metals.

Metal parts of a structure, such as eave troughs, down spouts, ladders, chutes, or other metal parts shall not be substituted for the main lightning conductor. Likewise, metal roofing or siding having a thickness of less than $^{3}/_{16}$ in. (4.8 mm) shall not be substituted for main lightning conductors.

3-12.4 "U" or "V" Pockets.

Conductors shall maintain a horizontal or downward coursing free from "U" or "V" (down and up) pockets. Such pockets, often formed at low positioned chimneys, dormers, or other projections on sloped roofs, or at parapet walls, shall be provided with a down conductor from the base of the pocket to ground, or to an adjacent down-lead conductor. (*See Figure 3-12.4.*)

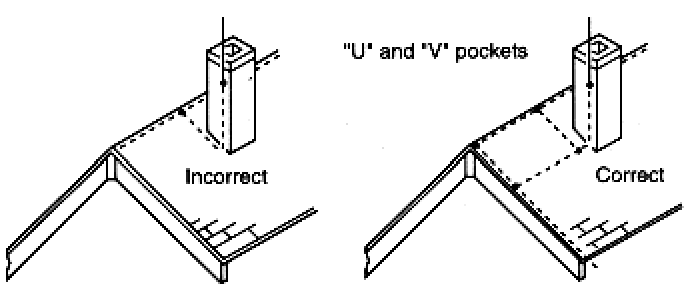

Figure 3-12.4 Pockets.

3-12.5 Conductor Bends.

No bend of a conductor shall form an included angle of less than 90 degrees, nor shall it have a radius of bend less than 8 in. (203 mm). (*See Figure 3-12.5.*)

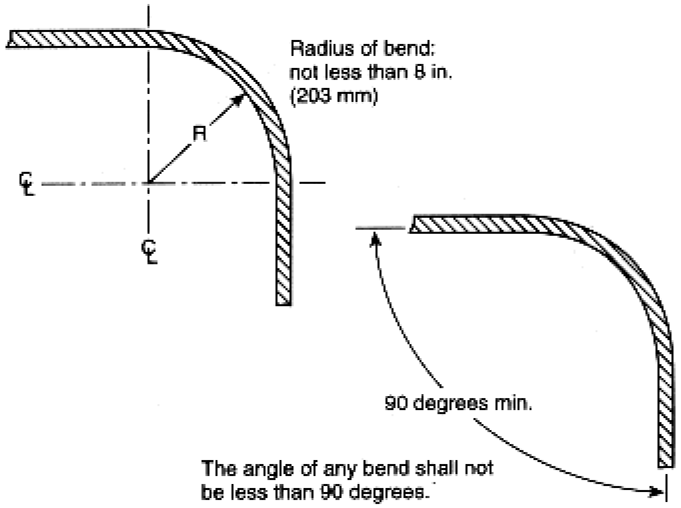

Figure 3-12.5 Conductor bends.

3-12.6 Conductor Supports.

Conductors shall be permitted to be coursed through air without support for a distance of 3 ft (0.9 m) or less. Conductors that must be coursed through air for longer distances shall be provided with a positive means of support that will prevent damage or displacement of the conductor.

3-12.7 Roof Conductors.

Roof conductors shall be coursed along ridges of gable, gambrel, and hip roofs, around the perimeter of flat roofs, behind or on top of parapets, and across flat or gently sloping roof areas as required to interconnect all air terminals. Conductors shall be coursed through or around obstructions (such as cupolas, ventilators, etc.) in a horizontal plane with the main conductor.

3-12.8 Cross-Run Conductors.

Cross-run conductors (main conductors) are required to interconnect the air terminals on flat or gently sloping roofs that exceed 50 ft (15 m) in width. For example, roofs from 50 ft (15 m) to 100 ft (30 m) in width require one cross run, roofs 100 ft (30 m) to 150 ft (46 m) in width require two cross runs, etc. Cross-run conductors shall be connected to the main perimeter cable at intervals not exceeding 150 ft (46 m).

3-12.9 Down Conductors.

Down conductors shall be as widely separated as practicable. Their location depends on such considerations as: the placement of air terminals, the most direct coursing of conductors, earth conditions, security against displacement, the location of large metallic bodies, and the location of underground metallic piping systems.

3-12.10 Number of Down Conductors.

At least two down conductors shall be provided on any kind of structure, including steeples. Structures exceeding 250 ft (76 m) in perimeter shall have a down conductor for every 100 ft (30 m) of perimeter or fraction thereof. The total number of down conductors on structures having flat or gently sloping roofs shall be such that the average distance between all down conductors does not exceed 100 ft (30 m). Irregular-shaped structures could require additional down conductors in order to provide a two-way path from each air terminal. For a flat or gently sloping roof structure, only the perimeter of the roof areas requiring protection shall be measured. When determining the perimeter of a pitched roof structure, the horizontal projection (footprint) of the protected roof shall be measured. Lower roofs or projections that are located within a zone of protection shall not be required to be included in the perimeter measurement. (*See Figure 3-12.10.*)

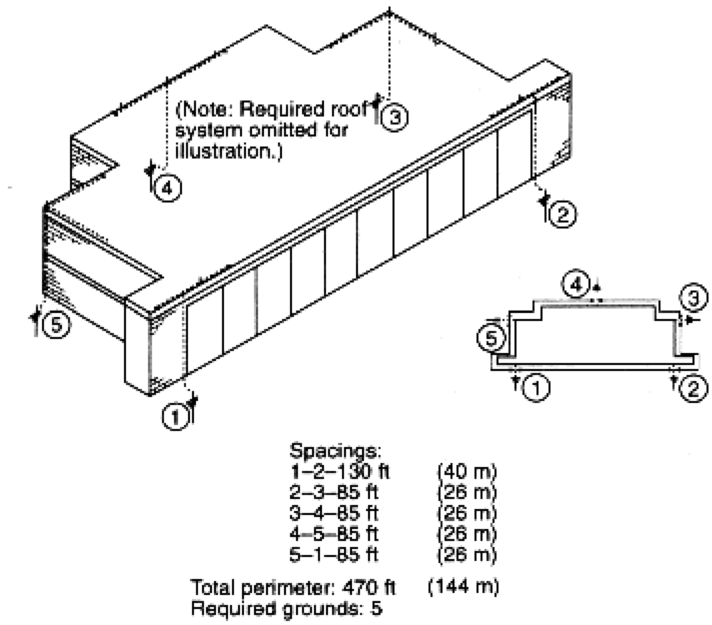

Figure 3-12.10 Quantity of down conductors.

3-12.11 Protecting Down Conductors.

Down conductors located in runways, driveways, school playgrounds, cattle yards, public walks, or other similar locations shall be guarded to prevent physical damage or displacement. If the conductor is run through ferrous metal tubing, the conductor shall be bonded to the top and bottom of the tubing. The down conductor shall be protected for a minimum distance of 6 ft (1.8 m) above grade level.

3-12.12 Down Conductor Entering Corrosive Soil.

Down conductors entering corrosive soil shall be protected against corrosion by a protective covering beginning at a point 3 ft (0.9 m) above grade level and extending for its entire length below grade.

3-12.13 Down Conductors and Structural Columns.

Down conductors coursed on or in reinforced concrete columns, or on structural steel columns shall be connected to the reinforcing steel or the structural steel member at its upper and lower extremities. In the case of long vertical members, an additional connection shall be made at intervals not exceeding 200 ft (60 m). Such connections shall be made using listed clamps or listed bonding plates, or by welding or brazing. The use of PVC conduit or other nonmetallic chase does not negate the need for these interconnections unless sufficient separation is provided to satisfy the bonding requirements of Sections 3-22, 3-23, and 3-24. Where such is not the case, provisions shall be made to assure the required interconnection of these parallel vertical paths.

3-13 Conductor Fasteners.

Conductors shall be securely fastened to the structure upon which they are placed, at intervals not exceeding 3 ft (1 m). The fasteners, attached by nails, screws, bolts, or adhesives as necessary, shall not be subject to breakage and shall be of the same material as the conductor, or of a material equally resistant to corrosion as that of the conductor. No combination of materials shall be used that forms an electrolytic couple of such nature that, in the presence of moisture, corrosion will be accelerated.

3-14 Masonry Anchors.

Masonry anchors used to secure lightning protection materials shall have a minimum outside diameter of $^1/_4$ in. (6.4 mm) and shall be set with care. Holes made to receive the body of the anchor shall be of the correct size, made with the proper tools, and preferably made in the brick, stone, or other masonry unit rather than in mortar joints. When the anchors are installed, the fit shall be tight against moisture thus reducing the possibility of damage due to freezing.

3-15 Connector Fittings.

Connector fittings shall be used at all “end-to-end,” “tee,” or “Y” splices of lightning conductors. They shall be attached so as to withstand a pull test of 200 lb (890 N). Fittings used for required connections to metal bodies in or on a structure shall be secured to the metal body by bolting, brazing, welding, or using high-compression connectors listed for the purpose. Conductor connections shall be of the bolted, welded, high compression, or crimp-type. Crimp-type connections shall not be used with Class II conductors.

3-16 Ground Terminals.

Each down conductor shall terminate at a ground terminal dedicated to the lightning protection system. The design, size, depth, and number of ground terminals used shall comply with 3-16.1 through 3-16.4.

3-16.1 Ground Rods.

Ground rods shall be not less than $^1/_2$ in. (12.7 mm) in diameter and 8 ft (2.4 m) long. Rods shall be copper-clad steel, solid copper, hot-dipped galvanized steel, or stainless steel. Rods shall be free of paint or other nonconductive coatings.

NOTE: Research has been presented that warns that stainless steel is very susceptible to corrosion in many soil conditions. Extreme caution should be used with proper soil analysis when this type of rod is used.

Electrical system and telecommunication grounding electrodes shall not be used in lieu of lightning ground rods. This provision shall not prohibit the required bonding together of grounding electrodes of different systems.

NOTE: For further information, see NFPA 70, *National Electrical Code*®, which contains detailed information on the grounding of electrical systems.

3-16.1.1 Ground Rod Terminations. The down conductor shall be attached to the ground rod by bolting, brazing, welding, or using high-compression connectors listed for the purpose. Clamps shall be suitable for direct soil burial.

3-16.1.2 Deep Moist Clay Soil. The lightning conductors or ground rods shall extend vertically not less than 10 ft (3 m) into the earth. The earth shall be compacted and made tight against the length of the conductor or ground rod. (*See Figure 3-16.1.2.*)

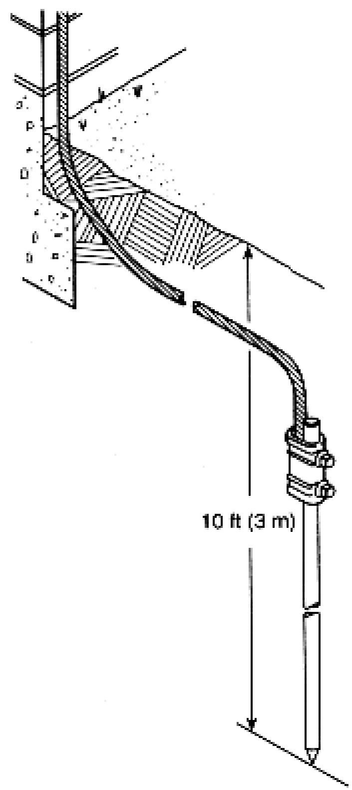

Figure 3-16.1.2 Grounding in moist clay-type soil.

3-16.1.3 Sandy or Gravelly Soil. In sand or gravel, two or more ground rods, at not less than 10 ft (3 m) spacings, shall be driven vertically to a minimum depth of 10 ft (3 m) below grade. (*See Figure 3-16.1.3.*)

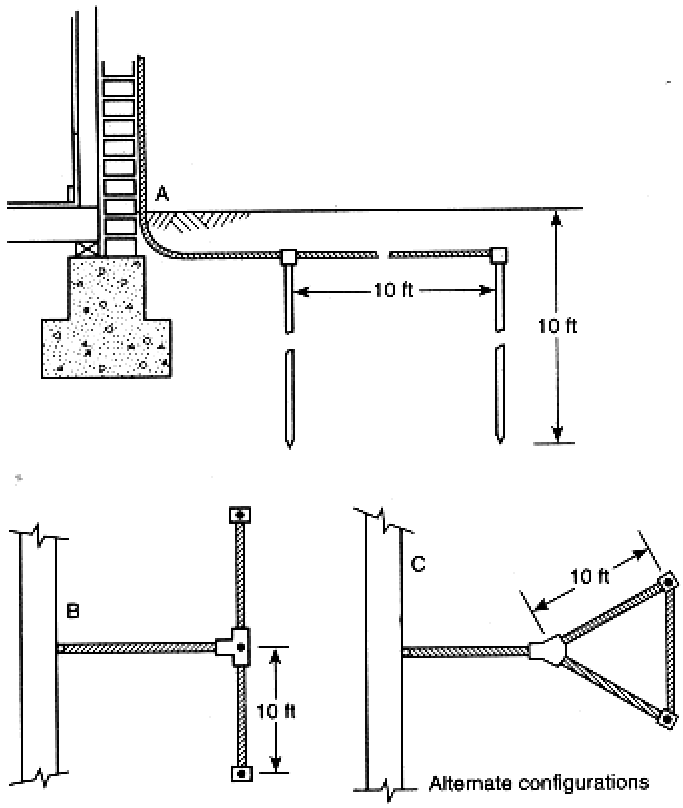

Figure 3-16.1.3 Grounding in sandy or gravelly soils.

3-16.1.4 Shallow Topsoil. Where bedrock is near the surface, the conductor shall be laid in trenches extending away from the building at each down conductor. These trenches shall be not less than 12 ft (3.7 m) in length and from 1 ft to 2 ft (0.3 m to 0.6 m) in depth in clay soil. In sandy or gravelly soil, the trench shall be not less than 24 ft (7.5 m) in length and 2 ft (0.6 m) in depth. If these methods should prove impractical, an acceptable alternative would be to carry the lightning protection cable in trenches of a depth specified above or, if this is impossible, directly on bedrock a minimum distance of 2 ft (0.6 m) from the foundation or exterior footing and terminate by attachment to a buried copper ground plate at least 0.032 in. (0.8 mm) thick and having a minimum surface area of 2 ft^2 (0.18 m^2).

3-16.1.5 Soil Less than 1 ft (0.3 m) Deep. If the soil is less than 1 ft (0.3 m) in depth, down conductors shall be connected to a loop conductor installed in a trench or in rock crevices around the structure. The loop conductor shall be not smaller than the equivalent of a main size lightning conductor. Optional plate electrodes may be attached to the loop conductor to enhance its earth contact where the measured grounding resistance is found to be too high to provide effective grounding. (*See Figure 3-16.1.5.*)

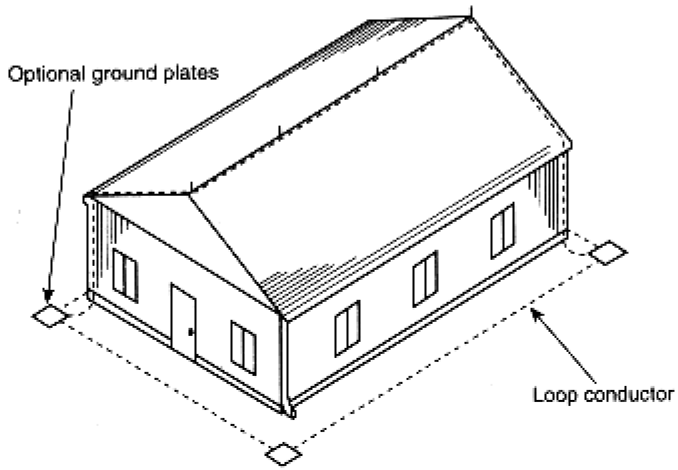

Figure 3-16.1.5 Grounding in soil less than 1 ft (0.3 m) deep.

3-16.2 Concrete Encased Electrodes.

Concrete encased electrodes shall only be used in new construction. The electrode shall be located near the bottom of a concrete foundation or footing that is in direct contact with the earth and shall be encased by not less than 2 in. (50.8 mm) of concrete. The encased electrode shall consist of:

(a) Not less than 20 ft (6.1 m) of bare copper main size conductor, or

(b) An electrode consisting of at least 20 ft (6.1 m) of one or more steel reinforcing bars or rods not less than $^{1}/_{2}$ in. (12.7 mm) in diameter that have been effectively bonded together by either welding or overlapping 20 diameters and securely wire-tying.

3-16.2.1 Concrete Encased Electrode Terminations. The down conductor(s) shall be permanently attached to the concrete encased electrode system by bolting, brazing, welding, or using high-compression connectors listed for the purpose.

3-16.3 Ground Ring Electrode.

A ground ring electrode encircling a structure shall be in direct contact with earth at a depth of not less than $2^{1}/_{2}$ ft (762 mm) or encased in a concrete footing in accordance with 3-16.2. It shall consist of not less than 20 continuous ft (6.1 m) of bare copper main size conductor.

3-16.3.1 Ground Ring Electrode Terminations. The down conductor(s) shall be permanently attached to the ground ring electrode by bolting, brazing, welding, or using high-compression connectors listed for the purpose. Clamps shall be suitable for direct burial.

3-16.4 Combinations.

Combinations of the above grounding terminals are permitted.

3-17 Common Grounding.

All grounding media in or on a structure shall be interconnected to provide a common ground potential. This shall include lightning protection, electric service, telephone and antenna system grounds, as well as underground metallic piping systems. Such piping systems include water service, well casings located within 25 ft (7.6 m) of the structure, gas piping, underground conduits, underground liquefied petroleum gas piping systems, etc. Interconnection to a gas line shall be made on the customer's side of the meter. Main size lightning conductors shall be used for interconnecting these grounding systems to the lightning protection system.

3-17.1 Common Ground Bondings.

If electric, telephone, or other systems are bonded to a metallic water pipe, only one connection from the lightning protection system to the water pipe system is required, provided that the water pipe is electrically continuous between all systems. If it is not electrically continuous, due to the use of plastic pipe sections or for other reasons, the nonconductive sections shall be bridged with main size conductors or the connection shall be made at a point where electrical continuity is assured.

3-18 Concealed Systems.

3-18.1 General.

Requirements covering exposed systems shall also apply to concealed systems, except conductors may be coursed under roofing materials, under roof framing, behind exterior wall facing, between wall studding, in conduit chases, or embedded directly in concrete or masonry construction. If a conductor is run in metal conduit, it shall be bonded to the conduit at the points where it enters and where it emerges from the conduit.

3-18.2 Masonry Chimneys.

Chimney air terminals and conductors shall be permitted to be concealed within masonry chimneys or to be attached to the exterior of masonry chimneys and routed through the structure to concealed main conductors.

3-18.3 Concealment in Steel Reinforced Concrete.

Conductors or other components of the lightning protection system concealed in steel reinforced concrete units shall be connected to the reinforcing steel. Concealed down conductors shall be connected to the vertical reinforcing steel in accordance with 3-12.13. Roof conductors or other concealed horizontal conductor runs shall be connected to the reinforcing steel at intervals not exceeding 100 ft (30 m).

3-18.4 Ground Terminals.

Ground terminals for concealed systems shall comply with Section 3-16. Ground terminals located under basement slabs or in crawl spaces shall be installed as near as practicable to the outside perimeter of the structure. Where rod or cable conductors are used for ground terminals, they shall be in contact with the earth for a minimum of 10 ft (3 m) and shall extend to a depth of not less than 10 ft (3 m) below finished grade, except as permitted by 3-16.3 and 3-16.4.

3-19 Structural Steel Systems.

3-19.1 General.

The structural steel framework of a structure shall be permitted to be utilized as the main conductor of a lightning protection system if it is electrically continuous or is made so.

3-19.2 Air Terminals.

Air terminals shall be connected to the structural steel framing by direct connection, by use of individual conductors routed through the roof or parapet walls to the steel framework, or by use of an exterior conductor that interconnects all air terminals and that is connected to the steel framework. Where such an exterior conductor is used, it shall be connected to the steel framework of the structure at intervals not exceeding 100 ft (30 m).

3-19.3 Connections to Framework.

Conductors shall be connected to areas of the structural steel framework, cleaned to base metal, by use of bonding plates having a surface contact area of not less than 8 in.^{2} (5200 mm^2) or by welding or brazing. Drilling and tapping the steel column to accept a threaded connector shall also be an acceptable method. The threaded device shall be installed with five threads fully engaged and secured with a jam-nut. The threaded portion of the connector shall be not less than $^1/_2$ in. (12.7 mm) in diameter. Bonding plates shall have bolt pressure cable connectors and shall be bolted, welded, or brazed securely to the structural steel framework so as to maintain electrical continuity. Where rust protective paint or coating is removed, the base steel shall be protected with a conductive, corrosion inhibiting coating.

3-19.4 Ground Terminals.

Ground terminals shall be connected to approximately every other steel column around the perimeter of the structure at intervals averaging not more than 60 ft (18 m). Connections shall be made near the base of the column in accordance with the requirements in 3-19.3.

3-19.5 Bonding Connections.

Where metal bodies located within a steel-framed structure are inherently bonded to the structure through the construction, separate bonding connections shall not be required.

3-20 Metal Antenna Masts and Supports.

Metal antenna masts or supports located on a protected structure shall be connected to the lightning protection system using main size conductors and listed fittings unless they are within a zone of protection.

3-21 Surge Suppression.

Devices suitable for protection of the structure shall be installed on electric and telephone service entrances and on radio and television antenna lead-ins.

NOTE: Electrical systems and utilization equipment within the structure can require further surge suppression. Such protection is not part of this standard. Documents such as ANSI/IEEE C-62.1, NFPA 70, *National Electrical Code* and UL 1449 provide additional information.

3-22 Metal Bodies.

Certain metal bodies located outside or inside a structure contribute to lightning hazards because they are grounded, or they assist in providing a path to ground for lightning currents. Such metal bodies shall be bonded to the lightning protection system in accordance with Sections 3-22, 3-23, and 3-24. (*See Appendix J for a technical discussion of lightning-protection potential-equalization bonding.*)

3-22.1 General.

In determining the necessity of bonding a metal body to a lightning protection system, the following factors shall be considered.

(a) Bonding is only required if there is likely to be a sideflash between the lightning protection system and another grounded metal body.

(b) The influence of a nongrounded metal body, such as a metal window frame in a nonconductive medium, is limited to its effectiveness as a short circuit conductor should a sideflash occur and, therefore, does not necessarily require bonding to the lightning protection system.

(c) Bonding distance requirements depend on a technical evaluation of the number of down conductors and their location, the interconnection of other grounded systems, the proximity of grounded metal bodies to the down conductors, and the flashover medium (i.e., air or solid materials).

(d) Metal bodies located in a steel-framed structure may be inherently bonded through construction and further bonding would not be required.

3-22.2 Materials.

Horizontal loop conductors used for the interconnection of lightning protection system downlead conductors, ground terminals, or other grounded media shall be sized no smaller than that required for the main lightning conductor. (*See Tables 3-4* and *3-5*.)

Conductors used for the bonding of grounded metal bodies, or isolated metal bodies, requiring connection to the lightning protection system shall be sized in accordance with bonding conductor requirements in Tables 3-4 and 3-5.

3-23 Potential Equalization.

3-23.1 Ground-Level Potential Equalization.

All grounded media in and on a structure shall be connected to the lightning protection system within 12 ft (3.6 m) of the base of the structure in accordance with Section 3-17.

For structures exceeding 60 ft (18 m) in height, the interconnection of the lightning protection system ground terminals, and other grounded media, shall be in the form of a ground loop conductor.

NOTE: For structures 60 ft (18 m) or less in height, a loop conductor should be provided for the interconnection of all ground terminals and other grounded media. Regardless of the building height, ground loop conductors should be installed underground in contact with earth. Ground-level potential equalization allows use of a ground ring electrode as a ground loop conductor. A ground ring electrode conforming to 3-16.3 shall be permitted to be utilized for the ground loop conductor.

3-23.2 Roof-Level Potential Equalization.

For structures exceeding 60 ft (18 m) in height, all grounded media in or on the structure shall be interconnected within 12 ft (3.6 m) of the main roof level.

NOTE: In the case of flat or gently sloping roofs, the roof conductors required by 3-12.7 shall be permitted to be used for achieving roof-level potential equalization. In the case of pitched roofs, the interconnection should be a loop placed at the eave level.

3-23.3 Intermediate-Level Potential Equalization.

Intermediate-level potential equalization is accomplished by the interconnection of the lightning protection system downlead conductors and other grounded media at the intermediate levels between the roof and the base of a structure in accordance with the following:

(a) *Steel-Framed Structures.* Intermediate-loop conductors are not required for steel-framed structures where the framing is electrically continuous.

(b) *Reinforced Concrete Structures where the Reinforcement Is Interconnected and Grounded in Accordance with 3-18.3.* The lightning protection system down-lead conductors and other grounded media shall be interconnected with a loop conductor at intermediate levels not exceeding 200 ft (60 m).

(c) *Other Structures.* The lightning protection down-lead conductors and other grounded media shall be interconnected with a loop conductor at intermediate levels not exceeding 60 ft (18 m).

3-24 Bonding of Metal Bodies.

3-24.1 Long, Vertical Metal Bodies.

(a) *Steel-Framed Structures.* Grounded and ungrounded metal bodies exceeding 60 ft (18 m) in vertical length shall be bonded to structural steel members as near as practical to their extremities unless inherently bonded through construction at these locations.

(b) *Reinforced Concrete Structures where the Reinforcement Is Interconnected and Grounded in Accordance with 3-18.3.*

Grounded and ungrounded metal bodies exceeding 60 ft (18 m) in vertical length shall be bonded to the lightning protection system as near as practical to their extremities, unless inherently bonded through construction at these locations.

(c) *Other Structures.* Bonding of grounded or ungrounded long, vertical metal bodies shall be determined by 3-24.2 and 3-24.3, respectively.

3-24.2 Grounded Metal Bodies.

This section covers the bonding of grounded metal bodies not covered in 3-24.1. Where grounded metal bodies have been connected to the lightning protection system at only one extremity, the following formula shall be used to determine if additional bonding is required. Branches of grounded metal bodies connected to the lightning protection system at their extremities shall require bonding to the lightning protection system in accordance with the following formula if they change vertical direction more than 12 ft (3.6 m).

NOTE: Where such bonding has been accomplished either inherently through construction or by physical contact between electrically conductive materials, no additional bonding connection is required.

(a) *Structures over 40 ft (12 m) in Height.* Grounded metal bodies shall be bonded to the lightning protection system where located within a distance “D” as determined by the formula:

$$D = \frac{h}{6n} \bullet K_m$$

Where “h” is the vertical distance between the bond being considered and the nearest lightning protection system bond.

The value of “n” is related to the number of down conductors that are spaced at least 25 ft (7.6 m) apart and located within a zone of 100 ft (30 m) from the bond in question and is calculated as follows:

1. Where bonding is required within 60 ft (18 m) from the top of any structure:

n = 1 where there is only one down conductor in this zone.

n = 1.5 where there are only two down conductors in this zone.

n = 2.25 where there are three or more down conductors in this zone.

K_m = 1.0 if the flashover is through air, or 0.50 if through dense material such as concrete, brick, wood, etc.

2. Where bonding is required below a level 60 ft (18 m) from the top of a structure, “n” is the total number of down conductors in the lightning protection system.

(b) *Structures 40 ft (12 m) and Less in Height.* Grounded metal bodies shall be bonded to the lightning protection system where located within a distance “D” as determined by the formula:

$$D = \frac{h}{6n} \bullet K_m$$

Where “h” is either the height of the building or the vertical distance from the nearest bonding connection from the grounded metal body to the lightning protection system and the point on the down conductor where the bonding connection is being considered.

The value of “n” is related to the number of down conductors that are spaced at least 25 ft (7.6 m) apart and located within a zone of 100 ft (30 m) from the bond in question and is calculated as follows:

n = 1 where there is only one down conductor in this zone.

n = 1.5 where there are only two down conductors in this zone.

n = 2.25 where there are three or more down conductors in this zone.

K_m = 1.0 if the flashover is through air, or 0.50 if through dense material such as concrete, brick, wood, etc.

3-24.3 Isolated (Nongrounded) Metallic Bodies.

An isolated metallic body, such as a metal window frame in a nonconducting medium, that is located close to a lightning conductor and to a grounded metal body will influence bonding requirements only if the total of the isolated distances between the lightning conductor and the isolated metal body, and between the isolated metal body and the grounded metal body is equal to or less than the calculated bonding distance. (*See Figure 3-24.3.*)

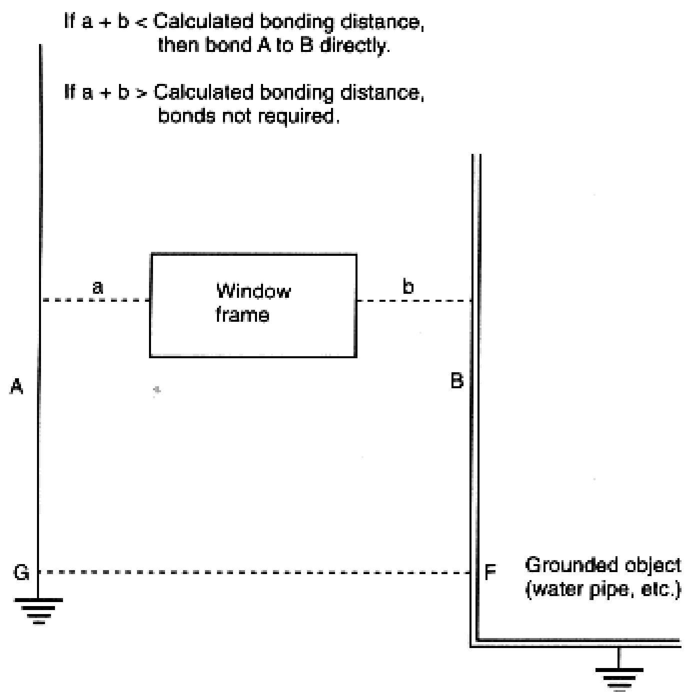

Figure 3-24.3 Effect of isolated (grounded) metallic bodies, such as window frame, in nonconductive media.

A bonding connection is required when the total of the shortest distance between the lightning conductor and the isolated metal body, and the shortest distance between the isolated metal body and the grounded metal body is equal to or less than the bonding distance as calculated in accordance with 3-24.2. Bondings shall be made between the lightning protection system and the grounded metal body and need not run through or be connected to the isolated metal body.

NOTE: In addition to the bonding of metal bodies, surge suppression should be provided to protect power, communication, and data lines from dangerous overvoltages and sparks caused by the lightning strikes. (*See Appendix J for a discussion of bonding and an understanding of problems often encountered.*)

Chapter 4 Protection for Miscellaneous Structures and Special Occupancies

4-1 General.

Special consideration shall be given to the miscellaneous structures and special occupancies covered in this chapter. All requirements of Chapter 3 shall apply except as modified.

4-2 Masts, Spires, Flagpoles.

These slender structures require one air terminal, down conductor, and ground terminal. Electrically continuous metal structures do not require air terminals or down conductors but do require ground terminals.

4-3 Grain, Coal, and Coke Handling and Processing Structures.

On wood frame elevators, provision shall be made to allow for the settling and rising of the structure as grain is loaded and unloaded.

4-4 Metal Towers and Tanks.

Metal towers and tanks constructed so as to receive a stroke of lightning without damage need only bonding to ground terminals as required in Chapter 3, except as provided in Chapter 6.

4-5 Air-Inflated Structures.

Air-inflated structures shall be protected with a mast-type or overhead ground wire-type system in accordance with Chapter 6, or with a lightning protection system in accordance with Chapter 3.

4-6 Concrete Tanks and Silos.

Lightning protection systems for concrete (including prestressed concrete) tanks containing flammable vapors, flammable gases, liquids that can produce flammable vapors, and concrete silos containing materials susceptible to dust explosions shall be provided with either external conductors or with conductors embedded in the concrete in accordance with Chapters 3 or 6.

Chapter 5 Protection for Heavy-Duty Stacks

5-1 General.

A smoke or vent stack is classified as heavy-duty if the cross-sectional area of the flue is greater than 500 in.^{2} (0.3 m^2) and the height is greater than 75 ft (23 m). (*See Figure 5-1.*)

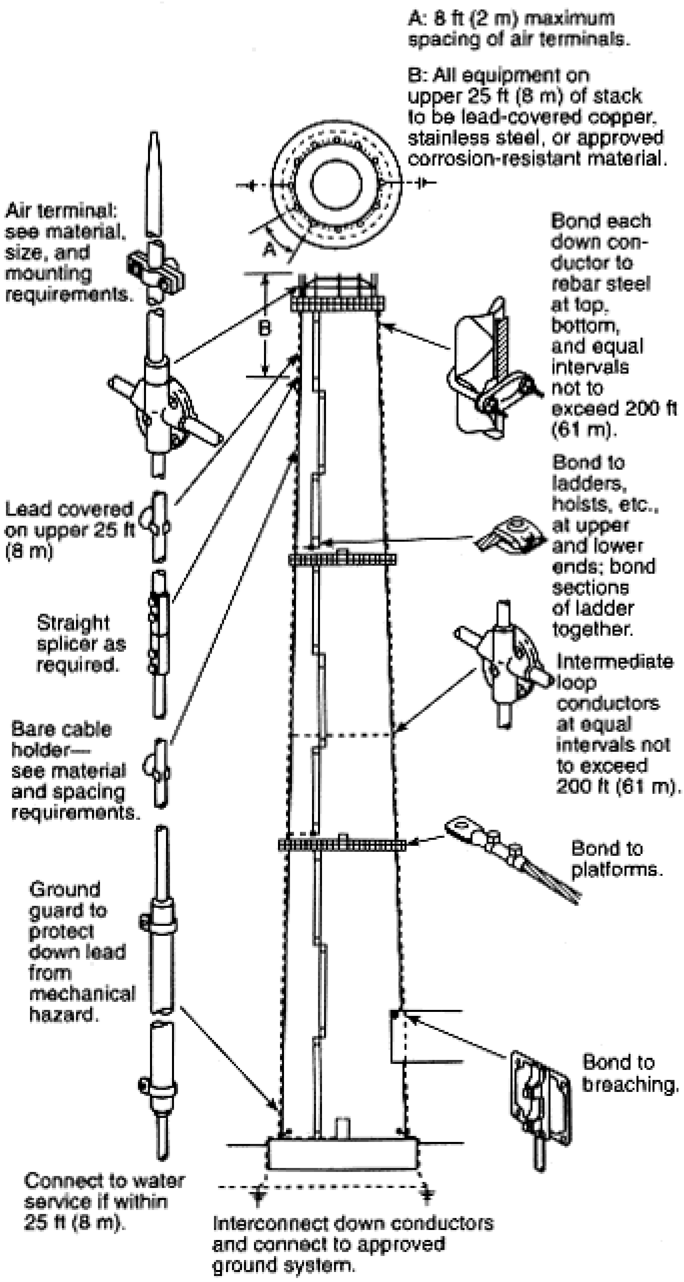

Figure 5-1 Heavy-duty stack.

5-2 Materials.

Materials shall be Class II as shown in Table 3-5, and as described in this chapter.

5-2.1 Corrosion Protection.

Copper and bronze materials used on the upper 25 ft (7.6 m) of a stack shall have a continuous covering of lead having minimum thickness of $^1/_{16}$ in. (1.6 mm) to resist corrosion by flue gases. Such materials include conductors, air terminals, connectors, splicers, and cable holders. Stacks that extend through a roof less than 25 ft (7.6 m) shall have a lead covering only on those materials above the roof level.

5-3 Air Terminals.

Air terminals shall be made of solid copper, stainless steel, or Monel Metal. They shall be located uniformly around the top of cylindrical stacks at intervals not exceeding 8 ft (2.4 m). On square or rectangular stacks, air terminals shall be located not more than 24 in. (600 mm) from the corners and shall be spaced not more than 8 ft (2.4 m) apart around the perimeter.

5-3.1 Air Terminal Heights.

The height of air terminals above the stacks shall be not less than 18 in. (460 mm) nor more than 30 in. (760 mm). They shall be at least $^5/_8$ in. (15 mm) in diameter, exclusive of the corrosion protection. Top-mounted air terminals shall not extend more than 18 in. (460 mm) above the top of the stack.

5-3.2 Air Terminal Mountings.

Air terminals shall be properly secured to the stack and shall be connected together at their lower end with a conductor forming a closed loop around the stack. Side-mounted air terminals shall be secured to the stack at not less than two locations. An anchored base connector shall be considered as one location.

5-3.3 Steel Hoods.

Stacks that have electrically continuous steel hoods covering the lining and column, and a metal thickness of not less than $^3/_{16}$ in. (4.8 mm), shall not require air terminals. The hood serves as a top loop conductor and shall be connected to each down conductor using a connection plate of not less than 8 in.^{2} (5200 mm^2) securely bolted or welded to the hood.

5-4 Conductors.

Conductors shall be copper, weighing not less than 375 lb per 1000 ft (558 g per m) without the lead covering. The size of any wire in the conductor shall be not less than 15 AWG.

5-4.1 Down Conductors.

Not less than two down conductors shall be provided. They shall be located on opposite sides of the stack and lead from the loop conductor at the top to ground terminals. Down conductors shall be interconnected within 12 ft (3.6 m) of the base by a loop conductor, preferably below grade. The down conductor shall also be interconnected with a loop conductor at approximately equal intervals not to exceed 200 ft (67 m). Down conductors shall be protected from physical damage or displacement for a distance of not less than 8 ft (2.4 m) above grade.

5-5 Fasteners.

Fasteners shall be of copper, bronze, or stainless steel. They shall be anchored firmly to the stack by masonry anchors or lay-in attachments. The threaded shank of fasteners shall be not less than $^1/_2$-in. (13-mm) diameter for air terminals and $^3/_8$-in. (10-mm) diameter for conductors. Vertical conductors shall be fastened at intervals not exceeding 4 ft (1.2 m) and horizontal conductors at intervals not exceeding 2 ft (0.6 m).

5-6 Splices.

Splices in conductors shall be as few as practicable and shall be attached so as to withstand a pull test of 200 lb (890 N). All connections and splices shall be by bolting, brazing, welding, or using high-compression connectors listed for the purpose. All connectors and splicers shall make contact with the conductor for a distance not less than $1^1/_2$ in. (38 mm), measured parallel to the axis of the conductor.

5-7 Reinforced Concrete Stacks.

All reinforcing steel shall be made electrically continuous and bonded to each down conductor within 12 ft (3.6 m) of the top and base of the stack and at approximately equal intervals not to exceed 200 ft (67 m). Tying or clipping of reinforcing steel shall be an acceptable means of ensuring continuity. Clamps or welding shall be used for all connections to the reinforcing steel and to the down conductors.

5-8 Bonding of Metal Bodies.

Bonding of metal bodies on a heavy-duty stack shall comply with the requirements of Sections 3-22, 3-23, and 3-24 and as described herein.

5-8.1 Potential Equalization.

(a) *Ground Level of Stack.* All interior and exterior grounded media shall be interconnected by a loop conductor within 12 ft (3.6 m) of the base of the stack. This shall include, but not be limited to, lightning protection down conductors, conduit, piping, elevators, ladders, and breeching steel and reinforcing steel.

(b) *Top Level of Stack.* All interior and exterior grounded media shall be interconnected within 12 ft (3.6 m) of the top of the stack.

(c) *Intermediate Levels of Stack.* All interior and exterior vertical grounded media shall be interconnected at approximately equal intervals not to exceed 200 ft (67 m).

5-8.2 Isolated (Nongrounded) Protruding Metal Bodies.

(a) Isolated protruding metal bodies 150 ft (50 m) or more above the base and on the exterior of a stack are subject to a direct strike and shall be interconnected to the lightning protection system. These shall include, but not be limited to, rest platforms, jib hoists, and other metal bodies protruding 18 in. (460 mm) or more from the column wall.

(b) Isolated metal bodies on the interior of a reinforced steel stack, or within the zone of protection on the exterior shall not be required to be connected to the lightning protection system.

5-9* Grounding.

A ground terminal, suitable for the soil conditions encountered, shall be provided for each down conductor. Ground terminals shall be in accordance with Section 3-16, except ground rods shall be a copper-clad or stainless steel rod having a diameter of not less than $^5/_8$ in. (15.9 mm) and shall be at least 10 ft (3 m) in length.

5-10 Metal Stacks.

Heavy-duty metal stacks having a metal thickness of $^{3}/_{16}$ in. (4.8 mm) or greater do not require air terminals or down conductors. They shall be grounded by means of at least two ground terminals located on opposite sides of the stack. If the stack is an adjunct of a building or located within the sideflash distance as determined by Sections 3-22, 3-23, and 3-24, it shall be interconnected to the lightning protection on the building. If the stack is located within the perimeter of a protected building, two connections shall be made between the stack conductors and the nearest main building lightning conductors at or about the roof level.

5-10.1 Metal Guy Wires and Cables.

Metal guy wires and cables used to support metal stacks shall be grounded at their lower ends if anchored in concrete, or to a building or other nonconductive support.

Chapter 6 Protection for Structures Containing Flammable Vapors, Flammable Gases, or Liquids that Can Give Off Flammable Vapors

6-1 Reduction of Damage.

6-1.1*

This chapter applies to the protection of structures containing flammable vapors, flammable gases, or liquids that can give off flammable vapors. For the purpose of this chapter, the term “structure” shall apply to the vessel, tank, or other container in which this material is contained.

6-1.2

Certain types of structures used for the storage of liquids that can produce flammable vapors, or used to store flammable gases are essentially self-protecting against damage from lightning strokes and need no additional protection. Metallic structures that are electrically continuous, tightly sealed to prevent the escape of liquids, vapors, or gases, and of adequate thickness to withstand direct strokes in accordance with 6-3.2 are inherently self-protecting. Protection of other structures may be achieved by the use of air terminals, masts, overhead ground wires, or other types of protective devices.

6-1.3

Chapters 3 through 5 of this standard give requirements for the protection of buildings and miscellaneous property against lightning damage. Because of the nature of the contents of the structures considered in this chapter, extra precautions shall be taken. In these structures, a spark that would otherwise cause little or no damage might ignite the flammable contents and result in a fire or explosion.

6-2 Fundamental Principles of Protection.

Protection of these structures and their contents from lightning damage requires adherence to the following principles:

(a) Liquids that can give off flammable vapors shall be stored in essentially gastight structures.

(b) Openings where flammable concentrations of vapor or gas can escape to the atmosphere shall be closed or otherwise protected against the entrance of flame.

(c) Structures and all appurtenances (e.g., gauge hatches, vent valves) shall be maintained in good operating condition.

(d) Flammable air-vapor mixtures shall be prevented, to the greatest possible extent, from accumulating outside of such structures.

(e) Potential spark gaps between metallic conductors shall be avoided at points where flammable vapors may escape or accumulate.

6-3 Protective Measures.

6-3.1 Materials and Installation.

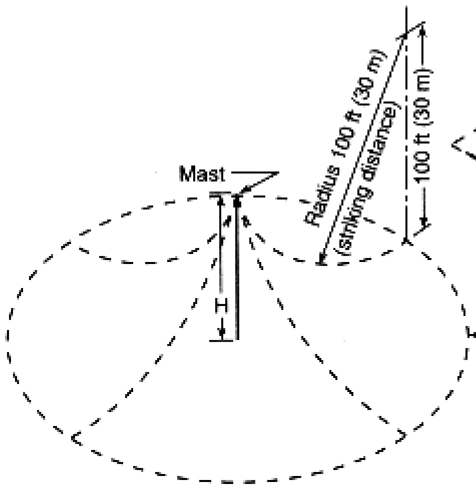
Conductors, air terminals, and grounding connections shall be selected and installed in accordance with the requirements of Chapter 3 and as described in this chapter. Overhead ground wires shall be noncorrosive for the conditions existing at the site. The overhead ground wire selected shall be sized to be equivalent in cross-sectional area to a main conductor and shall be self-supporting with minimum sag under all conditions. It shall be constructed of materials such as aluminum, copper, copper- or aluminum-clad steel, lead or galvanized steel, or stainless steel.

6-3.2 Sheet Steel.

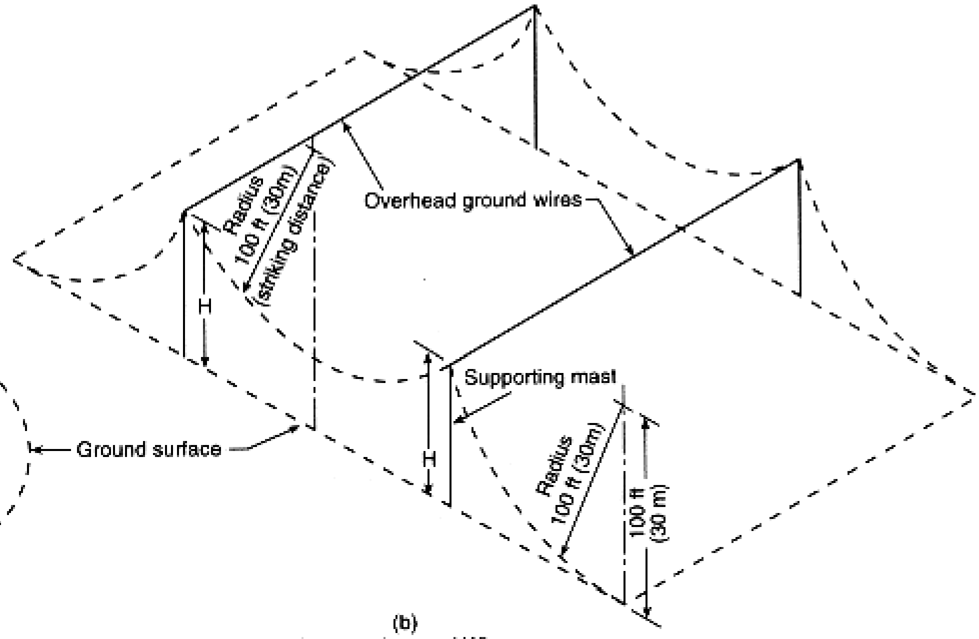
Sheet steel less than $^{3}/_{16}$ in. (4.8 mm) in thickness might be punctured by severe strokes and shall not be relied upon as protection from direct lightning strokes.

6-3.3 Rods, Masts, and Overhead Ground Wires.

6-3.3.1 The zone of protection of a lightning protection mast is based on the striking distance of the lightning stroke (the distance over which final breakdown of the initial stroke to ground, or to a grounded object, occurs). Since the lightning stroke may strike any grounded object within the striking distance of the point from which final breakdown to ground occurs, the zone of protection is defined by a circular arc concave upward. [*See Figure 6-3.3.1(a).*] The radius of the arc is the striking distance, and the arc passes through the tip of the mast and is tangent to the ground. Where more than one mast is used, the arc passes through the tips of adjacent masts. [*See Figures 6-3.3.1(b) and 6-3.3.1(c).*]

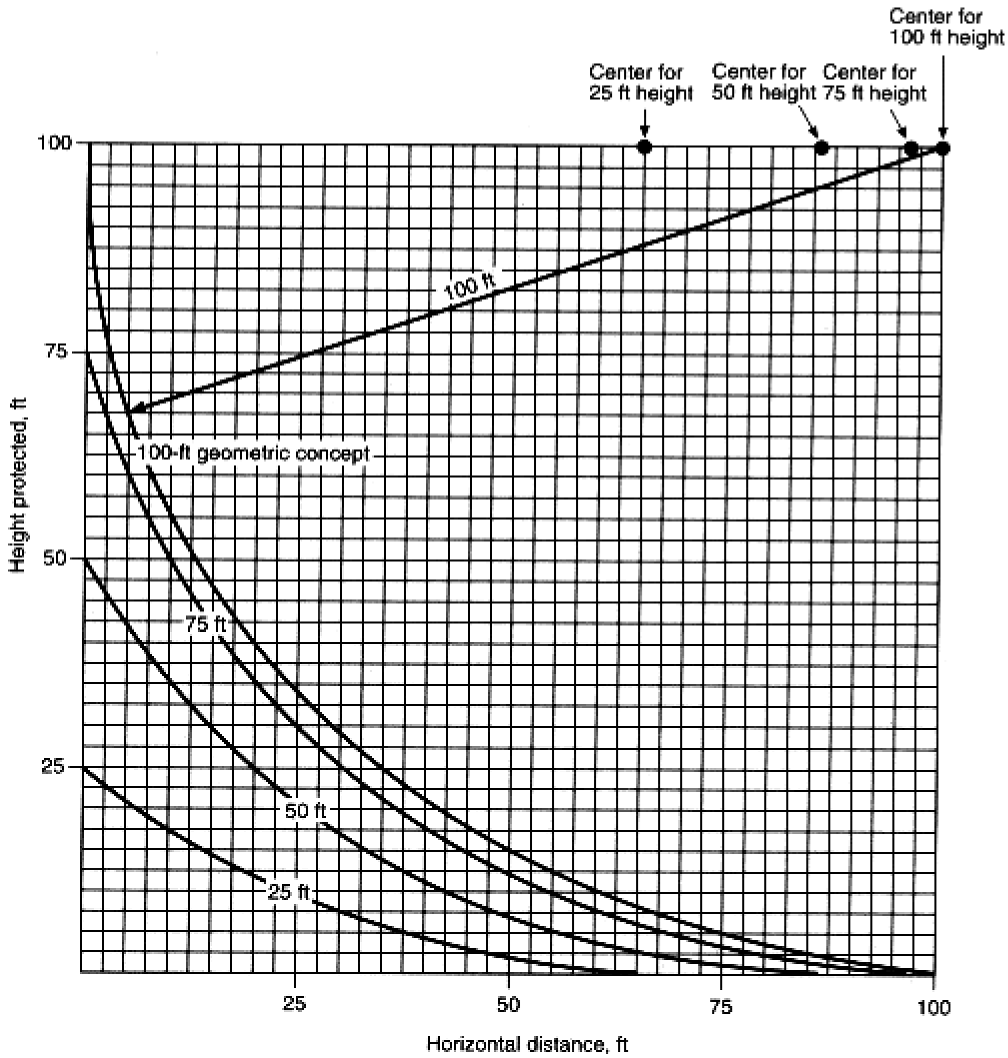


(a)
Single mast
Zone of protection defined by dashed lines.



(b)
Overhead ground Wires
Zone of protection defined by ground wire(s)
and dashed lines.

Figure 6-3.3.1(a) Single mast zone of protection. **Figure 6-3.3.1(b) Overhead ground wires.**



Note: The distance can be determined analytically for a 100 ft (30 m) striking distance with the following equation:

$$d = \sqrt{h_1 (200 - h_1)} - \sqrt{h_2 (200 - h_2)}$$

where: d = horizontal distance, ft
h_1 = height of higher mast, ft
h_2 = height of lower mast, ft
SI units : 1 ft = 0.30 m

Figure 6-3.3.1(c) Zone of protection 100-ft (30-m) striking distance.

The striking distance is related to the peak stroke current and thus to the severity of the lightning stroke; the greater the severity of the stroke, the greater the striking distance. In the vast majority of cases, the striking distance exceeds 100 ft (30 m). Accordingly, the zone based on a striking distance of 100 ft (30 m) is considered to be adequately protected.

The zone of protection afforded by any configuration of masts or other elevated, conductive grounded objects can readily be determined graphically. Increasing the height of a mast above the striking distance will not increase the zone of protection.

6-3.3.2 The zone of protection of an overhead ground wire is based on a striking distance of 100 ft (30 m) and is defined by 100-ft (30-m) radius arcs concave upward. [*See Figure 6-3.3.1(b).*] The supporting masts shall have a clearance from the protected structure as under 6-3.3.3.

6-3.3.3 To prevent sideflashes, the minimum distance between a mast or overhead ground wire and the structure to be protected shall be not less than the bonding distance or sideflash distance. Sideflash distance from a mast can be calculated from the formula

$$D = \frac{h}{6}$$

Where:

h =height of structure (or object under consideration).

Sideflash distance from a catenary can be calculated as

$$D = \frac{l}{6n}$$

Where:

l = length of lightning protection cable between its grounded point and the point under consideration.

n = 1 where there is a single overhead conductor that exceeds 200 ft (67 m) in horizontal length.

n = 1.5 where there is a single overhead wire or more than one wire interconnected above the structure to be protected, such that only two down conductors are located greater than 20 ft (6 m)and less then 100 ft apart.

n = 2.25 where there are more than two down conductors spaced more than 25 ft (7.6 m) apart within a 100-ft (30-m) wide area that are interconnected above the structure being protected.

The masts or overhead ground wires shall be grounded and interconnected with the grounding system of the structure to be protected. The grounding requirements of Chapter 3 shall apply.

6-3.3.4 Masts of wood, used either separately or with ground wires, shall have an air terminal extending at least 2 ft (0.6 m) above the top of the pole, securely attached to the pole (*see Figure 6-3.3.4*), and connected to the grounding system. As an alternative, an overhead ground wire or a down conductor, extending above or across the top of the pole, can be used as the air terminal. In case of an overhead ground-wire system, the pole guy wire can be used as the down conductor. (*See Figure 6-3.3.4.*) For metallic masts, the air terminal and the down conductor shall not be required.

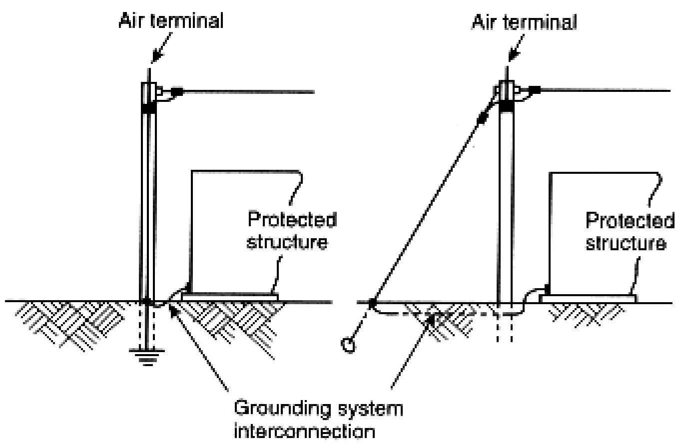


Figure 6-3.3.4 Alternate grounding method for overhead ground-wire protection.

6-4 Protection of Specific Classes of Structures.

6-4.1 Aboveground Tanks at Atmospheric Pressure Containing Flammable Vapors or Liquids that Can Give Off Flammable Vapors.

6-4.1.1 Fixed Roof Tanks. Metallic tanks with steel roofs of riveted, bolted, or welded construction, with or without supporting members, used for the storage of liquids that give off flammable vapors at atmospheric pressure are considered to be protected against lightning (inherently self-protecting) if the following requirements are met:

(a) All joints between metallic plates shall be riveted, bolted, or welded.

(b) All pipes entering the tank shall be metallically connected to the tank at the point of entrance.

(c) All vapor or gas openings shall be closed or provided with flame protection where the stored stock might produce a flammable air-vapor mixture under storage conditions.

(d) The roof shall have a minimum thickness of $^{3}/_{16}$ in. (4.8 mm).

(e) The roof shall be welded, bolted, or riveted to the shell.

6-4.1.2 Floating Roof Tanks.

(a) *General.* Fires have occurred when lightning has struck the rims of open-top floating roof tanks where the roofs were quite high and the contents volatile. Similar above-the-seal fires have occurred when direct lightning strokes to the rims of floating roof tanks have ignited flammable vapors within the open shells. These have occurred where roofs were low. The resulting seal fires have been at small leakage points in the seal. An effective defense against ignition by a direct stroke is a tight seal.

Fires have also occurred in the seal space of open-top floating roof tanks as a result of lightning-caused discharges. These have occurred most frequently in tanks having floating roofs and seals with vapor spaces below the flexible membranes. Similar vapor spaces will be formed where tanks are fitted with secondary seals in compliance with environmental regulations. Ignition can be from a direct stroke or from the sudden discharge of an induced (bound) charge on the floating roof, released when the charge on a cloud discharges to ground or to another cloud.

(b) *Protection.* Where floating roofs utilize hangers located within a vapor space, the roof shall be electrically bonded to the shoes of the seal through the most direct electrical path at intervals not greater than 10 ft (3 m) on the circumference of the tank. These shunts shall consist of flexible Type 302, 28-gauge [$^1/_{64}$ in. × 2 in. (0.4 mm × 51 mm)] wide stainless steel straps, or the equivalent in current-carrying capacity and corrosion resistance. The metallic shoe shall be maintained in contact with the shell and without openings (such as corrosion holes) through the shoe. Tanks without a vapor space at the seal do not require shunts at the seal. Where metallic weather shields cover the seal, they shall maintain contact with the shell.

Where a floating roof is equipped with both primary and secondary seals, the space between the two seals might contain a vapor-air mixture within the flammable range. If the design of such a seal system incorporates electrically conductive materials and a spark gap exists within that space, or could be created by roof movement, shunts shall be installed so that they directly contact the tank shell above the secondary seal. The shunts shall be spaced at intervals not greater than 10 ft (3 m) and shall be constructed so that metallic contact is maintained between the floating roof and the tank shell in all operational positions of the floating roof.

6-4.1.3 Metallic Tanks with Nonmetallic Roofs. Metallic tanks with wooden or other nonmetallic roofs are not considered to be self-protecting, even if the roof is essentially gastight and sheathed with thin metal and with all gas openings provided with flame protection. Such tanks shall be provided with air terminals. Such air terminals shall be bonded to each other, to the metallic sheathing, if any, and to the tank shell. Isolated metal parts shall be bonded as provided in Section 3-22. In lieu of air terminals, any of the following may be used: conducting masts, overhead ground wires, or a combination of masts and overhead ground wires.

6-4.1.4 Grounding Tanks. Tanks shall be grounded to conduct away the current of direct strokes and to avoid the buildup and potential that might cause sparks to ground. A metal tank shall be grounded by one of the following methods:

(a) A tank is connected without insulated joints to a grounded metallic piping system.

(b) A vertical cylindrical tank rests on earth or concrete and is at least 20 ft (6 m) in diameter, or rests on bituminous pavement and is at least 50 ft (15 m) in diameter.

(c) By bonding the tank to ground through a minimum of two ground terminals, as described in Section 3-16, at maximum 100-ft (30-m) intervals along the perimeter of the tank. This also applies to tanks with an insulating membrane beneath the tank.

6-4.2 Earthen Containers at Atmospheric Pressure Containing Flammable Vapors or Liquids that Can Give Off Flammable Vapors.

Earthen containers enclosing flammable vapors or liquids that can give off flammable vapors, lined or unlined, having combustible roofs shall be protected by air terminals, separate masts, overhead ground wires, or a combination of these devices.

6-4.3

Above ground nonmetallic tanks shall be protected as described in 6-3.3.

Chapter 7 Protection for Watercraft

7-l General. The intent of this chapter is to provide lightning protection requirements for watercraft while in water. Lightning protection systems installed on watercraft shall be installed in accordance with the provisions of this chapter.

NOTE 1: A lightning protection system installed in accordance with the requirements of this chapter offers no protection for a watercraft that is out of the water.

NOTE 2: Personnel on small watercraft shall exit the water as quickly as practical when an approaching thunderstorm is noticed. (*See Appendix C for information on personnel safety.*)

NOTE 3: A lightning protection system is not intended to afford protection if any part of the watercraft contacts a power line or other voltage source while in water or on shore.

7-2 Materials.

7-2.1

The materials used in the lightning protection system shall be resistant to corrosion. The use of combinations of metals that form detrimental galvanic couples shall be avoided.

7-2.2

In those cases where it is impractical to avoid a junction of dissimilar metals, the corrosion effect shall be permitted to be reduced by the use of suitable plating or special connectors, such as stainless steel connectors used between aluminum and copper alloys.

Exception: Except for the use of conducting materials that are part of the structure of the watercraft, such as aluminum masts, only copper shall be used in a lightning conductor system. All copper conductors shall be the grade ordinarily required for commercial electrical work, which generally is designated as providing 98-percent conductivity where annealed.

7-2.3 Copper Conductors.

Copper cable conductors shall be of a diameter not less than No. 4 AWG (41,740 CM) for the main down conductor, not less than No. 6 AWG for two parallel paths, or No. 8 AWG for more than two paths (such as those to shrouds and stay connections on sailboats). The thickness of any copper ribbon or strip (except for grounding plates and strips as discussed in 7-5.1) shall not be less than No. 20 AWG. Where other materials are used, the gauge shall be such as to provide conductivity equal to or greater than the required conductor size.

NOTE: See NFPA 302, *Fire Protection Standard for Pleasure and Commercial Motor Craft,* Table 7-12.5 for minimum strand sizes for watercraft conductors.

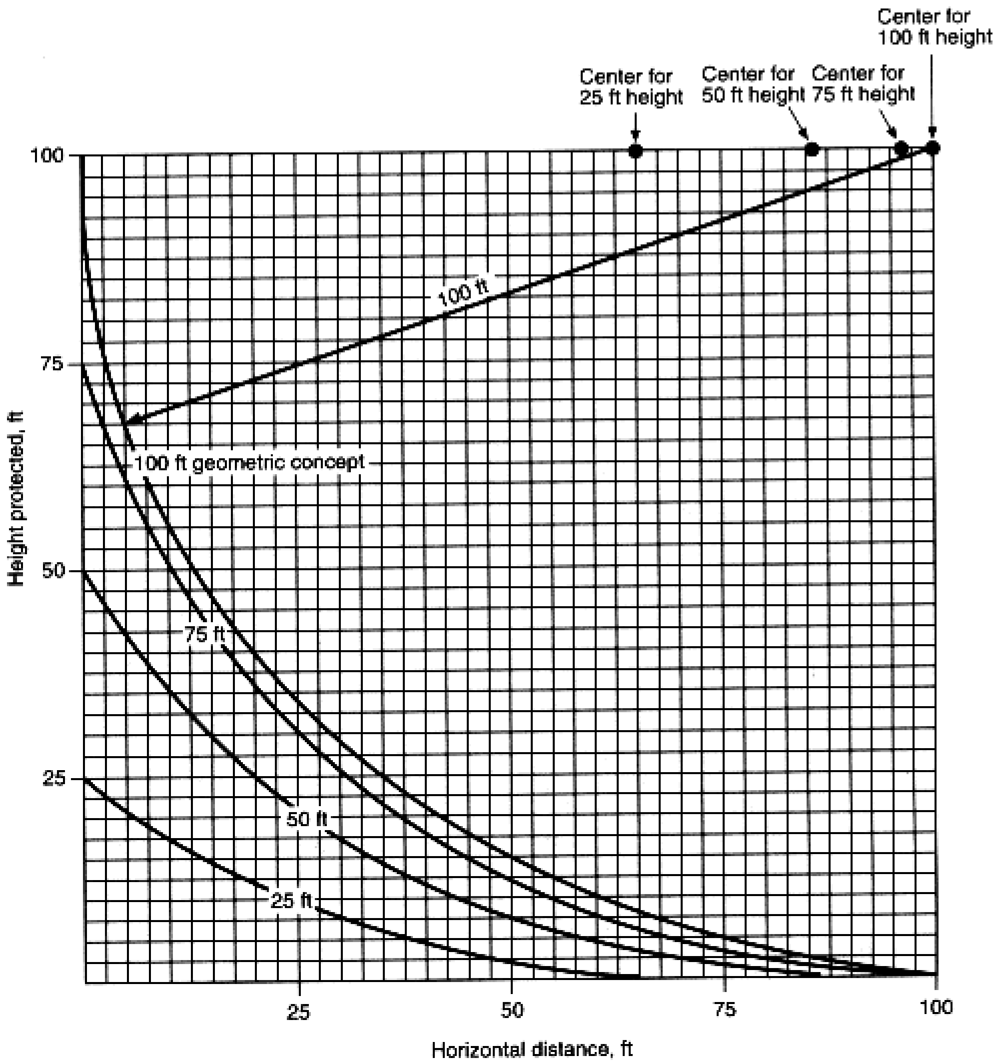
7-2.4 Joints.

Joints shall be mechanically strong and shall be made such that they do not have an electrical resistance in excess of that of 2 ft (0.610 m) of conductor.

7-3 Antennas, Masts, and Overhead Ground Wires.

7-3.1 General.

The zone of protection for watercraft is based on a striking distance of 100 ft. The zone of protection afforded by any configuration of masts or other elevated conductive objects can be readily determined graphically or mathematically as shown in Figure 7-3.1(a). Figure 7-3.1(b) provides an example of how the zone of protection is to be determined for a watercraft with multiple masts.



Note: The distance can be determined analytically for a 100 ft (30 m) striking distance with the following equation:

$$d = \sqrt{h_1 (200 - h_1)} - \sqrt{h_2 (200 - h_2)}$$

where: d = horizontal distance, ft
h_1 = height of air terminal, ft
h_2 = height of object to be protected, ft
For SI units : 1 ft = 0.305 m

Figure 7-3.1(a) Zone of protection 100 ft (30 m) striking distance.

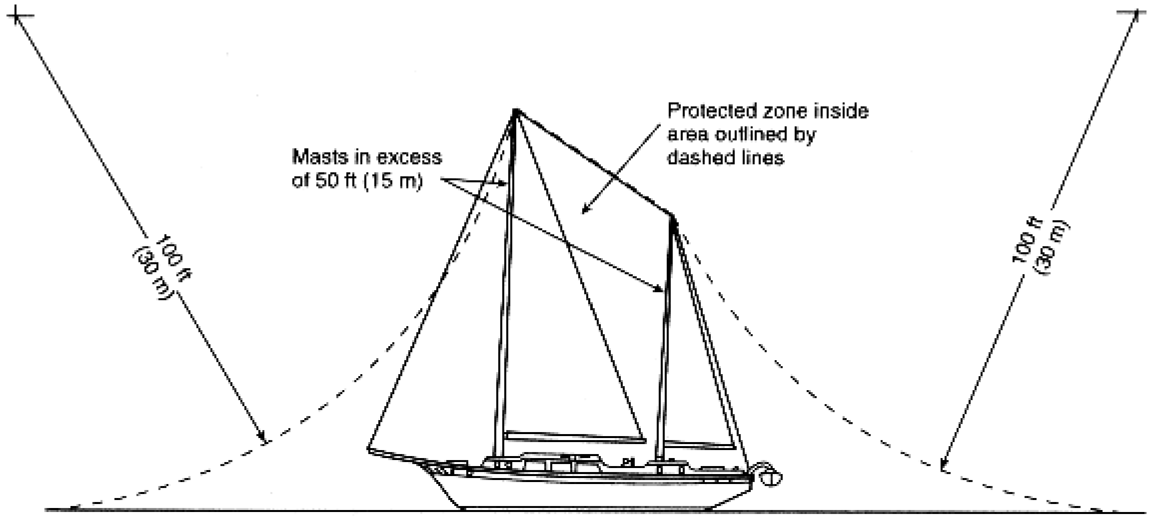


Figure 7-3.1(b) Diagram of boat with masts in excess of 50 ft (15 m) above the water-protection based on lightning strike distance of 100 ft (30 m).

7-3.2 Air Terminals.

Air terminals (including conductive masts, etc.) meeting the requirements of Section 3-9 shall be so located and of sufficient height to provide a zone of protection that covers the entire watercraft. They shall be mechanically strong to withstand the roll and pitching action of the hull as well as heavy weather. The air terminal shall be permitted to be raked at an angle but shall be substantially vertical.

7-3.3 Metallic Masts.

A metallic mast used as an air terminal shall have a conductivity equivalent to a No. 4 AWG copper conductor. They shall be grounded in accordance with the requirements provided in Sections 7-4 and 7-5.

7-3.4 Nonmetallic Masts.

A nonmetallic mast not within the zone of protection of an air terminal shall be provided with an air terminal as described in Section 3-9. The air terminal shall extend a minimum of 6 in. (152 mm) above the mast. The air terminal shall be provided with a copper conductor or strip securely fastened to the mast. The down conductor shall have a conductivity equivalent to a No. 4 AWG copper conductor. A grounding system meeting the requirements of Section 7-5 shall also be provided.

7-3.5 Radio Antennas.

A solid metal vertical radio antenna shall be permitted to serve as an air terminal for small nonmetallic watercraft, provided a provision is made to ground the metal antenna with a conductor equivalent to a No. 4 AWG copper conductor. The conductor shall be routed vertically to the lightning grounding plate, the lightning grounding strip under the watercraft, or to an equalization bus. The height of the antenna shall be sufficient to provide the required zone of protection for the watercraft and its occupants.

Because a loading coil presents a high impedance to the flow of lightning currents, the coil shall be shorted, equipped with a surge suppression device (lightning arrester) for bypassing the lightning current or grounded above the coil.

Nonmetallic radio antennas with spirally wrapped conductors shall not be used for lightning protection.

7-3.6 Temporary Air Terminal.

On small watercraft that cannot be equipped with a permanent air terminal, a temporary air terminal shall be permitted. The temporary air terminal shall be located so as to provide a zone of protection covering the entire watercraft and its occupants when installed. Temporary air terminals shall have a conductivity equivalent to a No. 4 AWG copper conductor.

Exception: A solid stainless steel whip antenna or equivalent shall be permitted to be used as a temporary air terminal.*

The location of the air terminal base shall be such that persons on the watercraft can avoid physical contact with the air terminal or its base.

7-4 Conductors.

7-4.1 Lightning Grounding Conductors.

Lightning grounding conductors shall be routed directly to a ground, as discussed in Section 7-5, to the maximum extent practicable (minimizing bends, etc.). Lightning grounding conductors also shall be routed as remotely as possible from the watercraft's wiring to minimize sideflashes and to avoid introducing high voltages into the watercraft's wiring system. The watercraft wiring system shall be routed perpendicular to the lightning grounding conductors where practicable.

7-4.2* Interconnecting Conductors.

An interconnecting conductor, equivalent to No. 8 AWG copper conductor, shall be provided at all locations where sideflashes are likely to occur. Large metallic masses that are subject to sideflashes shall be connected to the lightning grounding plate(s), the lightning grounding strip, or to the equalization bus, if provided, in accordance with Section 7-6.

7-4.3 Metallic Tanks.

Metallic tanks shall be connected directly to the lightning ground plate(s), the lightning grounding strip, or to the equalization bus.

7-4.4 Shrouds and Stays.

Shrouds and stays shall be permitted as part of the path to ground from the air termination point on the mast to the lightning grounding plate or strip. The aggregate conductivity and inductance, including the mast, shall be not less than that of a No. 4 AWG copper conductor. Where stainless steel shrouds and stays are used in the lightning protection system, every shroud or stay shall be connected at its lower end or at the chainplates directly to the lightning grounding plate or lightning grounding strip with conductors having the minimum size of a No. 8 AWG copper conductor.

Stainless steel shrouds of small diameter and stays on small sailboats that are trailered which do not have the required conductivity (less than that of a No. 8 AWG copper conductor) shall be grounded at their lower ends in addition to the grounding of the mast. The mast shall serve as the primary lightning conductor.

7-5 Grounding.

7-5.1 Watercraft with Metal Hulls.

If an electrical connection exists between a metallic hull and a lightning air terminal or other metallic superstructure of sufficient height to provide the zone of protection specified in Section 7-3, no further protection shall be necessary; however, surge suppression in accordance with Section 3-21 shall be provided. Conducting objects projecting above metal masts or superstructures shall be grounded with a grounding conductor connected to the metal hull or superstructure.

7-5.2 Watercraft with Nonmetallic Hulls.

Grounding plates or strips shall be installed on the underside of the hull of nonmetallic watercraft to provide a path for the lightning current into the water.

7-5.2.1 Grounding Plate. A grounding plate of copper, copper alloys, or stainless steel shall be provided. The plate shall have a minimum size of 1 $ft^2 \times {}^3/_{16}$-in. (0.09 $m^2 \times$ 4.8-mm) thick. It shall be located as closely as possible below the lightning air terminal. Through-hull connectors shall be metallic and have a cross-sectional area equivalent to a No. 4 AWG copper conductor.

7-5.2.2 Grounding Strip. An external grounding strip of copper, copper alloys, or stainless steel installed under the watercraft running fore and aft, shall have a minimum thickness of ${}^3/_{16}$ in. (4.8 mm) and a minimum width of ${}^3/_4$ in. (l9 mm). The length of the strip shall be permitted to extend from a point located directly below the lightning protection air terminal to the aft end of the watercraft where a direct connection shall be made to the engine. The total length of the strip shall be not less than 4 ft (1.2 m).

In a sailboat, the backstray and engine shall be electrically connected to the aft end of the strip. The strip shall be secured to the hull with one, or preferably two galvanically compatible throughbolts at each end. The bolts shall have a minimum cross-sectional area equivalent to a No. 4 AWG copper conductor. The strip shall be located so that it is submerged under all operating conditions. If the single strip is not located so as to be continuously submerged when the vessel is heeled either to port or starboard, then a strip shall be required on both port and starboard sides. Where more than one grounding strip is provided, all of the grounding strips shall be bonded together.

All terminations to the strip shall be made as short and direct as possible.

Additional through-hull connections shall be permitted to be located along the length of the strip for additional connections such as those on a two masted sailboat. Because of the possibility of stray current corrosion of the securing bolts, the number of through-hull bolts shall be kept to a minimum. To minimize the number of through-hull bolt connections, an equalization bus shall be permitted to be installed in accordance with Section 7-6.

The aft end of the grounding strip shall be connected directly to the engine negative ground terminal to provide a path inside the hull for any stray dc currents that are imposed on the through-hull bolts from the lightning grounding strip where those bolts contact bilge water.

7-6 Interconnection of Metallic Masses.

7-6.1 Equalization Bus.

On watercraft where several connections are made to the lightning grounding strip, an equalization bus shall be permitted to be installed inside the boat to minimize the number of through-hull bolts necessary. The equalization bus, if used, shall be installed inside the watercraft parallel to the underwater location of the lightning grounding strip. Permanently installed large metallic masses inside the watercraft shall be connected directly to the equalization bus. The equalization bus shall be connected to the underwater lightning grounding strip at both ends.

7-6.2 Seacocks and Through-Hull Fittings.

Seacocks and through-hull fittings shall not be connected to the main down conductor but shall be permitted to be connected to the underwater grounding strip, the lightning grounding plate, or the equalization bus.

NOTE: Seacocks are particularly susceptible to damage and leaking after a strike and should be inspected after all suspected strikes.

7-6.3 Metal Masses.

Metal masses such as engines, generators, metallic tanks, steering systems located inside the vessel, and other items such as metal life rails shall be connected to the lightning grounding plate, grounding strip or equalization bus as directly as possible.

7-6.4 Engine Grounding.

To minimize the flow of the lightning discharge currents through the engine bearings, it shall be permissible to ground the engine block directly to the lightning grounding plate or lightning grounding strip rather than to an intermediate point in the system.

7-6.5 Protection of Equipment.

Wherever possible, electronic equipment shall be enclosed in metal cabinets that are connected to the lightning grounding system with a minimum of a No. 8 AWG copper conductor. Surge suppression devices shall be installed on all wiring entering or leaving electronic equipment.

7-7 Nonmetallic Watercraft.

7-7.1 Sailboats.

Sailboats without inboard engines that are equipped with metallic masts and metallic rigging shall be considered to be adequately protected if the mast and the rigging chain plates are all connected to a lightning grounding plate or lightning grounding strip located directly below the mast.

7-7.1.1 Open Day-Sailors. Because the stainless steel rigging and preventors usually are not equivalent to No. 8 AWG copper conductor, adequate protection depends on the grounding of the rigging as well as the metal masts or the continuous metallic tracks on nonmetallic masts. These shall be connected at the lower ends to a lightning grounding plate or a lightning strip located directly below the mast. Metallic rudders at the aft end of the boat shall not be used as the lightning ground for the mast because of the need for a long, horizontal conductor to be run to the aft end of the boat. The tiller or other connections to metallic rudders the operator will contact shall be of nonconductive materials. Metallic keels or centerboards shall be directly connected to the lightning grounding plate or strip, or shall be permitted to serve as the lightning grounding means if they provide the l ft^2 (0.09 m^2) area required to be in contact with the water. If a centerboard is used as the lightning grounding means, a warning sign shall be provided that clearly states that the centerboard shall be in the down position in order to function as a lightning ground.

7-7.1.2 Cruising Sailboats. All shrouds, stays, sail tracks, and metallic masts shall be connected to the lightning grounding system, since it is assumed that occupants of the boat will be in proximity of forestays, backstays, and shrouds during the normal operation of the boat. Grounding of all metallic masses on the boat shall be in accordance with all applicable sections of this standard.

7-7.2* Power Boats.

Where practicable, lightning protection shall be provided through the use of a metallic radio antenna as described in Section 7-3.5, or a temporary air terminal as described in Section 7-3.6.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.2

Electric generating facilities whose primary purpose is to generate electric power are excluded from this standard with regard to generation, transmission, and distribution of power. Most electrical utilities have standards covering the protection of their facilities and equipment. Installations not directly related to those areas and structures housing such installations can be protected against lightning by the provisions of this standard.

Lightning protection systems for structures used for production of storage of explosive materials require special consideration because of the sensitivity to arc or spark ignition of the structures' contents. Appendix K provides guidance for protection of structures housing explosive materials. Other standards and handbooks that provide guidance for military applications are found in Appendix M.

A-2-2 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-2-2 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-2-2 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

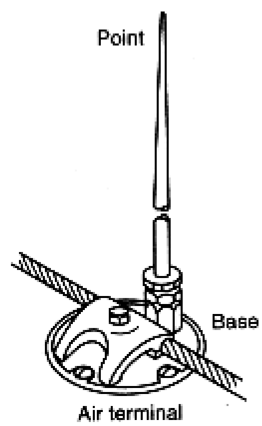

Figure A-2-2(a).

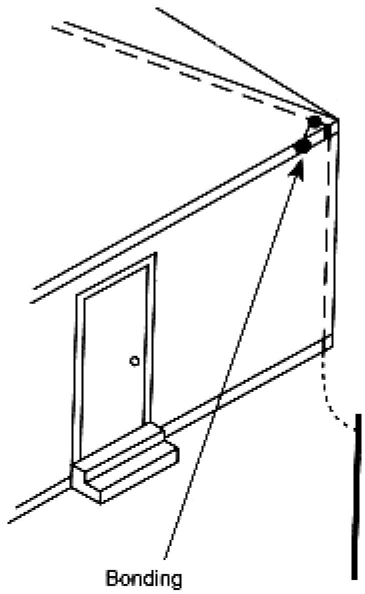

Figure A-2-2(b).

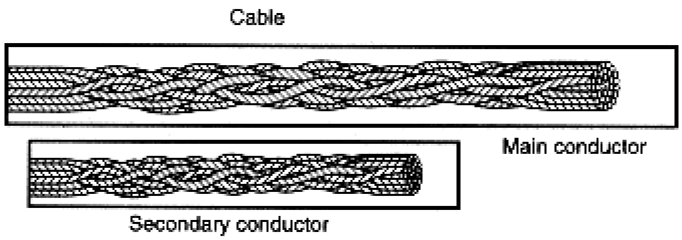

Figure A-2-2(c).

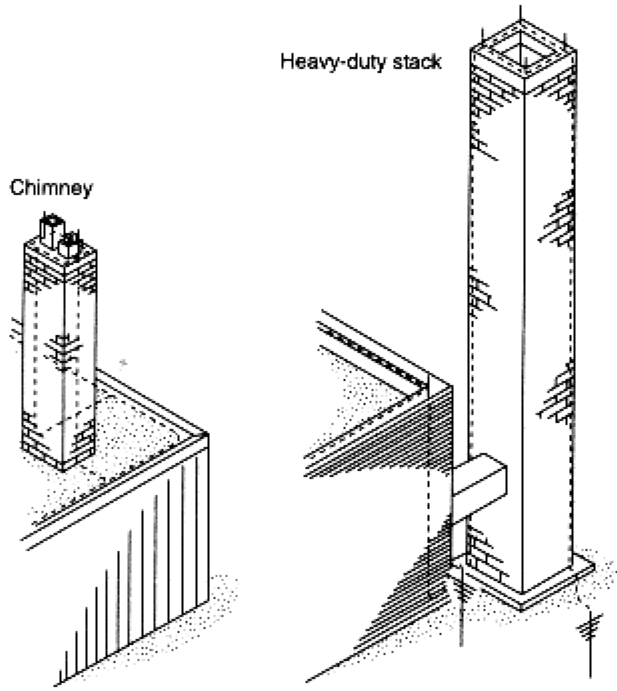

Figure A-2-2(d).

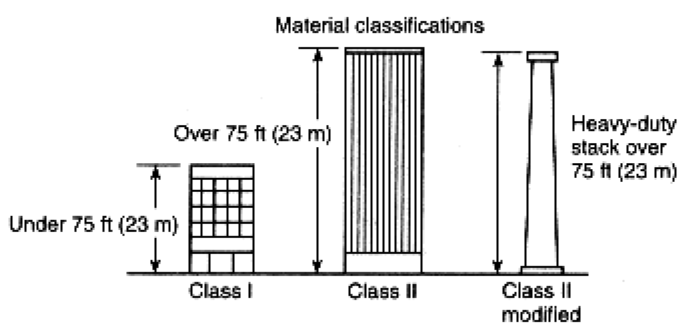

Figure A-2-2(e).

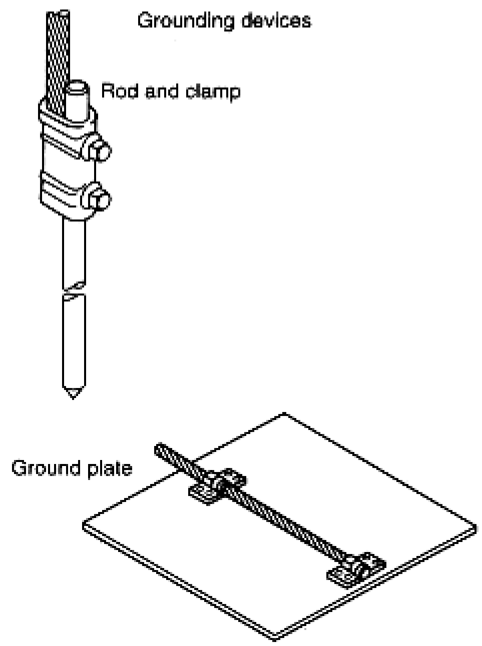

Figure A-2-2(f).

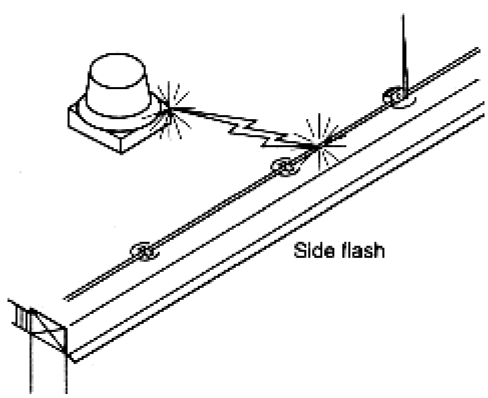

Figure A-2-2(g).

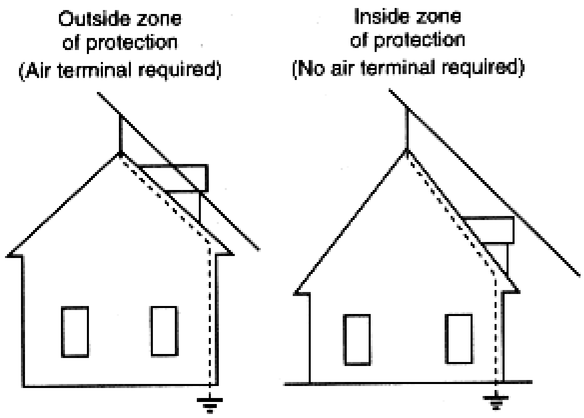

Figure A-3-11.2.

A-5-9

A ground grid located within 50 ft (15 m) of the foundation of a stack and constructed of wires meeting the requirements of this standard for main conductors is an acceptable ground terminal and, if the stack is located within 50 ft (15 m) of the grid in all directions, can also serve as the bottom loop conductor required by 5-4.1.

A-6-1.1

Flammable vapors can emanate from a flammable liquid [flash point below 100°F (37.8°C)] or a combustible liquid [flash point at or above 100°F (37.8°C)] when the temperature of the liquid is at or above its flash point. This chapter applies to these liquids when stored at atmospheric pressure and ambient temperature. Providing that the temperature of the liquid remains below the flash point, combustible liquids stored under these conditions will not normally release significant vapors since their flash point is defined to be at or above 100°F (37.8°C).

Metallic tanks, vessels, and process equipment that contain flammable or combustible liquids or flammable gases under pressure normally do not require lightning protection, since this equipment is well shielded from lightning strikes. Equipment of this type is normally well grounded and is thick enough not to be punctured by a direct strike.

This chapter applies to flammable or combustible liquids such as gasoline, diesel, jet fuel, fuel oil, or crude oil stored at atmospheric pressure. It does not apply to liquids or gases stored under pressure, such as liquefied natural gases or liquefied petroleum gases.

A-7-3.6

A solid stainless steel whip antenna or equivalent is permitted to be used because of its higher melting temperature, however it does not provide as low a resistance as a No. 4 AWG copper conductor.

A-7-4.2

Sideflash distances can be calculated using the formulas provided in Section 3-24. Sideflashes are more likely to occur if the routing of the lightning conductor is horizontal for some distance and if the metallic object provides a more direct path to ground.

A-7-7.2

At the approach of a thunderstorm, personnel should head for shore and quickly seek a land-based protected structure. There are many methods available by which lightning can be detected. These range from listening for static on AM radios, to single station detection devices, to sophisticated lightning location systems.

Appendix B Inspection and Maintenance of Lightning Protection Systems

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

B-1 Inspection of Lightning Protection Systems.

B-1.1 Frequency of Inspections.

It is understood that all new lightning protection systems must be inspected following completion of their installation. However, it is also very important to make periodic inspections of existing systems. The interval between inspection should be determined by such factors as:

(a) classification of structure or area protected;

(b) level of protection afforded by the system;

(c) immediate environment (corrosive atmospheres);

(d) materials from which components are made;

(e) the type of surface to which the lightning protection components are attached.

B-1.1.1 In addition to the above, a lightning protection system should be inspected whenever any alterations or repairs are made to a protected structure, as well as following any known lightning discharge to the system.

B-1.1.2 It is recommended that lightning protection systems be visually inspected at least annually. In some areas where severe climatic changes occur it may be advisable to visually inspect systems semiannually or following extreme changes in ambient temperatures. Complete, in-depth inspections of all systems should be completed every 3 to 5 years. It is recommended that critical systems be so inspected every 1 to 3 years depending on occupancy or the environment in which the protected structure is located.

B-1.1.3 In most geographical areas, and especially in areas that experience extreme seasonal changes in temperature and rainfall, it is advisable to stagger inspections so that earth resistance measurements, for example, are made in the hot, dry months as well as the cool, wet months. Such staggering of inspections and testing is important in assessing the effectiveness of the lightning protection system during the various seasons throughout the year.

B-1.2 Visual Inspection.

Visual inspections are made to ascertain the following:

(a) The system is in good repair.

(b) There are no loose connections that might result in high resistance joints.

(c) No part of the system has been weakened by corrosion or vibration.

(d) All down conductors and ground terminals are intact (non-severed).

(e) All conductors and system components are securely fastened to their mounting surfaces and are protected against accidental mechanical displacement as required.

(f) There have not been additions or alterations to the protected structure that would require additional protection.

(g) There has been no visual indication of damage to surge suppression (over voltage) devices.

(h) The system complies in all respects with the current edition of this standard.

B-1.3 Complete Testing and Inspection.

Such testing and inspection includes the visual inspections described above in addition to the following:

(a) Perform tests to verify continuity of those parts of the system that were concealed (built-in) during the initial installation and that are not now available for visual inspection.

(b) Conduct ground resistance tests of the ground termination system and its individual ground electrodes if adequate disconnecting means have been provided. These test results should be compared with previous, or original, results or current accepted values, or both, for the soil conditions involved. If it is found that the test values differ substantially from previous values obtained under the same test procedures, additional investigations should be made to determine the reason for the difference.

(c) Perform continuity tests to determine if suitable equipotential bonding has been established for any new services or constructions that have been added to the interior of the structure since the last inspection.

B-1.4 Inspection Guides and Records.

Inspection guides or forms should be prepared and made available to the authority responsible for conducting inspections of lightning protection systems. These guides should contain sufficient information to guide the inspector through the inspection process so that he or she may document all areas of importance relating to the methods of installation, the type and condition of system components, test methods, and the proper recording of the test data obtained.

B-1.5 Records and Test Data.

The inspector or inspection authority should compile and maintain records pertaining to the following:

(a) The general condition of air terminals, conductors, and other components.

(b) The general condition of corrosion protection measures.

(c) The security of attachment of conductors and components.

(d) Resistance measurements of various parts of the ground terminal system.

(e) Any variations from the requirements contained in this standard.

B-2 Maintenance of Lightning Protection Systems.

B-2.1 General.

Maintenance of a lightning protection system is extremely important even though the lightning-protection design engineer has taken special precautions to provide corrosion protection, and has sized the components according to their particular exposure to lightning damage. Many system components tend to lose their effectiveness over the years because of corrosion factors, weather-related damage, and stroke damage. The physical, as well as the electrical, characteristics of the lightning protection system must be maintained in order to maintain compliance with design requirements.

B-2.2 Maintenance Procedures.

B-2.2.1 Periodic maintenance programs should be established for all lightning protection systems. The frequency of maintenance procedures is dependent on the following:

(a) weather related degradation;

(b) frequency of stroke damage;

(c) protection level required;

(d) exposure to stroke damage.

B-2.2.2 Lightning protection system maintenance procedures should be established for each system and should become a part of the overall maintenance program for the structure that it protects.

A maintenance program should contain a list of more or less routine items that can serve as a checklist so that a definite maintenance procedure can be followed regularly. It is the repeatability of the procedures that enhance the effectiveness of a good maintenance program.

A good maintenance program should contain provisions for the following:

(a) Inspection of all conductors and system components.

(b) Tightening of all clamps and splicers.

(c) Measurement of lightning protection system resistance.

(d) Measurement of resistance of ground terminals.

(e) Inspection or testing, or both, of surge suppression devices to determine their effectiveness compared with similar new devices.

(f) Refastening and tightening of components and conductors as required.

(g) Inspection and testing as required to determine if the effectiveness of the lightning protection system has been altered due to additions to, or changes in, the structure.

B-2.3 Maintenance Records.

Complete records should be kept of all maintenance procedures and routines and should include corrective actions that have been or will be taken. Such records provide a means of evaluating system components and their installation. They also serve as a basis for reviewing maintenance procedures as well as updating preventive maintenance programs.

Appendix C Guide for Personal Safety from Lightning

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

C-1

The purpose of this appendix is to furnish a guide for personal safety from lightning. Personnel may be at risk prior to any visual or audible indication of a thunderstorm. Any time that conditions exist that might lead to lightning activity, personnel safety should be considered. Lightning warning systems are available to provide early warning of lightning activity.

C-2 Personal Conduct.

C-2.1

Do not go out-of-doors or remain out, unless it is necessary. Seek shelter as follows:

(a) dwellings or other buildings that are protected against lightning;

(b) underground shelters such as subways, tunnels, and caves;

(c) large metal-frame buildings;

(d) large unprotected buildings;

(e) enclosed automobiles, buses, and other vehicles with metal tops and bodies;

(f) enclosed metal trains and street cars;

(g) enclosed metal boats or ships;

(h) boats that are protected against lightning;

(i) city streets that may be shielded by nearby buildings.

C-2.2

If possible, avoid the following places, which offer little or no protection from lightning:

(a) small, unprotected buildings, barns, sheds, etc.;

(b) tents and temporary shelters;

(c) automobiles (nonmetal top or open);

(d) trailers (nonmetal or open).

C-2.3

Certain locations are extremely hazardous during thunderstorms and should be avoided if at all possible. Approaching thunderstorms should be anticipated, and the following locations avoided when storms are in the immediate vicinity:

(a) hilltops and ridges;

(b) areas on top of buildings;

(c) open fields, athletic fields, golf courses;

(d) parking lots and tennis courts;

(e) swimming pools, lakes, and seashores;

(f) near wire fences, clotheslines, overhead wires, and railroad tracks;

(g) under isolated trees;

(h) near electrical appliances, telephones, plumbing fixtures, and metal or electrically conductive objects.

C-2.4

In the above locations, it is especially hazardous to be riding in or on any of the following during thunderstorms:

(a) open tractors or other farm machinery operated in open fields;

(b) golf carts, scooters, bicycles, or motorcycles;

(c) open boats (without masts) and Hovercraft;

(d) automobiles (nonmetal top or open).

C-2.5

It may not always be possible to choose a location that offers good protection from lightning. Follow these rules when there is a choice in selecting locations:

(a) Seek depressed areas—avoid mountaintops, hilltops, and other high places.

(b) Seek dense woods—avoid isolated trees.

(c) Seek buildings, tents, and shelters in low areas—avoid unprotected buildings and shelters in high areas.

(d) If you are hopelessly isolated in an exposed area, drop to your knees and bend forward, putting your hands on your knees.

C-3 Protection for Personnel in Watercraft.

C-3.1

Inasmuch as the basic purpose of protection against lightning is to ensure the safety of personnel, it is appropriate that the following precautions and suggestions be listed in addition to all applicable recommendations in the preceding sections.

C-3.2

One should remain inside a closed boat, as far as practical, during a lightning storm and should not dangle arms or legs in the water.

C-3.3

To the extent consistent with safe handling and navigation of the boat during a lightning storm, one should avoid making contact with any items connected to a lightning protection system and especially in such a way as to bridge between these items. For example, it is undesirable that an operator be in contact with reversing gear levers and spotlight control handle at the same time.

C-3.4

No one should be in the water during a lightning storm.

Appendix D Protection for Livestock in Fields

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

D-1 General.

D-1.1

The nature of the exposure of livestock in fields is such that it is not possible to eliminate the hazard entirely. However, application of the recommendations contained in this Appendix should minimize the hazard.

D-1.2

The loss of livestock due to lightning during thunderstorms is caused in large measure by herds congregating under isolated trees in open pastures or drifting against ungrounded wire fences and receiving a sufficient discharge to kill them.

D-1.3

In pastures where shelter is available from wooded areas of considerable size, isolated trees should be removed unless protection is provided.

D-1.4

Fences built with metal posts set in the earth are as safe from lightning as it is practical to make them, especially if the electrical continuity is broken. Breaking the electrical continuity is very useful in that it reduces the possibility of a lightning stroke affecting the entire length of a fence, as it can if the stroke is direct and the fence continuous, even though grounded. The fences that give rise to the most trouble are those constructed with posts of poorly conducting material, such as wood.

D-2 Grounding of Wire Fences.

D-2.1

Where it is desirable or necessary to mitigate the danger from wire fences constructed with posts of nonconducting material, D-2.2 and D-2.3 should be applied.

D-2.2 Iron Posts.

Ground connections may be made by inserting at intervals galvanized-iron posts, such as are ordinarily used for farm fencing, and attaching in electrical contact all of the wires of the fence, or by driving a length of not less than $^{1}/_{2}$ in. (12.7 mm) in diameter galvanized-iron pipe beside the fence and attaching the wires by ties of galvanized-iron wire. If the ground is normally dry, the intervals between metal posts should not exceed about 150 ft (46 m). If the ground is normally damp they may be placed up to about 300 ft (92 m) apart.

D-2.3 Depth of Grounds.

Pipes should be extended into the ground at least 2 ft (0.6 m).

D-3 Breaking Continuity of Fence.

D-3.1

In addition to grounding the fence, its electrical continuity should be broken by inserting insulating material in breaks in the wires at intervals of about 500 ft (150 m). These insertions may be in the form of fence panels of wood or lengths of insulating material to the ends of which the wires can be attached. Such lengths of insulating material may consist of strips of wood about 2 in. × 2 in. × 24 in. (50 mm × 50 mm × 600 mm), or their equivalent as far as insulating properties and mechanical strength are concerned.

D-3.2

In areas where herds may congregate along fences, the continuity should be broken at more frequent intervals than described in D-3.1.

Appendix E Protection for Picnic Grounds, Playgrounds, Ball Parks, and Other Open Places

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

E-1 Picnic Grounds and Playgrounds.

Protection from lightning may be provided by the methods indicated in E-1.1 or E-1.2.

E-1.1 Shelters with Lightning Protection Systems.

Provide shelters with closed or open sides that are equipped with lightning protection systems. Down conductors should be shielded with nonconductive material resistant to impact and climate conditions to at least an 8-ft (2.4-m) height. Shelters with earthen floors should have: (1) ground terminals interconnected by an encircling, buried, bare copper conductor, or (2) ground terminals provided with buried radial conductors run out at least 10 ft (3 m) from the ground terminal away from the shelter.

E-1.2 Masts and Overhead Ground Wires.

Erect masts (poles) on opposite sides of the grounds and near the edges. Overhead wires should be strung between the masts at least 20 ft (6.1 m) above the ground level. Down conductors should be connected to the overhead wires with ground terminals. Down conductors should be shielded with material resistant to impact and climate conditions to at least an 8-ft (2.4-m) height. The wires should be not less than No. 4 AWG copper or equivalent. If steel masts are used, down leads are not necessary but the foot of the mast should be grounded. If the area to be protected is extensive, it may be necessary to erect several masts around the perimeter so that the area is covered by a network of wires to form a zone of protection. [*See Figures 6-3.3.1(a) and (b) in Chapter 6 for illustration.*]

E-2 Ball Parks and Racetracks.

E-2.1 Roofed Grandstands.

Roofed grandstands are included within the scope of this standard.

E-2.2 Open Grandstands and Open Spectator Areas.

Open grandstands and open spectator areas should be provided with masts and overhead ground wires as described in E-1.2.

E-3 Beaches.

Beaches should be provided with shelters as described in E-1.1.

E-4 Piers.

E-4.1 Covered Piers.

Covered piers are included within the scope of this standard.

E-4.2 Open Piers.

Open piers should be provided with masts and overhead ground wires as described in E-1.2.

Appendix F Protection for Trees

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

F-1 General.

Trees with trunks within 10 ft (3 m) of a structure, or with branches that extend to a height above the structure should be equipped with a lightning protection system because of the danger of sideflash, fire, or superheating of the moisture in the tree, which could result in splintering of the tree. It might be desirable to equip other trees with a lightning protection system because of particular value to the owner. (*See Figure F-1.*)

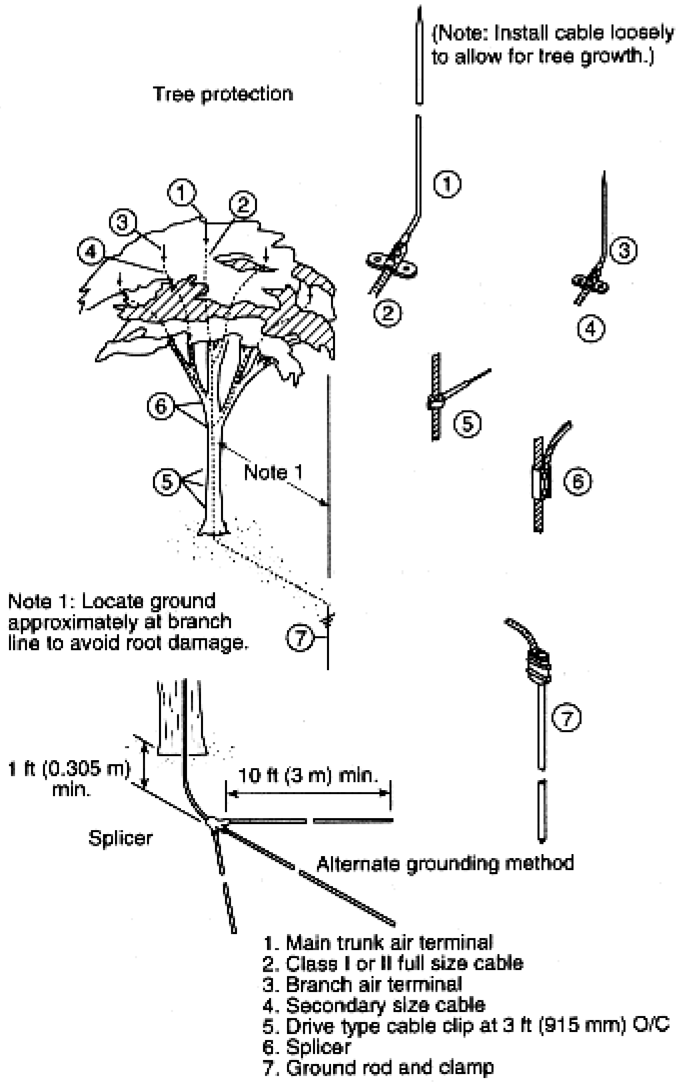

Figure F-1 Protection for trees.

F-2 Methods and Materials.

F-2.1 Conductors.

Conductors should conform to the requirements of Chapter 3.

F-2.2 Coursing of Conductors.

A single conductor should be run from the highest part of the tree along the trunk to a ground connection. If the tree is forked, branch conductors should be extended to the highest parts of the principal limbs. If the tree trunk is 3 ft (0.9 m) in diameter or larger, two down conductors should be run on opposite sides of the trunk and interconnected.

F-2.3 Air Terminals.

The conductors should be extended to the highest part of the tree terminating with an air terminal.

F-2.4 Attachment of Conductors.

Conductors should be securely attached to the tree in such a way as to allow for swaying in the wind and growth without danger of breakage.

F-2.5 Ground Terminals.

Ground terminals for conductors should:

(a) Be made from each conductor, descend the trunk of the tree, extend three or more radial conductors in trenches 1 ft (0.3 m) deep, and be spaced at equal intervals about the base to a distance of not less than 10 ft (3 m);

(b) Have the radial conductors extended to the branch line not less than 25 ft (7.6 m);

(c) Have the out ends connected to the radial conductors with a conductor that encircles the tree at a depth of not less than 1 ft (0.3 m); and

(d) Be bonded to an underground metallic water pipe where available within 25 ft (7.6 m) of the branch line.

Appendix G Protection for Parked Aircraft

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

G-1 General Principles.

G-1.1

Aircraft includes airplanes, helicopters, and lighter-than-air craft. They can best be protected by being placed inside a properly lightning-protected hangar. Hangar facilities should be provided with grounding receptacles to permit interconnection of metal aircraft with the hangar lightning protection system. It is important that hangar floors, aprons, and aircraft parking areas be kept free of gasoline or other flammable liquids.

G-1.2

All metal airplanes parked outside hangars should be grounded. This grounding may be achieved by the use of adequately grounded metal tie-down cables or the equivalent. Aircraft having fabric or plastic covering materials can be protected by connecting its metal frame to ground. For additional protection of aircraft parked outside hangars, an overhead ground wire or mast-type lightning protection system may be provided. The height should be in accordance with the zones of protection described in Chapter 3.

G-1.3

The effects of lightning strikes to metal and composite aircraft are a matter of continuous study. The use of surge suppression circuitry on critical navigational, radio-communication, and radar equipment can help to minimize these effects. Suitable equipment and electrical wiring layout can also aid in reducing lightning-induced problems.

G-1.4

Commercial aircraft have grown considerably larger in recent years and in many cases are taller than surrounding airport terminal buildings. A review of available lightning-strike injury data indicates that nearly all of the reported personnel injuries were the result of lightning-induced static discharge.

G-1.5

The grounding methods used for aircraft undergoing fuel servicing and certain maintenance operations are not necessarily adequate to provide effective lightning protection for aircraft or personnel. The installation of additional grounding straps, preferably at the aircraft's extremities, during thunderstorm activity will provide alternative paths to ground for any current flow resulting from the rapid adjustment in the aircraft surface charge. Experience has shown that additional grounding straps offer little protection in the event of a direct strike to the aircraft. Fuel servicing operations and other maintenance operations involving the use of flammable liquids or the release of flammable vapors should be suspended during lightning storms. Refer to NFPA 407, *Standard for Aircraft Fuel Servicing*, and NFPA 410, *Standard on Aircraft Maintenance*.

G-1.6

Baggage handling, exterior maintenance, and servicing of parked aircraft should be suspended when a thunderstorm is in the vicinity of an airport. Lightning-warning equipment can be utilized to aid in determining when to suspend these operations. There are many detection methods capable of detecting and tracking approaching storms. One such method, atmospherics, is being used to establish lightning-detection networks that now cover approximately half of the United States. While atmospherics equipment can give positional information of distant lightning, it gives no warning of a cloud directly overhead becoming electrified. Devices that measure some property of the electric field can detect the development of a hazardous condition and provide a warning prior to the first discharge.

G-1.7

Cables connected to parked aircraft should not be handled when a thunderstorm is in the vicinity. The use of hand signals, without the use of headsets, is recommended for ground-to-cockpit communications during this period.

Appendix H Risk Assessment Guide

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

H-1 General.

H-1.1

This lightning risk assessment guide is prepared to assist in the analysis of various criteria to determine the risk of loss due to lightning. As a guide, it is not possible to cover each special design element that may render a structure more or less susceptible to lightning damage. In special cases, personal and economic factors may be very important and should be considered in addition to the assessment obtained by use of this guide.

H-1.2

If the structure is in a high risk situation, a risk index (R) should be computed for a wide range of structures in the environment concerned. The structure's index is then compared to the index of these other structures so that a judgment of local risk weighting can be made.

H-2 Determining the Risk.

The assessment of risk index (R) is given in Table H-2. The risk index (R) is obtained by dividing the sum of the values given in Tables H-2(a) through H-2(e) by the lightning frequency index value obtained from Table H-2(f).

The risk index (R) is:

$$D = \frac{A + B + C + D + E}{F}$$

Table H-2 Assessment of Risk, R

R Value	Risk Value
0-2	Light
2-3	Light to Moderate
3-4	Moderate
4-7	Moderate to Severe
Over 7	Severe

The computed "R" values for the eastern United States should be multiplied by a factor varying from 1.5 in the northeast to 0.5 in the southeast. This factor is due to the differences in storm characteristics in these regions.

Table H-2(a) Index "A" – Type of Structure

Structure	Index Value
Single family residence less than 5,000 ft^2 (465 m^2)	1
Single family residence over 5,000 ft^2 (465 m^2)	2
Residential, office, or factory building less than 50 ft (15 m) in height:	
Covering less than 25,000 ft^2 (2,323 m^2) of ground area	3

Covering over 25,000 ft^2 (2,323 m^2) of ground area	5
Residential, office, or factory building from 50 ft to 75 ft (15 m to 23 m) high	4
Residential, office, or factory building from 75 ft to 150 ft (23 m to 46 m) high	5
Residential, office, or factory building from 150 ft (46 m) or higher	8
Municipal services buildings, fire, police, water, sewer, etc.	7
Hangars	7
Power-generating stations, central telephone exchanges	8
Water towers and cooling towers	8
Libraries, museums, historical structures	8
Farm buildings	9
Golf shelters and other recreational shelters	9
Places of public assembly such as schools, churches, theaters, stadiums	9
Slender structures such as smokestacks, church steeples and spires, control towers, lighthouses, etc.	10
Hospitals, nursing homes, housing for the elderly or handicapped	10
Buildings housing the manufacture, handling, or storage of hazardous materials	10

Table H-2(b) Index "B" – Type of Construction

Structural Framework	Roof Type	Index Value
Nonmetallic	Wood	5
(Other than wood)	Composition	3
	Metal — not continuous	4
	Metal — electrically continuous	1
Wood	Wood	5
	Composition	3
	Metal — not continuous	4
	Metal — electrically continuous	2

Over 70	1

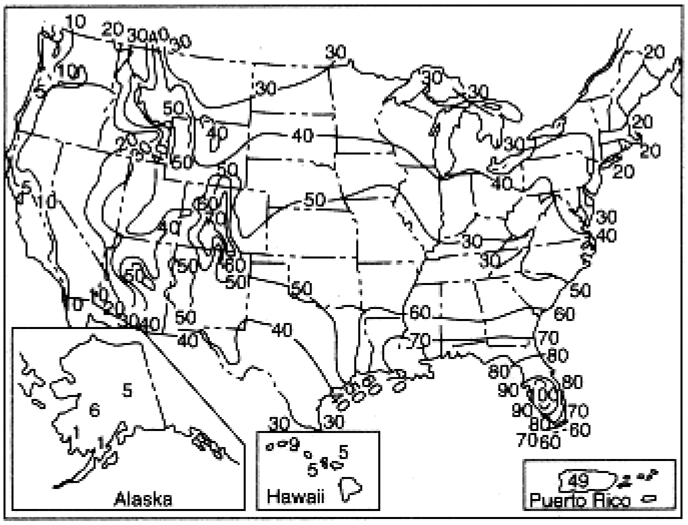

Figure H-2(f)(a) Statistics for continental United States showing mean annual number of days with thunderstorms. The highest frequency is encountered in south-central Florida. Since 1894, the recording of thunderstorms has been defined as the local calendar day during which thunder was heard. A day with thunderstorms is so recorded regardless of the number occurring on that day. The occurrence of lightning without thunder is not recorded as a thunderstorm. Statistics vary widely with local and climatic conditions. (Data supplied by Environmental Science Service Administration, U.S. Department of Commerce.)

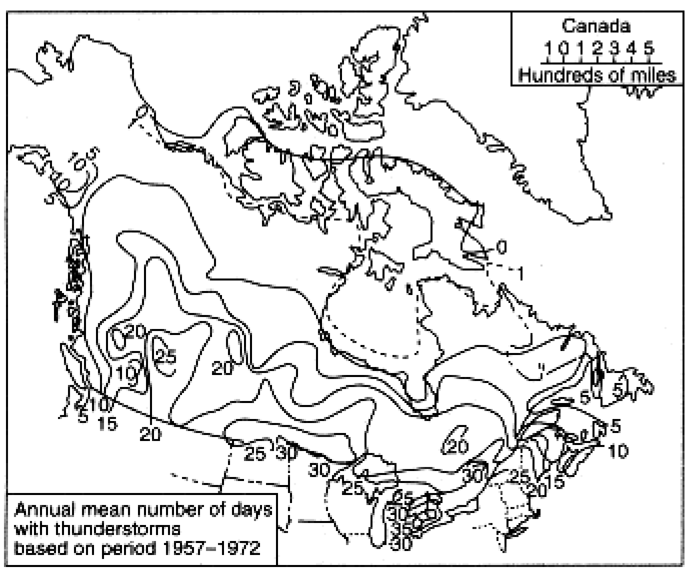

Figure H-2(f)(b) Canadian statistics showing annual average number of days with thunderstorms. Data based on the period 1957-1972. (Meteorological Division, Department of Transportation, Canada.)

Appendix I Ground Measurement Techniques

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

In order to determine the ground resistance of a lightning protection system, it is necessary to remove it from any other ground connection. This may prove a virtually impossible task necessitating certain assumptions. In reality, ground-resistance measuring equipment works at low frequencies relative to the lightning discharge. The resistance it computes is therefore often affected by the resistance of power-system ground electrodes or a similar ground medium that may be several thousand feet from the structure being protected. The ground resistance to be used to calculate lightning conductor potentials when a high-frequency lightning discharge strikes a building must be the grounds in the immediate area of the building, not the remote ones that ground measuring equipment probably monitor.

If the building is small, and the lightning protection system can be disconnected totally from any other grounding network, its resistance can be measured by the three-point technique described below. If the building is large or cannot be disconnected totally from any other grounding network, then the ground resistance of individual isolated lightning-protection ground rods should be measured by the three-point technique described below and this resistance multiplied by a factor depending on the number of ground rods.

The principle of ground resistance measurement is shown in Figure I. L is the lightning ground rod or ground rod system, P is a test probe, and A an auxiliary current probe. M is the standard ac measuring equipment for three-point technique ground resistance measurements. Convenient distances for LP and LA are 75 ft (22 m) and 120 ft (36 m), respectively. In general, P should be at 62 percent of the distance from L to A. If 120 ft (36 m) is not convenient, it could be increased significantly [or reduced to no less than 50 ft (15.2 m)] provided LP is increased proportionately.

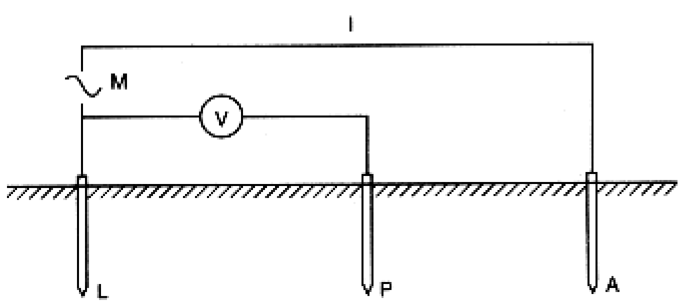

Figure I Measurement of ground resistance.

A current I is passed through the electrode or electrodes to be tested, L, and through an auxiliary probe A. The distance LA is long compared to the electrode length. The voltage V between L and P is measured by the test equipment, which also monitors I and calculates the ground resistance R as V/I. Alternating current is used to avoid errors due to electrolytic factors in the soil and to remove effects due to stray currents.

Three-point ground resistance measuring equipment using these principles is relatively inexpensive and allows direct reading of R.

Variations in soil resistivity due to temperature and moisture fluctuations can affect the measured ground resistance. A good designer will measure ground resistance under average or high resistivity conditions in order to design a lightning protection system to function adequately.

If the building ground is complex in nature, the resistance of single ground rods may be measured and certain assumptions made. The average single ground rod resistance, R_m, must be multiplied by a factor depending on the number of lightning-protection ground rods, n, spaced at least 35 ft (10.7 m) apart.

The total system ground resistance, R, can be calculated from the formula:

$$R = 1.1 \left(\frac{R_m}{n} \right)$$

Appendix J Explanation of Bonding Principles

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

Lightning strikes may give rise to harmful potential differences in and on a building. The major concern in the protection of a building is the occurrence of potential differences between the conductors of the lightning protection system and other grounded metal bodies and wires belonging to the building. These potential differences are caused by resistive and inductive effects and can be of such a magnitude that dangerous sparking can occur. In order to reduce the possibility of sparking, it is necessary to equalize potentials by bonding grounded metal bodies to the lightning protection system.

Where installing (or modifying) lightning protection systems on existing structures, bonding of certain grounded metal bodies may present difficult installation problems due to the inaccessibility of building systems. Placement of conductors to avoid grounded metal bodies or increasing the number of down conductors to shorten the required bonding distances are options to overcome these problems.

Figure J illustrates the generation of these potential differences.

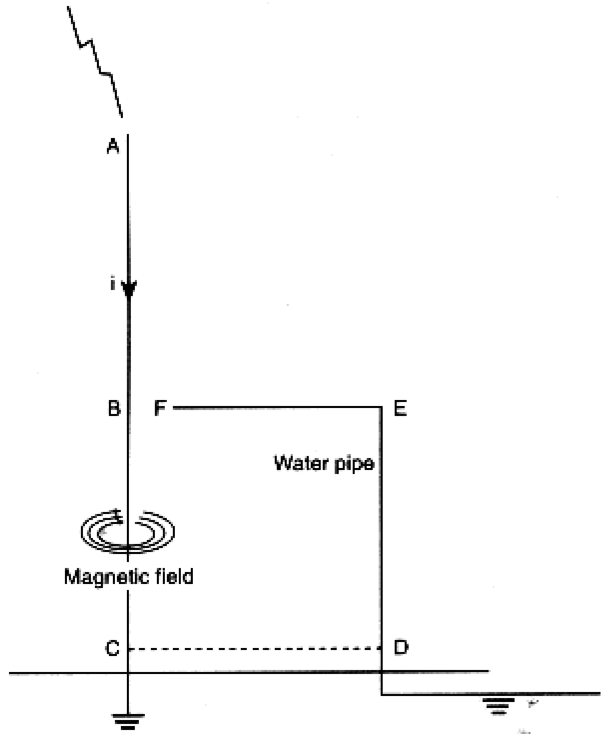

Figure J The magnetic field around a conductor.

(a) *Resistive Effect.* In the situation where conductor C is connected only to a ground terminal and the water pipe is independently grounded, a large potential may exist between B and F. Assuming a resistance of 20 ohms between C and ground and a lightning current of 100,000 amps, then Ohm's law (voltage = current X resistance) indicates that a potential of 2 million volts exists on conductor ABC. Because no current is initially passing through the water pipe, its potential is zero volts. The difference of potential of 2 million volts between B and F is sufficient for a sideflash of over 6 ft (2 m). In order to reduce this potential difference to zero, this standard requires equalization of potentials at ground level in accordance with 3-23.1. Such a bond is shown as CD in Figure J.

With bond CD in position the resistance between B and F is essentially zero, and hence during a lightning strike the potential at B due to the resistive effect is similar to that at F. Therefore the resistive effect can be neglected for bonding purposes.

(b) *Inductive Effect.* When a large current passes down the lightning conductor ABC a magnetic field is generated in circular motion around the conductor as shown in Figure J. The higher the lightning current, the higher the magnetic field. These magnetic field lines can be referred to as magnetic flux.

The loop BCDEF is intercepted by these lines of magnetic flux. The rate of change of the flux passing through this loop induces a voltage in the loop, creating a potential difference between B and F. This potential difference can be of the order of a few million volts, again causing a sideflash.

The bonding techniques described in this standard call for bonding the gaps, such as BF, over which high potentials exist in order to remove the spark and provide a safe path to ground for the current. The bonding-distance formulas are calculated from the laws of physics, making assumptions on the relevant lightning characteristics that influence the induced voltage. These assumptions for this standard are made for an extremely severe lightning current, thereby providing a bonding distance that is almost totally protective.

The voltage across the gap BF is related to the size of the loop BCDEF but dominantly to the height BC rather than CD; hence the height "h" term in the formulas of 3-24.2. Equalizing the potentials at frequent heights in accordance with Section 3-23 also reduces the size of the loop BCDEF, thereby keeping the gap voltage to a controllable value that can be removed by simple bonding.

One factor that is difficult to control is the problem related to power and communication lines entering the building. For all intents, such lines are at ground potential relative to the extremely high induced voltages. If the line DEF was such an electrical, telephone, power, or data line not bonded at ground, the voltage across the loop would be enhanced by the resistive effect described by Ohm's law as well as by the inductive effect, and hence BF could soon approach breakdown. This would lead to sparks causing fire as well as the obvious electrical, electronic, and human life problems. All such lines entering the building should have electrical bonding through surge protection as specified in Section 3-21, thereby reducing the resistive component and controlling dangerous sparking and damage. If just one wire, however, does not have such suppression devices the dangers described above still exist, even to the protected building and the electrical equipment. Table J shows sample calculations.

Table J Sample Calculations of Bonding Distances

		n = 1.0	n = 1.5	n = 2.25
h (ft)	**K_m**		**D**	
10	1.0	1 ft 8 in.	1 ft 1$^3/_8$ in.	9 in.
	0.5	10 in.	6$^3/_4$ in.	4$^1/_2$ in.
20	1.0	3 ft 4 in.	2 ft 2$^3/_4$ in.	1 ft 6 in.
	0.5	1 ft 8 in.	1 ft 1$^3/_8$ in.	9 in.
30	1.0	5 ft 0 in.	3 ft 4 in.	2 ft 2$^3/_4$ in.
	0.5	2 ft 6 in.	1 ft 8 in.	1 ft 1$^3/_8$ in.
40	1.0	6 ft 8 in.	4 ft 6 in.	3 ft
	0.5	3 ft 4 in.	2 ft 3 in.	1 ft 6 in.

In order to reduce the voltage across the gap BF so as to make bonding less necessary, it is possible to provide more down conductors. This standard requires down conductors every 100 ft (30 m) (*see 3-12.10*), but the number of down conductors, “n,” required in the bonding formula of 3-24.2 is restricted. It can be shown theoretically for structures less than 60 ft (18 m) in height that for a series of planar down conductors spaced 50 ft (15 m) apart “n” can be no bigger than 1.5, and for a similar three-dimensional situation “n” can be no bigger than 2.25. These values of “n” also apply to the upper 60 ft (18 m) of a tall structure. As the lightning current passes into the lower portion of a tall structure, however, the value of “n” must be calculated on the assumption that the current flow down the structure is much more symmetrical through the down conductors. This implies that for all but the upper 60 ft (18 m) of a structure the bonding distance can be calculated from a formula involving a larger value of “n,” as shown in 3-24.2.

Sideflashing can easily occur to grounded objects within the building. The intensity of the electric field in air is greater than that in concrete by approximately a factor of two, allowing for a reduction of the sideflash distance through a wall cavity.

If an individual touches a correctly bonded connection within the building, he or she should suffer no harm. This scenario is similar to that of a bird sitting on a high-voltage wire unaware that the bird’s potential is changing from over a thousand volts positive to over a thousand volts negative several times a second.

Appendix K Protection of Structures Housing Explosive Materials

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

K-1 General.

This appendix provides the minimum technical requirements for lightning protection of structures housing explosive materials.

K-1.1

Due to the possibility of danger to the surrounding area, an increased level of protection efficiency as defined herein is necessary for such structures. The decision of when to protect these structures should be left to the authority having jurisdiction.

K-1.2

The protection of the contents contained in structures housing explosives must take into account the packages used to contain these materials as well as bonding or grounding requirements specified by the authority having jurisdiction.

K-2 Design Considerations.

Lightning protection systems designed to protect structures housing explosives and energetic materials should be based on a striking distance of 100 ft (33 m) as discussed in 6-3.3.

NOTE: When the effects of electromagnetic coupling are of concern, a mast of overhead wire (catenary) systems might be preferred over integral systems unless a Faraday cage or shield is required. The removal (isolation) of the down conductors will reduce the magnetic field strength in the structure and reduce the probability of a sideflash from a down conductor.

K-3 Types of Systems.

K-3.1 Mast-type Systems.

Mast-type systems should be designed as specified in 6-3.3.2.

K-3.2 Overhead Wire (Catenary) Systems.

Catenary systems should be designed as specified in 6-3.3.2.

K-3.3 Integral Systems.

An integral lightning protection system is a system that utilizes air terminals mounted directly on the structure to be protected. These types of air termination systems are as described in Chapter 3. Air terminal spacing should be modified as necessary to provide a zone of protection defined by a 100-ft (33-m) striking distance.

When an integral lightning protection system is used to protect the structures covered by this chapter, it is critical that the bonding requirements of Chapter 3 be met. It is also critical that a rigorous maintenance schedule be maintained for this type of system.

K-3.4 Faraday Cage.

The optimum scheme for protecting extremely sensitive operations from all forms of electromagnetic radiation is to enclose the operation(s) or facility inside a Faraday cage. A true Faraday cage is difficult to construct and economically justified only for critical facilities or where extremely sensitive operations warrant this level of protection.

Effective lightning protection is similarly provided by metallic structures such as those formed by the steel arch or the reinforcing steel in the walls and floors of earth-covered magazines if the steel reinforcement is bonded together and it meets the minimum ground system resistance requirements of K-4.

K-4 Grounding.

K-4.1 General.

A ground loop conductor is required for all lightning protection systems used to protect the subject structures. All down conductors, structural steel, ground rods, and other grounding systems should be connected to the ground loop conductor.

Exception: For structures with areas of 500 ft^2 (46.5 m^2) or less or those that can be protected by a single mast or air terminal, the ground loop conductors are not required.

K-4.2 Metal Portable Magazines.

Portable magazines that meet the requirements of a Faraday cage as described in K-3.4 should be grounded using a minimum of two ground terminations located at opposite corners within 1 ft (0.305 m) of ground level for large portable magazines. Additional ground rods should be added so the spacing should not exceed 60 ft (18.3 m) on average. Primary size conductors should be used to interconnect the portable magazine to the ground rods.

K-5 Bonding.

K-5.1 General.

It is critical that the bonding requirements of Chapter 3 be enforced for the protection of structures housing explosives or other energetic materials. The material used to bond items to the grounding loop conductor should meet the requirements of Section 3-2. Section 3-2 provides the requirements for the use of dissimilar metals.

K-5.2 Bonding Resistance.

The resistance of any object bonded to the lightning protection system should not exceed 1 ohm. For static dissipative systems such as conductive floors, workbenches, etc., bond resistance of 1 megohm is acceptable.

K-5.3 Painting.

Wires and conductors bonded to the lightning protection system should not be painted.

K-5.4 Magazines.

K-5.4.1 Earth-Covered Magazines. Metal ventilators, steel doors, door frames, and steel reinforcement should be bonded to the structure's grounding system. Incoming power, data, and communication cables should be bonded to the ground loop conductor or steel reinforcement as it enters the structure.

K-5.4.2 Metal Portable Magazines. Portable box-type magazines made of $^3/_{16}$-in. (4.8-mm) steel or equivalent where the walls, floor, and roof are welded together should require bonding of the doors across the hinges. Bonding of services, data lines, and communication lines should also be provided.

K-5.5 Fences.

Fences should have bonding across gates as well as other discontinuities and should be bonded to the lightning protection system ground loop conductor if they cross or come within the sideflash distance of the structure of a lightning protection system. Bonding across discontinuities in metallic fences should be provided as necessary to provide electrical continuity.

K-5.6 Railroad Tracks.

All railroad tracks that cross or come within the sideflash distance of a structure's lightning protection system should be bonded to the lightning protection system ground loop conductors. If the tracks are used to carry electrical signals, they should have insulated joints immediately external to bond the lightning protection system's ground loop conductor. If these tracks enter a facility, they should also be bonded to the frame of the structure (or equivalent).

K-6 Surge Suppression.

Surge suppression is required for all power, communication, or data conductors entering or exiting a structure housing explosives.

K-7 Maintenance and Inspection.

The effectiveness of a lightning protection system is best ensured by a quality control program designed to ensure that the system is not degraded by age, mechanical damage, or modifications to the structure. A maintenance and inspection plan should be developed for all protection systems used to protect structures housing explosives.

The initial installation should be inspected by the authority having jurisdiction (or their designated representative). It should be recertified after any work is done on the structure.

K-7.1 General.

To ensure that the protection system used to protect structures housing explosives is properly maintained, it is necessary that it be inspected visually twice a year and electrically approximately once a year. To ensure that the systems are tested during all four seasons over a 6-year period, 7-month and 14-month test cycles are suggested.

K-7.2 Visual (7-Month) Test.

The lightning protection system should be visually inspected every 7 months for evidence of corrosion or broken wires/connections. All necessary repairs should be made immediately. Any detected damage to the system should be entered in the test records as recommended in B-1.5.

K-7.3 Electrical (14-Month) Test.

The lightning protection system should be tested electrically every 14 months. The test should be conducted in accordance with the appropriate test equipment manufacturer's instructions by personnel familiar with lightning protection system testing.

K-7.4 Test Equipment.

Only those instruments designed specifically for earth ground systems testing are acceptable for use in ground resistance testing. The instrument must be capable of measuring 0 to 10 ohms ± 1 ohm. The instrument used to measure bonding resistance must be capable of measuring 0 to 1 ohm ± 0.1 ohm.

Appendix L Principles of Lightning Protection

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

L-1 Fundamental Principles of Lightning Protection.

L-1.1

The fundamental principle in the protection of life and property against lightning is to provide a means by which a lightning discharge can enter or leave the earth without resulting damage or loss. A low impedance path should be offered, which the discharge current will follow in preference to all alternative high impedance paths offered by building materials such as wood, brick, tile, stone, or concrete. When lightning follows the higher impedance paths, damage may be caused by the heat and mechanical forces generated during the passage of the discharge. Most metals, being good electrical conductors, are virtually unaffected by either the heat or the mechanical forces if they are of sufficient size to carry the current that can be expected. The metal path must be continuous from the ground terminal to the air terminal. Care should be exercised in the selection of metal conductors to assure the integrity of the lightning conductor for an extended period. A nonferrous metal such as copper or aluminum will provide, in most atmospheres, a lasting conductor free of the effects of rust or corrosion.

L-1.2

Parts of structures most likely to be struck by lightning are those that project above surrounding parts such as chimneys, ventilators, flagpoles, towers, water tanks, spires, steeples, deck railings, shafthouses, gables, skylights, dormers, ridges, and parapets. The edge of the roof is the part most likely to be struck on flat-roofed buildings.

L-2 Lightning Protection Systems.

L-2.1

Lightning protection systems consist of three basic parts that provide the low impedance metal path required: (a) a system of air terminals on the roof and other elevated locations, (b) a system of ground terminals, and (c) a conductor system connecting the air terminals to the ground terminals. Properly located and installed, these basic components assure that the lightning discharge will be conducted harmlessly between the air terminals and the ground terminals.

L-2.2

While intercepting, conducting, and dissipating the main discharge, the three basic protection system components do not assure safety from possible secondary effects of a lightning strike. Therefore, secondary conductors are provided to interconnect metal bodies to assure that such metal bodies are maintained at the same electrical potential so as to prevent sideflashes or spark-over. Surge suppression devices are also provided to protect power lines and associated equipment from both direct discharges and induced currents.

L-2.3

Metal parts of a structure may be used as part of the lightning protection system in some cases. For example, the structural metal framing, which has sufficient cross-sectional area to equal the conductivity of main lightning conductors, and which is electrically continuous, may be used in lieu of separate down conductors. In such cases, air terminals are bonded to the framework at the top, and ground terminals are provided at the bottom, as described elsewhere in this standard. Structures with $^{3}/_{16}$-in. (4.8-mm) thick, or thicker, metal shells or skins that are electrically continuous might not require a system of air terminals and down conductors.

L-3 Items to Consider when Planning Protection.

L-3.1

The best time to design a lightning protection system for a structure is during the planning phase, and the best time to install the system can be during construction. System components may be built-in so as to be protected from mechanical displacement and environmental effects. In addition, aesthetic advantages may be gained by such concealment. It is generally less expensive to meet lightning protection requirements during construction.

L-3.2

The structure should be examined, and installation of air terminals should be planned for all areas or parts likely to receive a lightning discharge. The object is to intercept the discharge immediately above the parts liable to be struck and to provide a direct path to earth, rather than to attempt to divert the discharge in a direction it would not be likely to take. The air terminals should be placed high enough above the structure to obviate danger of fire from the arc.

L-3.3

Conductors should be installed to offer the least impedance to the passage of stroke current between the air terminals and earth. The most direct path is best, and there should be no sharp bends or narrow loops. The impedance of the conductor system is practically inversely proportional to the number of widely separated paths. Accordingly, there should be at least two paths to ground and more, if practicable, from each air terminal. The number of paths is increased and the impedance decreased by connecting the conductors to form a cage enclosing the building.

L-3.4

Properly made ground connections are essential to the effective functioning of a lightning protection system, and every effort should be made to provide ample contact with the earth. This does not necessarily mean that the resistance of the ground connection should be low, but rather that the distribution of metal in the earth or upon its surface in extreme cases should be such as to permit the dissipation of a stroke of lightning without damage.

L-3.5

Low resistance is desirable, but not essential, as may be shown by the extreme case on the one hand of a building resting on moist clay soil, and on the other by a building resting on bare solid rock. In the first case, if the soil is of normal resistivity or from 4,000 ohm-centimeters to 50,000 ohm-centimeters, the resistance of a ground connection made by extending the conductor 10 ft (3 m) into the ground will be from about 15 ohms to 200 ohms, and two such ground connections on a small rectangular building have been found by experience to be sufficient. Under these favorable conditions, providing adequate means for collecting and dissipating the energy of a flash without serious chance of damage is a simple and comparatively inexpensive matter.

L-3.6

In the second case, it would be impossible to make a ground connection in the ordinary sense of the term because most kinds of rocks are insulating, or at least of high resistivity, and in order to obtain effective grounding other more elaborate means are necessary. The most effective means would be an extensive wire network laid on the surface of the rock surrounding the building to which the down conductors could be connected. The resistance to earth at some distant point of such an arrangement would be high but at the same time the potential distribution about the building would be substantially the same, as though it were resting on conducting soil, and the resulting protective effect also would be substantially the same.

L-3.7

In general, the extent of the grounding arrangements will depend on the character of the soil, ranging from simple extension of the conductor into the ground where the soil is deep and of high conductivity to an elaborate buried network where the soil is very dry or of very poor conductivity. Where a network is required, it should be buried if there is soil enough to permit it, as this adds to its effectiveness. Its extent will be determined largely by the judgment of the person planning the installation with due regard to the rule: the more extensive the underground metal available, the more effective the protection.

L-3.8

Where practicable, each ground connection should extend or have a branch that extends below and at least 2 ft (0.6 m) away from the foundation walls of the building; otherwise there is a chance of the wall being damaged.

L-3.9

When a lightning conductor system is placed on a building, within or about which there are metal objects of considerable size within a few feet of a conductor, there will be a tendency for sparks or sideflashes to jump between the metal object and the conductor. To prevent damage, interconnecting conductors should be provided at all places where sideflashes are likely to occur.

L-3.10

Lightning currents entering protected buildings on overhead or underground power lines, or telephone conductors, or television or radio antennas are not necessarily restricted to associated wiring systems and appliances. Therefore, such systems should be equipped with appropriate protective devices and bonded to assure a common potential.

L-3.11

Because a lightning protection system is expected to remain in working condition for long periods with minimum attention, the mechanical construction should be strong, and the materials used should offer resistance to corrosion and mechanical injury.

L-4 Inspection and Maintenance of Lightning Protection Systems.

It has been shown that in cases where damage has occurred to a protected structure, the fault was due to additions or repairs to the building or to deterioration or mechanical damage that was allowed to go undetected and unrepaired, or both. Therefore, it is recommended that an annual visual inspection be made and that the system be thoroughly inspected every 5 years.

L-5 Indirect Losses.

In addition to direct losses such as destruction of buildings by lightning, fire resulting from lightning, the killing of livestock, etc., indirect losses sometimes accompany the destruction or damage of buildings and their contents. An interruption to business or farming operations, especially at certain times of the year, may involve losses quite distinct from, and in addition to, the losses arising from the direct destruction of material property. There are cases where whole communities depend on the integrity of a single structure for their safety and comfort. For example, they may depend on a water-pumping plant, a telephone relay station, a police station, or a fire station. A stroke of lightning to the unprotected chimney of a pumping plant, for example, might have a serious consequence from a lack of sanitary drinking water, irrigating water, or water for fire protection.

Appendix M Referenced Publications

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

M-1

The following documents or portions thereof are referenced within this standard for informational purposes only and thus should not be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

M-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA

02269-9101.

F.I. 86-1

Question 1: Is it the intent of 3-12.13 that down conductors be bonded to the reinforcing steel at the top and bottom where conductors are sleeved with PVC and embedded in concrete?

Answer: Yes.

Question 2: Is it the intent of 3-12.13 to apply conductors installed in PVC conduit embedded in concrete?

Answer: Yes.

Question 3: Is it the intent of 3-12.13 that conductors embedded in steel reinforced concrete be bonded to the reinforcing steel where conductors enter and emerge from the concrete?

Answer: Yes.

Question 4: Is it the intent of 3-12.13 that conductors embedded in steel reinforced concrete be bonded to the reinforcing steel where conductors enter and emerge from the concrete even if entrance and exit is not at the top and bottom?

Answer: Yes.

NFPA 801

1995 Edition

Standard for Facilities Handling Radioactive Materials

1995 Edition

This edition of NFPA 801, *Standard for Facilities Handling Radioactive Materials*, was prepared by the Technical Committee on Atomic Energy and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 14-16, 1994, in Toronto, Ontario, Canada. It was issued by the Standards Council on January 13, 1995, with an effective date of February 7, 1995, and supersedes all previous editions.

The 1995 edition of this document has been approved by the American National Standards Institute.

Origin and Development of NFPA 801

The Committee on Atomic Energy was organized in 1953 for the purpose of providing the fire protection specialist with certain fundamental information about radioactive materials and their handling and to provide designers and operators of such laboratories with some guidance on practices necessary for fire safety. The first edition of NFPA 801, whose coverage was limited to laboratories handling radioactive materials, was adopted at the 1955 Annual Meeting.

In 1970 the format was revised, and it was updated to reflect current thinking and practices. It was also expanded to apply to all locations, exclusive of nuclear reactors, where radioactive materials are stored, handled, or used.

The 1975 edition was a reconfirmation of the 1970 edition with editorial changes.

The 1980 edition included a clarified statement regarding the presence of and levels of radiation; cautionary statements about the assumption of risks by the fire officer and the importance of training in the handling of radioactive materials by fire department personnel; a clarification concerning the variations of the intensity of a radiation field; and a restyling of the document to conform with the NFPA *Manual of Style*.

The 1985 edition revised and updated previous material for clarification in recognition of technology and terminology changes.

The 1991 edition was a total revision of the document and included a complete reorganization of the chapters. This was done to provide an update of the latest technology and to improve the document's user friendliness.

This latest 1995 edition includes a variety of updates necessary to convert the document from a recommended practice to a standard. One of the more noteworthy changes is a revised scope statement to recognize a threshold value with respect to the amount of radioactive materials that are stored, handled, or used.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the safeguarding of life and property from fires in which radiation or other effects of nuclear energy might be a factor.

NFPA 801
Standard for
Facilities Handling Radioactive Materials

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 6 and Appendix C.

Chapter 1 Introduction

1-1 Scope.

1-1.1*

This standard addresses fire protection requirements intended to reduce the risk of fires and explosions at facilities handling radioactive materials. These requirements are applicable to all locations where radioactive materials are stored, handled, or used in quantities and conditions requiring a U.S. Nuclear Regulatory Commission license to possess or use these materials or in equal quantities or conditions at other locations.

1-1.2

This standard shall not apply to research or power reactors that are covered by NFPA 802, *Recommended Fire Protection Practice for Nuclear Research and Production Reactors*, and NFPA 803, *Standard for Fire Protection for Light Water Nuclear Power Plants*.

1-2* Purpose.

This standard provides requirements for personnel responsible for the design or operation of facilities that involve the storage, handling, or use of radioactive materials.

1-3 Alternative Methods.

1-3.1

Nothing in this standard is intended to prevent or discourage the use of alternative methods, practices, or devices, provided that sufficient technical data are submitted to the authority having jurisdiction to demonstrate that the alternative method, material, practice, or device is equivalent to or superior to the requirements of this standard.

1-3.2

It is intended that a designer capable of applying more complete and rigorous analysis to special or unusual problems shall have latitude in the development of the applicable design. In such cases, the designer shall be responsible for demonstrating the validity of the approach. This standard does not do away with the need for competent engineering judgment and is not intended as a design handbook.

1-4 Retroactivity.

1-4.1

The provisions of this standard shall be considered necessary to provide a reasonable level of protection from loss of life and property from fire or explosion. They reflect situations and the state of the art at the time the standard was issued.

1-4.2

Unless otherwise noted, the provisions of this standard shall not be applied retroactively, except in those cases where it is determined by the authority having jurisdiction that the existing situation involves a distinct hazard to life or adjacent property.

1-5 Definitions.

Alpha Particle. A positively charged particle emitted by certain radioactive materials, identical to the nucleus of a helium atom. It is the least penetrating of the three common types of radiation (alpha, beta, gamma) emitted by radioactive material, as it is stopped by a sheet of paper. It is not dangerous to plants, animals, or people unless the alpha-emitting substance has entered the body.

Approved. Acceptable to the authority having jurisdiction.

NOTE: The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Beta Particle. An elementary particle emitted from a nucleus during radioactive decay, with a single electrical charge and a mass equal to 1/1,837 that of a proton. A negatively charged beta particle is identical to an electron, and a positively charged beta particle is called a positron. Beta radiation can cause skin burns, and beta-emitters are harmful if they enter the body. However, beta particles are easily stopped by a thin sheet of metal.

Canyon. An enclosure beside or above a series of hot cells for the purpose of servicing the hot cells.

Cave. A small hot cell intended for a specific purpose and limited equipment.

Combustible.* Any material that, in the form in which it is used and under the conditions anticipated, will ignite and burn. A material that does not meet the definition of noncombustible or limited-combustible.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C).

NOTE: See NFPA 30, *Flammable and Combustible Liquids Code*.

Criticality. The state of sustaining a chain reaction, as in a nuclear reactor.

Criticality Incident. An accidental, self-sustained nuclear fission chain reaction.

Decontamination. The removal of unwanted radioactive substances from personnel, rooms, building surfaces, equipment, etc., to render the affected area safe.

Fire Area. That portion of a building or facility that is separated from other areas by fire barriers.

Fire Barrier. A fire barrier is a continuous membrane, either vertical or horizontal, such as a wall or floor assembly, that is designed and constructed with a specified fire resistance rating to limit the spread of fire and that will also restrict the movement of smoke. Such barriers might have protected openings.

Fire Brigade. As used in this standard, refers to those facility personnel trained in plant fire-fighting operations.

Fire Door. A door assembly rated in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, and installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

Fire Hazards Analysis. A comprehensive assessment of the potential for a fire at any location to ensure that the possibility of injury to people or damage to buildings, equipment, or the environment is within acceptable limits.

Fire Prevention. Measures directed toward avoiding the inception of fire.

Fire Protection. Methods of providing for fire control or fire extinguishment.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with the test procedures of NFPA 251, *Standard Methods of Fire Tests of Building Construction and Materials*.

Fire Risk Analysis. An analysis to quantify the fire risk by determining the probability of a fire and to evaluate the probability of resultant injury to people or damage to buildings or equipment.

Fire Zone. Subdivisions of fire areas in which fire detection or suppression systems provide alarm information indicating the location of fire at a central fire control center.

Flame Spread Rating. A relative measurement of the surface burning characteristics of building materials when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psi (276 kPa) absolute pressure at 100°F (37.8°C).

Gamma Rays. High-energy, short-wavelength electromagnetic radiation. Gamma radiation frequently accompanies alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded against by dense material, such as depleted uranium, lead, water, concrete, or iron.

Glove Box. A sealed enclosure in which items inside the box are handled exclusively using long rubber or neoprene gloves sealed to ports in the walls of the enclosure. The operator places hands and forearms into the gloves from the room side of the box in order to maintain physical separation from the glove box environment while retaining the ability to manipulate items inside the box with relative freedom while viewing the operation through a window.

Hot Cell. A heavily shielded enclosure in which radioactive material can be handled safely by persons working from outside the shield using remote tools and manipulators while viewing the work through special leaded glass or liquid-filled windows or through optical devices.

Isotope. Any of two or more forms of an element having the same atomic number and similar chemical properties but differing in mass number and radioactive behavior.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Limited-Combustible.* A building construction material that, in the form in which it is used, has a potential heat value not exceeding 3,500 Btu/lb (8,141 kJ/kg) and has either a structural base of noncombustible material with a surfacing not exceeding $^{1}/_{8}$ in. (3.2 mm) that has a flame spread rating not greater than 50, or other material having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion, even on surfaces exposed by cutting through the material on any plane.

NOTE: See NFPA 220, *Standard on Types of Building Construction*.

Listed. Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Noncombustible.* A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat. Materials that are reported as passing ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, shall be considered noncombustible materials.

Radiation. The emission and propagation of energy through matter or space by means of electromagnetic disturbances that display both wave-like and particle-like behavior. The term includes streams of fast-moving particles, such as alpha and beta particles, free neutrons, and cosmic radiation. Nuclear radiation is that emitted from atomic nuclei in various nuclear reactions including alpha, beta, and gamma radiation and neutrons.

Radiation Area. An area accessible to personnel in which there exists radiation, originating in whole or in part within radioactive material, at such levels that a major portion of the body could receive a dose in excess of 5 millirems during any single hour or a dose in excess of 100 millirems during any five consecutive days.

Radioactivity. The spontaneous decay or disintegration of an unstable atomic nucleus accompanied by the emission of radiation.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Standard. A document that contains only mandatory provisions using the word “shall” to indicate requirements. Explanatory material may be included only in the form of fine-print notes, in footnotes, or in an appendix.

1-6 Units.

Metric units in this document are in accordance with the International System of Units, which is abbreviated officially as “SI” in all languages.

NOTE: For a full explanation, see ASTM E380, *Standard Practice for Use of the International System of Units*.

Chapter 2 Administrative Controls

2-1 General.

2-1.1*

The intent of this chapter shall be met by incorporating the provisions of this chapter in facility operating procedures or as otherwise determined by management.

2-1.2

Administrative controls for changes in processes or equipment shall be developed to include fire protection concerns.

2-1.3

The administrative controls for facilities shall be reviewed and updated periodically.

2-2* Management Policy and Direction.

Corporate management shall establish policies and institute a program to promote life safety, the conservation of property, and the continuity of operations through provisions of fire prevention and fire protection measures at each facility.

2-3* Fire Hazards Analysis.

2-3.1

A documented fire hazards analysis shall be initiated early in the design process or when configuration changes are made to ensure that the fire prevention and fire protection requirements of this standard have been evaluated. This evaluation shall consider the facility’s specific design, layout, and anticipated operating needs. The evaluation shall consider acceptable means for separation or control of hazards, the control or elimination of ignition sources, and the suppression of fires. (*See Chapter 3*.)

2-3.2*

For existing facilities, a documented fire hazards analysis shall be performed for all areas of the facility.

2-4 Fire Prevention Program.

A written fire prevention program shall be established and shall include the following:

(a) Fire safety information for all employees and contractors, including familiarization with fire prevention procedures, emergency alarms and procedures, and procedures for reporting a fire;

(b) Documented facility inspections conducted at least monthly, including provisions for remedial action to correct conditions that increase fire hazards;

(c) A description of the general housekeeping practices and the control of transient combustibles;

(d) Control of flammable and combustible liquids and gases in accordance with the applicable documents referenced in Chapter 5;

(e) Control of ignition sources, including, but not limited to, grinding, welding, and cutting;

NOTE: See NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

(f)* Fire reports, including an investigation and a statement on the corrective action to be taken; and

NOTE: See NFPA 901, *Uniform Coding for Fire Protection*.

(g) The restriction of smoking to properly designated and supervised areas of the facility.

2-5 Testing, Inspection, and Maintenance.

2-5.1

Upon installation, all fire protection systems shall be inspected and tested in accordance with the applicable documents referenced in Chapter 4.

2-5.2

All fire protection systems and equipment shall be periodically inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, and the applicable documents referenced in Chapter 4.

2-5.3

Testing, inspection, and maintenance shall be documented by means of written procedures, with results and follow-up actions recorded. Specific acceptance criteria shall be provided for each operation.

2-6 Impairments.

2-6.1

A written procedure shall be established to address impairments to fire protection systems and shall include the following:

(a) Identification and tracking of impaired equipment,

(b) Identification of personnel to be notified, and

(c) Determination of needed fire protection and fire prevention measures.

2-6.2

Impairments to fire protection systems shall be as short in duration as practicable. If the impairment is planned, all necessary parts and personnel shall be assembled prior to removing the protection system(s) from service. When an unplanned impairment occurs, or when a system has discharged, the repair work or fire protection system restoration shall be expedited.

2-6.3

Once repairs are completed, tests shall be conducted to ensure proper operation and restoration of full fire protection equipment capabilities. Following restoration to service, those parties previously notified of the impairment shall be advised.

2-7* Fire Emergency Plan.

A written fire emergency plan shall be developed and shall include the following:

(a) Response to fire alarms and fire systems' supervisory alarms;

(b) Notification of personnel identified in the plan;

(c) Evacuation from the fire area of personnel not directly involved in fire-fighting activities;

(d)* Coordination with security forces, radiation protection personnel, and other designated personnel for the admission of public fire department and other emergency response agencies;

(e) Fire extinguishment activities, particularly those that are unique to the facility handling radioactive materials (*see Appendix B*);

NOTE: NFPA 600, *Standard on Industrial Fire Brigades*, and OSHA 1910.156, *Fire Brigades*, should be consulted for additional information.

(f) Requirements for periodic drills and exercises to verify the adequacy of the fire emergency plan, including practice sessions coordinated around previously developed valid emergency scenarios particular to the facility; and

(g) Fire prevention surveillance.

NOTE: See NFPA 601, *Standard on Guard Service in Fire Loss Prevention.*

2-8 Fire Emergency Organization.

2-8.1

A fire emergency organization shall be provided.

2-8.2

The size of the facility and its staff, the complexity of fire-fighting problems, and the availability and response time of a public fire department shall determine the composition of the fire emergency organization.

2-8.3

Fire emergency organizations shall conduct drills at least quarterly, and they shall be critiqued by competent individuals. The drill critique shall be documented, and recommendations for improvements shall be implemented. Practice sessions shall be coordinated around previously developed valid emergency scenarios particular to the facility.

Chapter 3 General Facility Design

3-1* Special Considerations.

Provisions to limit contamination shall be based on the fire hazards analysis. The design of facilities handling radioactive materials shall incorporate the following:

(a) Limits on areas and equipment subject to contamination; and

(b) Design of facilities, equipment, and utilities to facilitate decontamination.

3-2 Location with Respect to Other Buildings and within Buildings.

3-2.1

Facilities having quantities of radioactive materials that might become airborne in case of fire or explosion shall be located or segregated from other important buildings or operations.

3-2.2

Particular attention shall be given to the location of intakes and outlets of air-cleaning systems to reduce contamination potential.

3-3* Planning for Contamination Control.

The facility shall be designed to provide construction that confines a potential radiation contamination incident and shall include surface finishes that are easy to clean.

3-4* Fire Area Determination.

The facility shall be subdivided into separate fire areas as determined by the fire hazards analysis for the purposes of limiting the spread of fire, protecting personnel, and limiting the consequential damage to the facility. Fire areas shall be separated from each other by barriers with fire resistance commensurate with the potential fire severity.

3-5 Construction.

Buildings in which radioactive materials are to be used, handled, or stored shall be fire resistive or noncombustible (Type I or Type II in accordance with NFPA 220, *Standard on Types of Building Construction*).

3-6* Openings in Fire Barriers.

3-6.1*

All openings in fire barriers shall be protected consistent with the designated fire resistance rating of the barrier.

3-6.2

Fire doors and fire windows used in fire barriers shall be installed and maintained in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

3-7 Shielding.

Any permanent or temporary shielding materials shall be noncombustible.

Exception: Where noncombustible materials cannot be used, limited-combustible materials shall be used and appropriate fire protection measures shall be provided as determined by the fire hazards analysis.

3-8 Interior Finish.

3-8.1

Interior finish in areas processing or storing radioactive materials shall be noncombustible and, where practicable, shall be nonporous for ease of decontamination.

3-8.2

Interior finish in areas not critical to the processing of radioactive materials shall be Class A or

Class B in accordance with NFPA *101®, Life Safety Code®*.

3-9* Heating, Ventilating, and Air Conditioning.

3-9.1

The design of the ventilation shall be in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems;* NFPA 90B, *Standard for the Installation of Warm Air Heating and Air Conditioning Systems;* and NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

NOTE: In addition, see NFPA 204M, *Guide for Smoke and Heat Venting*.

Exception: Where shutdown of the ventilation system is not permitted, fire dampers shall not be required for ventilation duct penetrations. Alternative means of protecting against fire propagation shall be provided.

3-9.2

The ventilation system shall be arranged such that the area containing dispersible radioactive materials remains at a lower pressure than that of adjoining areas of the facility before and during any fire incident, including during and following any actuation of fire protection systems.

3-9.3

Duct work from areas containing radioactive materials passing through nonradioactive areas shall be of noncombustible construction and shall be protected from possible exposure fires by materials having an appropriate fire resistance rating as determined by the fire hazards analysis.

3-9.4

Self-cleaning filters that pass through a viscous liquid generally yield a radioactive sludge requiring disposal and, therefore, shall be avoided, if possible, in areas where radioactive materials are handled. Because of the combustible nature of the liquid, additional fire protection features shall be provided as determined by the fire hazards analysis.

3-9.5

Roughing filters, where necessary, shall be constructed of noncombustible materials.

Exception: Where combustible filters or particulates are present in the ventilation system, additional fire protection features shall be provided as determined by the fire hazards analysis.*

3-9.6 HEPA Filtration Systems.

3-9.6.1 All HEPA filtration systems shall be analyzed in the fire hazards analysis.

3-9.6.2* HEPA filtration systems with a leading surface area greater than 16 ft^2 (1.49 m^2) shall be provided with fire detection and suppression systems.

3-9.7 Smoke Control.

3-9.7.1* Fresh-air inlets shall be located to reduce the possibility of radioactive contaminants being introduced. Such inlets shall be located where it is most unlikely for radioactive contaminants to be present.

3-9.7.2 Smoke, corrosive gases, and the nonradioactive substances that might be freed by a fire shall be vented from their place of origin directly to a safe location. Radioactive materials that are released by fire shall be confined, removed from the exhaust ventilation airstream, or released under controlled conditions.

3-9.7.3 Ventilation systems designed to exhaust smoke or corrosive gases shall be evaluated to ensure that inadvertent operation or failures shall not violate the controlled areas of the facility design.

3-9.7.4 Smoke control systems shall be provided for fire areas based upon the fire hazards analysis.

NOTE: Separate smoke control systems are preferred; however, smoke ventilation can be integrated into normal ventilation systems using automatic or manually positioned dampers and motor speed control.

3-9.7.5 Smoke exhaust from areas that at any time contain radioactive substances shall not be ventilated outside the building. Smoke control systems for such areas shall be connected to treatment systems to preclude release of radioactive substances.

3-9.7.6 Enclosed stairwells shall be designed to minimize smoke infiltration during a fire.

NOTE: Stairwells serve as escape routes and fire-fighting access routes. Suitable methods of ensuring a smoke-free stairwell include pressurization of stairwells (*see NFPA 90A, Standard for the Installation of Air Conditioning and Ventilating Systems*) and the construction of smokeproof towers. (*See NFPA 101, Life Safety Code*.)

3-9.7.7 Where natural-convection ventilation is used, the smoke and heat ventilation shall be provided in accordance with the fire hazards analysis.

NOTE: Where mechanical ventilation is used, 300 cfm (8.5 m^3/min) is equal to 1 ft^2 (0.09 m^2) of natural-convection vent area.

3-9.7.8* The ventilation system shall be designed, located, and protected such that airborne corrosive products or contamination shall not be circulated.

3-9.7.9 The power supply and controls for mechanical ventilation systems shall be located outside the fire area served by the system or protected from fire damage.

3-9.7.10 Fire suppression systems shall be installed to protect filters that collect combustible material, unless the elimination of such protection is justified by the fire hazards analysis.

3-10 Drainage.

CAUTION: For facilities handling fissionable materials, areas where water can accumulate shall be analyzed for criticality potential.

3-10.1*

Provisions shall be made in all fire areas of the facility for removal of all liquids directly to safe areas or for containment within the fire area in order to reduce the potential for flooding of equipment and adverse impact on other areas. Drainage and the prevention of equipment flooding shall be accomplished by one or more of the following:

(a) Floor drains;

(b) Floor trenches;

(c) Open doorways or other wall openings;

(d) Curbs for containing or directing drainage;

(e) Equipment pedestals; or

(f) Pits, sumps, and sump pumps.

3-10.2 Drainage Design.

3-10.2.1 The provisions for drainage in areas handling radioactive materials and in any associated drainage facilities (pits, sumps, and sump pumps) shall be sized to accommodate all of the following:

(a) The spill of the largest single container of any flammable or combustible liquids in the area;

(b) The credible volume of discharge (as determined by the fire hazards analysis) for the suppression system operating for a period 30 min where automatic suppression is provided throughout;

(c) The volume based on a manual fire-fighting flow rate of 500 gpm (1892.5 L/min) for a duration of 30 min where automatic suppression is not provided throughout, unless the fire hazards analysis demonstrates a different flow rate and duration;

(d) The contents of piping systems and containers that are subject to failure in a fire where automatic suppression is not provided throughout; and

(e) Credible environmental factors such as rain and snow where the installation is outside.

3-10.2.2 Radioactive or potentially radioactive drainage piping shall not be routed through clean areas.

3-10.3

Floor drainage from areas containing flammable or combustible liquids shall be trapped to prevent the spread of burning liquids beyond the fire area.

3-10.4

Where gaseous fire suppression systems are installed, floor drains shall be provided with adequate seals, or the fire suppression system shall be sized to compensate for the loss of fire suppression agent through the drains.

3-11 Emergency Lighting.

3-11.1

Emergency lighting shall be provided for means of egress in accordance with NFPA *101*, *Life Safety Code*.

3-11.2

Emergency lighting shall be provided for critical operations areas, i.e., areas where personnel might be required to operate valves, dampers, and other controls in an emergency.

3-12 Lightning Protection.

Lightning protection, where required, shall be provided in accordance with NFPA 780, *Lightning Protection Code*.

3-13 Light and Power.

3-13.1*

An auxiliary power system shall be available to supply power for temporary lighting, ventilation, and radiation monitoring equipment in those facilities where the radioactive materials being handled are potentially dangerous to personnel.

3-13.2*

Electrical conduits leading to or from radioactively "hot" areas shall be sealed internally to prevent the spread of radioactive materials. Only utilities required for operation within radioactively "hot" areas shall enter the hot area.

3-13.3

Less hazardous dielectric fluids shall be used in place of hydrocarbon-based insulating oils for transformers and capacitors located inside buildings or where they are an exposure hazard to important facilities.

3-13.4

All electrical systems shall be installed in accordance with NFPA 70, *National Electrical Code*®.

3-14 Storage.

3-14.1 General.

Chemicals, materials, and supplies shall be in separate storerooms located in areas where no work with radioactive materials is conducted.

Exception: Those quantities of chemicals, materials, and supplies needed for immediate or continuous use.

3-14.2 Storage of Radioactive Materials.

3-14.2.1 Radioactive materials shall not be stored in the same area as combustible materials. Separate or remotely located noncombustible storage facilities shall be used to store radioactive materials safely.

3-14.2.2* Special consideration shall be given to the storage of radioactive compressed gases, as their release under fire or explosion conditions can result in a severe life safety threat and loss by contamination. Storage facilities for such gases shall be designed with special consideration given to the specific characteristics of the gases.

3-14.2.3* Care shall be exercised in selecting the locations for the storage of radioactive waste material. Such material shall not be located near the fresh-air intakes to the heating, ventilation, and air conditioning systems nor the air intakes for air compressors.

Chapter 4 General Fire Protection Systems and Equipment

4-1* General Considerations.

4-1.1

A fire hazards analysis shall be conducted to determine the fire protection requirements for the facility.

4-1.2

Automatic sprinkler protection provides the best means for controlling fires and shall be provided unless the hazards analysis in Section 2-3 dictates otherwise. As determined by the fire hazards analysis, special hazards shall be provided with additional fixed protection systems.

4-1.3*

For locations where fissile materials might be present that could create a potential criticality hazard, combustible materials shall be excluded. If combustible materials are unavoidably present in a quantity sufficient to constitute a fire hazard, water or another suitable extinguishing agent shall be provided for fire-fighting purposes. Fissile materials shall be arranged such that neutron moderation and reflection by water shall not present a criticality hazard.

4-2 Water Supply.

4-2.1* General.

4-2.1.1 The water supply for the permanent fire protection installation shall be based on the largest fixed fire suppression system(s) demand, including the hose stream allowance, in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-2.1.2 For common service water/fire protection systems, the maximum anticipated service water demand shall be added to the fire protection demand.

4-2.1.3 The fire protection water supply system shall be arranged in conformance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps;* NFPA 22, *Standard for Water Tanks for Private Fire Protection;* and NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*, as applicable.

4-2.2

Where an auxiliary supply is required by the fire hazards analysis, each supply shall be capable of meeting the requirements of 4-2.1.

4-2.2.1 Where multiple fire pumps are required, the pumps shall not be subject to a common failure, electrical or mechanical, and shall be of sufficient capacity to meet the fire flow requirements determined by 4-2.1 with the largest pump out of service.

4-2.2.2* Fire pumps shall be automatic-starting with manual shutdown. The manual shutdown shall be at the pump controllers only.

NOTE: For unattended facilities, see Section 4-9.

4-2.2.3* If tanks are for dual-purpose use, they shall be arranged to provide the water supply requirements as determined by 4-2.1 for fire protection use only.

4-2.2.4* Where water tanks are used, they shall be filled from a source capable of replenishing the supply for the fire protection needs of an 8-hour period.

4-2.3

If multiple water supplies are used, each water supply shall be connected to the fire main by separate connections that are arranged and valve controlled to minimize the possibility of multiple supplies being impaired simultaneously.

4-3* Valve Supervision.

All fire protection water system control valves shall be monitored under a periodic inspection program (*see Chapter 2*) and shall be supervised by one of the following methods:

(a) Electrical supervision with audible and visual signals on the main fire control panel or at another constantly attended location in accordance with NFPA 72, *National Fire Alarm Code;* or

(b) Valves locked open with keys available only to authorized personnel.

4-4 Supply Mains and Hydrants.

4-4.1

Supply mains and fire hydrants as required by the fire hazards analysis shall be installed on the facility site in accordance with NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

4-4.1.1 Where required by the fire hazards analysis, the supply mains shall be looped and of sufficient size to supply the flow requirements as determined by 4-2.1.

4-4.1.2 Indicator control valves shall be installed to provide adequate sectional control of the fire main loop to minimize protection impairments.

4-4.2

Each hydrant shall be equipped with a separate shutoff valve located on the branch connection to the supply main.

4-5 Standpipe and Hose Systems.

4-5.1

Standpipe and hose systems shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

4-5.2

Hose station location shall take into account safe egress for personnel operating hose lines.

4-5.3

Spray nozzles having shutoff capability and listed for use on electrical equipment shall be provided on hoses located in areas near energized electrical equipment.

4-6 Portable Fire Extinguishers.

Suitable fire extinguishers shall be installed in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

4-7 Fire Suppression Systems and Equipment.

4-7.1*

Fire suppression systems and equipment shall be provided in all areas of a facility as determined by the fire hazards analysis. Where required, the design of the fire suppression systems shall be in accordance with the following NFPA standards:

NFPA 11, *Standard for Low-Expansion Foam*

NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*

NFPA 13, *Standard for the Installation of Sprinkler Systems*

NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*

NFPA 17A, *Standard for Wet Chemical Extinguishing Systems*.

4-7.2

The selection of the extinguishing agent system shall be based upon:

(a) Type of hazard;

(b) Effect of agent discharge on equipment;

(c) Health hazards;

(d) Cleanup after agent discharge;

(e) Effectiveness of agent in suppressing fire;

(f) Cost of agent, including life cycle costs;

(g) Availability of agent;

(h) Criticality safety; and

(i) Environmental impact.

4-8 Fire Signaling Systems.

4-8.1

Fire detection and automatic fixed fire suppression systems shall be equipped with local audible and visual notification appliances with annunciation on the main fire control panel or at another constantly attended location in accordance with NFPA 72, *National Fire Alarm Code*.

4-8.2

Automatic fire detectors shall be installed in accordance with NFPA 72, *National Fire Alarm Code*, and as required by the fire hazards analysis.

4-8.3

The fire signaling system for the facility communications system shall provide the following:

(a) Manual fire alarm system by which employees can report fires or other emergencies,

(b) Facility-wide alarm system by which personnel can be alerted of an emergency,

(c) Two-way communications for the facility emergency organization if determined to be required by the fire hazards analysis (*see Sections 2-3 and 2-7*), and

(d) Means to notify the public fire department.

4-9* Unattended Facilities.

4-9.1

Additional fire protection measures shall be provided if the fire hazards analysis identifies that a delayed response or lack of communications in an unattended facility can result in a major fire spread prior to the arrival of fire-fighting personnel.

4-9.2

Remote annunciation of the fire-signaling panels shall be transmitted to one or more constantly attended locations.

Chapter 5 Special Hazards in Nuclear Facilities

5-1* General.

5-1.1

Combustion and safety controls and interlocks shall be tested periodically and after major maintenance activities in accordance with the equipment manufacturer's recommendations.

5-1.2

Flammable and combustible liquids shall be stored and handled in accordance with NFPA 30, *Flammable and Combustible Liquids Code*.

5-1.3

Flammable and combustible gases shall be stored and handled in accordance with NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites;* NFPA 50A, *Standard for Gaseous Hydrogen Systems at Consumer Sites;* NFPA 54, *National Fuel Gas Code;* NFPA 55, *Standard for the Storage, Use, and Handling of Compressed and Liquefied Gases in Portable Cylinders;* and NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*.

5-1.4

Solid and liquid oxidizing agents shall be stored and handled in accordance with NFPA 43A, *Code for the Storage of Liquid and Solid Oxidizers*.

5-1.5

Combustible metals shall be stored and handled in accordance with NFPA 480, *Standard for the Storage, Handling, and Processing of Magnesium Solids and Powders;* NFPA 481, *Standard for the Production, Processing, Handling, and Storage of Titanium;* and NFPA 482, *Standard for the Production, Processing, Handling, and Storage of Zirconium*.

5-1.6

Fire protection for laboratories involved with radioactive materials shall be in accordance with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*.

5-1.7

Ovens, furnaces, and incinerators involved with radioactive materials shall be in accordance with the requirements of NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment;* NFPA 86, *Standard for Ovens and Furnaces;* NFPA 86C, *Standard for Industrial Furnaces Using a Special Processing Atmosphere;* and NFPA 86D, *Standard for Industrial Furnaces Using Vacuum as an Atmosphere*.

5-2* Hospitals.

The appropriate form of fire protection for areas where radioactive materials exist in hospitals shall be based on the fire hazards analysis. Additional precautions shall be taken as required if the radioactive materials are stored or used in ways that might cause them to be more susceptible to release from their containers.

5-3 Fuel Fabrication and Fuel Reprocessing Facilities.

5-3.1

Special hazards related to the fire problems associated with fuel fabrication facilities shall be controlled by at least one of the following:

(a) Location,

(b) Safe operating procedures,

(c) Fixed protection systems,

(d) Inerting, or

(e) Any other methods acceptable to the authority having jurisdiction.

5-3.2* Flammable and Combustible Liquids and Gases.

5-3.2.1 In enclosed spaces in which combustible gas could accumulate outside of the storage vessels, piping, and utilization equipment, combustible-gas analyzers that are appropriate to the specific gas shall be installed. The analyzer shall be set to alarm at a concentration no higher than 25 percent of the lower explosive limit.

5-3.2.2 Flammable and combustible liquids in enclosed spaces in which vapors could accumulate outside of the storage vessels, piping, and utilization equipment, shall be installed with combustible-vapor analyzers appropriate for the vapors generated. The analyzer shall be set to alarm at a concentration no higher than 25 percent of the lower explosive limit.

5-3.2.3 In addition to the requirements of NFPA 30, *Flammable and Combustible Liquids Code,* for bulk storage of major combustible or flammable liquid gas piping systems, the fire hazards analysis shall consider the need for automatic shutoffs, excess flow valves, or emergency vents as required.

5-3.2.4 Safety controls and interlocks for bulk-storage, major combustible or flammable liquid gas piping systems shall be tested periodically and tested after maintenance operations.

5-3.2.5 Piping for all hazardous gas systems shall be periodically leak-tested at least annually or as required by the equipment manufacturer.

5-3.2.6 Hydraulic fluids used in presses or other hydraulic equipment shall be the synthetic, fire-resistant (low-hazard) type.

5-3.3 Solvents.

5-3.3.1* Where a flammable or combustible solvent is used, it shall be handled in a system that does not allow uncontrolled release of vapors. Approved operating controls and limits shall be established. An approved fixed system for fire extinguishing shall be installed or its absence justified to the satisfaction of the authority having jurisdiction.

5-3.3.2* Solvent distillation and recovery equipment for flammable or combustible liquids shall be isolated from areas of use by 3-hour fire barriers.

5-3.4*

In order to ensure the safe operation of process evaporators, such as Plutonium Uranium Reduction and Extraction (PUREX), means shall be provided to prevent entry of excess quantities of water-soluble solvents into the evaporators.

5-3.5*

Operating controls and limits for the handling of pyrophoric materials shall be established to the satisfaction of the authority having jurisdiction. A supply of an appropriate extinguishing medium shall be available in all areas where fines and cuttings of such materials are present. (*See Section 5-1*.)

5-4 Hot Cells, Glove Boxes, Hoods, and Caves.

5-4.1

All glove boxes, hoods, cells, and caves shall be provided with a means of fire detection if used in the handling of pyrophoric materials, oxidizers, or organic liquids.

5-4.2*

Fire suppression shall be provided in all glove boxes, cells, hoods, and caves that might contain combustible metals or organic liquids in quantities that could cause a breach of integrity.

5-4.3 Hot Cells.

5-4.3.1 Hot cells shall be of noncombustible construction. Liquid-filled windows shall contain a noncombustible medium, such as zinc bromide solution.

5-4.3.2 Where hydraulic fluids are used in master slave manipulators, synthetic fire-resistant (low-hazard) hydraulic fluids shall be used.

5-4.3.3 Combustible concentrations inside the cells shall be kept to a minimum. Where combustibles are present, a fixed extinguishing system shall be installed in the cell. If explosive concentrations of gases or vapors are present, an inert atmosphere shall be provided, or the cell and ventilation system shall be designed to withstand pressure excursions.

5-4.3.4 Noncombustible filters shall be used, or a fire suppression system shall be provided. (*See also Section 4-7*.)

5-4.3.5 A documented daily housekeeping inspection shall be made for each hot cell.

5-4.4* Glove Boxes.

5-4.4.1 The glove box and window shall be of noncombustible construction.

5-4.4.2 The number of gloves shall be limited to the minimum necessary to perform the operations. When the gloves are not being used, they shall be tied outside the box. When the gloves are no longer needed for operations, the gloves shall be removed and glove port covers installed.

5-4.4.3 The concentration of combustibles shall be kept to a minimum. Where combustibles are present, a fire suppression system or fixed inerting system shall be provided. If fixed extinguishing systems are utilized, the internal pressurization shall be calculated in order to prevent gloves from failing or being blown off.

5-4.4.4 Fire dampers shall be provided between glove boxes that are operated in series.

5-4.4.5 Noncombustible filters shall be used, or a fire suppression system shall be provided.

5-4.4.6 A documented daily housekeeping inspection shall be made for each glove box.

Chapter 6 Referenced Publications

6-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

6-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.1

The objectives of this standard are to reduce personal hazards, provide protection from property damage, and minimize process interruption resulting from fire and explosion. Radioactive contamination might or might not be a factor in these risks.

A-1-2

The nature of radioactive materials is such that their involvement in fires or explosions can impede the efficiency of fire-fighting personnel, thus causing increased potential for damage by radioactive contamination.

Various types of emitted radiation are capable of causing damage to living tissue. In particular, fire conditions can cause the formation of vapors and smoke that contaminate the building of origin or neighboring buildings and outdoor areas. The fire protection engineer's main concern is to prevent the release or loss of control of these materials by fire or during fire extinguishment. This is especially important because radioactivity is not detectable by any of the human senses.

For additional requirements for light water nuclear power reactors, see NFPA 803, *Standard for Fire Protection for Light Water Nuclear Power Plants*, and the recommendations for research reactors described in NFPA 802, *Recommended Fire Protection Practice for Nuclear Research and Production Reactors*.

A-1-5 Definitions.

Combustible. The three terms used to describe the combustibility of materials — noncombustible, limited-combustible, and combustible — have specific definitions. When attempting to classify the combustibility of a material, ensure that the definitions of all three terms are thoroughly understood.

Limited-Combustible. The three terms used to describe the combustibility of materials — noncombustible, limited-combustible, and combustible — have specific definitions. When attempting to classify the combustibility of a material, ensure that the definitions of all three terms are thoroughly understood.

Noncombustible. The three terms used to describe the combustibility of materials — noncombustible, limited combustible, and combustible — have specific definitions. When attempting to classify the combustibility of a material, ensure that the definitions of all three terms are thoroughly understood.

A-2-1.1

Chapter 2 provides criteria for the development of administrative procedures and controls necessary for the execution of fire prevention and fire protection activities and practices for facilities handling radioactive materials.

A-2-2

Proper preventive maintenance of operating equipment as well as adequate facility personnel training are important aspects of a viable fire prevention program.

A-2-3 Fire Hazards Analysis.

A thorough analysis of the fire potential is necessary to incorporate adequate fire protection into the facility design. Integrated design of systems is necessary to ensure the safety of the facility and the operators from the hazards of fire and to protect property and continuity of production.

The following steps are recommended as part of the analysis procedure:

(1) Prepare a general description of the physical characteristics of the facilities that outlines the fire prevention and fire protection systems to be provided. Define the fire hazards that can exist, and state the loss-limiting criteria to be used in the design of the facility.

(2) List the codes and standards to be used for the design of the fire protection systems. Include the published standards of the National Fire Protection Association. Indicate specific sections and paragraphs.

(3) Define and describe the characteristics associated with potential fire for all areas that contain combustible materials, such as maximum fire loading, hazards of flame spread, smoke generation, toxic contaminants, and contributing fuels. Consider the use and effect of noncombustible and heat-resistant materials.

(4) List the fire protection system criteria and the criteria to be used in the basic design for such items as water supply, water distribution systems, and fire pump safety.

(5) Describe the performance criteria for the detection systems, alarm systems, automatic suppression systems, manual systems, chemical systems, and gas systems for fire detection, confinement, control, and extinguishment.

(6) Develop the design considerations for suppression systems and for smoke, heat, and flame control, combustible and explosive gas control, and toxic and contaminant control. Select the operating functions of the ventilating and exhaust systems to be used during the period of fire extinguishment and control. List the performance criteria for the fire and trouble annunciator warning systems and the auditing and reporting systems.

(7) Consider the qualifications necessary for personnel performing inspection checks and the frequency of testing needed to maintain reliable alarm, detection, and suppression systems.

(8) Use the features of building and facility arrangements and the structural design features to generally define the methods for fire prevention, fire extinguishing, fire control, and control of hazards created by fire. Fire barriers, egress, fire walls, and the isolation and containment features that should be provided for flame, heat, hot gases, smoke, and other contaminants should be carefully planned. Outline the drawings and list of equipment and devices that are needed to define the principal and auxiliary fire protection systems.

(9) Identify the dangerous and hazardous combustibles and the maximum quantities estimated to be present in the facility. Consider where these materials can be appropriately located in the

facility.

(10) Review the types of potential fires, based on the expected quantities of combustible materials, their estimated severity, intensity, duration, and the hazards created. For each of the types reviewed, indicate the total time involved and the time for each step from the first alert of the fire hazard until safe control and extinguishment is accomplished. Describe in detail the facility systems, functions, and controls that will be provided and maintained during the fire emergency.

(11) Define the essential electric circuit integrity needed during fire. Evaluate the electrical and cable fire protection, the fire confinement control, and the extinguishing systems that will be needed to maintain their integrity.

(12) Carefully review and describe the control and operating room areas and the protection and extinguishing systems provided for these areas. Do not overlook the additional facilities provided for maintenance and operating personnel, such as kitchens, maintenance storage, and supply cabinets.

(13) Analyze the available forms of back-up or public fire protection that can be considered for the installation. Review the back-up fire department, equipment, number of personnel, special skills, and training needed.

(14) List and describe the installation, testing, and inspection necessary during construction of the fire protection systems that demonstrate the integrity of the systems as installed. Evaluate the operational checks, inspection, and servicing needed to maintain such integrity.

(15) Evaluate the program for training, updating, and maintaining competence of the facility fire-fighting and operating crew. Provisions should be required to maintain and upgrade the fire-fighting equipment and apparatus during facility operation.

(16) Review the qualifications for the fire protection engineer or consultant who will assist in the design and selection of equipment. This individual will also inspect and test the physical features of the completed system and develop the total fire protection program for the operating facility.

(17) Evaluate life safety, protection of critical process/safety equipment, provisions to limit contamination, potential for radioactive release, and restoration of the facility after a fire.

A-2-3.2

A fire risk analysis might also be required to be performed.

A-2-4

Figure A-2-4(f) Sample fire report.

A-2-7

It is important that the responding fire brigade or public fire fighting forces be familiar with access, facility fire protection systems, emergency lighting, specific hazards, and methods of fire control.

A-2-7

(d) Using information provided by a health physicist, the level of radiation risk to be assumed should be decided by the officer in charge of the fire-fighting operation, based on the knowledge and importance of the operation to be accomplished.

A-3-1 Special Considerations.

The design and installation of service facilities such as light and power, heating and ventilation, storage, and waste disposal at facilities not handling radioactive materials might not present any unusual problems. The introduction of radioactive materials into a facility poses additional hazards to both personnel and property that warrant special consideration of these services. Inadequate attention to the design features of service facilities unfortunately has contributed to the extent of decontamination found to be necessary following fires and explosions. It is considered good practice to analyze the design of each service for the purpose of determining the effect the service would have upon the spread of contamination following a fire or criticality accident. An appraisal of the severity of contamination spread then can be used to determine the necessity for modifying the design of the service facility under consideration.

A-3-3 Planning for Decontamination.

The extent to which decontamination might be necessary depends upon the amount of radioactive material being released, its half-life, its chemical and physical form, and the type of radiation emitted. Taking all of these factors into account, a realistic assumption should be made as to the extent of a possible contamination incident. When decontamination is necessary, it can be costly and time consuming. These factors tend to raise costs and therefore justify capital expenditures to reduce them to a minimum through good emergency planning procedures.

A-3-4

Determination of fire area boundaries should be based on consideration of the following:

(a) Types, quantities, density, and locations of combustible material and radioactive materials;

(b) Location and configuration of equipment;

(c) Consequences of losing equipment;

(d) Location of fire detection and suppression systems; and

(e) Personnel safety/exit requirements.

It is recommended that most fire barriers separating fire areas be of 3-hour fire resistance rating unless a fire hazards analysis indicates otherwise. If a fire area is defined as a detached structure, it should be separated from other structures by an appropriate distance (*see NFPA 80A, Recommended Practice for Protection of Buildings from Exterior Fire Exposures*). Fire area boundaries typically are provided as follows:

(a) To separate manufacturing areas and radioactive materials storage areas from each other and from adjacent areas;

(b) To separate control rooms, computer rooms, or combined control/computer rooms from adjacent areas. Where a control room and computer room are separated by a common wall, the wall might not be required to have a fire resistance rating;

(c) To separate rooms with major concentrations of electrical equipment, such as switchgear rooms and relay rooms, from adjacent areas;

(d) To separate battery rooms from adjacent areas;

(e) To separate a maintenance shop(s) from adjacent areas;

(f) To separate the main fire pump(s) from the reserve fire pump(s), where these pumps provide the only source of water for fire protection;

(g) To separate fire pumps from adjacent areas;

(h) To separate warehouses and combustible storage areas from adjacent areas;

(i) To separate emergency generators from each other and from adjacent areas;

(j) To separate fan rooms and plenum chambers from adjacent areas; and

(k) To separate office areas from adjacent areas.

A-3-6

Penetration seals provided for electrical and mechanical openings should be listed or should meet the requirements of ASTM E814, *Fire Tests of Through-Penetration Fire Stops*, or UL 1479, *Fire Tests of Through-Penetration Fire Stops*.

A-3-6.1

Fire barriers also might be permitted to serve as radiation shields, HVAC air envelopes, or flood or watertight enclosures, and these concerns also should be taken into consideration.

A-3-9

Ventilation of a nuclear facility involves balanced air differentials between building areas, comfort ventilation, and heat removal from areas where heat is generated by equipment. This need also includes fire area isolation and smoke removal equipment, as well as equipment for filtering radioactive gases.

A-3-9.1

If plastic ducts are used, they should be listed fire retardant types and should be evaluated in the fire hazards analysis.

A-3-9.5 Exception.

The use of filters of low combustibility, such as those that comply with UL 586, *Standard for Test Performance of High Efficiency Particulate, Air Filter Units*, and UL 900, *Standard for Test Performance of Air Filter Units*, is recommended. Their use reduces the likelihood of the spread of contamination by fire. In the absence of protection systems within the ducts and for the filter banks, fires in combustible filters become extremely difficult to extinguish.

A-3-9.6.2 HEPA filtration systems with a leading surface area of 16 ft^2 (1.49 m^2) or less can be provided with fire detection and suppression systems to preclude the filter media being damaged by hot gases and flames.

A-3-9.7.1 For example, fresh-air inlets should not be located near storage areas of combustible radioactive waste material that, upon ignition, could discharge radioactive combustion products that might be picked up by the ventilating system.

A-3-9.7.8 A breakdown in an air-cleaning system can be more serious if the discharged air can be drawn immediately into another system. General isolation of radiation facilities from all other facilities causes an increase in both construction and operating costs but should be undertaken if justified by a study of the possible results of a contamination incident. In order to avoid unnecessary accidents, such facilities should be located separately from those handling explosives or flammable materials.

A-3-10.1

For further information, see NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, Appendix A.

A-3-13.1

The lights, ventilation, and operation of much remote-controlled equipment are dependent upon a reliable source of electrical power. The location of transformers, switches, and control panels should be well-removed from high-activity areas to ensure that maintenance work can be done without direct exposure to radiation from such areas. The need for effective ventilation during and immediately after an emergency such as a fire is of considerable importance.

A-3-13.2

It is important that electrical equipment be selected for its ease of decontamination and early restoration to service in those areas where a contamination is considered likely.

A-3-14.2.2 Special noncombustible storage facilities located remotely from the main facility might be necessary in some cases.

A-3-14.2.3 If the products of combustion of waste materials containing long-lived and highly active radioactive materials are dispersed through heating, ventilation, and air conditioning or compressed air systems, a decontamination problem of serious magnitude could result.

A-4-1

The facilities covered in this document vary widely in terms of function and the type of operations, as well as the type and quantity of radioactive material that might be present. The intent of this section is to specify the fire protection requirements for only those fire areas (or the whole) of the facility where radioactive materials are present.

A-4-1.3

In handling fissile materials, precautions should be taken not only to protect against the normal radiation hazard but also against the criticality hazard caused by the assembly of a minimum critical mass. To avoid criticality during fire emergencies, fissile materials that have been arranged to minimize the possibility of a criticality hazard should be moved only if absolutely necessary. If it becomes necessary to move such fissile materials, it should be done under the direction of a responsible person on the staff of the facility and in batches that are below the critical mass, or the materials shall be moved in layers that minimize the possibility of a criticality occurring. Since water is a reflector and a moderator of neutrons, concern for a criticality hazard sometimes leads to the unjustified and unevaluated exclusion of fire protection water from the area where fissile materials are stored or handled. The possibility of water moderation and reflection causing a criticality accident can be calculated in advance. If, in fact, such a hazard exists, combustible material that would necessitate the use of water for fire fighting should be eliminated. In many facilities, fissile materials are stored and handled in sprinklered areas.

A-4-2.1

Water quality can present long-term problems related to fire protection water supply. Factors to be considered should include water hardness, corrosiveness, presence of micro-organisms, and other problems that are unique to the type of facility.

A-4-2.2.2 For further information, see NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

A-4-2.2.3 For further information, see NFPA 22, *Standard for Water Tanks for Private Fire Protection*.

A-4-2.2.4 The 8-hour requirement for refilling can be extended if the initial supply exceeds the recommendations of 4-2.1. It normally is preferred for the refilling operation to be accomplished on an automatic basis.

A-4-3

All fire protection water system control valves should be supervised as recommended in NFPA 26, *Recommended Practice for the Supervision of Valves Controlling Water Supplies for Fire Protection*.

A-4-7.1

For the design of closed-head foam-water sprinkler systems, see NFPA 16A, *Standard for the Installation of Closed-Head Foam-Water Sprinkler Systems*.

A-4-9

Facilities that are operated unattended or with minimal staffing present special fire protection concerns. Consideration should be given both to the delayed response time for the fire brigade or public fire-fighting personnel and to the lack of personnel available to alert others on-site to a fire condition.

A-5-1

The principal fire hazards encountered in special radiation facilities will vary with the particular occupancy. In general, the requirements of this standard apply to all facilities handling radioactive materials within the scope of the document. Special occupancy fire hazards associated with particular operations are described in this chapter along with the special fire protection methods that apply to those hazards, with the exception of hazards associated with nuclear power plants and nuclear research reactors.

A-5-2

Radioactive materials are used in hospitals for a variety of purposes, including biomedical tracers, disease therapy, and laboratory analysis. General fire protection requirements for hospitals should be in accordance with NFPA 99, *Standard for Health Care Facilities*.

Radioactive materials used in hospitals rarely constitute a fire hazard themselves. Most often, the fire hazard associated with these materials is contamination of personnel, equipment, buildings, or the environment as a result of fire damage to containers and the subsequent release of radioactive materials.

Biomedical Tracers. Radioactive solutions can be administered to a patient intravenously or orally. The movement of the solution, as traced by monitoring the radioactivity level in different parts of the body, indicates the rate of various metabolic processes or the flow rate of blood. By comparing research data on healthy individuals with that of those known to have specific diseases, a patient's condition can be diagnosed without surgery.

Disease Therapy. Radioactive solutions can be administered to a patient intravenously or orally. The solution is designed to concentrate in specific organs or diseased tissue. The irradiation of the organ or tissue by the concentrated solution can alter the functioning of the organ (such as the thyroid gland) or kill diseased tissue (such as certain cancer cells).

Laboratory Analysis. Radioactive materials in solutions of known concentration are frequently used for laboratory analysis.

A-5-3.2

Combustible gases, such as hydrogen, ethylene, propane, acetylene, and natural gas, present both fire and explosion hazards. They should be used only in accordance with operating controls and limits required by the applicable NFPA standards.

A-5-3.3.1 Where solvents are used in fuel processing, consideration should be given to using solvents with the lowest fire and explosion hazard consistent with the requirements of the process.

A-5-3.3.2 Explosion-relief panels should be provided for solvent recovery areas.

A-5-3.4

Where using nitric acid during scrap recovery, experience and experiments have confirmed that exothermic reactions of distinctive violence can occur between tributylphosphate and uranyl nitrate or between tributylphosphate and nitric acid, or both.

A-5-3.5

Fines and cuttings from materials such as zirconium constitute a pyrophoric hazard.

A-5-4.2

The preferred method of suppression is an automatic sprinkler system, although other methods of suppression also may be permitted where installed in accordance with the applicable NFPA standard.

A-5-4.4

The external radiation hazard present during fabrication of Uranium-235 fuel elements is of a low order. Uranium-233 and Plutonium-239 present severe inhalation hazards to personnel; therefore, an enclosed protection system should be required to be used. These systems are called glove boxes. They can be extensive, with an appreciable amount of glass, and can present unique fire protection problems. Under normal conditions, substantial protection can be provided against the existing radiation hazard. On the other hand, if a criticality incident should occur, the type and quantity of radiation emitted can create grave hazards to personnel. Even a small fire within a glove box can produce serious consequences if not controlled properly. Fire control systems and procedures for glove boxes should be carefully developed and implemented before the boxes are used. Generally, such protective systems are custom-designed for the specific application.

Appendix B Sources of Radiation — The Nature of the Fire Problem

B-1 General.

B-1.1

Radioactive materials are substances that spontaneously decay, emitting energetic rays or particles in the process. Certain radioactive elements occur in more than one form. The various forms are chemically identical but differ in their atomic weights and are called isotopes. Those that are radioactive are called radioactive isotopes (radioisotopes). It is possible for an element to have one or more nonradioactive (stable) isotopes and one or more radioactive isotopes (radionuclides). Each of the radioisotopes emits a definitive type or types of radiation. In discussing radioactive material, therefore, it is always necessary to use the terminology that identifies the particular isotope, such as Uranium-238 or, alternatively, 238 Uranium.

B-1.1.1 Some radioisotopes occur in nature and can be separated by various physical or chemical processes; others are produced in particle accelerators or nuclear reactors.

B-1.1.2 Emissions from radioactive materials cannot be detected directly by any of the human senses. Radioactive materials themselves present no unusual fire hazards, as their fire characteristics are no different from the fire characteristics of the nonradioactive form of the same element.

B-1.1.3 The presence of radioactive materials can complicate a fire-fighting situation by presenting hazards unknown to the fire fighter and causing real or wrongly anticipated hazards to fire fighters, which can inhibit normal fire-fighting operations. The dispersal of radioactive materials by fumes, smoke, water, or by the movement of personnel can cause a radiation contamination incident that can contribute significantly to the extent of damage, complicate cleanup and salvage operations, delay the restoration of normal operations, and affect personnel safety.

B-2 Fire Problems.

B-2.1

Facilities handling radioactive materials should be designed and operated with special recognition given to the properties of radioactive materials. The effects of the presence of radioactive substances on the extent of loss caused by fire or explosion include:

(a) Possible interference with manual fire fighting due to the fear of exposure of fire fighters to radiation.

(b) Possible increased delay in salvage work and in resumption of normal operations following fire, explosion, or other damage due to radioactive contamination and the subsequent need for decontamination of buildings, equipment, and materials.

(c) Possible increase in the total damage due to buildings and equipment contaminated beyond the point where they are usable.

B-2.2

Radioactive materials can be expected to melt, vaporize, become airborne, or oxidize under fire conditions. None of these alterations will slow or halt radioactivity. It is conceivable that certain radioactive materials under fire conditions might be converted to radioactive vapor or oxidized to a radioactive dust or smoke. This dust or smoke could be carried by air currents and subsequently deposited on other parts of the burning buildings or even on neighboring buildings or land. These aggravated loss and personal injury characteristics of radioactive materials justify a high degree of protection against fire and explosion at those facilities where these potential hazards exist. The use of least combustible building components and equipment is highly desirable in those areas where radioactive materials are to be stored or used. Some form of automatic protection, such as automatic sprinklers, is highly advantageous wherever combustibles are encountered. The installation of automatic extinguishing systems reduces the need for personnel exposure to possible danger, starts the fire control process automatically, sounds an alarm, and makes efficient use of the available water supply. However, caution should be exercised to ensure that the hazards of criticality and reactivity are considered.

B-2.3

Some commonly encountered radionuclides are pyrophoric (e.g., uranium, plutonium) and, as such, should be given special consideration. Radionuclides generate heat and might need to be cooled in storage; these also require special consideration.

B-2.4

In view of the possibility of the spread of radioactive materials during a fire, certain precautions and procedures should be incorporated into emergency planning for fire-fighting operations.

B-2.5

The property manager should keep the local fire department advised of the locations and general nature of radioactive materials available. Emergency planning is essential so that fire fighters can function at maximum efficiency without exposure to harmful radiation and without unwarranted fears of the radiation hazard that can inhibit the fire-fighting effort. Where criticality incidents or exposure to radioactive materials is possible, mutual aid arrangements should maximize the use of on-site expertise. Specific provision should be made where necessary by the property manager and the fire department for monitoring service, protective clothing, and respiratory protective equipment, the need for which should be determined by the nature of the specific hazard. The radiation hazard usually can be anticipated in emergency planning studies.

B-3 Radiation Hazards and Protection Methods.

B-3.1

Significant levels of radiation exposure can occur under emergency conditions and can cause acute injury or death. However, fire fighters should be aware that radiation exposures that are tolerable in the event of a fire or other accident, especially where rescue operations are warranted, are unacceptable on a regular basis.

B-3.2 Nature of the Hazard of Radioactivity.

In order that fire-fighting personnel understand how to protect themselves against dangerous amounts of radiation effectively, it is necessary that they be familiar with the basic nature of radiation and the safeguards that generally are provided under normal operating conditions at those facilities where this hazard exists. While quite brief and simplified, the following paragraphs should assist the fire fighter in identifying those areas of concern:

(a) Radioactivity can be defined as the spontaneous emission of rays or particles during a change in an atom's nucleus. Radioactive decay is the spontaneous disintegration of a nucleus. Each radioactive isotope has a half-life — a period of time that is a characteristic of the particular isotope in which the intensity of nuclear radiation ascribable to that isotope progressively decreases by half. However, products formed by the radioactive decay of the original isotope can, in turn, be radioactive.

(b) The units for measuring the quantity of radioactivity in the source material are the curie, the millicurie (one one-thousandth curie), and the microcurie (one one-millionth curie). The term curie was originally designated as the standard for measuring the disintegration rate of radioactive substances in the radium family (expressed as 3.7×10^{10} atomic disintegrations per sec per gram of radium). It has now been adapted to all radioisotopes and refers to the amount of the isotope that has the same disintegration rate as 1 gram of radium.

Historically, the curie has been, and remains, the most commonly used unit for source strength. However, the SI unit for source strength is the becquerel. One becquerel is equal to one disintegration per sec. Hence, one curie is equal to 3.7×10^{10} becquerels.

(c) The sources of radiation likely to be encountered induce alpha particles, beta particles, gamma rays, and neutrons. The first three emit from many radioactive materials, and neutrons are likely to be present in the vicinity of nuclear reactors or accelerators only while reactors or accelerators are in operation, or they can emit from certain special neutron source materials. Neutrons, alpha particles, and beta particles are small bits of matter — smaller than an individual atom. Gamma rays (and x-rays) are electromagnetic radiations (similar to radio waves but with much shorter wavelengths).

(d) All radioactive emissions are capable of injuring living tissue. The fact that these radiations are not detectable by the senses makes them insidious, and serious injury can occur without an individual's awareness. Because of their relatively high penetrating power, gamma rays and neutrons can be a serious external hazard (i.e., potential severe danger even when from a source outside the body). Beta particles, which are less penetrating, can be somewhat of an external hazard if encountered within inches but are mainly an internal hazard; alpha particles, because of their extremely low penetrating power, are entirely an internal hazard (i.e., injure the body only if emanating from a source within the body after having entered the body by inhalation or ingestion or through a wound).

(e) These radiations are measured in roentgens, a unit representing the amount of radiation absorbed or the amount that will produce a specific effect. Radiation doses are measured in rems, a dose unit that will produce a specified effect in humans. The ultimate effect upon the human body depends on how and where the energy is expended. In industry, safeguards are provided for the purpose of keeping radiation exposure to personnel to a practical minimum and under certain amounts.

Historically, the roentgen and rem have been, and remain, the most commonly used units for radiation dosage. The current SI unit for dosage is the sievert. One sievert is equal to 100 rem. A sievert is equivalent to one joule per kilogram.

(f) In an emergency case, such as a necessary rescue operation, it is considered acceptable for the exposure to be raised within limits for single doses. The EPA 520/1-75-001, *Manual of Protective Action Guide and Protective Actions for Nuclear Incidents*, has recommended that, in a life-saving action, such as search for and removal of injured persons or entry to prevent conditions that would injure or kill numerous persons, the planned dose to the whole body should not exceed 75 rems. During circumstances that are less threatening to life, where it is still desirable to enter a hazardous area to protect facilities, to eliminate further escape of effluents, or to control fires, it is recommended that the planned dose to the whole body should not exceed 25 rems. These rules can be applied to a fire fighter for a single emergency; further exposure is not recommended. Internal radiation exposure by inhalation or ingestion can be guarded against by adequate respiratory equipment.

B-3.3 Personnel Protection Methods.

Monitoring is the process of measuring the intensity of radiation associated with a person, object, or area. It is done by means of instruments that can be photographic or electronic. Instruments used by personnel for radiation detection or measurement include:

(a) Film badge — a piece of photographic film that records gamma and beta radiation

(b) Pocket dosimeter — measures gamma radiation

(c) Geiger-Muller counter — measures beta and gamma radiation

(d) Scintillation counter — measures alpha, beta, and gamma radiation

(e) Ionization chamber — measures alpha, beta, and gamma radiation

(f) Proportional counter — measures alpha radiation

(g) Gamma survey meter — measures intensity of gamma radiation

(h) TLD (Thermoluminescent Dosimeter)   a crystal chip that records beta, gamma, and neutron radiation.

B-3.3.1 Common effects of excessive (200 roentgens or more) nuclear radiation on the body include vomiting, fever, loss of hair, loss of weight, decrease in the white blood cell count, and increased susceptibility to disease. Radioactive materials absorbed into the body often tend to accumulate at a particular location (e.g., plutonium and strontium tend to collect in the bone). The radioactivity concentrated in a particular organ gradually destroys the cell tissue so that the organ is no longer capable of performing its normal function, and the entire body suffers.

B-3.3.2 Radiation injury requires prompt, highly specialized treatment. Instruments should be provided to detect radiation contamination in clothing or on the skin. There should be a routine monitoring of the degree of exposure to the various particles and rays. Personnel working in the facility will generally be required to wear pocket radiation meters or indicators that are examined periodically, and records of the exposure should be kept for future reference.

B-3.3.3 The practice of placarding dangerous areas is for the protection of both regular operating personnel and those, such as fire fighters, who might have to deal with an emergency situation. If fire fighters are to have the best protection, they should inspect the premises where there might be radiation hazards to consider during fire operations well before a fire occurs. Also, by frequent follow-up inspections, they should reach an agreement with the emergency director or other personnel directing the facilities regarding steps to be taken in case of fire.

B-3.3.4 Fire fighters who might attend fires in properties where there are hazards of radioactivity should be given special training in proper protective clothing and cleanup or decontamination of their persons, clothing, or equipment. In all cases, they should have available and be trained in the use of suitable radiation monitoring equipment or have monitoring specialists with them.

B-3.4 Protection from External Radiation.

In the case of external nuclear radiation, the dosage and resulting injury to humans can be kept to a minimum in several ways:

(a) The smallest possible portion of the body only should be exposed (e.g., the hands, rather than the entire body).

(b) The time spent in the hazardous area and, therefore, the time of exposure, can be kept to a minimum by efficient organization of the work procedure.

(c) The intensity of radiation during exposure can be minimized by maintaining the greatest possible distance from the radiation source (e.g., by using long-handled tools for manipulating radioactive materials); or by the use of suitable materials interposed between the radiation source and the person to serve as a shield. Radiation intensity decreases inversely by an amount equal to the square of the distance from the source only where the source is a point source. This relationship is more complex with multiple point sources and does not apply to large sources until the distance is equal to one-half the maximum dimension of the source. Practically speaking, this could be 30 ft to 50 ft (9.1 m to 15.2 m). The cases in which a fire fighter will encounter a single point source are probably in the minority, and, therefore, the more conservative formula should be used.

B-3.5 Protection from Internal Radiation.

The possibility of radioactive materials entering the body can be reduced by wearing protective face masks and clothing while in a hazardous area. These masks should fit properly and be of a type that prevents the entry into the lungs or digestive system of the particular radioactive materials encountered. Clothing should be of such type to prevent the entry of radioactive materials into the body through wounds, scratches, or skin abrasions. Eating, drinking, smoking, and chewing should be prohibited while exposed to, or while awaiting decontamination after being in, radioactive areas.

B-3.5.1 Personnel working with radioisotopes are commonly subjected to routine biomedical checks for possible ingested radioactivity. Where applicable, routine checks also are made to verify that a permissible concentration of radioactive material in the body, the air, or elsewhere has not been exceeded.

B-3.5.2 Biomedical checks are promptly conducted whenever human ingestion of dangerous quantities of radioactive materials is suspected for any reason. When fire fighters are exposed to radiation and there is any doubt as to the severity of the exposure, they should be given a biomedical examination.

B-4 Sealed and Unsealed Radioactive Materials.

B-4.1

For purposes of this standard, a "sealed" radiation source is one that is tightly encapsulated (or the practical equivalent by bonding or other means) and is not intended to be opened at the facility. An "unsealed" source is one that is not so sealed or is intended to be opened at the facility, or both.

B-4.2

The protection of properties against the spread of radioactive contamination as the result of fire or explosion is simplified considerably by the fact that many radioactive materials are shipped, stored, and, in some cases, used, without ever exposing the radioactive material itself to air. In many cases the shipping containers, or even the use containers, might have sufficient integrity to withstand a fire or an external explosion. Examples include metallic cobalt-60 sources tightly encapsulated in steel and sealed sources used in "beta gauge" thickness and measuring devices. There have been several instances of stainless steel encapsulated beta gauge sources surviving appreciable fire exposures without release of the radioactive isotope contained therein.

B-4.3

The principal reason radioactive materials are sealed is to prevent spread of contamination. In some cases, the manufacturer of the container might not thoroughly consider fire resistance, and it is important to remember that a sealed source can burst if its contents are subject to thermal expansion as a result of exposure to fire.

B-4.4

Unsealed sources, such as can be found in laboratories during their transfer and use, can be spread about readily during a fire or an explosion.

B-5 Applications.

B-5.1

The specific application for ionizing radiation is governed somewhat by the physical makeup of its source, its sealed or unsealed form, and sometimes by its radiation intensity.

B-5.2

Most of the thousands of scientific and industrial uses of radioactive materials take advantage of one or more of the types of radiations emitted, i.e., alpha, beta, gamma rays, and neutrons. Certain radioisotope applications take advantage of the ultrasensitive detection capability of certain instruments for extremely small amounts of radioisotopes. Other uses take advantage of the ability of radiation to penetrate matter, while the extremely energetic sources have the ability to bring about biological, chemical, and physical changes.

B-5.3

The most common nuclear radiation applications can be grouped into the following categories:

(a) Radioisotope "tracer" applications utilize small amounts of short-lived, unsealed sources, involving easily detectable radiation emissions of the particular radioisotope employed. Such applications have found wide use in medical diagnosis, biological and agricultural explorations, water surveys, irrigation control, underground leak and seepage detection, atmospheric pollution, flow and transport rates in processing operations, lubrication and wear measurements, rapid chemical analysis for continuous process control, and activation analysis.

(b) Radioactive gauges and process control instruments utilize the more penetrating types of radiation from sources that are sealed to prevent the radioactive material from leaking. The radioactive material in no way enters into the system or process. This includes a wide range of operations, from measuring thickness or density to monitoring height and levels in storage and process equipment.

(c) Certain of the intensive sources of radiation have the ability to ionize gases. One of the important applications is the prevention of the accumulation of static electricity on moving machinery. The ionized air affects an "atmospheric grounding" and prevents buildup of static charges (radium and polonium as low-penetrating alpha emitters have been used, along with the more penetrating beta emitter, krypton-85). These sources also are being used as activating agents with self-luminous (phosphorescent) paints and coatings for various markings, emergency lighting, and instrument panels.

(d) Radioactive materials are being employed in the development of atomic batteries (as "isotopic power fuels"). The small currents generated are utilized in low-current demand micro-circuits; also, the liberation of thermal energy during radioisotope decay is converted into useful electricity through thermoelectric couples or thermionic systems. The sources include some fission products and some of the radioactive materials obtained by neutron irradiation of special target materials.

(e) Powerful sources are used in industrial radiography and nondestructive testing of critical process equipment. The leading industrially used isotope of high-energy emission is cobalt-60, which is obtained by the activation of cobalt in a reactor.

The industrial radiographer has a choice of x-ray machines or radioisotopes. In many cases, the latter offers the most advantages. The increased availability of cobalt-60 and iridium sources has resulted in radiographic inspections becoming commonplace. Steel thicknesses from $^1/_2$ in. to 6 in. (12.7 mm to 152 mm) can be evaluated radiographically, and many companies are now licensed to provide such examination services.

Other radioisotopes that have less energetic gamma ray emissions than cobalt-60 are coming into wider use for lighter materials such as aluminum, copper, zinc, and thin sections of steel.

(f) Powerful sources of high intensity radiation, such as cobalt-60, are used in food preservation and in radiological sterilization of pharmaceutical and medical supplies. Research and development indicate considerable promise in polymerization of plastics, vulcanization of rubber, improvement of wood properties, graft polymerization of plastics, and catalyzation of chemical reactions.

B-6 Nuclear Reactor Fuel Element Manufacture.

B-6.1

Certain radioactive nuclides are fissile. Neutrons absorbed by such nuclides emit additional neutrons plus energy, largely in the form of heat. Because more neutrons are emitted than are absorbed, a self-sustained nuclear chain reaction is possible when certain conditions are met. These conditions include a minimum quantity of fissile material (critical mass) and other factors such as shape, geometry, reflection, and moderation (or slowing of neutrons). Fissile materials used in a nuclear reactor are arranged in specific arrays using fuel elements in order to optimize conditions for fission to take place. When a nuclear chain reaction takes place where it was not intended, a criticality accident is said to have occurred.

B-6.2

In addition to the hazards of radiation and the potential for accidental criticality, fuel element manufacture often involves the use of combustible metals such as uranium and plutonium and combustible cladding material such as zirconium. The prevention of fires involving combustible metals requires special techniques. (*See NFPA 480, Standard for the Storage, Handling, and Processing of Magnesium Solids and Powders; NFPA 481, Standard for the Production, Processing, Handling, and Storage of Titanium; and NFPA 482, Standard for the Production, Processing, Handling, and Storage of Zirconium*.)

B-6.3

It is important to remember that nuclear fuel elements are extremely valuable, and extraordinary precautions can be necessary to protect them from the effects of an otherwise inconsequential fire.

B-7 Nuclear Fuel Reprocessing.

B-7.1

Reactors generally are capable of utilizing only a very small portion of the fuel contained in their elements, and, as a result, it is economical to recover the remaining fuel by processing the so-called “spent” elements in specially designed facilities. These facilities contain large quantities of radioactive materials (fission products) extracted from spent nuclear fuel elements that were produced as by-products during nuclear fission. Processing operations usually involve large quantities of flammable or corrosive liquids, or both. Fire and explosion hazards are present, and the possibility of an accidental criticality incident, although guarded against and remote, also is present.

B-7.2

The large quantities of highly radioactive materials present necessitate massive shielding for personnel safety, and most chemical processing and maintenance operations are conducted entirely by remote controls. Fire hazards are present during the sawing and chopping of fuel elements containing combustible metals, either in the form of fuel or cladding, and in the chemical processing operation. Specially designed fire detection and control systems are used to protect these operations. Ventilating systems should be arranged to maintain their integrity under fire conditions. Such facilities handling large quantities of highly radioactive materials demand the application of a high degree of fire protection planning in all areas.

B-8 Particle Accelerators.

B-8.1

Particle accelerators include Van de Graaff generators, linear accelerators, cyclotrons, synchrotrons, betatrons, and bevatrons. These machines are used, as their name implies, to accelerate the various charged particles that compose atoms to tremendous speeds and, consequently, to high energy levels. Radiation machines furnish scientists with atomic particles in the form of a beam that can be utilized for fundamental studies of atomic structure. In addition, they furnish high-energy radiation that can be utilized for radiography, therapy, or chemical processing.

B-8.1.1 These machines emit radiation only while in operation, and attempts to extinguish a fire in the immediate vicinity of the machine should be delayed until the machine power supply can be disconnected.

B-8.1.2 Certain "target" materials become radioactive when bombarded by atomic particles, and, for this reason, monitoring equipment should be used during fire-fighting operations to estimate the radiation hazard. The usual hazard presented by particle accelerators is largely that posed by electrical equipment. There are, however, some other significant hazards. Some installations have used such hazardous materials as liquid hydrogen, or other flammable materials, in considerable quantities. Large amounts of paraffin have been used for neutron shielding purposes, and the possible presence of combustible oils used for insulating and cooling is an additional hazard.

B-8.2

Industrial applications include chemical activation, acceleration of polymerization in plastics production, and the sterilization and preservation of packaged drugs and sutures. The general fire protection and prevention measures for these machines should include the use of noncombustible or limited-combustible (Type I or Type II) construction housing, noncombustible or slow-burning (*see IEEE-383, Standard for Type of Class IE Electric Cables, Field Splices and Connections for Nuclear Power Generating Stations*) wiring and interior finishing, and the elimination of as much other combustible material as possible (*see NFPA 220, Standard on Types of Building Construction*). Automatic sprinkler protection should be provided for areas having hazardous amounts of combustible material or equipment. Special fire protection should be provided for any high-voltage electrical equipment.

B-9 Isotope Production Facilities.

B-9.1 General.

Practical methods for production of radioactive isotopes include neutron activation of naturally occurring elements in reactors, fission of fissile material in reactors and extraction of radioactive fission products, and absorption of subatomic particles by atoms exposed in reactors or particle accelerators.

B-9.2 Isotope Production in Reactors.

Radioisotopes are produced in nuclear reactors by either bombardment of stable atoms with neutrons or other subatomic particles that cause transformation of the stable nucleus of the atom into an unstable or radioactive nucleus, or by separation of radioactive fission products from uranium used in the reactor.

B-9.2.1 Activation of isotopes in reactors generally is the result of the exposure of an element to a neutron flux resulting in a transmutation of the element due to neutron capture and alpha, beta, or proton decay. Fire hazards associated with reactor operations for this type of isotope production are described in NFPA 802, *Recommended Fire Protection Practice for Nuclear Research and Production Reactors*.

B-9.2.2 Various radioisotopes are produced as the result of fission of uranium in reactors. These isotopes can be removed from the fuel by chemical extraction following removal of the fuel from the reactor. Fire protection for reactor operations is described in NFPA 802, *Recommended Fire Protection Practice for Nuclear Research and Production Reactors*.

B-9.3 Radiation Machines.

Some radioisotopes are produced by exposing stable isotopes to high-energy subatomic particles. High-velocity subatomic particles are accelerated in particle accelerators such as Van de Graaff generators, linear accelerators, cyclotrons, or synchrotrons. These machines involve high-voltage electric and magnetic fields and produce radiation only while operating. Fire hazards associated with such machines are similar to any large electrical installation.

Appendix D Additional Publications

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

The following is a selection of additional reference materials.

The National Council on Radiation Protection and Measurement has issued a number of reports on specific radiation protection subjects. These reports are available from NCRP Publications, P.O. Box 4867, Washington, DC 20008, or from the U.S. Government Printing Office. Some applicable publications include:

NCRP 30, *Safe Handling of Radioactive Materials-NBS Handbook 92,* 1964.

NCRP 38, *Protection Against Neutron Radiation,* 1971.

NCRP 39, *Basic Radiation Protection Criteria,* 1971.

Standards of the U.S. Nuclear Regulatory Commission for protection against radiation are published in the *Code of Federal Regulations*, Part 20, Chapter 1, Title 10, available at most libraries. Revisions are printed in the Federal Register, available at subscribing libraries or by subscription from the U.S. Government Printing Office.

Nuclear Safety, a bimonthly magazine is available from the U.S. Government Printing Office. It covers many areas of interest, including general safety, accident analysis, operating experiences, and current events.

Specific requirements for facilities handling radioactive materials have been issued by the American Nuclear Insurers, Town Center, Suite 300S, 29 South Main Street, West Hartford, CT 06107-2445, and the MAERP Reinsurance Association, 1151 Boston-Providence Turnpike, Norwood, MA 02062.

NFPA 802

1993 Edition

Recommended Practice for Fire Protection for Nuclear

1993 Edition

This edition of NFPA 802, *Recommended Practice for Fire Protection for Nuclear Research and Production Reactors*, was prepared by the Technical Committee on Atomic Energy and acted on by the National Fire Protection Association, Inc. at its Fall Meeting held November 16-18, 1992, in Dallas, TX. It was issued by the Standards Council on January 15, 1993, with an effective date of February 12, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 802

This recommended practice was tentatively adopted at the Annual Meeting in May 1958. As a result of suggestions received during the period of its circulation, new text was added in the sections on the Boiling Water Reactor and on Educational and Training Reactors, and it was adopted in May 1960, as revised.

A completely revised and updated edition was adopted in May 1974. Revisions in the 1983 edition included the substitution of ionizing in place of gamma to include other types of radiation to which one may be exposed. Changes to the 1988 edition included a caution to special problems that may be caused by graphite reactors.

The revisions to this latest edition include expanding the scope to cover production reactors and revising the title from *Recommended Fire Protection Practice for Nuclear Research Reactors* to *Recommended Practice for Fire Protection for Nuclear Research and Production Reactors*.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: The safeguarding of life and property from fires in which radiation or other effects of nuclear energy might be a factor.

NFPA 802

Recommended Practice for

Fire Protection for Nuclear Research and Production Reactors

1993 Edition

NOTICE: Information on referenced publications can be found in Chapter 5 and Appendix A.

Chapter 1 Introduction

1-1 Scope.

1-1.1

This recommended practice covers the protection of life and property from the consequences of fire in nuclear reactor facilities other than those producing electricity.

1-1.2

Nuclear electric generating facilities are excluded, except for applicable and generic portions of NFPA 803 that relate to nuclear research and production reactors. (*See NFPA 803, Standard for Fire Protection for Light Water Nuclear Power Plants*.)

1-2 Purpose.

This recommended practice is prepared for the use and guidance of those charged with the design, construction, operation, and protection of nuclear research reactor facilities. It covers those requirements essential to assure that the consequences of fire will have minimum impact upon the safety of personnel, the physical integrity of the facility, and the continuity of operations.

1-3 General Information.

1-3.1 Power Level.

High power levels are generally associated with power reactors. Small units such as some package research reactors may pose problems due to their capability of being located in existing facilities or multiple occupancy buildings. While the maximum credible loss in nuclear terms may be much reduced, the fire exposure may actually be greater.

1-3.2 Coolants and Moderators.

These may run the gamut from simple water systems in pool reactors, to pumped water systems in boiling water reactors (BWR) or pressurized water reactors (PWR), or to circulating gas systems in high temperature gas reactors (HTGR). Particular fire protection problems are presented by liquid metal-cooled reactors, which generally use sodium systems. Particular fire protection problems may also be presented by liquid metal fast breeder reactors and graphite moderated reactors.

1-3.3 Fuel.

The susceptibility and quantity of the fuel material itself may be a factor. While uranium and plutonium are combustible metals, fuel elements composed of these metals generally use oxide fuels (in effect the fuel is already “burnt” and therefore incapable of combustion) but some reactors may use other forms, such as carbide, which may be pyrophoric. Even when such forms are not subject to fire exposure, such as in a water pool reactor, the manufacture, storage, and handling of the fuel may pose fire protection problems.

1-3.4 Shielding.

The nature of the shield material used for biological radiation protection varies from massive concrete to paraffin or wood-plastic compositions. Beyond the fuel contribution of some material, a fire burning or melting shielding can pose a radiation exposure problem to responding emergency forces.

1-3.5 Control Systems.

Reactor control systems and safety systems are of utmost importance. The control system design is fitted to the technical characteristics of the reactor and capable of producing power changes at acceptable rates. The control system design also makes it possible to produce and maintain the desired power level within the reactor in such a manner that excessive temperatures are avoided. The safety system also is adapted to the characteristics of the reactor and the instrument and control systems. It responds to signals from the instruments in such ways as to prevent, by automatic action, operational variables from exceeding safe limits. It also, on appropriate signals, warns of incipient changes in performance and, if necessary, shuts down the reactor.

1-3.5.1 Since the control system is vital to the adequate functioning and safe operation of the reactor, the protection of the control room, cableways, emergency power supply, and electrically or hydraulically operated equipment in general is of prime importance. Protection for the control room should be fully consistent with that for important computer rooms (*see NFPA 75, Standard for the Protection of Electronic Computer/Data Processing Equipment, or AEC Publication WASH 1245-1, Standard for Fire Protection of AEC Electronic Computer/Data Processing Systems*).

1-3.5.2 While comprehensive, automatic control systems are essential elements in reactor safety, the effectiveness of the total safeguards also depends on the proper execution of operating procedures that are technically sound and comprehensive.

1-3.6 Classification.

There is no single system of reactor classification. Reactors are generally classified by a combination name indicating one or more of its properties such as end-use, type of coolant or moderator, fuel form, neutron speed, and others. These are generally shortened to an acronym in common usage. Thus we have:

HTGR — High Temperature Gas Cooled Reactor

LMFBR — Liquid Metal Fast Breeder Reactor

1-3.7 Units.

Metric units of measurement in this recommended practice are in accordance with the modernized metric system known as the International System of Units (SI). One unit (liter), outside of but recognized by SI, is commonly used in international fire protection. If a value for measurement as given in this document is followed by an equivalent value in other units, the first stated is to be regarded as the requirement. A given equivalent value may be approximate.

1-4 Definitions.

Approved. Acceptable to the “authority having jurisdiction.”

NOTE: The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The “authority having jurisdiction” is the organization, office or individual responsible for “approving” equipment, an installation or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The “authority having jurisdiction” should utilize the system employed by the listing organization to identify a listed product.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Reactor Safety Considerations

2-1 General.

While it is beyond the scope of this publication to discuss the entire range of problems associated with the operation of reactors, it is appropriate to enumerate a number of identifiable problems that have a specific bearing on fire protection.

2-2 Fire Control Problems Due to Radiation Effects.

2-2.1

It should be kept in mind that almost every nuclear reactor will have areas of intense radioactivity associated with it. In fire fighting operations, it is essential not to disturb any part of the structure that is provided for shielding from radiation. In many cases the targets are themselves radioactive and the shielding may be combustible.

2-2.2

During fuel element changes or when the reactor is opened, the potential for radiation exposure to personnel is increased. Specialized shielding equipment, remote handling devices, and protected storage casks or water pools are used to reduce to a minimum this potential for exposure.

2-2.3

There is always the possibility, under emergency conditions, that admittance of personnel to the area housing the reactor or process areas would be forbidden due to high radiation levels or due to radioactive materials in dust or vapors that would be dangerous to inhale or ingest. It is essential that complete preplanning be carried out between the public fire department and the reactor management: where and how and to what extent the public fire department would be called upon to function.

2-2.4

It is important that reactor operations management recognize that in those areas in which fire fighting forces may not be admitted under some accident situations, complete reliance must be placed on proper design, use of noncombustible materials, and built-in fixed protection.

2-2.5

The permissible radiation to which fire fighters and other emergency personnel may expose themselves is a subject on which no simple statement can be made. One kind of exposure comes from external exposure to ionizing radiation. Another comes from radioactive substances that may be inhaled or ingested.

2-2.6

The exact limits should be defined by the emergency program established for the particular installation. Limits for routine workers, as defined in NRC regulations applicable to NRC contractors and in the *Code of Federal Regulations*, Title 10, Part 20, applicable to NRC licensees, are based on continuing exposure at those levels for a working lifetime. It does not apply to emergency or once-in-a-lifetime exposure. There are no mandatory limits in this situation, although the Bureau of Standards Handbook 59 recommended a 25-rem emergency exposure limit without affecting the normally allowed accumulation rates for workers. Some facilities have adopted 50 rems as an emergency limit. On the other hand, the National Council on Radiation Protection Report No. 39, *Basic Radiation Protection Criteria*, suggests that under emergency conditions that involve lifesaving actions the planned whole body dose should not exceed 100 rems, and during other less urgent emergencies, such as fighting fires, the planned whole body dose should not exceed 25 rems. In emergency situations such as fire fighting, the actual exposures may be uncertain, and exposures should be controlled by the amount of good to be achieved, just as for any other hazard fire fighters are expected to face. The pertinent point is that the exposure that can be permitted in emergency situations can be many times the routine day-after-day exposure limits and not pose a threat to the life of the fire fighter.

2-2.7

The problem of internal radiation exposure is entirely different from the external exposure problem, and establishing limits for emergencies is impracticable in the face of measuring difficulties inherent in emergencies. This is really no different than the problem presented by trying to define inhalation limits for smoke, carbon monoxide, and other products of combustion. Fortunately, the mandatory use of self-contained breathing apparatus in radiation emergencies can materially reduce the problem. This problem is discussed more fully in the AEC publication *Living With Radiation, Part 1, Fundamentals*, and *Part 2, Fire Service Problems*.

2-2.8

Radioactive materials, like other particulate matter, may be transported in the smoke of a fire. If deposited on the body or clothing, it can create a potential exposure problem requiring decontamination procedures such as washdown, clothing removal, personnel showers, etc. Every facility should have procedures for decontaminating clothing, personnel, and equipment that may be exposed in emergency situations.

2-2.9

While many facilities provide, and require, special coveralls, shoe covers, etc., for all workers in the facility, it should be remembered that this is an administrative convenience for plant operations. It does not provide a level of radiation protection any greater than that provided by a fire fighter's turnout clothes. In no case should emergency response be delayed because of regulations intended for the administrative convenience of routine operations. Prefire planning should include recognition of such potential problem areas.

2-2.10

It is important that movement of personnel who may carry contamination from contaminated areas to uncontaminated areas be carefully controlled. Plans for such controls should be included in the facilities' emergency plans, and fire fighting forces should be indoctrinated in the emergency systems.

2-3 Accident Involving Fissionable Materials.

2-3.1

The fissionable materials, uranium-233 and -235 and plutonium, should be used with provisions to prevent the accidental assembly of fissionable material into critical masses.

2-3.2

Since water is a reflector and moderator of neutrons, it is theoretically possible that an arrangement of subcritical fissionable material could be made critical by the introduction of water. Storage containers, shelving, and storerooms are required to be designed to prevent the accidental assembly of a critical mass. In many cases, the areas are designed to be critically safe even when completely submerged in water. Emergency planning should include the effects of fire fighting water on such areas, assuming disruption of the contents by the accident or by fire hoses. If manual fire fighting poses a potential hazard under the worst conditions, then it is essential that any required fire-extinguishing capability be self-contained and automatic in operation.

2-3.3

If, during a fire, an assembly of fissionable material should become critical, it could not explode like an atomic bomb since special conditions are necessary for such an explosion. Experience to date has shown that such reactions have been self-limiting, but do result in minor distribution of radioactive products over the immediate area accompanied by a brief, very intense burst of nuclear radiation that could be lethal.

2-3.4

Reactors are normally loaded with a quantity of nuclear fuel greater than the minimum necessary to obtain an initial self-sustaining nuclear reaction. If loss of cooling results in melting or other fuel displacement, it is unlikely that a critical mass in a new form will result. The actual amount of fuel may vary from as little as about one pound to tens of thousands of pounds depending on fuel enrichment, fuel form, reactor type, and many other factors.

2-4 Fire in Control Systems.

2-4.1

The possible effects of heat, smoke, and corrosive gases on the operation of control systems require attention to features of good practice and fire protection so as to minimize interference with operation of these systems. Features of good design include compartmentalization, minimizing combustible materials, and installation of automatic fixed extinguishing systems. The physical separation of alternative systems for control and safe shutdown of the reactor should be considered and provided to the extent practical.

2-4.2

Electrical control mechanisms involve combustible insulation. Hydraulic controls sometimes involve combustible fluids. The control panels may be exposed to fire damage if located near wood platforms or in spaces having combustible building finish or furnishings.

2-4.3

If fire involving a reactor control system causes reactor shutdown, the need for continued cooling of fuel elements will be reduced, but will not, in most cases, be eliminated.

2-5 Loss of Coolant or Moderator.

2-5.1

Another type of possible accident might be the loss of either moderator or coolant in a reactor operated for a time at or near full power. Sufficient residual heat might remain in the reactor fuel elements to melt them. The possibility of this occurrence in research reactors is extremely remote.

2-5.2

The possibility of chemical reaction of core or coolant materials under conditions of equipment failure must be taken into account. Coolant fires may, for example, result from leaks in sodium or organic coolant systems; sodium-water reactions may result from failures in sodium-water heat exchangers, and graphite may burn if air is inadvertently introduced into a very hot graphite core. Core design questions are involved in the choice of core materials, in the prediction of chemical reaction and radiolysis rates in the core, and possibly in the selection of in-core instrumentation for the detection of troublesome chemical situations.

2-6 Hydrogen Explosions.

2-6.1

The intense gamma radiation to which light or heavy water is subjected causes some decomposition into hydrogen and oxygen. Sealed reactors using water for moderator or coolant, or both, are equipped with collecting chambers to prevent the accumulation of hydrogen-oxygen mixtures from occurring in the reactor or accompanying piping.

2-6.2

Usually the hydrogen and oxygen are recombined catalytically. In reactors such as the swimming pool type, the rate of evolution of hydrogen is such that dissipation of the gas through openings present in a normal building, doors, crevices, and the like, will be more than adequate to prevent concentrations of hydrogen within the explosive range.

2-7 Electric Circuits and Wiring.

2-7.1

Electrical circuitry and components in reactor facilities present the same type of fire protection problems as in other industrial facilities. The prime concern in the reactor facility is directed towards those circuits and components essential to continued operation of the reactor and particularly to those essential to a safe shutdown under emergency conditions. For these reasons, special care is devoted to redundancy of systems, emergency power supplies, separation, physical protection, and reliability.

2-7.2

Because of the prime importance of much of the electrical equipment in a reactor facility, it is essential that fire protection measures for electrical equipment be adequate to ensure continuity of operations, at least to the extent of assuring safe shutdown conditions. Protection of cables, separation of redundant circuits, protection of penetrations (particularly through fire-rated partitions), and adequacy of alarm and interlocks is essential. The smoke and toxic products of combustion developed in most electrical fires, together with the smaller number of people available for emergency response (as compared to a manufacturing facility) increase the need for automatic protection systems in critical areas.

2-7.3

Electrical fires in reactor facilities may present greater loss potentials than in other facilities. Due to the stringent quality and reliability requirements for reactor facilities, equipment damaged by smoke and other products of combustion may be replaced when the same equipment in nonnuclear facilities could be salvaged and restored to service. This aspect of the damage potential further justifies additional fire prevention and protection measures in the nuclear facility.

2-8 Incompatible Materials.

Careful design analysis is important to the reduction of the fire protection problems inherent in the use of materials that are incompatible in fire situations. As an example, the use of liquid metal as a reactor coolant may require special extinguishing systems not utilizing water. The possibility of water/liquid metal reactions may justify the exclusion of water systems from the area. When such a condition exists, it may impose more severe limitations on the presence of combustible oils, plastics, insulations, and other materials that generally require water for fire extinguishment. Where such mixed hazards exist, it is important that careful consideration be given to the potentials for a failure in one system to cause a failure in the incompatible system. In such cases, either a protection system should be provided that can insure the extinguishment of fire in either system before it can cause a rupture of the other systems, or a single protection system (such as inerting) should be developed that is adequate for either hazard. The difficulties inherent in such problems warrant the most thorough hazards analysis at the earliest design stages.

Chapter 3 Fire Protection for Nuclear Research and Production Reactor Facilities

3-1 Preplanning.

3-1.1

In planning the construction and operation of facilities of which a nuclear reactor is part, attention should be given to adequate fire and explosion protection. Regulatory bodies and insurance organizations are often a source of practical recommendations. These agencies, including the fire department and other organizations that might be called to a fire, should be consulted at the planning stage to avoid the need for later adoption of protective measures at increased cost and delay.

3-1.2

As in any industrial plant, the fire hazard in nuclear reactor assemblies is generally due to the normal features of combustibility of building construction and contents. However, the fire and explosion problem is complicated by certain factors not present to the same degree in other plants. The behavior of materials at high temperatures and pressures is involved. The factors of radioactivity and contamination introduce a special hazard.

3-1.3

NFPA 801, *Recommended Fire Protection Practice for Facilities Handling Radioactive Materials*, applies specifically to all such facilities except nuclear reactors. However, the provisions of that publication are applicable to the fire protection needs in reactor facilities.

3-2 Fire Problems.

3-2.1

All facilities handling radioactive materials should be designed and operated in accordance with the usual good practices, but with special recognition given to the unique properties of radioactive materials. The effects of the presence of radioactive substances upon the extent of loss caused by fire, explosion, or other perils are:

(a) Possible interference with manual fire fighting due to the real or imagined fear of exposure of fire fighters to radiation.

(b) Possible increased delay in salvage work and in resumption of normal operations following fire, explosion, or other damage due to radioactive contamination and the consequent need for decontamination of buildings, equipment, and materials.

(c) Possible increase in the total damage resulting from contamination of buildings and equipment.

3-2.2

It is possible that radioactive materials may melt, vaporize, oxidize, and become airborne under fire conditions. None of these physical or chemical changes will slow or halt the radioactivity. It is conceivable that certain radioactive materials under fire conditions might be converted to radioactive vapor or oxidized to a radioactive dust or smoke. This dust or smoke could be carried by air currents and subsequently deposited on other parts of the involved buildings or even on neighboring buildings or land. These loss- and personal injury-aggravating characteristics of radioactive materials justify a higher-than-normal degree of protection against fire and explosion at those facilities where this potential exists. The use of fire-resistive building components and equipment is highly desirable in those areas where radioactive materials are to be located or used. Automatic extinguishing systems are highly advantageous wherever combustibles are encountered, since this makes it less necessary for personnel to expose themselves to possible danger. These systems automatically begin the fire control process, sound an alarm, and make efficient use of the extinguishing agent available. (*See Section 2-8, Incompatible Materials, for possible exceptions.*)

3-3 Plant Organization for Fire Protection.

3-3.1

A fire prevention and protection organization should be established as an integrated department of plant management and provided sufficient responsibility, authority, and manpower to permit effective performance on a 24-hour-a-day basis.

3-3.2

In a well-organized reactor facility, fire control planning starts well before the fire occurs. The need for prefire planning for such facilities cannot be overemphasized. A statement of policy by the management of the facility as to the intent of the plan, its scope, its importance, and its organization will materially assist in its effective application. It should be published, reviewed at periodic intervals, kept current, and properly implemented.

3-3.3

The areas of consideration of facility management in designing their preplanning for an emergency program should include as a minimum the following:

(a) A self-inspecting program.

(b) An emergency and fire fighting organization with an outline for its training operation.

(c) Personnel control as it relates to emergency situations.

(d) Health physics group responsibilities.

(e) A coordinated response plan with public emergency forces, including periodic drills.

(f) Procedures for loss-minimization and decontamination.

(g) The safeguarding of valuable process data and records.

(h) Community relations.

3-4 Self-Inspection Program.

The self-inspection program should be formal and conducted objectively by knowledgeable employees who have a good understanding of the hazards to be safeguarded.

3-4.1

The reports of these inspections should be reviewed by management at a level that can initiate corrective action. The self-inspection report forms should be specifically designed for each facility and include all aspects of basic fire protection as well as those unique to the facility.

3-5 Planning for Handling Emergencies.

3-5.1

In a plant involving a nuclear reactor, the problems affecting decisions on how best to deal with a fire or other emergency are not those that can be solved by simply calling the public fire department. As many decisions as possible should be made with respect to the types of fire or emergency to be expected, and these decisions should be made in advance.

3-5.2

The emergency procedures should be thoroughly practiced if they are to be successful. The problem of fire fighting does not lend itself to haphazard attack. The particular fire fighting measures to be taken may involve shutting down or isolating parts of the plant or individual items of equipment. As far as possible, procedures should be developed for handling such situations.

3-5.3

In general, the plant fire brigade should be in immediate charge of a fire area or an area of damage, but the exact operations that it may perform should be those largely decided upon in advance.

3-5.4

In most plants involving a reactor there will be many parts of the property where fire fighting does not involve any abnormal situations. The places where special procedures are necessary should be identified and the procedures for the special areas thoroughly understood.

3-5.5

Arrangements should be made for the prompt calling of the public fire department through reliable recognized means. However, the plant fire protection department should plan in advance with the public fire departments the operations of fire fighters coming into the plant in order that their activities will be properly coordinated with the plant’s program for dealing with emergencies.

3-5.6

The plant manager in charge at the time of the emergency should know under what conditions the public fire forces may operate in the plant. This is necessary so the exposure of fire fighters to unnecessary danger may be avoided and the plant’s operations may not be unreasonably interrupted by emergency measures undertaken with good intent, but without a proper understanding of their consequences.

3-5.7

Where fire fighters may be called upon to deal with a situation involving radioactivity, the plant should provide the necessary instruments and personnel for evaluating the degree of hazard. For fire fighting or emergency operations in areas where fire fighters, including public mutual aid departments, might be exposed to radioactivity, the workers permitted in these areas should be fully trained and provided with suitable protective clothing, respiratory protective equipment of a suitable type, and instruments for recording radiation exposure for each individual.

3-5.8

The emergency planning should cover measures to prevent the spread of contamination and for effective and prompt decontamination in the event of accidental release of radioactive materials. Operations offices of the U.S. Nuclear Regulatory Commission can provide assistance in certain emergencies.

3-6 Location and Construction.

3-6.1

Site-selection studies should include a review of exposures from fire and explosion. Accessibility (e.g., in abnormal weather), floods, lightning-prone terrain, air traffic, seismicity, and tornado belts should be among the geographical, geological, and meteorological features requiring consideration for site selection. Deficiencies should require compensatory action from a protection point of view. Lightning protection should be in accordance with NFPA 780, *Lightning Protection Code*.

3-6.2

A good construction fire safety program should insure that all penetrations of a containment vessel, if provided, should be suitable for evacuation and remain open during the construction period. (*See NFPA 241, Standard for Safeguarding Construction, Alteration, and Demolition Operations.*)

3-6.3

Installation of utilities and equipment in the containment vessel requires special care to maintain a low level of combustibles.

Since reactor equipment must meet very high levels of quality assurance, reactor equipment that has been subjected to fire and smoke damage is much more likely to require replacement than similarly exposed equipment in normal industrial installations. Special efforts are warranted to reduce the usual accumulation of packing cases, cartons, insulation, and other combustibles to an acceptable level. This may take the form of conducting all uncrating operations outside the containment vessel and providing special handling devices to transport unpackaged items into the vessel.

3-6.4

The difficulties of access and visibility, if a fire occurs where a containment vessel is provided, warrant the provision of temporary fixed automatic extinguishing systems when combustibles cannot be effectively controlled. Temporary interior hose stations and an ample supply of portable extinguishing equipment should be provided within easy reach of all portions of the vessel. Because of the smoke confinement potential, only very fast manual response may be effective and manual fire fighting equipment should be provided in quantities considerably in excess of normal construction practice to insure the earliest response.

3-6.5

The site of a nuclear reactor should have an adequate and highly reliable water supply system. It should be designed to provide water for fire protection and also to provide water for various normal and emergency requirements. Site facilities for disposal or retention of water that may be contaminated should also include sufficient capacity to handle runoff during fire fighting. Buildings protected by automatic extinguishing systems will generally require less retention capacity than facilities that are dependent upon manual fire fighting efforts.

3-6.6

Features of building construction that would introduce fire or explosion complications should be avoided. All construction should be noncombustible to avoid complications of fire hazard. For example, where all finish materials are used for decorative, acoustical, or insulation purposes, they should be noncombustible and of types to make decontamination more easily accomplished.

3-6.7

The exposure of the reactor to other buildings should be minimized by such means as spatial separation or by suitable barriers with provision for entry and egress.

3-6.8

The design and arrangement of the facility should be such as to provide adequate fire exits for people working in any of the areas of the facility. NFPA *101*,® *Life Safety Code*,® can serve as a guide.

3-7 Ventilation.

3-7.1

The designer should also consider fire and smoke spread within the building in the design of ventilation systems.

3-7.2

Air duct systems in a space or building may act as flues for heat or smoke, permitting fire and radioactive contaminants to spread. Large ducts and shafts are spaces in which the installation of automatic extinguishing systems and/or dampers may be needed. Ducts should be noncombustible and installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*. Filters should be of the UL Class 1 Type. High efficiency particulate air filters should conform to UL Standard 586 and Military Specification MIL-F-51068C; combustible filters should not be used.

3-8 Electrical Equipment.

3-8.1

Electrical equipment should be installed in accordance with NFPA 70, *National Electrical Code*.® Special consideration should be given to methods whereby radioactive contaminating substances carried by smoke or fumes may be prevented from entering electrical conduit ducts and fittings. Openings into devices or equipment should be sealed to prevent the entrance of contaminants.

3-8.2

Wiring ducts through walls, floors, and ceilings introduce an opportunity for the spread of fire or contaminated liquid or gas from one space to another. Fire stops in and around ducts should separate one space from another.

3-8.3

Electrical control equipment, wiring, or other electrical facilities that are important to the operation and safe shutdown of a reactor plant should be protected by automatic extinguishing systems and fire barriers. The degree of protection needed should be determined by an analysis of the fire exposure from the jacketing and insulation of the extensive wiring network and from combustible materials within or near the equipment. Extreme care in the layout and selection of materials and components, to minimize the fire loading and fire exposures to critical components, is needed during the design phase.

3-8.4

Emergency power supplies should be provided for essential control systems. Transfer to emergency supply should be done automatically upon interruption of the main power source. Emergency power supplies may consist of an automatically started, motor-generator set, an alternate feeder from the power generating station, or a set of batteries maintained under constant charge.

3-8.5

Controls should be of fail-safe design so that loss of control systems will not produce a hazardous condition, such as loss of reactor control. Where this is not possible or control is necessary under conditions of adversity, duplicate control circuitry should be provided.

3-8.6

Circuits and equipment depended on for primary safety should be electrically supervised; that is, the circuits arranged so that they carry current under normal conditions, with relays arranged to drop out and produce audible or visible signals if the circuits are accidentally broken. In the case of circuits and equipment intended to monitor special services such as air supply, liquid level in tanks and so forth, where this information is important to the safety of the installation, the supervised circuit and equipment should be arranged so that a break or a ground in a conductor on the circuit will result in a trouble signal rather than an alarm signal. Where extreme reliability is needed, the circuit should be arranged to produce the alarm signal even if a broken wire or a ground accidentally occurs. Under these conditions, the arrangement of circuit and parts should be such that an audible signal cannot be silenced without a corresponding visual signal.

3-9 Flammable Liquids and Gases.

3-9.1

The use of nonflammable cleaning solvents is strongly encouraged. Flammable liquids, except for amounts required for actual operations, should be stored in accordance with NFPA 30, *Flammable and Combustible Liquids Code*. The use of even small quantities of flammable liquids in safety cans should be permitted in and about the reactor assembly only with specific permission from the plant fire protection manager.

3-9.2

Flammable liquids or gases that may of necessity be piped into the nuclear reactor areas should have outside emergency shutoffs. Piping, valves, and safety devices should be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*, and NFPA 54, *National Fuel Gas Code*.

3-9.3

Compressed flammable gas cylinders should be stored outside the reactor area in a ventilated cutoff room or outdoors, to be brought in only for purposes specifically authorized.

3-10 Ordinary Combustibles.

3-10.1

Combustibles associated with reactors are not limited to those having characteristics requiring special protective measures. The quantity of ordinary combustibles, such as wood and paper, is frequently the most serious factor in fire exposure.

3-10.2

Combustible materials, whether for shielding, for experiments or research, for maintenance, or for any use unrelated to reactor operation, should not be allowed to expose the reactor or critical components. Operations requiring the use of combustibles should be in other appropriate adequately protected areas.

3-11 Extinguishing Systems.

3-11.1

Both operation of the reactor and emergency shutdown depend on control mechanisms and equipment that should be designed so that a fire will not prevent their vital operations. Therefore, continuity of operation of critical control equipment may dictate the use of extinguishing agents other than water. Systems employing carbon dioxide, halogenated hydrocarbons, dry chemical, and foam may be required. Physical and chemical compatibility of the extinguishing agent to the hazard to be protected should be considered in system selection. These systems should be designed and installed in accordance with the applicable NFPA standard. Guidance may be found in NFPA 11, *Standard for Low Expansion Foam and Combined Agent Systems*; NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*; NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*; NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*; NFPA 12B, *Standard on Halon 1211 Extinguishing Systems*; NFPA 13, *Standard for the Installation of Sprinkler Systems*; NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*; NFPA 16, *Standard on Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*; NFPA 16A, *Recommended Practice for the Installation of Closed-Head Foam-Water Sprinkler Systems*; and NFPA 17, *Standard for Dry Chemical Extinguishing Systems*.

3-11.2

Automatic sprinkler systems or specially designed automatic fixed water spray systems should be the first consideration for fire protection in those locations where fire possibilities exist. Such systems can operate with full effectiveness under conditions of radiation or contamination that would make approach by fire fighters impossible. Water is usually preferable over other extinguishing media where there is need for retention and control of radioactive contaminants.

3-11.3

The collection and disposal of water used in fire fighting may be an important factor in limiting the extent of the reactor assembly or the areas of associated buildings affected by radioactive contamination. This consideration alone suggests that, for many of the building spaces, a well-designed sprinkler system is preferable to dependence on manual fire fighting. It is better to pipe water for fire fighting into spaces where a fire might have to be fought through a system of automatic sprinklers or a system specially designed for the purpose, rather than have to combat a fire by directing hose lines into a smoke-obscured space and distributing the water in a less efficient manner.

3-11.4

In spaces where water used in fire fighting would be subject to possible contamination, the collection and disposition of water so used should be provided for in the facilities of the reactor plant. This usually means waterproofed floors and controlled floor drainage. Substantial capacity of such drainage systems would be required if hose streams and manual fire fighting is necessary. With sprinklers, or specially designed systems, relatively smaller amounts of water may have to be disposed of. Also, “on-off” sprinklers and flow cycle valves may be considered to further minimize water discharge.

3-11.5

The relative importance of ventilation to release heat, smoke, and hazardous gases developed in a fire is mitigated to some degree by automatic sprinklers or by a specially designed protection system. Such systems tend to reduce three-dimensional problems to more manageable two-dimensional ones.

3-12 Standpipe and Hose System.

A network of inside hose connections should be provided throughout the facility. Spacing and installation should conform to NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*. Nozzles should be adjustable spray/straight stream type. In the vicinity of electrical equipment, nozzles approved for Class C areas should be used.

3-13 Portable Fire Extinguishers.

3-13.1

For first-aid fire protection, suitable fire extinguishers should be installed in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

All employees who may at any time be expected to operate a fire extinguisher or hand hose should receive training and be assigned to first-aid fire fighting duty in accordance with a carefully worked out plan for each department of their plant.

3-13.2

Incipient fires may be controlled by portable fire extinguishers. This phase of fire control is particularly important, even though automatic extinguishing systems and hand hose connections have been provided. A supply of portable hand fire extinguishers suitable for use on the specific hazards encountered should be provided (*see NFPA 10, Standard for Portable Fire Extinguishers*).

3-13.3

Special fire potentials sometimes encountered involve unusual chemicals or combustible metals. Some special extinguishers are effective on incipient fires in combustible metals. Dry powder extinguishers, approved for combustible metal fires, are effective on most such materials (*see NFPA 480, Standard for the Storage, Handling and Processing of Magnesium; NFPA 481, Standard for the Production, Processing, Handling, and Storage of Titanium; and NFPA 482, Standard for the Production, Processing, Handling, and Storage of Zirconium*).

3-13.4

Some extinguishing agents may have undesirable effects on personnel and some types of equipment. It is important that this possibility be evaluated.

3-14 Fire Detection.

3-14.1

It should be recognized that fire detection in itself does not extinguish the fire and is only as good as the follow-up action to be provided.

3-14.2

The need for and the type of detection services should be related to the hazard, the extinguishing systems, public and private fire departments, or combinations of these.

3-14.3

Various devices are available that operate on different principles for detecting fire. These include, but are not limited to, the principles of fixed temperature, rate-of-temperature-rise, presence of combustible products, IR or UV flame sensing, or a combination of some of these principles.

3-14.4

A properly engineered fire detection system in accordance with NFPA 72 and NFPA 72E can be used to: (1) alert the building occupants of a fire condition so they can evacuate the premises, (2) summon organized assistance to undertake, or assist in, fighting the fire, (3) shut down equipment or processes that may contribute to the consequences of a fire, and (4) actuate fire control equipment.

3-14.5

If no private fire control organization is available and the public protection forces are inadequate or distant, a good detection system will serve to alert personnel to evacuate the building.

3-15 Fire Hazard Analysis.

3-15.1

A thorough fire hazard analysis is necessary to incorporate adequate fire protection into the facility design. Integrated design of systems is necessary to insure the safety of the facility and the operators from the hazards of fire and to insure that fire cannot prevent the safe shutdown of the reactor under emergency conditions.

3-15.2

The following steps are recommended as part of the analysis procedure.

3-15.2.1 Prepare a general description of the physical characteristics of the facility that will outline the fire prevention and fire protection systems to be provided. Define the fire hazards that can exist and state the fire risk evaluation to be used in the design of the facility. Describe the design basis fire that will be considered and used in the design of the fire protection system.

3-15.2.2 List the codes and standards that will be used for the design of the fire protection systems. Include the published standards of the National Fire Protection Association. Select the specific sections and paragraphs, not general items.

3-15.2.3 Define and describe the potential fire characteristics for all individual plant areas that have combustible materials, such as: maximum fire loading, hazards of flame spread, smoke generation, toxic contaminants, and fuel contributed. Consider the use and effect of noncombustible and heat-resistant materials.

3-15.2.4 List the fire protection system requirements and the criteria to be used in the basic design for such items as water supply, water distribution systems, and fire pump capacity.

3-15.2.5 Describe the performance requirements for the detection systems, alarm systems, automatic suppression systems, manual systems, chemical systems, and gas systems for fire detection, confinement, control, and extinguishing.

3-15.2.6 Develop the design considerations for suppression systems and for smoke, heat, and flame control, combustible and explosive gas control, toxic and contaminate control. Select the operating functions of the ventilating and exhaust systems during the period of fire extinguishing and control. List the performance requirements for the fire and trouble annunciator warning system.

3-15.2.7 In the review and selection of the appraisal and trend evaluation systems that may be provided with the alarm detection system in the fire protection system, consider the qualifications required for the personnel performing the inspection checks and the frequency of testing to maintain a reliable alarm detection system.

3-15.2.8 The features of the facility generally define the methods for fire prevention, fire extinguishing, fire control, and control of hazards created by fire. Fire barriers, egress, fire walls, and the isolation and containment features that should be provided for flame, heat, hot gases, smoke, and other contaminants should be carefully planned. Outline the drawings and list of equipment and devices that are needed to define the principal and auxiliary fire protection systems.

3-15.2.9 Prepare a list of the dangerous and hazardous combustibles and the maximum amounts estimated to be present in the facility. Evaluate where these will be located in the facility.

3-15.2.10 Review the types of maximum credible fires, based on the quantities of combustible materials, their estimated severity, intensity, duration, and the hazards created. Indicate for each of the types reviewed the total time involved and the time for each step from the first alert of the fire hazard until safe control, extinguishment, or safe shutdown of the facility is accomplished. Describe in detail the plant systems, functions, and controls that will be provided and maintained during the fire emergency.

3-15.2.11 Define the essential electric circuit integrity needed during the fire. Evaluate the fire confinement control and extinguishing systems that will be required to maintain their integrity.

3-15.2.12 Analyze what is available in the form of backup or public fire protection to be considered for the installation. Review the backup fire department, equipment, manpower, special skills, and training required.

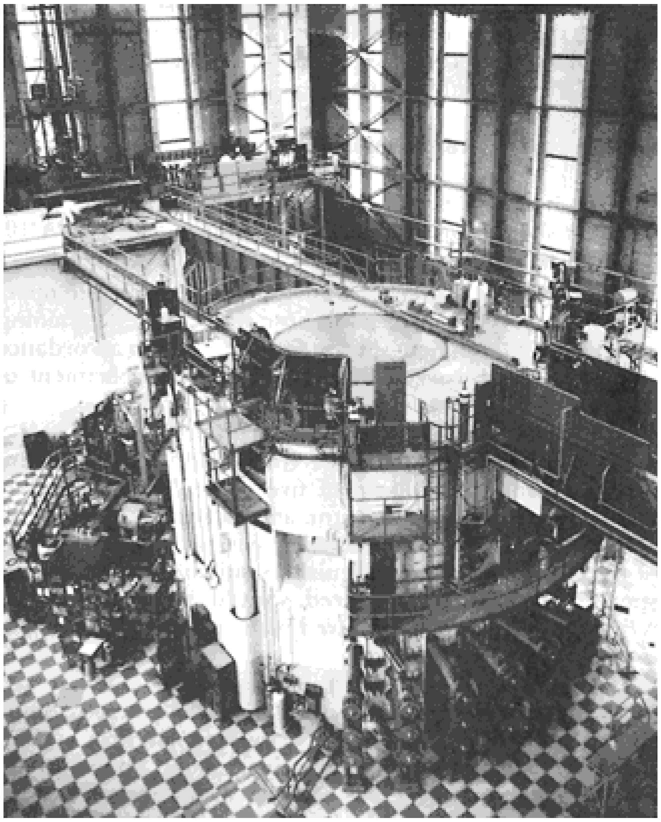
3-15.2.13 List and describe the installation, testing, and inspection required during construction of the fire protection systems that demonstrate the integrity of the systems as installed. Evaluate the operational checks, inspection, and servicing required to maintain this integrity.

3-15.2.14 Review the qualification requirements for the fire protection engineer or consultant who will assist in the design and selection of equipment. This person will also inspect and test the complete physical aspects of the system and develop the complete fire protection program for the operating plant.

Chapter 4 Problems of Specific Research and Production Reactor Types

4-1 General.

The principal fire hazards are likely to be due to the peculiar circumstances existing in any occupancy in which research is being carried on. With a number of research projects calling for the use of numerous experimental facilities, the normal condition is to find much experimental apparatus set up. This provides a degree of congestion that involves potential fire hazards to both material and personnel. The use of combustible materials should be very strictly limited. (*See Figure 4-1.*)



(*Courtesy Atomic Energy of Canada, Ltd.*)

Figure 4-1 This illustration shows what the working space around a research reactor may look like. The congestion of valuable instruments and apparatus explains why it is necessary to strictly limit combustible material. This is the Canadian NRX heavywater moderated reactor. It has heavy shielding including a heavy cover.

4-1.1

Combustible acoustic or other wall finishes introduce unnecessary fire hazards. Furniture should be noncombustible.

4-2 Fire Protection.

The principal fire protection needed is to deal with a congested accumulation of combustible material. Even with the best supervision, there is likely to be enough combustible material to seriously damage experimental apparatus in case of fire. Fire, smoke, and the fire fighting operations could spread contamination throughout the building.

4-2.1

General protective measures should include portable extinguishers and automatic fixed extinguishing systems for the working space around the reactor and application of the principles of containment in the design and arrangement of the building.

4-2.2

Normal use of these reactors is at power levels where ordinary convection and thermal radiation will dissipate heat produced at the core. Some do require additional cooling, usually by water.

4-2.3

The collection and disposal of water used in fire fighting may be extremely important in preventing the spread of contamination. For this reason a well-designed fire protection system is preferable to manual fire fighting. If sprinklers and floor drains are properly arranged, water used in fixed systems can be better controlled than if the water must be employed through hose lines.

4-3 Access and Ventilation.

The design of the working space around the reactor should be such that controlled ventilation of smoke from small fires is possible. In connection with this, the exposure hazard due to smoke being radioactive must be considered. It is not likely that this radioactivity would be from fission products, but from induced radiation in experiments.

4-3.1

Working space around the reactors should, as a matter of common practice, provide at least two avenues of escape for personnel, and these exits should be arranged as remote, one from the other, as possible. These avenues are also necessary to provide access for manual fire fighting operations as necessary.

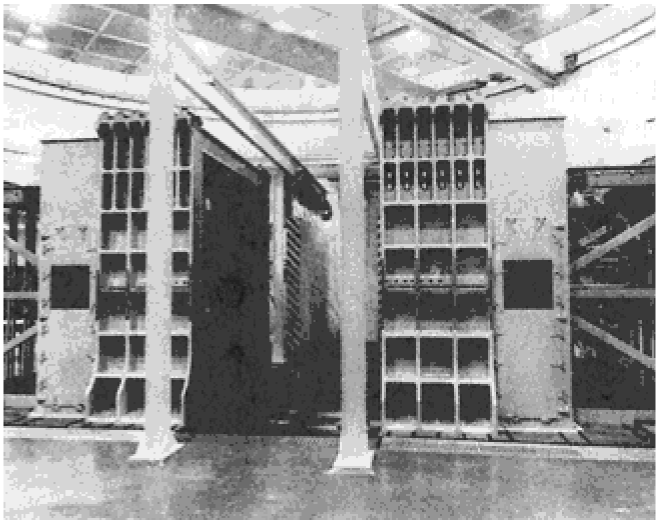
4-4 Site Factor.

While research reactors could, under conditions of poor building design, introduce some exposure hazard, their fire exposure hazard on the whole is low, and the radioactive contamination potential does not appear to be excessive.

4-5 Critical Experiment.

4-5.1 Field of Use.

The critical experiment involves the components of a reactor without the assembly necessarily being as complete as would be a final design. It is strictly for experimental purposes. (*See Figure 4-5.1.*)



(*Credit: Argonne National Laboratory, Idaho Div.*)

Figure 4-5.1 National Reactor Testing Station, Idaho. Pictured is the Zero Power Plutonium Reactor (ZPPR) assembly machine located in the reactor cell of the facility. The ZPPR facility is in support of the Fast Breeder Reactor Program. The reactor is shown with the two halves separated and the personnel shields and loading platform retraced. The matrix face [10 ft (3.05 m) by 10 ft (3.05 m)] of the stationary half can be seen at the left center of the photograph. Rod drives with their support frames are also mounted at the back of each half of the reactor.

4-5.1.1 The critical experiment is assembled for the purpose of learning from actual operation many of the characteristics of the reactor system under study. These include (1) verification of the calculated value of critical mass, (2) an approximation, by neutron flux measurement, of the distribution of power within the core, (3) indication of the temperature coefficient of reactivity, (4) effects and calibration of control devices, and (5) studies of the behavior of different materials used in the core.

4-5.1.2 Critical experiments can be made entirely for obtaining technical information and data without any specific type of reactor being represented.

4-5.2 Description.

The construction of the critical facility is such as to allow differences in the kinds, amounts and arrangement of core, moderator, and reflector components.

4-5.2.1 The general arrangement of the parts resembles the type of the reactor under study, but because of the low power generation, pressurizing of high-pressure water designs may not be necessary, shielding may be reduced, and the overall construction greatly simplified. Low power generation eliminates the heat transfer apparatus necessary to cool the reactor.

4-5.2.2 The critical experiment does not produce a significant quantity of highly radioactive fission products as a power reactor does. Thus, after operation, the reactor can usually be disassembled and the parts studied without extensive protection against radiation.

4-5.3 Fuel.

In these experiments the fuel might be any of the materials suitable for the purpose ranging from completely noncombustible to the involvement of pyrophoric materials.

4-5.4 Controls.

The critical assembly usually is initially equipped with standard control actuators. As an assembly approaches the final design, parts of a control system of new design may be introduced to check operating characteristics.

4-5.4.1 Extra controls, safety devices, and "scram" provisions are usually used in experimental work, since there may be errors or inaccuracies in calculated characteristics. Some of these extra safety measures may include safety rods, means for quickly dumping liquid moderators or reflectors, or arrangements for withdrawing sections of the core or solid moderators or reflectors. Provisions for injecting a neutron-absorbing material or "nuclear poison" such as a boron-containing liquid compound or metal are sometimes used.

4-5.5 Criticality.

A critical experiment is a reactor operating up to and at times slightly above the critical state. Even if the amount of fissionable material in excess of the critical amount in a critical assembly is small, it is possible to produce a nuclear excursion that might result in a power level such that the heat cannot be removed fast enough to prevent a melt-down of fuel components. Radioactive contamination of the experiment room may result, requiring extensive decontamination operations. It is possible, but not probable, that such an accident might rupture the walls or roof of the room, releasing activity to the balance of the building or the outside atmosphere.

4-5.6 Hazards.

The fact that the critical experiment is a research operation may mean that a variety of materials and apparatus will be brought into the working spaces. Hazards associated with the combustibility, flammability, and explosiveness of these, and their reactivity with air, water, and chemicals, should be kept in mind in evaluating the hazard in and near the buildings where the reactor experiments are going on.

4-5.6.1 The use of combustible materials should be eliminated wherever possible, and combustible types of thermal insulation should be completely avoided. Where electrical cables, cords, or wires appear in great numbers, their electrical insulation should be of fire resistant types. Combustible acoustic or other combustible wall finishes introduce unnecessary fire hazards in such an occupancy. Experimental apparatus should be installed on noncombustible boards. Furniture of all sorts should be strictly limited and of noncombustible types.

4-5.6.2 The production of fuel elements should not be in the same area as the reactor. Fuel elements should be stored with care to prevent possible assembly of a critical mass.

4-5.7 Fire Protection.

Automatic extinguishing systems should be installed throughout with special consideration given to other extinguishing media when automatic sprinklers may be unsuitable.

4-5.7.1 As in other reactor plants, the control of water from hose streams is likely to be more difficult than the control of water used in fire fighting from automatic sprinklers or specially designed systems. In every case, the design should involve means for collection of water runoff from fire fighting operations in such a way as to prevent the spread of contamination or the accidental build-up of a critical mass.

4-5.7.2 The exact form of organization for fire protection will depend on circumstances. The critical experiment may be carried on at a location that has an adequate organization responsible for fire protection matters. If not, an organization for fire protection is a necessary part of the management of the critical experiment. The kind of work being done in connection with a critical experiment does not permit leaving decisions with respect to fire fighting matters in the hands of a custodial force. It may be necessary for the building in which the experiment is being carried on to be constantly under the supervision of some person technically competent to handle the overall use of the reactor and its building.

4-5.7.3 In addition, the custodial force should be fully instructed in fire fighting and ventilating procedures, and arrangements must be made in advance so that, if members of a public fire department are likely to respond to a fire call, there will be some responsible administrative officer or custodian who will know under what arrangements the public fire force may go to work. Such arrangements should be worked out between the administration of the reactor property and the chief officer of the city or fire district.

4-5.8 Access and Ventilation.

Radiation shielding will be employed although critical experiments are carried on at near-zero power output. This shielding may be temporary walls or partitions, or it may involve a fixed arrangement of spaces to separate those in which there is radioactivity from those in which there is not. The design of the working space around the reactor should be such that the ventilation of smoke from small fires is possible. The exposure hazard due to radioactive smoke should be considered. Regularly occupied working spaces should provide at least two avenues of escape for personnel, and these exits should be arranged as remote one from the other as possible. The objective should be not only providing exits but also providing means by which access is possible for the operations to control a fire emergency.

In certain experimentation, airborne contamination may be a problem. Where this is the case, the design of the system used for ordinary air conditioning or ventilation should be arranged to cope with such potential contamination.

4-5.9 Site Factors.

The critical experiment may involve a very wide range of hazards to other properties depending upon the nature of the experiment. Consideration of the fundamental dangers of explosion and contamination should be considered in locating the reactor. If adequate water is not available for fire protection as well as for the experiment, additional water for fire fighting purposes should be stored at the site.

4-6 Open Pool Reactor (Swimming Pool Reactor).

4-6.1 Field of Use.

The open pool (swimming pool) reactor is useful for research purposes and is considered versatile, economical, and relatively safe. The shielding that can be provided by the water moderator, and the visibility afforded by its transparency are operating advantages.

4-6.2 Description.

The reactor itself is basically an open top tank filled with purified water. The water in the tank serves as coolant, moderator, reflector, and shield. One pool of this type is concrete, 40 ft long, 20 ft wide, and 20 ft deep (12.2 m long, 6.1 m wide, and 6.1 m deep). Some reactors have a considerable number of ports (beam holes) in the wall so that various experimental apparatus may be set up for the use of the radiation produced (*see Figure 4-6.2*). The building housing the reactor and the working space around it would ordinarily have a tight wall and roof of metal or concrete.

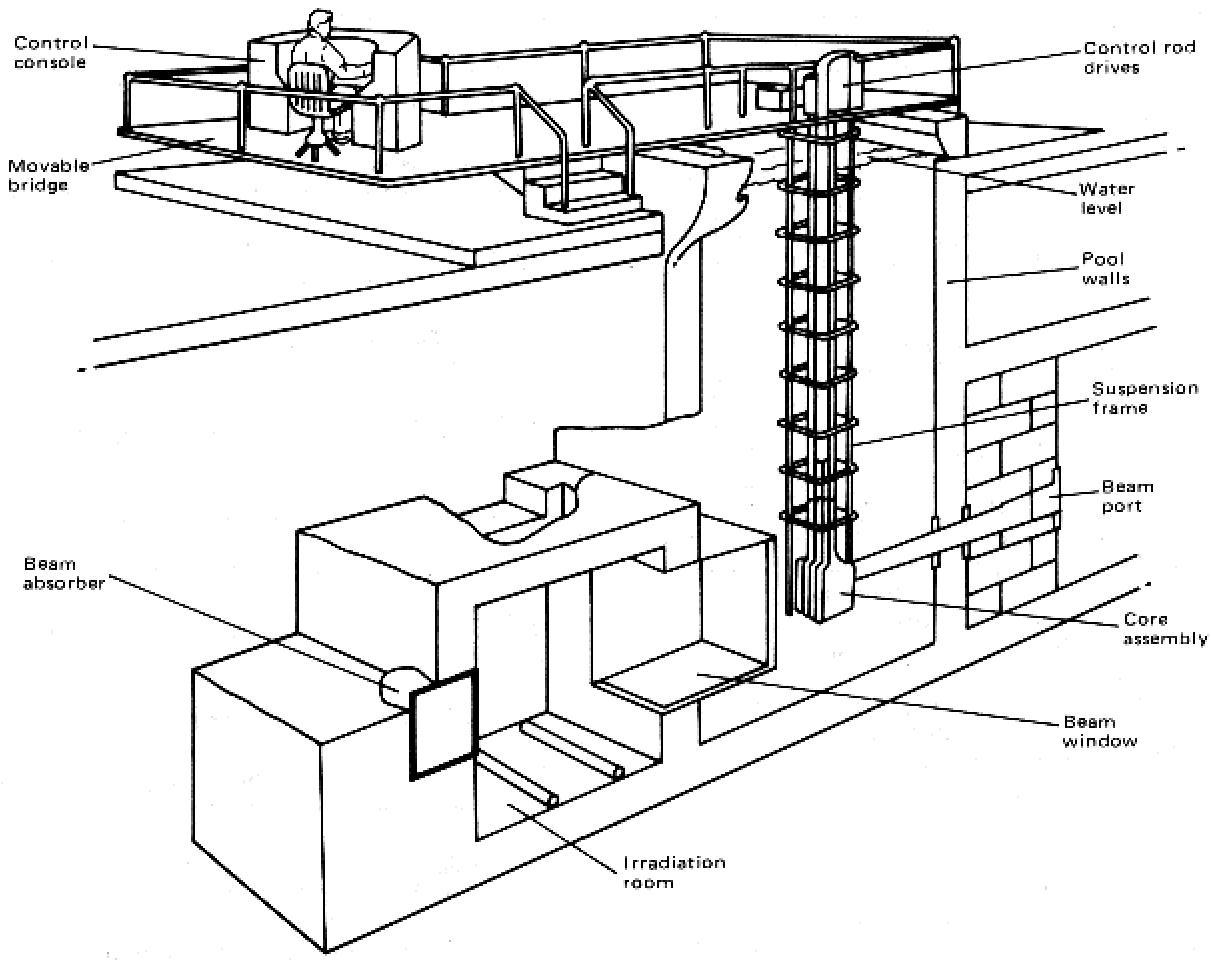


Figure 4-6.2 Open pool (swimming pool) reactor assembly.

4-6.3 Fuel.

The fuel is usually highly enriched uranium in rods or plates. A typical element consists of aluminum-clad plates grouped into fuel assemblies usually about 24 in. by 3 in. by 3 in. (610 mm by 76 mm by 76 mm). (Enriched uranium simply means that the percentage of U-235 is higher than in natural uranium. The higher the enrichment the smaller the fuel core can be.) A cluster of rods or plates is arranged in a core suspended by a cage in the water from a movable bridge across the top of the pool.

4-6.4 Controls.

Control of the rate at which neutrons are produced is provided by inserting boron or cadmium rods in the proper geometrical pattern between the fuel elements to absorb neutrons. Usually two or three rods are used as control rods and one or two are safety shutdown rods in combination with from 15 to 30 fuel elements. The movement of control rods and fuel elements is accomplished by control mechanisms electrically or hydraulically operated. These are so arranged that, in case of electric or hydraulic failure, the control rods will return by gravity to a position that will shut down the reactor.

4-6.5 Criticality.

In this type of reactor, a critical mass can be reached with about 6 lb (2.7 kg) of 90 percent enriched uranium fuel in a pool of the dimensions described. With lesser degrees of enrichment, more fuel would be required.

4-6.6 Hazards.

This being a water-moderated reactor, hydrogen and oxygen are produced in small amounts by the action of radiation. Provision must be made for safe disposal of this by ventilation.

4-6.6.1 Certain reactor or reactor fuel materials may be subject to chemical action between themselves or such materials as the water moderator, especially at the high temperatures that may be produced accidentally. Obvious hazards are those in the electrical control equipment. Accidents to the electrical equipment should not result in a hazard in the reactor. Because these reactors are used for research many varieties of chemicals may be brought into the working area around the reactor by various experimental setups (*see Figure 4-6.2*). Hazards associated with the combustibility, flammability, and explosiveness of these chemicals and their reactivity with air, water, and other chemicals should be kept in mind in evaluating the hazard in the reactor building at any given time.

4-6.6.2 Defects in fuel element cladding may permit leakage of some radioactive products into the water of the pool.

4-6.6.3 Combustible acoustic or other wall finishes introduce unnecessary fire hazards. Furniture should be noncombustible.

4-6.6.4 General protective measures should include portable extinguishers and automatic extinguishing systems.

4-6.6.5 Normal use of this type of reactor is at power levels where ordinary convection will dissipate heat produced at the core. Heat could be produced rapidly enough to release steam at the pool surface in the event of failure or slow operation of controls. Violent boiling may spread contamination outside of the reactor pool. This might prevent the use of the reactor for an extended period of time and present a decontamination problem. The worst conceivable (but highly improbable) disturbance might produce steam violent enough to cause local structural damage, blow off any apparatus at the top of the pool and probably damage the building.

4-6.7 Site Factors.

While this type of reactor could, under conditions of poor building design, introduce some exposure hazard, its fire exposure hazard, on the whole, is low, and the radioactive contamination hazard does not appear to be excessive. Because of the reactor’s requirement for water, it would likely be located in a place where a satisfactory water supply for fire fighting could be provided.

4-6.8 Organization for Fire Protection.

There should be a fire protection organization. The use of a research reactor means that teams of scientists from a number of separate agencies (several departments of a university, for example) are likely to be occupying the premises at any given time. Each may be performing experiments that introduce some fire hazard condition.

4-6.8.1 The agency responsible for the operation of the reactor or plant should consider having on duty during all working times persons technically competent to handle the overall use and operation of the reactor and the building. Whether the reactor and the building may safely be left in the hands of a custodian at times when it is not used, such as nights, weekends, or holidays, should be considered. In addition, the custodial force should be fully instructed in fire fighting and ventilation procedures, and arrangements should be made in advance so that, if members of a public fire department are likely to respond to a fire call, there will be some responsible administrative officer or custodian who will know under what arrangements the public fire force may go to work. Such arrangements should be worked out between the administration of the reactor property and the officials of the city or fire district.

Appendix A A Selection of Additional Reference Material

This Appendix is not part of the recommendations of this NFPA document, but is included for information purposes only.

A-1

The U.S. Department of Energy prepared the following (general interest) publication, which may be ordered from the Department of Energy Technical Information Center, P.O. Box 62, Oak Ridge, TN 37830:

Operational Accidents and Radiation Exposure Experience Within the United States Atomic Energy Commission, 1943-1982, 125 pages, Fall 1971.

A-2

The National Council on Radiation Protection and Measurements has issued a number of reports on specific radiation protection subjects. Price lists are available from NCRP Publications, P.O. Box 4867, Washington, DC 20008, or from the U.S. Government Printing Office. Some applicable publications include:

NCRP 30, *Safe Handling of Radioactive Materials NBS Handbook 92*, 1964

NCRP 38, *Protection Against Neutron Radiation*, 1971

NCRP 39, *Basic Radiation Protection Criteria*, 1971.

A-3

Standards of the U.S. Nuclear Regulatory Commission for protection against radiation are published in the *Code of Federal Regulations* as Part 20, Chapter 1, Title 10, available at most libraries. Revisions are printed in the *Federal Register*, available at subscribing libraries or by subscription from the Government Printing Office.

A-4

A bimonthly magazine, *Nuclear Safety*, is available from the Government Printing Office. It covers many areas of interest, including general safety, accident analysis, operating experiences, and current events.

A-5

Specific requirements for reactor fire protection have been issued by the American Nuclear Insurers, The Exchange, 270 Farmington Ave., Farmington, CT 06032, and the Mutual Atomic Energy Reinsurance Pool, 1151 Boston-Providence Turnpike, Norwood, MA 02062.

NFPA 803

1993 Edition

Standard for Fire Protection for Light Water Nuclear Power Plants

1993 Edition

This edition of NFPA 803, *Standard for Fire Protection for Light Water Nuclear Power Plants*, was prepared by the Technical Committee on Atomic Energy and acted on by the National Fire Protection Association, Inc. at its Fall Meeting held November 16-18, 1992, in Dallas, TX. It was issued by the Standards Council on January 15, 1993, with an effective date of February 12, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 803

The Committee on Atomic Energy was organized in 1953 for the purpose of providing guidance on practices necessary for fire safety in facilities handling radioactive materials. A *Recommended Fire Protection Practice for Nuclear Reactors*, NFPA 802, was developed and officially adopted in 1960. Following a serious fire in 1975 at the Brown's Ferry Plant of the TVA, the Nuclear Regulatory Commission expressed the need for a fire protection standard specifically covering nuclear power plants. The Committee started work on the preparation of this document early in 1976, and their efforts resulted in the first edition being issued in 1978.

Changes in the 1983 edition included a more precise title for the document as well as a complete revision to the chapter on fire alarm systems. The 1988 edition brought the standard into conformance with the NFPA *Manual of Style* as well as making several editorial changes to better explain various sections. This 1993 edition incorporates a variety of changes to the document.

Committee Scope: The safeguarding of life and property from fires in which radiation or other effects of nuclear energy might be a factor.

NFPA 803

Standard for
Fire Protection for Light Water Nuclear Power Plants

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
For information on referenced publications see Chapter 18.

Chapter 1 Introduction

1-1* Scope.

This standard covers the protection of light water nuclear power plants from the consequences of fire, including safety to life of on-site personnel, protection of property, and continuity of production. Nuclear safety is provided for in other documents such as Nuclear Regulatory Commission (NRC) regulations.

1-2 Purpose.

This standard is prepared for the use and guidance of those charged with the design, construction, operation, and protection of light water nuclear power plants. This standard covers those requirements essential to assure that the consequences of fire will have minimum impact on the safety of construction and operating personnel, the physical integrity of plant components, and the continuity of plant operations. Additional emphasis is on requirements dictated by the need to protect the lives of constructors and operators from the consequences of fire and to conform to best fire protection engineering practice.

1-3 Definitions.

Approved. Acceptable to the “authority having jurisdiction.”

NOTE: The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The “authority having jurisdiction” is the organization, office or individual responsible for “approving” equipment, an installation or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

Combustible. Any material that, in the form in which it is used and under the conditions anticipated, will ignite and burn.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code.*)

Fire Area. That portion of a building or plant that is separated from other areas by fire barriers.

Fire Barrier. Those components of construction (walls, floors, or floor/ceiling assemblies and their supports, including beams, joists, columns, penetration seals or closures, fire doors, and fire dampers) that are rated by approval laboratories in hours of resistance to fire and are used to prevent the spread of fire.

Fire Brigade. As used in this standard, refers to those persons trained in plant fire fighting operations.

Fire Door. A door assembly rated in accordance with NFPA 252, *Standard Method of Fire Tests of Door Assemblies*, and installed in accordance with NFPA 80, *Fire Doors and Fire Windows*.

Fire Loading. The amount of combustibles present in a given situation, expressed in Btu per square foot.

Fire Prevention. Measures directed towards avoiding the inception of fire.

Fire Protection. Methods of providing for fire control or fire extinguishment.

Fire Protection Manager. The person directly responsible for the fire prevention and fire protection program at the plant.

Fire Rated Penetration. An opening in a fire barrier for the passage of pipe, cable, duct, etc., that has been sealed so as not to reduce the integrity of the fire barrier.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with the test procedures of NFPA 251, *Standard Methods of Fire Tests of Building Construction and Materials*.

Fire Zone. Subdivisions of fire areas in which fire detection and/or suppression systems provide alarm information indicating the location of fire at a central fire control center.

Flame Spread Rating. A relative measurement of the surface burning characteristics of building materials when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psi (276 kPa) absolute pressure at 100°F (37.8°C).

Labeled. Equipment or materials to which has been attached a label, symbol or other identifying mark of an organization acceptable to the “authority having jurisdiction” and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Limited Combustible. A building construction material that, in the form in which it is used, has a potential heat value not exceeding 3500 Btu per pound (8141 kJ/kg) and either has a structural base of noncombustible material with a surfacing not exceeding a thickness of $^1/_8$ in. (3.2 mm) that has a flame spread rating not greater than 50, or other material having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion, even on surfaces exposed by cutting through the material on any plane. (*See NFPA 220, Standard on Types of Building Construction.*)

Listed. Equipment or materials included in a list published by an organization acceptable to the "authority having jurisdiction" and concerned with product evaluation, that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The "authority having jurisdiction" should utilize the system employed by the listing organization to identify a listed product.

Noncombustible Material. A material that, in the form in which it is used and under the conditions anticipated, will not ignite, support combustion, burn, or release flammable vapors when subjected to fire or heat. Materials reported as noncombustible, when tested in accordance with ASTM E136, *Test for Behavior of Materials in a Vertical Tube Furnace at 750°C*, shall be considered noncombustible materials.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

1-4 Introduction and Special Problems Relating to the Protection of Light Water Nuclear Electric Generating Stations.

1-4.1 General Introduction.

Fire protection is both an art and a science. Perfection and practice in the art is the objective, with fire prevention being the ultimate goal. Fire prevention in the absolute sense is only possible where there is no combustible material to fuel a fire. The presence of combustible material creates a fire potential, no matter how slight. Thus, fire prevention must, as a first priority, consider the presence of any combustible material as a variance.

The total elimination of combustible material is seldom possible; therefore, fire protection requires additional measures to limit the consequences of fire.

A defense-in-depth philosophy of fire prevention, control, and extinguishment shall be adopted and implemented to minimize and mitigate the effects of fire and reduce hazards to personnel and property damage to acceptable minimums.

A well-balanced fire protection program includes prevention, detection, extinguishment of fires, safety to life, and preservation of property. The protection of the environment and of the public against nuclear hazards takes priority over that of the plant itself and is addressed by the appropriate regulatory agencies. However, the size of nuclear power plants makes the economic impact of a forced outage such that protection measures must be extended to include provisions to assure their continued operation.

1-4.2 Special Considerations in Fire Protection Encountered at Light Water Nuclear Power Plants.

Consideration of the need for nuclear safety results in several areas of fire protection emphasis unique to the nuclear electric generating station; for example:

(a) Reactor shutdown systems.

(b) Cooling system integrity.

(c) Filtering system integrity.

(d) Ventilating system integrity.

NOTE: *See Appendix B.*

1-4.3 Defense-in-depth.

1-4.3.1 Light water nuclear power plants use the concept of defense-in-depth to achieve the high degree of safety required in the nuclear safety systems of the plant. This concept shall be extended to fire protection for the remaining areas of the plant.

1-4.3.2 With respect to the fire protection program the defense-in-depth principle is aimed at achieving an adequate balance in:

(a) Preventing fires from starting.

(b) Detecting fires quickly and suppressing those fires that occur, thereby limiting damage.

(c) Designing the plant to limit the consequences of fire.

NOTE: No one of these echelons can be perfect or complete by itself. Strengthening any one can compensate in some measure for weaknesses, known or unknown, in the others.

1-4.4 Fire Protection Management Program.

The fire protection program for a nuclear power plant shall cover design features, personnel, procedures, plans, and equipment. Senior management participation in this program shall begin with early design concepts and plant layout and continue through plant operation. In order to effectively develop and conduct this program, a fire protection manager shall be appointed at the conceptual stage of the project. The manager shall be selected on the basis of education, experience, and advancement as an industrial fire protection engineer. The manager shall establish liaison with all internal departments, with all authorities having jurisdiction, and with the public fire department.

1-5 Units.

Metric units of measurement in this standard are in accordance with the modernized metric system known as the International System of Units (SI). One unit (liter), outside of but recognized by SI, is commonly used in international fire protection. If a value for measurement as given in this standard is followed by an equivalent value in other units, the first stated is to be regarded as the requirement. A given equivalent value may be approximate.

Chapter 2 Functional Subdivisions of the Plant Layout

2-1

Safety to the lives of on-site personnel, protection of property, and continuity of power production as affected by the possibility of fires shall be given appropriate consideration in the general arrangement of the nuclear power plant. For the purposes of fire hazard analysis the plant component facilities shall be divided into primary facilities, secondary facilities, and support facilities as follows:

NOTE: The nuclear power plant will generally consist of the following functional facilities, which would be expected to vary in their physical relationship to each other from plant to plant.

(a) Typical Primary Facilities.

Reactor Building. Houses the reactor within a containment structure and its integral or freestanding shield.

Reactor Auxiliary Building. Contains reactor auxiliary and emergency core cooling system (ECCS) equipment.

Control Building. Houses the main and auxiliary control panels, emergency switchgear, and batteries.

Turbine Building. Houses the turbine generator and turbine generator auxiliaries.

Steam Generator Building. Houses the steam generator.

Intake Pumping Station. Houses the condenser circulating water makeup pumps, the raw service water and fire protection pumps, and all necessary valves and strainers for these systems.

Electrical Switchyard. Encompasses the electrical transmission system coming into the site and leaving the site.

Emergency Power Generation Facility. That facility designed to provide on-site emergency power in the event of an off-site power failure.

Emergency Service Water Pumping Station. Houses the emergency service water pumps and all necessary valves, strainers, and electrical switchgear for these systems.

Condenser Circulating Water Pumping Station. Houses the condenser circulating water pumps, pump isolation valves, pump suction and discharge conduits, and associated electrical equipment.

Electrical Control and Communications Building. Houses the switchyard relays and terminal communications equipment and may act as a control center for the switchyard up until the time the main control room becomes operational.

Main Heat Rejection System. Includes cooling towers and facilities associated with spray ponds and canals.

Station Transformers. Those transformers that provide auxiliary power to the plant or transmit power from the plant.

(b) Typical Secondary Facilities.

Fuel Building. Inclusion of primary equipment in this building would require upgrading of the affected portions of the building to primary facility status.

Radwaste Building. Houses the equipment for processing radioactive waste from the plant.

Makeup Water Treatment Plant. Facility for producing high purity water before use in the reactor or its support systems.

Condenser Circulating Water Treatment Building. Houses the plant and condenser circulating water biocide treatment system.

Demineralizer Regeneration Building. Contains facilities for regeneration and cleaning of resins from the plant condensate polishing system.

(c) Typical Support Facilities.

Office Building. Houses the offices for the plant's administrative employees and contains plant records.

Service Building. Encompasses the guard house, main gate, and office space for the plant's security force.

Auxiliary Boiler Building. Contains boilers for providing heating steam and steam to operate plant auxiliary equipment during the time that the nuclear steam supply is not available.

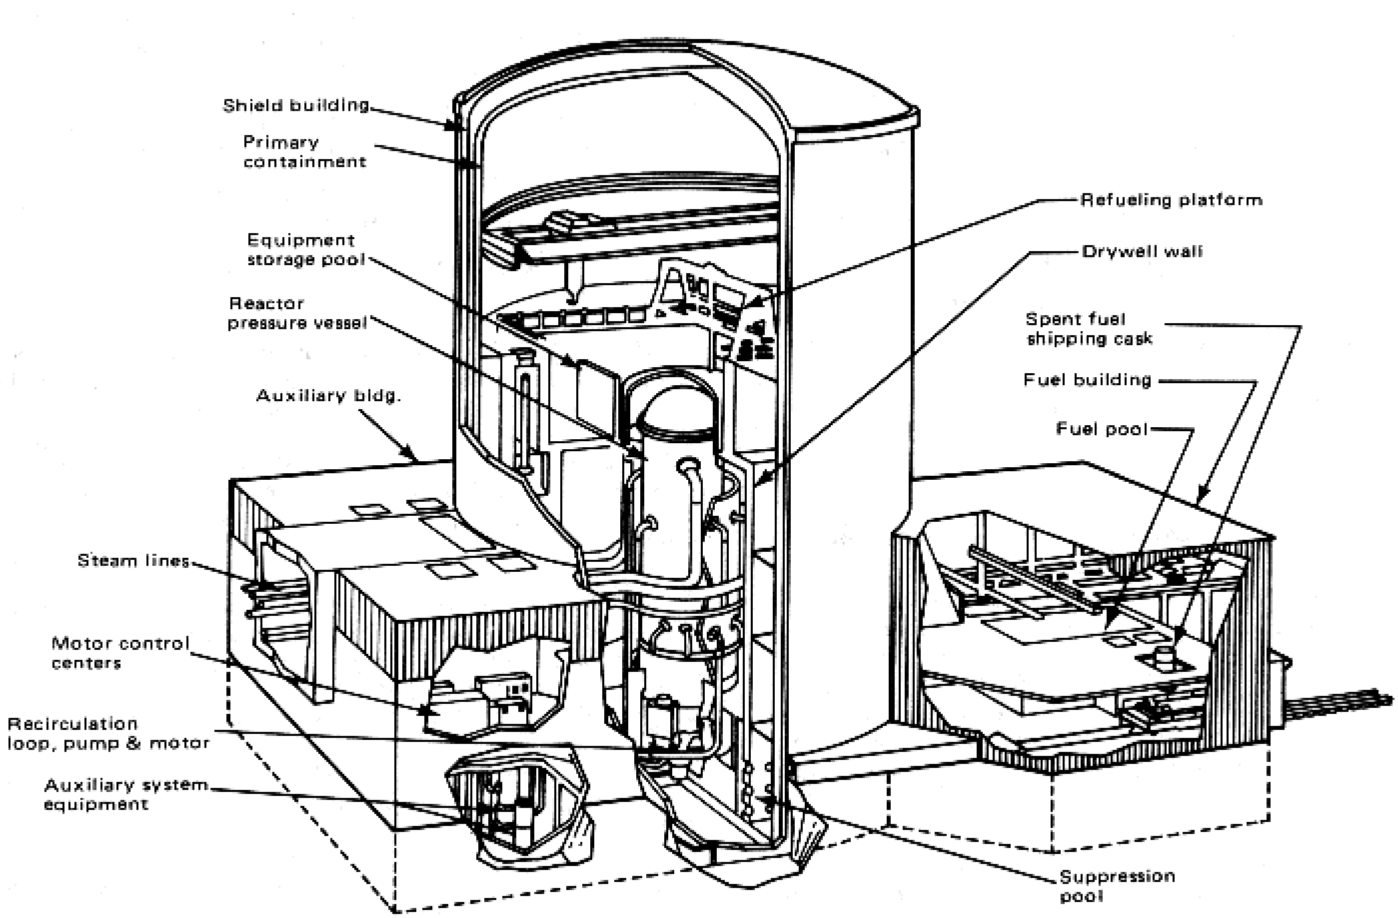

Figure 2-1 Mark III reactor building, fuel building, and auxiliary building.

2-2

For these three types of facilities, safety to the lives of on-site construction and operating personnel and loss of property shall be given consideration as specified in Chapter 17 and elsewhere in this standard.

2-3

For primary and secondary facilities the cost of lost revenue and replacement power in addition to property loss shall be factored into the fire hazard analysis for determining the cost/benefit ratio for selecting the appropriate fire protection systems.

2-4*

A fire hazard analysis shall be developed that will define the fire hazards that can exist and describe the loss limiting criteria to be used in the design of the facility. The fire hazard analysis shall take into consideration the basic data of the plant such as the functional subdivision of the facility, the controlled zones that have limited access, and the general plant layout of equipment or systems to develop the fire zone and the ratings of fire barriers.

Chapter 3 Inventory of Flammable and Combustible Materials

3-1

Combustible materials in both large and small concentrations will be present in nuclear power plants, as in most other industrial plants, and it shall be assumed that outbreaks of fire occur for a variety of reasons.

3-2

For the purpose of assessing the fire loading, an inventory of all flammable and combustible materials shall be made for each fire area, identifying the location, type, quantity, and form of the materials. The materials shall be classified into:

(a) *Flammable and Combustible Materials.* Typical examples of flammable and combustible materials found in a nuclear power plant are:

Conventional fuels for emergency power units, auxiliary boilers, etc.
Lubricants and hydraulic oil.
Insulating materials (thermal and electric).
Building materials (incl. PVC and other plastics).
Filtering materials (e.g., oil bath filters, charcoal, etc.).
Cleansing materials.
Paints and solvents.
Packaging materials (e.g., bitumen, etc.).
Neutron shields (if organic materials).
Clothing.

(b) *Flammable Gases.* Typical examples of flammable gases found in a nuclear power plant are:

Hydrogen for generator cooling, for coolant conditioning of gas-cooled reactors, and from battery charging.

Propane or other fuel gases.

O_2 and H_2 by radiolysis in the core and addition of H_2 for improved recombination.

Gas for cutting and welding.

(c) *Combustible Radioactive Substances.* Typical examples of radioactive substances external to the reactor are:

Sealed radioactive materials, such as irradiated and/or plutonium containing fuel elements, irradiated control rods, neutron sources, etc.

Unsealed radioactive material, such as ion exchanger fillings and filter cartridges that have become loaded with radioactive substances, radwaste materials, etc.

3-3

While assessing the hazardous substances, ways and means of transporting the supplies of consumable goods on the site shall be considered.

3-4

Temporary but predictable and repetitive concentrations of combustible materials shall also be considered. These may include:

(a) Replacement of lubricating or hydraulic oils.

(b) Repainting equipment or structures.

(c) Replacement of combustible filter materials.

(d) Scaffolding or dunnage necessary to maintain or replace equipment.

(e) Spare equipment in shipping crates or boxes awaiting installation.

Chapter 4 Control of Combustible Material

4-1

Combustibles, other than those that are an inherent part of operation, shall be restricted to protected compartments or spaces.

4-2

As part of the protective measures, consideration shall be given to reducing the fire loading of contents in primary or secondary facilities by reducing the amount of combustible materials, wherever possible, as indicated in the following design features:

(a) Provision of separate piping systems for the lubricating system and control system of the turbine generators.

(b) Use of an approved low hazard synthetic hydraulic fluid in the control systems.

(c) Use of approved noncombustible insulation materials on components.

4-2.1

Flammable and combustible liquid storage and use shall be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*. Where oil-burning equipment, stationary combustion engines, or gas turbines are used, they shall be installed and used in accordance with NFPA 31, *Standard for the Installation of Oil-Burning Equipment*, or NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*, as appropriate.

4-2.2 Hydrogen.

The storage and use of hydrogen shall be in accordance with NFPA 50A, *Standard for Gaseous Hydrogen Systems at Consumer Sites*.

4-2.3

Flammable and combustible liquid and gas piping shall be in accordance with ANSI B31.1 or ANSI B31.7, including Addenda a-1972, b-1971, and c-1971, as applicable.

Chapter 5 Construction Materials and Fire Loading in Buildings

5-1

The use of plastics such as polyurethane and polyvinyl chloride (PVC) shall be minimized and used generally at locations totally inaccessible to ignition and effects of fire exposure.

NOTE: Halogenated plastics, such as polyvinyl chloride (PVC), release chlorine and hydrogen chloride gas during a fire; these gases are toxic and corrosive.

5-2

Construction materials for nuclear power plants shall be classified by at least one of the following tests:

(a) NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

(b) NFPA 251, *Standard Method of Fire Tests of Building Construction and Materials*.

5-2.1

Certain materials of construction that do not meet the definition of noncombustible or limited combustible may have to be used in a nuclear power plant, and thus the location in the plant, the amount exposed to ignition, and the proposed fire protection system shall be justified in writing and the approval of the plant fire protection manager and the authority having jurisdiction shall be obtained.

5-3

Wall and structural components, thermal insulation materials, radiation shielding materials, and soundproofing shall be noncombustible, limited combustible, or listed by a testing laboratory for flame spread, smoke, and fuel contribution of 25 or less in its use configuration.

5-4

Suspended ceilings, including light diffusers, and their supports shall be of noncombustible or limited combustible construction. Electrical wiring above suspended ceilings shall be in metallic conduit or solid bottom, solid covered ferrous raceways. Otherwise concealed spaces shall be devoid of combustibles.

5-5

Roof coverings shall be Class A as determined by tests described in NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*. Metal roof deck construction shall be Class I (Factory Mutual Approved) or “fire-acceptable” (as tested by Underwriters Laboratories Inc.).

5-6

Transformers installed inside of buildings shall be either dry type or insulated and cooled with an approved liquid, unless installed in vaults in accordance with Article 450 of NFPA 70, *National Electrical Code*.®

5-7

Cooling towers constructed of combustible or nonapproved construction shall be protected with deluge sprinkler systems in accordance with NFPA 214, *Standard on Water-Cooling Towers*. Fire hydrants shall be operational at the cooling tower site prior to beginning construction activities.

NOTE: Since cooling towers can be vital to the operation of the plant and reconstruction can be lengthy, noncombustible construction should be used.

Chapter 6 General Building Arrangement

6-1 General Fire Area Requirements.

6-1.1

The nuclear power plant shall be subdivided into separate fire areas to minimize the risk of spread of fire and the resultant consequential damage from corrosive gases, fire suppression agents and smoke and contamination from radioactive substances. In addition, subdivisions shall provide access for manual fire suppression activities.

6-1.2

In multi-unit plants, each unit shall be separated from the other either by distance or fire barriers. The distance or fire barrier rating shall be determined from the fire hazard analysis. (*See NFPA 80A, Recommended Practice for Protection of Buildings from Exterior Fire Exposures*.)

6-2 Specific Fire Separation Requirements.

6-2.1

An approved fire barrier having a fire resistance rating of 3 hours, with automatic- or self-closing fire doors having a fire protection rating of 3 hours, and with approved penetration protection, shall be provided as follows:

(a) To separate all contiguous buildings, such as turbine, reactor containment, auxiliary fuel handling, control, radwaste, service, administration, and other areas as dictated by reactor design and fire hazard analysis.

(b) To isolate turbine generator lube oil conditioning or system room and lube oil storage tank from turbine buildings and adjacent areas.

(c) To isolate emergency diesel generator rooms or buildings (emergency power generating areas) from each other and adjacent plant areas.

(d) To separate diesel fire pumps from other pumps in the same pumphouse.

(e) To separate all areas with concentrations of cables, such as cable spreading rooms, cable tunnels, cable penetration areas, cable shafts or chases, included within the reactor containment, from adjacent areas.

(f) To isolate auxiliary boiler rooms from adjacent areas.

6-2.2

Where fire barriers are constructed to prevent vertical spread of fire, stairways, elevator shafts, and trash chutes shall be enclosed with walls or partitions having a fire resistance rating of 2 hours. Openings in such walls or partitions shall be protected with approved automatic- or self-closing fire doors having a fire protection rating of $1^1/_2$ hours.

6-2.3

Buildings shall be protected from exposure fires involving oil filled transformers by locating the transformer casing, conservator tank, and cooling radiators at least 50 ft (15.2 m) from buildings or by providing a two-hour fire barrier between transformers and exposed buildings (*see Figure 6-2.3*). A one-hour fire barrier or a distance of 30 ft (9.1 m) shall be provided between adjacent transformers. Means shall be provided to contain oil spills.

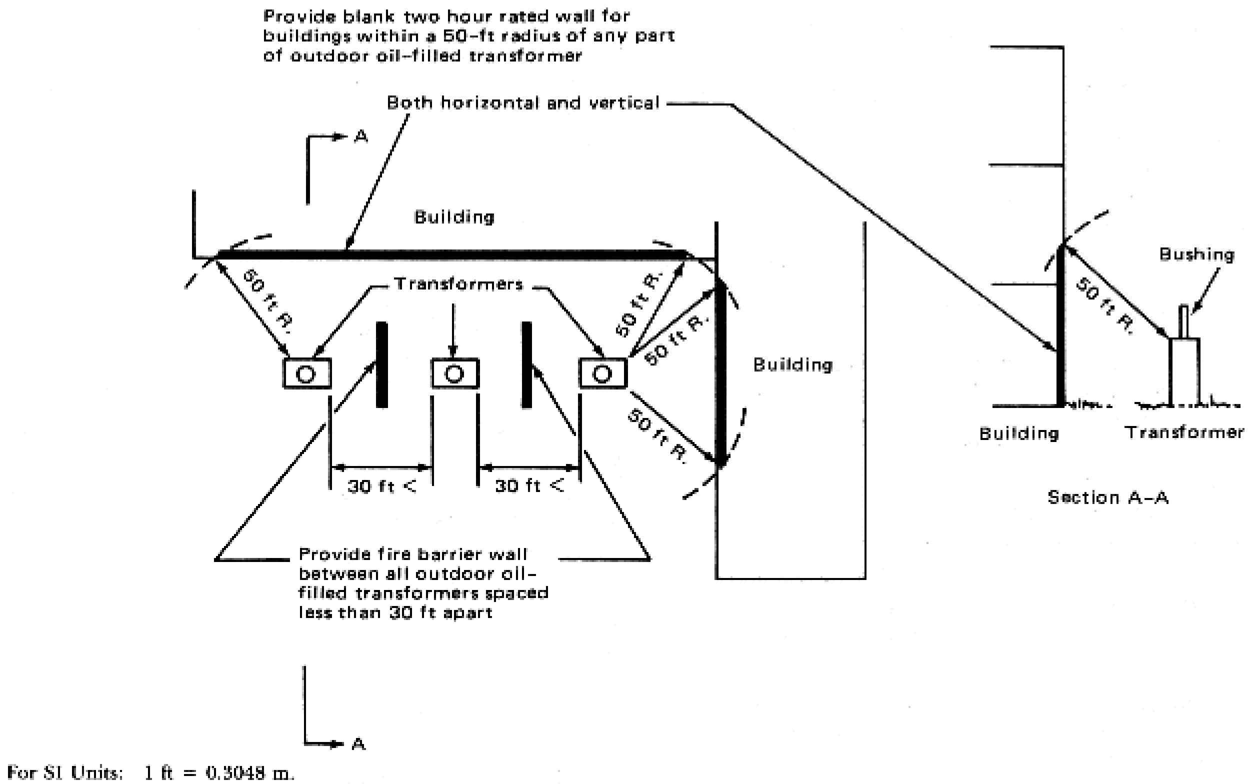

Figure 6-2.3.

6-3 Protection of Openings in Fire Barriers.

6-3.1 Electrical and Mechanical Penetrations.

Where electrical or mechanical equipment, other than ventilation ducts, must penetrate a fire barrier, the penetration shall be sealed (firestopped) with a material or device that maintains the required fire resistance rating of the fire barrier. The penetration seal (fire stop) shall be qualified in accordance with NFPA 251, *Standard Methods of Fire Tests of Building Construction and Materials*, except as modified herein:

(a) Temperatures on the unexposed surfaces of the penetration seal (fire stop) shall be measured and reported to the authorities having jurisdiction. The temperatures on the unexposed side for the metallic parts of the penetration (e.g., cable trays, conductors, pipe, etc.) shall also be measured and reported to the authorities having jurisdiction. The results of the test shall be incorporated into the plant's fire hazard analysis. (*See Section 2-4.*)

(b) Immediately following the termination of the fire endurance test a hose stream test shall be conducted using the NFPA 251 solid-stream test or a spray-stream test conforming to the following criteria:

1. Spray nozzle that produces a long-range, narrow-angle (not exceeding 30 degrees) high velocity spray.

2. Nozzle shall discharge a minimum of 75 gpm at 75 psi at 10 ft (4.7 liters/sec at 517 kPa at 3 m) from the test specimen.

3. Duration of application shall be not less than $2^1/_2$ minutes for every 100 sq ft (9 m^2) of area.

(c) The penetration seal (fire stop) shall be determined acceptable provided that:

1. Fire does not propagate to the unexposed side of the test assembly nor shall there be any visible flaming on the unexposed side.

2. Temperature readings on the unexposed side shall not be high enough to ignite combustible material as evaluated in the fire hazard analysis.

3. Penetration seal does not permit projection of water from hose stream test.

NOTE: If electrical or mechanical chases or shafts pass through a fire area without opening into that area, the penetration seals at fire barriers are not required provided the chases or shafts are enclosed with assemblies having fire resistance ratings not less than those of the fire barriers through which they pass.

6-3.2 Penetrations for Ventilation Ducts.

Where ventilation ducts must penetrate fire barriers, the ducts and opening protections shall comply with the provisions of Chapter 7 of this standard.

6-4 Reliability Considerations.

6-4.1

In accordance with the scope of this standard, it shall be recognized that continuing power production consideration dictates additional fire subdivision of the plant beyond that required for nuclear safety.

NOTE 1: The subdivision into fire areas for redundant nuclear safety systems is covered by other documents. (*See Appendix B.*)

NOTE 2: A fire that might be capable of damaging only one division of a redundant system, and therefore be acceptable from the standpoint of nuclear safety, may not be acceptable from a standpoint of forced plant outage. Additional fire protection systems or fire barriers may be required.

6-4.2

When evaluating the length of plant outage, as a result of possible fire, consideration shall be given to the length of time required to satisfy the demands of all of the authorities having jurisdiction for examining causes of the fire, planning of the repairs and reconstruction, testing, and documentation of the adequacy of the restoration process.

6-4.3 Cable Construction.

6-4.3.1 Cable insulating materials represent a major source of fire loading throughout the plant, and special consideration shall be given to their installation and protection.

6-4.3.2 As a minimum requirement, cable construction shall meet the fire and flame test requirements of IEEE No. 383. Meeting the requirements of IEEE No. 383 shall not eliminate the need for protection as specified in this standard.

Chapter 7 Heating, Ventilating, and Air Conditioning

7-1 Introduction.

Ventilation of a nuclear power plant involves balanced air differentials between plant areas, comfort ventilation, and heat removal from areas where heat is generated by equipment. This need also includes fire area isolation and smoke removal equipment, as well as equipment for filtering radioactive gases. The design of ventilation systems is further complicated by the seismic, tornado, and missile criteria for building penetrations.

7-2 Basic Standards.

NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*; NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*; and NFPA 204M, *Guide for Smoke and Heat Venting*, are the basic standards that shall be followed for the design, installation, and operation of the ventilation systems necessary for normal and emergency operation of the plant except as modified below.

7-3 General Requirements.

7-3.1 Smoke and Corrosive Gas Removal.

7-3.1.1* Automatic shutdown of ventilation systems by temperature or smoke detectors as prescribed by applicable NFPA standards in the following buildings shall be consistent with nuclear safety and safety of on-site personnel:

(a) Reactor building.

(b) Auxiliary building.

(c) Control building.

(d) Turbine building.

(e) Intake pumping station.

(f) Emergency service water pumping station.

(g) Condenser circulating water pumping station.

(h) Electrical control and communications building.

(i) Fuel building.

(j) Emergency power generating building.

7-3.1.2 Smoke, corrosive gases, and the nonradioactive substances that might be freed by the fire shall be vented from their place of origin directly to a safe location. Radioactive materials that might be released by the fire shall be confined, removed from the exhaust ventilation air stream, or released under controlled conditions.

7-3.1.3 Ventilation systems designed to exhaust smoke or corrosive gases shall be evaluated to ensure that inadvertent operation or failures will not violate the controlled areas of the plant design.

7-3.1.4 Smoke ventilation shall be provided for fire areas based upon the fire hazard analysis.

NOTE 1: Separate smoke ventilation systems are preferred; however, smoke venting can be integrated into normal ventilation systems using automatic or manually positioned dampers and motor speed control.

NOTE 2: The lack of smoke and heat venting in areas of relatively high combustible loading can result in significant damage to structural components.

NOTE 3: Automatic or manual actuation of smoke and heat venting will be determined by the fire hazard analysis.

Smoke ventilation from areas that may contain radioactive substances shall not be ventilated outside the building. These smoke ventilation systems shall be connected to gas treatment systems to preclude release of radioactive substances.

7-3.1.5 The fresh-air supply intakes to all areas shall be located remotely from the exhaust air outlets and smoke vents of other fire areas to minimize the possibility of contaminating the intake air with the products of combustion.

7-3.1.6 Enclosed stairwells shall be designed to minimize smoke infiltration during a fire.

NOTE: Stairwells serve as escape routes and fire fighting access routes. Suitable methods of ensuring a smoke-free stairwell include pressurization of stairwells (*see NFPA 90A*) and the construction of smokeproof towers (*see 5-2.3 of NFPA 101,® Life Safety Code.®*)

7-3.1.7 When natural-convection ventilation is used, a minimum ratio of vent area to floor area shall be one to 200 except in oil hazard areas where a one to 100 ratio shall be provided.

NOTE: When mechanical ventilation is used, 300 cfm (8.5 m^3/min) is equal to 1 sq ft (0.09 m^2) of natural convection vent area.

7-3.1.8 To prevent corrosion that might be caused by direct release of chemicals in case of fire, the acids and alkalines used for the primary coolant treatment plant and stored in appreciable quantities on the site shall be protected so as not to increase the risk of damage in case of a fire.

7-3.1.9 The power supply and controls for mechanical ventilation systems shall be located outside the fire area served by the system or protected from fire damage.

7-3.2 Duct Systems.

7-3.2.1 Plastic ducts, including fire retardant types, shall not be used for ventilating systems.

7-3.2.2 Ventilation ducts that pass through fire areas that they do not serve shall not degrade the fire integrity of the fire rated enclosure.

NOTE: Fire dampers or fire doors compatible with the rating of the barrier may be required at the duct penetrations to the fire area. (*See 7-3.2.3.*)

7-3.2.3 Fire dampers shall be provided to prevent the passage of smoke, heat, or flame through ventilation ducts from one area to another.

7-3.2.3.1 Approved fire dampers having a rating of $1^1/_2$ hours shall be installed where ventilation ducts penetrate fire barriers having a required fire resistance rating of 2 hours or less. Where ventilation ducts penetrate required 3-hour fire barriers, approved fire dampers having a fire protection rating of 3 hours shall be installed.

Exception: Fire dampers are not required for ventilation duct penetrations where shutdown of the ventilation system is not allowed.

7-3.2.4 Fire dampers shall be equipped with thermal elements. The closure of fire dampers shall be guaranteed by mounting the damper directly into the separating wall or by protecting the duct up to the damper according to the fire resistance of the separating wall structure.

7-3.2.5 Interconnections of individual fire areas via the ventilation system shall be avoided insofar as possible. Where this is not possible, the necessary precautions shall be taken to prevent the spread of smoke and fire by such routes.

NOTE: Fire dampers in the interconnecting ventilation ducts should be provided when the ventilation system cannot be sectioned off in the normal manner. (*See 7-3.2.3.*)

7-3.2.6 False floors or suspended ceilings shall not be employed as common pressure equalizing chambers for redundant ventilation systems but may be used for distribution of air to the corresponding room.

7-3.3 Filters.

7-3.3.1 Air entry filters shall have noncombustible filter media. They shall produce a minimum amount of smoke (UL Class 1) when subjected to heat. In order to decrease the fire hazard of these filters and of oil bath type filters, only approved fire-resistive adhesives and oils with an open-cup flash point equal to or greater than 464°F (240°C) and that do not produce appreciable smoke shall be used. HEPA filters shall meet the requirements of UL 586.

7-3.3.2 Fire suppression systems shall be installed to protect filters that collect combustible material, unless the elimination of such protection is justified by the fire hazard analysis.

7-3.4 Special Equipment for Emergency Personnel.

Self-contained breathing apparatus using full-face, positive-pressure masks approved by NIOSH (National Institute for Occupational Safety and Health) shall be provided for fire brigade and control room personnel.

NOTE: Control room personnel may be furnished breathing air by a manifold system piped from a storage reservoir, if practical. Service or operating life should be a minimum of one-half hour for the self-contained units. At least two extra air bottles should be located on site for each self-contained breathing unit. In addition, an on-site 6-hour supply of reserve air should be provided and arranged to permit quick and complete replenishment of exhausted supply air bottles as they are returned. If compressors are used as a source of breathing air, only units approved for breathing air should be used.

Chapter 8 Fire Prevention Measures

8-1 Administrative Procedures and Controls.

NOTE: This section provides criteria for development of administrative procedures and controls necessary for the execution of the fire prevention and protection activities and practices for the operating plant. Included herein are the minimally accepted actions required of cognizant plant management to assure the performance of fire protection systems and personnel and the compliance with the fire prevention program.

8-1.1

The plant manager or delegated fire protection manager shall be responsible for assuring that the fire hazards analysis is periodically updated.

8-1.2

The plant manager or delegated fire protection manager shall be responsible for the following:

(a) Develop, implement, and periodically update as necessary a fire brigade plan in accordance with Chapter 14.

(b) Maintain housekeeping in such a manner so as to minimize the probability of fire causing loss of life or property damage.

(c) Develop, implement, and periodically update as necessary an emergency evacuation plan for all personnel.

(d) Develop, implement, and periodically update as necessary a welding and cutting safety procedure using NFPA 51B and NFPA 241 as guides. (*See Chapter 15.*)

(e) Restrict smoking and other sources of ignition to properly designated and supervised safe areas of the plant.

(f) Develop, implement, and periodically update as necessary a fire prevention surveillance plan integrated with periodic recorded rounds to all accessible unattended sections of the plant.

(g) Coordinate the periodic testing of all systems and equipment affecting fire prevention and fire protection in accordance with the applicable NFPA standards and/or the manufacturers'/installers' instructions and procedures to include maintenance of appropriate documentation.

(h) Develop an alternate protection plan for those instances when it becomes necessary to remove any fire protection equipment or system from service.

(i) Fire investigation and the coordination of all plant fire reporting. Responsibilities including reviewing fire reports, taking corrective action, and making the proper distribution of the reports.

(j) Conduct periodic inspections of the plant. A prepared checklist shall be used for the inspection. The areas of primary containment and high radiation areas normally inaccessible during plant operation shall be inspected as plant conditions permit but at least during each refueling outage. The results of each inspection shall be documented and retained for a period of two years.

8-1.3

Plant administrative procedures shall specify appropriate requirements governing the storage, use, and handling of flammable liquids and gases.

8-1.4

Plant administrative procedures shall specify appropriate requirements governing the control of electrical appliances, i.e., portable electrical heaters in critical areas.

8-1.5

The reduction and control of temporary fire loads in the plant is essential to provide defense-in-depth protection. As a minimum, plant administrative procedures shall require that the total fire loads, including temporary and permanent, will not exceed those quantities established for extinguishment by permanently installed fire protection systems and equipment except in approved controlled conditions. Under such conditions, the plant fire protection manager shall evaluate temporary fire loads using appropriate documented guidelines and shall be responsible for ensuring that applicable additional personnel and/or fire protection equipment is provided when limits are exceeded. The fire protection manager or designated representative shall conduct weekly walk-through inspections to ensure implementation of required controls. During major maintenance operations the frequency of these walk-throughs shall be increased to daily. These inspections shall be documented, and the records retained for a period of two years.

Transient fire loads, when allowed, shall be controlled and shall require the implementation of additional protective measures such as supplemental portable fire equipment, fire retardant impregnation, and fire watches, depending on the types and quantities of the transient combustibles and the potential fire exposure they present to the plant. Particular attention shall be given to the control of halogenated plastics. When the work is completed, the plant fire protection manager shall have the area inspected to confirm that the transient fire loads have been removed from the area. Extra equipment shall then be returned to its proper location. The results of this inspection shall be documented and retained for a period of two years.

8-1.6

Plant administrative procedures shall specify that all wood routinely used in the plant shall be approved pressure impregnated fire retardant type prior to being introduced into the plant.

8-1.7

Plant administrative procedures shall require an inplant review and prior approval of all work plans to assess potential fire hazard situations. Where such conditions are determined to exist special precautions shall be taken to define appropriate conditions under which the work is authorized.

8-2 Lightning Protection Measures for Buildings.

The plant shall be equipped with an approved lightning protection system. (*See NFPA 780, Lightning Protection Code.*)

8-3 Prevention Measures for Plant Equipment.

8-3.1

The ignition of leaked or spilled oil shall be minimized by:

(a) Keeping the oil from contact with hot parts of the steam systems (wall temperature ò ignition temperature), such as steam pipes and ducts, entry valve, turbine casing, reheater, and by-pass valve.

NOTE: Oil pipes should be located below steam lines.

(b) Using suitable electrical equipment.

(c) Sealing the insulation of hot plant components to prevent oil saturation.

(d) Use of concentric piping.

8-3.2

The ignition of gas shall be minimized by:

(a) Providing electrical installations suitable for hazardous (classified) locations as defined in Article 500 of NFPA 70, *National Electrical Code*, in those areas where the fire hazard analysis shows these locations to exist.

8-3.3

Ignition of flammable materials in auxiliary equipment shall be minimized by:

(a) Providing approved combustion safeguards on boilers and other fossil fuel-fired equipment in accordance with NFPA 85C, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boiler-Furnaces,* and NFPA 8501, *Standard for Single Burner Boiler Operation*.

(b) Constructing and installing equipment containing flammable or combustible liquids in accordance with NFPA 30, *Flammable and Combustible Liquids Code*, Chapter 5.

(c) Equipping all oil-filled transformers with:

1. High oil temperature limit switches in accordance with the manufacturer's recommendations, with an audible and visual signal or an automatic device to de-energize the transformer.

2. An overcurrent protection device.

3. A differential relay.

4. A gas detector and fault over-pressure relays with a warning signal and automated shut-down for equipment over 10 MW.

5. Lightning protection.

(d) Equipping generators with warning signals, automated shutdown, and the following protective devices:

1. Overvoltage or undervoltage.

2. Overcurrent.

3. Differential relays.

4. Reverse power relays.

5. Proper performance of systems providing cooling and sealing gas.

(e) Installing only air circuit breakers, low oil content circuit breakers, or circuit breakers filled with sulfur hexafluoride (SF_6) or similar nonflammable fluids when located indoors.

8-4 Prevention Measures for Operation of the Plant.

(*See Chapter 15*.)

Chapter 9 Fire Signaling Systems

9-1 Fire Signaling Systems.

9-1.1

Fire signaling systems shall be provided in all areas of the plant as required by the fire hazard analysis. The requirements of this chapter constitute the minimum acceptable protective signaling system functions when used in conjunction with NFPA 72, *Standard for the Installation, Maintenance, and Use of Protective Signaling System*. All components of the fire signaling systems shall be of an approved type.

9-1.2

The signaling system's initiating device and signaling line circuits shall provide emergency operation for fire detection, fire alarm, and water flow alarm during a single break or a single ground fault.

NOTE: See NFPA 72 for definitions of signaling line circuits and initiating device circuit.

9-1.3

Fire signaling equipment used for fixed fire suppression systems shall give audible and visual alarm and system trouble annunciation in the plant control room and the plant security office. A general alarm annunciation would be acceptable in one of the two locations. Local alarm shall be provided in the affected fire zone and to other locations as may be required by the authority having jurisdiction.

9-1.4

Audible signaling appliances shall produce a distinctive sound, used for no other purpose. (*See NFPA 72*.) Audible signaling devices shall be located and installed so that the alarm can be heard above ambient noise levels.

Exception: Visual signaling appliances may be used to supplement audible appliances in the protected areas. (See Section 9-3.)

9-1.5

Plant control room or plant security personnel shall be trained in the operation of all fire signaling systems used in the plant. (*See 9-1.3*.) This training shall include the ability to identify any alarm zone or fire protection system that is operating.

9-1.6

Fire signaling equipment and actuation equipment for the release of fixed fire suppression systems shall be connected to power supply sources in accordance with the requirements of NFPA 72.

9-1.7

Manual fire alarm boxes shall be installed as required by the fire hazard analysis. (*See NFPA 72*.) Where manual release devices are installed for the purpose of releasing an extinguishing agent in a fixed fire suppression system, they shall be clearly marked for that purpose.

9-1.8

All signals shall be permanently recorded in accordance with NFPA 72.

9-2 Fire Detectors.

Automatic fire detectors shall be selected and installed in accordance with:

(a) NFPA 72E, *Standard on Automatic Fire Detectors*.

(b) The design parameters required as a result of the fire hazard analysis of the plant area.

(c) The additional requirements of this standard.

When the fire hazard analysis shows that fire detection is needed, Table 9-2 shall be used in selecting the type of detectors to be installed. Additional considerations prior to selection shall include (1) response characteristics, (2) maintenance requirements, (3) testing requirements, (4) adaptability to environment, and (5) accessibility.

NOTE: This table is intended to show the types of fire detectors that have application to hazard areas listed. In some cases, more than one type of detector should be considered by the designer for application in a specific hazard area. Within each generic type of detector (*see NFPA 72E for detector types*) differences among specific principles of operation may suggest preference of a specific detector for specific hazards.

Table 9-2

Plant Area	Combustible Loading/ Fire Hazard (See Note 1)	Anticipated Fire Development	Obstruction Congestion or Construction	Ceiling Height	Venti-lation	Radioactive Contamina-tion or Corrosion	Ambient Tempera-ture	Acceptable Detector Choice (See 9-2) (See Note 2) *S	*T	*F	*O

NOTE 1: (comb, loading/fire hazard column)
The combustible loading for each fire area represents combustibles normally expected in these areas excluding transient combustibles, which shall be identified by the detailed fire hazard analysis of the respective plant area.
NOTE 2: "T" column under detectors
Automatic sprinklers, when selected as a suppression system from Table 10-1.2, also act as thermal, spot-type detectors. This could occur if sprinklers are used in a wet pipe, dry pipe, preaction wet pilot or preaction dry pilot configuration.
*Detector Designations: S — Smoke, T — Temperature, F — Flame, O — Other

9-3 Fire Signaling System Display and Supervision.

The fire signaling system display panel shall be located in the plant control room or the plant security office. Annunciation circuits connecting zone, main control, and remote annunciation panels shall be electrically supervised.

9-4 Maintenance, Inspection, and Acceptance Testing of Fire Signaling Systems.

Maintenance, inspection, and acceptance requirements shall be in accordance with appropriate NFPA standards for detection devices and signaling systems. The authority having jurisdiction shall be consulted on all alterations and additions to the system under its supervision.

9-5 Communications.

9-5.1

The plant public address system shall be available on a priority basis for fire announcements, directing plant fire brigades, and fire evacuation information.

9-5.2

Radio, telephone, or other 2-way communication systems shall be provided.

Chapter 10 Fire Suppression Systems

10-1 General.

10-1.1

Automatic suppression systems shall be provided in all areas of the plant as required by the fire hazard analysis. Except as modified in this chapter, the following NFPA standards shall be used:

NFPA 11, *Standard for Low Expansion Foam and Combined Agent Systems*

NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

NFPA 12, *Standard on Carbon Dioxide Systems*

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*

NFPA 13, *Standard for the Installation of Sprinkler Systems*

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*

NFPA 17, *Standard for Dry Chemical Systems.*

10-1.2

The extinguishing systems chosen shall be based on the design parameters required as a result of the fire hazard analysis. When the fire hazard analysis shows that a fixed extinguishing system is needed, Table 10-1.2 shall be used in selecting the type of system or combination of systems to be installed.

Table 10-1.2

Area or Hazard to Be Protected	Water Systems			Liquefied Compressed Gases			Foam Systems			Dry Chemical
	Automatic Sprinklers	Preaction Sprinklers	Deluge-Water Spray	Halon 1301	Halon 1211	Carbon Dioxide	Mech.	Foam-Water Systems	High Expansion	
Auxiliary Oil or Gas Boiler Room	X	X					X (oil)	X (oil)		X

Steam Valves (if combustible hydraulic fluid)			X			X				X
Staging, Storage and Warehousing Areas	X	X							X	
Truck and Railroad Bays (other areas of combustible										

NOTE 1: ...re used, means shall be provided for prompt actuation.
NOTE 2: Ceiling sprinklers may be required in addition.
NOTE 3: Release of extinguishing agent shall not be prevented if equipment is operating.
NOTE 4: Under floor only.
NOTE 5: Design concentrations shall be maintained during the entire coast down period.
NOTE 6: Combustible storage should be in metal cabinets.

10-1.3

Selection of extinguishing agent shall be based on:

(a) Type or class of hazard.

(b) Effect of agent discharge on critical equipment such as thermal shock, continued operability, water damage, over-pressurization, cleanup, etc.

(c) Health hazards.

10-1.4

A designated person(s) working in the plant shall be trained in the maintenance, inspection, operation, and emergency actuation of all fixed fire suppression systems installed in the plant, whether automatic or manual.

10-1.5*

Each fire suppression system shall be equipped with approved alarm devices, annunciated locally or in the hazard area. (*See 9-1.3.*)

10-1.6*

All shut-off valves controlling fire suppression systems (*see 10-2.2*) shall be supervised by one of the following methods:

(a) Electrical supervision with an audible signal annunciating in accordance with Chapter 9.

(b) Locking valves open.

10-2 Automatic Sprinkler and Water Spray Systems.

10-2.1

Where water is used as an extinguishing agent, systems shall be designed, installed, and maintained in accordance with the provisions of NFPA 13 and NFPA 15.

NOTE: Hydraulically calculated systems are preferred.

10-2.2

Each system shall have an independent connection to the plant yard main and be equipped with an approved indicating type control or shut-off valve.

NOTE: Multiple sprinkler and standpipe systems may be supplied by interior headers or fire protection loops. When provided, such headers or loops are considered an extension of the yard main system and should be provided with at least two connections to the yard main. The arrangement should be supplied and valved so that no single impairment can affect sprinkler and hose protection at the same time.

10-2.3

Drainage of all buildings shall be assessed to assure acceptable run-off or retention of fire protection water and to minimize damage.

NOTE 1: Equipment vulnerable to water damage should be placed on pedestals and floor openings should be curbed or sealed.

NOTE 2: The installation of a complete, properly engineered automatic sprinkler or water spray system in a building will generally reduce the draining and retention tank requirements, as compared to a building that relies primarily on manual fire fighting.

10-3 Liquefied Compressed Gas Suppression Systems.

10-3.1

In areas where appreciable Class C hazards exist and where the use of other agents might result in equipment malfunction or damage as determined by the fire hazard analysis, liquefied compressed gas extinguishing agent systems shall be installed. These systems, where required, shall be designed, installed, and maintained in accordance with the appropriate agent standard as follows:

Halon 1301 — NFPA 12A

Halon 1211 — NFPA 12B

Carbon Dioxide — NFPA 12.

10-3.2

When liquefied compressed gas extinguishing agent systems are used, they shall be automatically actuated by an approved method of detection meeting the requirements of NFPA 72 and NFPA 72E. To ensure rapid detection, particular attention shall be given to the choice of actuation means, the air flows usually involved, and the heat release rates for the hazard under fire conditions.

NOTE 1: For carbon dioxide total flooding systems that are automatically actuated in normally occupied areas, a predischarge alarm and time delay are required to allow for personnel evacuation of the area.

NOTE 2: Halon 1211 is not acceptable for total flooding use in normally occupied areas.

NOTE 3: Electrical equipment need not be de-energized prior to the discharge of these extinguishing agent systems, but shut-down is desirable if it can be accomplished.

10-4 Foam Systems.

10-4.1

Where fires involving flammable liquids and gases under pressure are likely, foam systems shall not be used. These systems, where required by the fire hazard analysis, shall be designed, installed, and maintained in accordance with the appropriate agent standard as follows:

Low Expansion Foam and Combined Agent Extinguishing Systems — NFPA 11

Medium- and High-Expansion Foam Systems — NFPA 11A

Deluge Foam-Water Sprinkler and Foam-Water Spray Systems — NFPA 16

NOTE 1: Foam systems may be used in areas where appreciable Class B hazards exist, especially where flammable liquid fuel in-depth or spills are likely.

NOTE 2: High-expansion foam systems are particularly suited for total flooding applications, but should not be used in normally occupied areas.

10-4.2

Foam systems shall be designed to be automatically actuated by an approved method of detection meeting the requirements of NFPA 72 and 72E.

10-4.3

Foam systems shall not be used to protect hazards involving energized electrical equipment.

10-5 Dry Chemical Systems.

10-5.1

Where appreciable Class B hazards exist, dry chemical systems shall be considered as appropriate protection.

NOTE 1: Dry chemical systems, utilizing multipurpose dry chemical, are also effective on Class A hazards, provided that “deep-seated” fires are not likely.

NOTE 2: Dry chemical systems may be used in conjunction with AFFF in a combined agent application, where securing action is required in addition to extinguishment.

NOTE 3: Electrical equipment need not be de-energized prior to system discharge, but shut-down is desirable if it can be accomplished.

NOTE 4: Dry chemical systems are not recommended for use in hazard areas where sensitive electrical equipment is located, due to the potential for damage to the equipment from the dry chemical and its products of decomposition where moisture and high temperatures are likely.

10-5.2

Where dry chemical systems are required by the fire hazard analysis, they shall be designed, installed, and maintained in accordance with the requirements of NFPA 17.

10-5.3

Dry chemical systems shall be designed to be automatically actuated by an approved method of detection meeting the requirements of NFPA 72 and 72E.

Chapter 11 Yard Mains and Hydrants

11-1

Outdoor fire hydrants and associated equipment shall be provided on the plant site for fire suppression undertaken by the plant fire brigade in the event of a major fire.

11-2

The yard mains shall be looped and shall be of sufficient size to meet the flow requirements specified in Section 12-4.

NOTE 1: Twelve-inch diameter cement-lined pipe is recommended. (*See NFPA 24, Standard for the Installation of Private Fire Service Mains and Their Appurtenances.*) Main sizes should be designed to encompass any anticipated expansion.

NOTE 2: The underground main should be arranged such that any one break will not put both a fixed water extinguishing system and hose lines protecting the same area out of service.

11-3

Sufficient indicator valves shall be installed to provide adequate sectional control of the fire water supply.

11-4

A sufficient number of hydrants shall be installed to provide two streams for every part of the interior of each building not covered by standpipe protection and to provide hose stream protection for every part of each building. There shall be sufficient hydrants to concentrate the required fire flow about any important structure with no hose line exceeding 500 ft (152 m) in length. Each hydrant shall have its own gate valve.

11-5

American National Fire Hose connection screw thread shall be specified. (*See NFPA 1963, Standard for Screw Threads and Gaskets for Fire Hose Connections.*)

11-5.1

Where threads of responding fire departments differ, adapters shall be provided at the hydrants.

Chapter 12 Water Supply

12-1

The water supply system for the permanent fire protection installation shall be determined by the fire hazard analysis.

12-2

A water supply shall be provided during the initial construction period as specified in 16-3(b).

12-3

The fire main system piping shall not serve service water system functions. The fire water loop shall meet the construction requirements of NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

12-4

The water supply for the permanent fire protection installation shall be based on the maximum automatic sprinkler or fixed water spray system demand, with simultaneous flow of 750 gpm at grade (2835 L/min) for hose streams and the shortest portion of the fire loop main out of service.

12-4.1

The use of multiple approved fire pumps shall be based on supplying the demand required in Section 12-4 with the largest pump out of service, utilizing different power sources.

12-4.2

Fire pumps shall meet the requirements of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and shall be automatic starting.

12-5

An automatic pressure maintenance pump (jockey pump) or a head tank shall be provided to keep the fire water main pressure at approximately 10 psig (68.9 kPa) above the start pressure setting of the fire pump(s).

12-6

Pumps shall take suction from acceptable sources of water (*see NFPA 20*). If the source is from tanks, at least two tanks shall be provided and each tank shall be sized to contain a minimum 2-hour fire water flow demand. Where tanks are used, these tanks shall be automatically filled from a source capable of providing a 2-hour supply for the fire protection requirement in 8 hours. Fire water supply tanks shall comply with NFPA 22, including freeze protection requirements.

NOTE: The 8-hour requirement for refilling may be reduced or eliminated if the initial supply exceeds the 2-hour supply requirement on a volume/ratio basis.

12-7

Salt and tidal water shall not be acceptable primary natural water sources.

12-8

The following supervisory signals, where applicable, shall be received in the control room or plant security office in accordance with Chapter 9:

(a) Pump running

(b) Power failure

(c) Failure to start

(d) Water level

(e) Pump room and tank temperatures.

Chapter 13 Portable Fire Extinguishers and Hand Hose Lines

13-1 Portable and Wheeled Fire Extinguishers.

13-1.1

Portable and wheeled fire extinguishers shall be installed, inspected, maintained, and tested in accordance with NFPA 10 and approved or listed by a testing laboratory.

13-1.2

Portable and wheeled fire extinguishers shall be selected for the specific class or classes of hazards using the following descriptive guide.

13-1.2.1 Class “A” Hazards. Portable and wheeled fire extinguishers for protecting Class “A” hazards shall be selected from the following: water types, foam, Halon 1211, or multipurpose dry chemical.

NOTE 1: Portable and wheeled fire extinguishers that contain water, water/antifreeze, or foam should not be used on energized electrical equipment because a personal electrical shock hazard would be present.

NOTE 2: Multipurpose dry chemical is not recommended for installation in locations having sensitive electronic equipment, due to the potential for damage to this equipment from the dry chemical and its decomposition products.

13-1.2.2 Class “B” Hazards. Portable and wheeled fire extinguishers for protection of Class “B” hazards shall be selected from the following: dry chemical types, Halon 1211, foam, or carbon dioxide.

NOTE 1: In addition to its extinguishing capabilities, foam can be utilized to secure a flammable liquid spill before ignition.

NOTE 2: Some of the extinguishing agents, i.e., carbon dioxide and foam, are relatively ineffective on fires involving flammable liquids under pressure.

13-1.2.3 Class "C" Hazards. Portable and wheeled fire extinguishers for protecting Class "C" hazards shall be selected from the following: Halon 1211, carbon dioxide, dry chemical types.

NOTE 1: Carbon dioxide units equipped with metal horns should not be used on fires in energized electrical equipment.

NOTE 2: Dry chemical is not recommended for use in an area where sensitive electrical equipment is located, due to the potential for damage to this equipment from a dry chemical and its products of decomposition.

13-1.2.4 Class "D" Hazards. Portable and wheeled fire extinguishers and extinguishing agents for the protection of Class "D" hazards shall be of types approved for use on the specific combustible metal hazard.

NOTE 1: Where approvals are not available for a specific combustible metal, recommendations of a manufacturer may be utilized providing proper test data or use records are available.

NOTE 2: Agent for Class "D" hazards can be applied utilizing a scoop and a container.

13-1.3

A sign shall be located adjacent to each portable and wheeled fire extinguisher and shall plainly indicate the type of fire for which it is intended.

13-1.4

All persons working in an area shall be thoroughly trained in the use of all types of portable and wheeled fire extinguishers in the area and shall be familiar with their location. This training shall include both the capabilities and limitations of each available type of extinguisher.

13-2 Hand Hose Lines.

13-2.1

Hand hose lines utilizing water, foam, carbon dioxide, or dry chemical shall be installed, inspected, and maintained in accordance with the following NFPA standards, respectively: NFPA 14, NFPA 11, NFPA 12, and NFPA 17.

13-2.2

Hand hose lines utilizing water, foam, carbon dioxide, and dry chemical shall be selected for the specific class or classes of hazards utilizing the following descriptive guide.

13-2.2.1 Class "A" Hazards. Hand hose lines for the protection of Class "A" hazards shall be selected from the following: water, foam, and dry chemical (multipurpose only). The nozzles for these hand hose lines shall be approved, electrically safe nozzles in the plant areas where Class "A" hazards involve energized electrical equipment.

13-2.2.2 Class "B" Hazards. Hand hose lines for the protection of Class "B" hazards shall be selected from among the following: water, foam, and dry chemical.

NOTE: Foam is not considered suitable alone for fires involving gases and liquefied gases nor for three-dimensional flammable liquid fires. If these hazards are encountered, hand portable, wheeled dry chemical fire extinguishers or dry chemical hand hose lines are most effective especially when used in combination.

13-2.2.3 Class “C” Hazards. Hand hose lines for the protection of Class “C” hazards shall be selected from: water, carbon dioxide, and dry chemical. Approved nozzles shall be provided for use on Class “C” hazard fires.

13-2.2.3.1 The use of hand hose lines involving water or energized electrical equipment shall take into consideration:

(a) The voltage of the equipment.

(b) The type of water stream used, i.e., solid vs. spray.

(c) The effect of electrically conductive water on the operability of the equipment.

(d) The most probable distance between the fire fighter and the energized electrical equipment.

(e) The location of energized electrical equipment in the drainage path that is likely to be encountered when water is used.

13-2.2.3.2 Where sensitive electrical control equipment is involved, due consideration shall be given to the effects of thermal shock on the operability of this equipment when using carbon dioxide hand hose lines.

13-2.2.3.3 Carbon dioxide hand hose lines shall not be used in normally inhabited enclosures unless provisions for evacuation (alarm, annunciation, etc.) are made before use.

13-2.2.4 Class “D” Hazards. Hand hose lines involving water, foam, and carbon dioxide shall not be used for the protection of Class “D” hazards.

13-2.3

A sign shall be located adjacent to each hand hose station and shall plainly indicate the type of fire for which it is intended.

13-2.4

Designated persons working in the area shall be thoroughly trained in the inspection, location, and use of all hand hose line devices. This training shall include the capabilities and limitations for each type of hose station.

Chapter 14 Manual Fire Fighting

14-1

Manual fire fighting forces shall be available from:

(a) The plant fire brigade formed from the shift personnel.

(b) The public fire department from the nearest town.

NOTE: Due to the relatively remote location of most nuclear plants, such departments are usually a considerable distance away.

14-2 Action Plan.

Detailed action plans shall be worked out by the fire protection manager for proper deployment of in-plant fire fighting personnel. The plan shall require testing to verify its practicability and completeness by means of semiannual fire drills. Such drills shall be documented and kept on file at the plant for a minimum period of one year. The action plan shall consider the need for coordination between private and public fire fighting forces during drills and emergencies.

NOTE: Involvement of state and local agencies in semiannual drills is encouraged.

14-3 Standard for Fire Defense Measures.

All fire protection systems and devices such as automatic fixed fire extinguisher systems, automatic fire alarm and various layout arrangements, i.e., fire doors, fire dampers, ventilation arrangements, smoke venting, etc., shall be subjected to recurring and documented checks and tests. The staff shall be trained and drilled so that each person is capable of acting quickly and efficiently in the event of fire or danger of fire. A senior management representative, along with the fire protection manager, shall be responsible for ensuring that the plant fire defense is the best possible in all respects, including that all fire fighting equipment and systems are in working order. This supervisory activity shall be done by developing a plant emergency plan.

14-4 Liaison with Public Fire Authorities.

Liaison between and interfacing with the fire protection manager and the public fire authorities shall be maintained. It shall be the duty of the fire protection manager, together with the plant manager and plant security manager, in consultation with the public fire department, to make plans for fire fighting and rescue, including assistance from other organizations, and to maintain these plans in a current mode. Fire fighters from the public fire department and from other fire departments, including other industrial fire brigades that may be expected to respond to a fire at the plant, shall be familiarized with the plant layout. The access routes to fires in the controlled area (to which access doors are locked) shall be planned in detail in advance. The public fire department shall be given instructions and trained how to react in areas where radioactive materials, radiation, or hazardous materials may be present.

14-5 Regular Training and Drills.

Fire brigade members shall be given regular training and practice in fire fighting and rescue routines, including radioactivity and health physics considerations, to ensure that each member is thoroughly familiar with the steps to be taken in the event of fire, which will contribute to maintaining the best possible preparedness for such contingencies. Each fire brigade member shall be capable of acting:

(a) To alarm the plant fire brigade and public fire department.

(b) To identify any alarm zone or fire protection system that has operated.

(c) To use available rescue and extinguishing devices.

(d) To actuate the fixed fire extinguishing systems, the smoke venting systems, etc.

(e) To cooperate with and assist the public fire department in its work.

(f) To train plant personnel in room entry procedures where total flooding fire suppression systems are used. (*See NFPA 12, NFPA 12A, and NFPA 12B.*)

14-6 Equipment for the Plant Fire Brigade.

14-6.1

The conventional equipment (*see NFPA 600*) for the plant fire brigade shall be selected to suit the entire plant site. To complement the conventional equipment the following equipment shall be provided to cope with the nuclear hazard:

(a) Protective clothing.

(b) Respiratory protective equipment (*refer to NFPA 1981*).

(c) Radiation monitors.

(d) Personal dosimeters.

14-6.2

A formal program for the care and maintenance of the fire brigade equipment shall be established by the owner through the fire protection manager.

Chapter 15 Planning and Fire Protection

15-1

The owner or delegated fire protection manager shall be responsible for the entire fire protection of the plant site from conception and throughout the operating life of the plant. Fire protection shall be accorded the same consideration as nuclear hazards.

15-2

Fire protection shall be incorporated into the design specifications for the plant.

15-3

Fire protection measures shall keep pace with the advancement of the plant construction and corresponding fire hazards.

15-4

Special hazard fire protection shall be operational prior to the introduction of the hazard, such as energizing a transformer or filling oil tanks within the plant. Fire barriers and fire doors shall be given priority for construction and installation to reduce the spread of fire.

15-5 Repairs and Revision Work.

Special attention shall be paid to repairs and revision work outside of established areas. The requirement that written permission from the fire protection manager must be obtained before embarking on cutting, welding, use of other open flames in repairing fire protection systems, and similar operations shall be adopted. (*See NFPA 51B.*)

Chapter 16 Fire Prevention and Fire Protection for the Construction Site

16-1

Fire at the construction site shall not threaten the safety of the operating plant.

NOTE: Under construction and prior to the receipt of nuclear fuel, a nuclear power plant does not differ in any fundamental respect from a conventional steam generating plant or any other industrial plant of similar size with respect to fire protection problems. Due to large numbers of on-site personnel and high value materials, an above-average level of fire protection on the site is justified during erection of the plant. When a nuclear power plant is constructed in the vicinity of an existing plant, it is important that the exposure to the existing plant be taken into consideration.

16-2 Fire Prevention.

The owner or his designated fire protection manager shall be responsible for fire prevention of the entire plant site during the construction period. The duties shall be to:

(a) Develop, implement, and periodically update as necessary a fire procedure for the project and a fire brigade plan.

(b) Maintain housekeeping in such a manner so as to minimize the probability of fire causing loss of life or property damage.

(c) Provide periodic coordination with the public fire department and the plant fire brigade. (*See Chapter 14.*)

(d) Develop, implement, and periodically update as necessary an emergency evacuation plan for all personnel.

(e) Develop, implement, and periodically update as necessary a welding and cutting safety procedure using NFPA 51B and NFPA 241 as guides.

(f) Control the use of temporary buildings including trailers, shacks, or shanties within the confines of the plant.

(g) Specify the use of noncombustible scaffolds, form work, decking, and partitions both inside and outside permanent buildings.

(h) Establish a hazardous material control plan prohibiting the storage of flammable liquids, Class II combustible liquids, gases, or other hazardous material in permanent buildings. These materials shall be stored in a building at least 50 ft (15.2 m) from any permanent building and stored in accordance with NFPA 30. Flammable liquids and Class II combustible liquids shall be handled in listed containers in accordance with NFPA 30.

(i) Specify the use of approved tarpaulins.

(j) Develop, implement, and periodically update as necessary a fire prevention surveillance plan to include periodic recorded rounds to all unattended sections of the plant.

(k) Coordinate the initial and periodic testing of all systems and equipment affecting fire prevention and fire protection in accordance with the applicable NFPA standards and/or the manufacturers'/installers' instructions and procedures to include maintenance of appropriate documentation.

(l) Develop an alternate protection plan for those instances when it becomes necessary to remove any fire protection equipment or system from service.

(m) Specify labeled heating devices and their fuel supply systems for use inside or within 30 ft (9.1 m) of temporary and permanent buildings.

16-3 Fire Protection.

The owner or his designated fire protection manager shall be responsible for the provision of the following fire protection systems and/or equipment:

(a) *General Alarm System.* The system(s) shall be such that personnel on the site will be alerted.

(b) Minimum construction water supply shall be available on the site and capable of furnishing at least 750 gpm (2835 liters/min) plus the demand of the largest fixed water extinguishing system at a residual pressure of 75 psig (517 kPa) for minimum 2-hour duration.

(c) A temporary hydrant system with a maximum distance between any two hydrants of 250 ft (76.2 m). Hose and hydrant equipment shall be provided to assure an overlap of protection.

(d) A standpipe system in any permanent building that has as much as two-floor equivalent wall heights erected. Additional standpipe hose connections shall be added to each floor level as soon as sufficient landings are available to fight fires from that level. Protection from freezing shall be addressed.

(e) Fire extinguishers in accordance with NFPA 10.

(f) Automatic fire extinguishing system in any building or area of combustible construction or occupancy if there is a life safety hazard or large concentration of valuable equipment, the loss of which would cause an economic impact (i.e., delay in start-up dates) to the completed plant. Examples: Warehouses, offices, craft shops, etc.

16-4

Requirements for plants and areas under construction shall be determined by NFPA 241, *Safeguarding Building Construction and Demolition Operations*, and it is recognized that egress requirements may need to exceed those of completed facilities due to personnel, materials, and operations involved. The late stages of construction usually present the largest personnel concentration and highest hazard to personnel from fire in the life cycle of the plant.

Chapter 17 Life Safety

17-1

NFPA *101*, *Life Safety Code*, shall be the standard for life safety in the design and operation of nuclear power plants.

17-2*

The operation and maintenance of a nuclear power plant involves unique operation and material in process, due to which the majority of the areas involved in the transfer of nuclear energy to electrical energy shall be considered as either a special purpose industrial occupancy or as an occupancy in an unusual structure as defined in NFPA *101*. This determination shall be made in the conceptual fire hazard analysis.

NOTE: These classifications consider that several areas will not normally be subject to human occupancy and that radioactive material is involved.

Chapter 18 Referenced Publications

18-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

18-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

Appendix A

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

A-1-1

There is information contained within this standard that is applicable to reactors other than light water reactors. Principles outlined in this standard are also applicable to nuclear production reactors. Applicable guidance for design and protection of production and research reactors may be found in this standard.

A-2-4 Fire Hazard Analysis.

A thorough analysis of the fire potential is necessary to incorporate adequate fire protection into the facility design. Integrated design of systems is necessary to ensure the safety of the plant and the operators from the hazards of fire and to protect property and continuity of production.

The following steps are recommended as part of the analysis procedure.

(1) Prepare a general description of the physical characteristics of the power facilities and plant location which will outline the "fire prevention" and "fire protection" systems to be provided. Define the fire hazards that can exist and state the loss limiting criteria to be used in the design of the plant.

(2) List the codes and standards that will be used for the design of the fire protection systems. Include the published standards of the National Fire Protection Association. Select the specific sections and paragraphs, not general items.

(3) Define and describe the potential fire characteristics for all individual plant areas which have combustible materials, such as: maximum fire loading, hazards of flame spread, smoke generation, toxic contaminants, and fuel contributed. Consider the use and effect of noncombustible and heat-resistant materials.

(4) List the fire protection system requirements and the criteria to be used in the basic design for such items as water supply, water distribution systems, and fire pump safety.

(5) Describe the performance requirements for the detection systems, alarm systems, automatic suppression systems, manual systems, chemical systems, and gas systems for fire detection, confinement, control, and extinguishing.

(6) Develop the design considerations for suppression systems and for smoke, heat, and flame control, combustible and explosive gas control, toxic and contaminate control. Select the operating functions of the ventilating and exhaust systems during the period of fire extinguishing and control. List the performance requirements for fire and trouble annunciator warning system and the auditing and reporting systems.

(7) Consider the qualifications required for the personnel performing the inspection checks and the frequency of testing to maintain a reliable alarm detection system.

(8) The features of building and facility arrangements and the structural design features generally define the methods for fire prevention, fire extinguishing, fire control, and control of hazards created by fire. Fire barriers, egress, fire walls, and the isolation and containment features that should be provided for flame, heat, hot gases, smoke, and other contaminants

should be carefully planned. Outline the drawings and list of equipment and devices which are needed to define the principal and auxiliary fire protection systems.

(9) Prepare a list of the dangerous and hazardous combustibles and the maximum amounts estimated to be present in the facility. Evaluate where these will be located in the facility.

(10) Review the types of fires, based on the quantities of combustible materials, their estimated severity, intensity, duration, and the hazards created. Indicate for each of the types reviewed the total time involved, and the time for each step from the first alert of the fire hazard until safe control and extinguishment is accomplished. Describe in detail the plant systems, functions, and controls that will be provided and maintained during the fire emergency.

(11) Define the essential electric circuit integrity needed during fire. Evaluate the electrical and cable fire protection, the fire confinement control, and extinguishing systems that will be required to maintain their integrity.

(12) Carefully review and describe the control and operating room areas and the protection and extinguishing systems provided thereto. Do not overlook the extra facilities provided for maintenance and operating personnel, such as kitchens, maintenance storage, and supply cabinets.

(13) Consider the fire hazards and potentials during construction of multiple units and the additional fire prevention and control provisions that will be required during the construction period where one unit is in operation. This may require additional professional fire department type of coverage.

(14) Analyze what is available in the form of “back-up” or “public” fire protection to be considered for the installation. Review the “back-up” fire department, equipment, manpower, special skills, and training required.

(15) List and describe the installation, testing, and inspection required during construction of the fire protection systems which demonstrate the integrity of the systems as installed. Evaluate the operational checks, inspection, and servicing required to maintain this integrity.

(16) Evaluate the program for training, updating, and maintaining competence of the station fire fighting and operating crew. Provisions should be required to maintain and upgrade the fire fighting equipment and apparatus during plant operation.

(17) Review the qualification requirements for the fire protection engineer or consultant who will assist in the design and selection of equipment. This person will also inspect and test the completed physical aspects of the system and develop the complete fire protection program for the operating plant.

A-7-3.1.1 The varying radiation dose rates found in different parts of a nuclear power plant and caused by airborne radioactive substances, radiation from plant systems, and radiation from contaminated surfaces are the reason for the subdivision of the plant premises into what are sometimes called controlled and uncontrolled areas in order to limit the exposure of the employees when working in different parts of the plant. This classification applies to normal operating conditions. The dose rates may change substantially in the event of a serious accident. The division of the premises into controlled and uncontrolled areas also affects the dividing into fire protection areas, the design of ventilation systems, and requirements concerning surface treatment of ceilings, walls, floors, etc. (International Guidelines for Fire Protection for Nuclear Power Plants).

The presence of gaseous or airborne radioactive substances imposes certain requirements on the pressure differentials and direction of the pressure gradient between adjoining rooms and within the ventilation systems of the plant. The radioactive substances must be kept under control by always maintaining the flow of air from the less towards the more contaminated rooms and regions. The usual way of smoke detection may therefore not always be applicable.

Depending on the type of reactor, the space, compartments, and adjoining rooms where the components of the primary reactor coolant circuit are installed may be used for emergency pressure relief in case of a rupture in the primary coolant circuit. Parts of the entire volume of the reactor building, or the containment, may be used in order to attain an acceptable equalized relief pressure. The required interconnections of the different compartments of the reactor building contradict the normal fire protection practice of subdividing large spaces into smaller isolated compartments for confinement of the damage by smoke and heat (International Guidelines for Fire Protection for Nuclear Power Plants).

A-10-1.5

On wet pipe sprinkler systems, alarm check valves are preferred.

A-10-1.6

Electric valve supervision is preferred. This method of valve supervision indicates to the operator the status of fire protection control valves at any given instant. Locks or seals do not assure that valves are open or closed.

A-17-2

In most fire and fire related incidents the primary duty of plant personnel should be to retain the integrity of systems designed for safe operation and shut down of nuclear facilities and containment of radioactive release. Provisions should be made that personnel can carry out this function in as safe a manner as possible with adequate means of egress and access to all areas of the plant.

Normal operation may involve relatively few personnel; however, certain activities, such as maintenance, testing, and start-up may involve a great number of occupants not necessarily familiar with plant layout and means of egress in emergency situations. Nuclear power plant design utilizes methods such as air locks and pressure differentials to segregate plant areas. These methods require full evaluation to assure the availability of means of egress and access in emergency situations.

In evaluating the exits for a completed facility, the number of personnel and occupancy hazard during maintenance, refueling, and testing should determine the exit requirements if greater potential for fire exists under these conditions.

Appendix B Codes and Standards

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

General. There are a number of publications relating to fire protection features of nuclear reactors, particularly power reactors. In terms of content, these can be grouped into two classes: those dealing with the property protection features of the plant as a whole, and those concerned with fire protection features affecting public safety or the protection of systems essential to nuclear safety of the reactor.

Regulatory Guides. Although none of these publications is mandatory, the Nuclear Regulatory Commission must be satisfied that effective fire protection is provided before an operating license is issued. This may be done by strict adherence to the guide or by proving that alternates will accomplish the job. However, the NRC guides are concerned with nuclear safety and protection of the public, with little direct application to the safety of employees and/or construction workers, to property protection of the plant as a whole, or to the continuity of power production. The purpose of a regulatory guide is, in its own words, to "make available specific parts of the Commission regulations, to delineate techniques used by the staff in evaluating specific problems or postulated accidents, or to provide guidance to applicants. Regulatory guides are not substitutes for regulations, and compliance with them is not required. Methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuance of a permit or license by the Commission."

Applicable Guides. Guides relating to the fire protection of nuclear reactors are described below.

Regulatory Guide 1.120 — Fire Protection Guidelines for Nuclear Power Plants. This was issued by the NRC for comment, but has not been finalized. It contains most of the provisions described in the Standard Review Plan.

Standard Review Plan 9.5.1 — Fire Protection System. NUREG 800 is the basic NRC document delineating their review procedures for nuclear power plant applications. Section 9.5.1 covers fire protection. While intended for the regulatory staff of NRC as guidance for review procedures, it serves as a useful planning guide to applicants. The current edition is the July 1981 revision.

Branch Technical Position APCSB 9.5-1. Guidelines for Fire Protection for Nuclear Power Plants. These guidelines are prepared by the branches having standards-making responsibilities for the subject in question, in this case the Auxiliary Power and Control Code of Federal Regulations 10 CFF Part 50, Appendix R — Fire Protection Program for Nuclear Power Facilities operating prior to January 1, 1979. These are the basic, mandatory requirements of the NRC applicable to the defined facilities. The general requirement for the fire protection and prevention programs are contained herein, as well as specific requirements for fire brigades, water supplies, safe shutdown capability protection, fire barrier seals, and other subjects. The Federal Register, Vol. 45, No. 105, of May 29, 1980, printed the Appendix, together with an analysis of the requirements and an excellent background discussion of the various NRC requirements and guides.

International Atomic Energy Authority (IAEA) Safety Guide on Fire Protection in Nuclear Power Plants. This document is currently being drafted to "provide specific guidance for the designer and the operating staff in complying with requirements for protection of systems important to nuclear safety." IAFA guides are useful references but are not mandatory in the U.S.

American Nuclear Insurers-Mutual Atomic Energy Reinsurance Pool and Nuclear Mutual Limited Standards. Each of these insurance pools issues standards covering the fire protection of the entire nuclear power plant. Substantial compliance is required for all plants insured within the pools. The scope of these requirements is broader than the above documents but life safety aspects for employees and construction workers are not a specific concern.

International Guidelines for the Fire Protection of Nuclear Power Plants. This is a comprehensive document published on behalf of the national nuclear risks insurance pools and associations. This is the broadest-scope document in print, covering protection features for the entire plant. Again, this is primarily property protection oriented, but is basically compatible with the U.S. insurance pools requirements and is a consensus document of the insurance pools involved.

NFPA 804

1995 Edition

Standard for Fire Protection for Advanced Light Water Reactor

Electric Generating Plants

1995 Edition

This edition of NFPA 804, *Standard for Fire Protection for Advanced Light Water Reactor Electric Generating Plants*, was prepared by the Technical Committee on Atomic Energy and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995.

This edition of NFPA 804 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 804

The need for fire protection in nuclear power facilities has been demonstrated in a number of incidents, including the Browns Ferry Fire in 1975 and other more recent incidents in the United States and abroad. Probabilistic risk assessments of existing plants have shown that fire represents one of the largest single contributors to the possibility of reactor damage. This document represents a comprehensive consensus of baseline fire protection requirements for all aspects of advanced lightwater reactor electric generating plants including the design, construction, operation, and maintenance.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the safeguarding of life and property from fires in which radiation or other effects of nuclear energy might be a factor.

NFPA 804

Standard for Fire Protection for Advanced Light Water Reactor Electric Generating Plants

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 10 and Appendix B.

Chapter 1 Introduction

1-1* Scope.

This standard applies only to advanced light water reactor electric generating plants, and provides minimum fire protection requirements to ensure safe shutdown of the reactor, minimize the release of radioactive materials to the environment, provide safety to life of on-site personnel, limit property damage, and protect continuity of plant operation. The fire protection is based upon the principle of defense in depth.

1-2 Purpose.

This standard is prepared for the use and guidance of those charged with the design, construction, operation, and regulation of advanced light water reactor electric generating plants. This standard covers those requirements essential to ensure that the consequences of fire will have minimum impact on the safety of the public and on-site personnel, the physical integrity of plant components, and the continuity of plant operations.

1-3 Equivalency Concepts.

1-3.1

Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety as alternatives to those prescribed by this standard, provided technical documentation is submitted to the authority having jurisdiction to demonstrate equivalency, and the system, method, or device is approved for the intended purpose.

1-3.2

The specific requirements of this standard shall be permitted to be modified by the authority having jurisdiction to allow alternative arrangements that will secure as nearly as practical the level of fire protection intended by this document, but in no case shall the modification afford less fire protection than that which, in the judgment of the authority having jurisdiction, would be provided by compliance with the corresponding provisions contained in this standard.

1-3.3

Alternative fire protection methods accepted by the authority having jurisdiction shall be considered as conforming with this standard.

1-4 Definitions.

Advanced Light Water Reactors (ALWR).* Advanced light water reactors are divided into two types:

(a) *Evolutionary Plants.* These are simpler, improved versions of conventional designs employing active safety systems.

(b) *Revolutionary Plants.* These are the result of completely rethinking the design philosophy of conventional plants. Revolutionary plants currently being proposed replace mechanical safe shutdown systems with passive features that rely on physical properties such as natural circulation, gravity flow, and heat sink capabilities.

Alternative Shutdown Capability. The ability to safely shut down the reactor and maintain shutdown using equipment and processes outside the normal reactor shutdown process.

ALWR. See Advanced Light Water Reactors.

Approved.* Acceptable to the authority having jurisdiction.

Associated Circuits of Concern. Those safety-related and non-safety-related circuits not directly required to perform a safe shutdown function that have a physical separation from the fire area less than that required by Section 5-4 and that have any of the following characteristics:

(a) *Type I.* A common power source with a required circuit in which the power source is not electrically protected from the nonrequired circuit by coordinated circuit breakers, fuses, or similar devices.

(b) *Type II.* A connection to equipment whose spurious operation could adversely affect safe shutdown capability.

(c) *Type III.* A common enclosure (e.g., cable tray, conduit, panel, or junction box) with a required circuit and that:

1. Is not electrically protected by circuit breakers, fuses, or similar devices, or

2. Could allow propagation of fire into the common enclosure.

A potential Type I or Type III circuit is not an associated circuit of concern if it has adequate electrical protection.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Cable Tray Fire Break. A noncombustible or limited-combustible material used for vertical cable trays to limit fire spread.

Cold Shutdown. A stable plant condition in which the affected reactor is subcritical and the average reactor coolant system temperature is less than or equal to 200°F (93°C).

Combustible. Any material that, in the form in which it is used and under the conditions anticipated, will ignite and burn. A material that does not meet the definition of noncombustible or limited-combustible.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code*.)

Defense in Depth. A principle aimed at providing a high degree of fire protection by achieving a balance of:

(a) Preventing fires from starting;

(b) Detecting fires quickly and suppressing those fires that occur, thereby limiting damage; and

(c) Designing the plant to limit the consequences of fire to life, property, environment, continuity of plant operation, and safe shutdown capability.

It is recognized that, independently, no one of these items is complete in itself. Strengthening any item can compensate for weaknesses, known or unknown, in the other items.

FHA. See Fire Hazards Analysis.

Fire Area.* That portion of a building or plant that is separated from other areas by boundary fire barriers.

Fire Area Subdivision.* A portion of a fire area separated from the remainder of the fire area by substantive barriers (not necessarily fire rated) or by plant physical features, such as pipe tunnels, or by spatial separation.

Fire Barrier. A continuous membrane, either vertical or horizontal, such as a wall or floor assembly, that is designed and constructed with a specified fire resistance rating to limit the spread of fire and that will also restrict the movement of smoke. Such barriers shall be permitted to have protected openings.

Fire Brigade.* As used in this standard, refers to those on-site persons trained in plant fire-fighting operations.

Fire Door. A door assembly rated in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, and installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

Fire Hazards Analysis (FHA). An analysis performed by fire protection and reactor systems engineers to evaluate potential in situ and transient fire hazards to determine the effect of fire in any location in the plant on the ability to shut down the reactor safely and minimize and control the release of radioactive materials to the environment; and to specify measures for fire protection.

Fire Prevention. Measures directed toward avoiding the inception of fire.

Fire Protection. Methods of providing fire detection, control, and extinguishment.

Fire Protection Manager. The person directly responsible for the fire prevention and fire protection program at the plant.

Fire-Rated Cables.* Cables with an hourly fire resistance rating based on maintaining functionality when exposed to fire tests in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

Fire-Rated Internal Conduit Seal. A conduit seal that is a tested and approved hourly rated fire seal in accordance with ASTM E 814, *Fire Tests of Through-Penetration of Fire Stops*.

Fire-Rated Penetration Seal. An assembly provided in an opening in a fire barrier for the passage of pipes, cable trays, etc., to maintain the fire resistance rating of the fire barrier.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with an approved test procedure appropriate for the component under consideration.

Fire Safe Shutdown. Actions, components, capabilities, and design features necessary to achieve and maintain safe shutdown of the reactor after a fire in a specific fire area.

Fire Safe Shutdown Component. Equipment, instrument sensing lines, or cables (including associated circuits of concern) that are required to safely shut down the plant in the event of fire. Fire safe shutdown components might or might not be nuclear safety related.

Fire Zone. Areas in which fire detection or suppression systems provide alarm information indicating the location of fire at a central fire control center.

First Break. The first place in a conduit run where the interior of the conduit is accessible to install a seal. The first break could be a condulet, a pull box, a junction box, or an electrical panel, at the equipment or open ended with cables exiting into a tray.

Flame Spread Rating. A relative measurement of the surface burning characteristics of building materials when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psi (276 kPa) absolute pressure at 100°F (37.8°C).

Free of Fire Damage. The necessary structures, systems, and components are free of fire damage if the structure, system, or component under consideration is capable of performing its intended function during and after a fire.

FSSD. See Fire Safe Shutdown.

High Impedance Faults. Fire-induced faults on non-safe shutdown essential circuits routed thorough a common fire area that are assumed to occur simultaneously and have a current magnitude below the trip point for the individual circuits. The sum of the currents generated by the simultaneous occurrence of such faults could trip the main circuit breaker and cause the loss of a safe shutdown power supply.

High-Low Pressure Interface. A valve or set of valves that separates a high pressure primary coolant system from a low pressure system. Fire induced faults on the valve(s) circuitry can cause (a) loss of the ability to close the valve(s), or (b) spurious opening of the valve(s), thereby inducing a loss of coolant accident (LOCA) or overpressurizing the low pressure system.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Limited-Combustible. A building construction material that, in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) and either has a structural base of noncombustible material with a surfacing not exceeding $^{1}/_{8}$ in. (3.2 mm) that has a flame spread rating not greater than 50, or other material having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion, even on surfaces exposed by cutting through the material on any plane. (*See NFPA 220, Standard on Types of Building Construction*.)

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Noncombustible. A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat. Materials that are reported as passing ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, shall be considered noncombustible.

Normal Operations. All modes of plant operation, ranging from 0 percent to 100 percent power, including refueling outages but not including extended outages when fuel is removed from the reactor.

Nuclear Safety Function. Any function that is necessary to ensure the integrity of the reactor coolant pressure boundary; the capability to shut down the reactor and maintain it in a safe shutdown condition; or the capability to prevent or mitigate the consequences of plant conditions that could result in potential off-site exposures that are a significant fraction of Title 10, *Code of Federal Regulations*, Part 100, “Reactor Site Criteria,” guideline exposures.

Nuclear Safety Related. Structures, systems, or components that, as defined by Title 10, *Code of Federal Regulations*, Part 100, “Reactor Site Criteria,” are required to remain functional to ensure:

(a) The integrity of the reactor coolant pressure boundary,

(b) The capability to shut down the reactor and maintain it in a safe shutdown condition, or

(c) The capability to prevent or mitigate the consequences of accidents that could result in potential off- site exposures comparable to the guideline exposures of 10 CFR 100.

Postulated Fire. A fire that is assumed to occur in a specific area of the plant. The origin of the fire and the combustible materials involved are not defined.

Power Block. Those structures having equipment required for plant operations (e.g., containment, auxiliary building, service building, control building, fuel building, rad waste, water treatment, turbine building, and intake structure).

Redundant Component, System, or Subsystem. A component, system, or subsystem that independently duplicates the essential function of another component, system, or subsystem.

Safe Shutdown. A shutdown with the reactivity of the reactor kept subcritical as specified by the technical specifications for the unit.

Safety Division. The designation applied to a given system or set of nuclear-safety-related components that enable the establishment and maintenance of physical, electrical, and functional independence from other redundant systems or sets of components. The terms division, train, and separation group, when used in this context, are interchangeable.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Spurious Operation. An unwanted change in state of equipment due to fire-induced faults (hot shorts, open circuits, or shorts to ground) on its power or control circuitry. Spurious operations include, but are not limited to:

(a) The opening (closing) of normally closed (open) valves,

(b) Starting (stopping) of pumps or motors,

(c) Actuation of logic circuits, or

(d) Inaccurate instrument reading.

Spurious Signal. A fire-induced signal that could cause the spurious operation of components or equipment, which would adversely affect the safe shutdown capability.

Chapter 2 Fire Protection Program

2-1 General.

2-1.1

This chapter establishes the criteria for an integrated combination of components, procedures, and personnel to carry out all activities involved in the fire protection program. It includes system and facility design, fire prevention, fire detection, notification, confinement, suppression, administrative controls, fire brigade organization, inspection and maintenance, training, quality assurance, and testing.

2-1.2

All elements of the site fire protection program shall be reviewed every two years, and updated as necessary.

Exception: Other review frequencies are acceptable where specified in site administrative procedures and approved by the authority having jurisdiction.

2-1.3

The intent of this chapter can be met by incorporating the features of this chapter in the safety analysis reports, operating procedures, program manual, policy documents, and other verifiable records as plant management determines.

2-2 Management Policy Direction and Responsibility.

2-2.1

A policy document shall be prepared that defines management authorities and responsibilities and establishes the general policy for the site fire protection program.

2-2.2

The policy document shall designate the senior management person with immediate authority and responsibility for the fire protection program.

2-2.3

The policy document shall define the fire protection interfaces with other organizations and assign responsibilities for the coordination activities.

2-2.4

The policy document shall include the authority for conflict resolution.

2-3 Fire Prevention Program.

A fire prevention program shall be established and documented to include:

(a) Fire safety information for all employees and contractors, including as a minimum familiarization with plant fire prevention procedures, fire reporting, and plant emergency alarms, including evacuation;

(b) Documented plant inspections including provisions for handling of remedial actions to correct conditions that increase fire hazards;

(c) A procedure for the control of general housekeeping practices and the control of transient combustibles;

(d) Procedures for the control of flammable and combustible gases in accordance with NFPA standards;

(e) Procedures for the control of ignition sources, such as smoking, welding, cutting, and grinding (*see NFPA 51B, Standard for Fire Prevention in Use of Cutting and Welding Processes*);

(f) A fire prevention surveillance plan (*see NFPA 601, Standard on Guard Service in Fire Loss Prevention*); and

(g) A fire reporting procedure, including investigation requirements and corrective action requirements.

2-4* Fire Hazards Analysis.

A documented fire hazards analysis shall be made for each site. The analysis shall document:

(a) The physical construction and layout of the buildings and equipment, including fire areas and the fire ratings of area boundaries;

(b)* An inventory of the principal combustibles within each fire subdivision;

(c) A description of the fire protection equipment, including alarm systems and manual and automatic extinguishing systems;

(d) A description of any equipment necessary to ensure a safe shutdown, including cabling and piping between equipment, and the location of such equipment;

(e) An analysis of the postulated fire in each fire area, including its effect on safe shutdown equipment, assuming automatic and manual fire protection equipment does not function;

(f) An analysis of the potential effects of a fire on life safety, release of contamination, impairment of operations, and property loss, assuming the operation of installed fire extinguishing equipment;

(g) An analysis of the potential effects of other hazards, such as earthquakes, storms, and floods, on fire protection;

(h) An analysis of the potential effects of an uncontained fire in causing other problems not related to safe shutdown, such as a release of contamination and impairment of operations;

(i) An analysis of the postfire recovery potential;

(j) An analysis of the emergency planning and coordination requirements necessary for effective loss control. This shall include any necessary compensatory measures to compensate for the failure or inoperability of any active or passive fire protection system or feature;

(k) An analysis for the protection of nuclear-safety-related systems and components from the inadvertent actuation or breaks in a fire protection system; and

(l) An analysis of the smoke control system, and the impact smoke can have on nuclear safety and operation for each fire area.

2-5 Procedures.

A formal procedure system for all actions pertaining to the fire protection program shall be established. This shall include:

(a) Inspection, testing, maintenance, and operation of fire protection systems and equipment, both manual and automatic, such as detection and suppression systems;

(b) Inspection, testing, and maintenance of passive fire protection features, such as fire barriers and penetration seals;

(c) Trend analysis requirements;

(d) Provisions for entering areas with access restrictions; and

(e) Training requirements.

2-6 Quality Assurance.

2-6.1

A quality assurance program shall be established in accordance with ASME NQA-1, Quality *Assurance Program Requirements for Nuclear Facilities*, for these aspects of the fire protection program related to nuclear safety:

(a) Design and procurement document control;

(b)* Instructions, procedures, and drawings;

(c)* Control of purchased material, equipment, and services;

(d)* Inspection;

(e)* Test and test control;

(f)* Inspection, test, and operating status;

(g)* Nonconforming items;

(h)* Corrective action;

(i)* Records; and

(j)* Audits.

2-6.2

The quality assurance program shall be documented in sufficient detail to verify its scope and adequacy.

2-7 Fire Emergency Plan.

A written fire emergency plan shall be established. As a minimum, this plan shall include:

(a) Response to fire and supervisory alarms;

(b) Notification of plant and public emergency forces;

(c) Evacuation of personnel;

(d) Coordination with security, maintenance, operations, and public information personnel;

(e) Fire extinguishment activities;

(f) Postfire recovery and contamination control activities;

(g) Control room operations during an emergency; and

(h) Prefire plan;

(i) A description of interfaces with emergency response organizations, security, safety, and others having a role in the fire protection program, including agreements with outside assistance agencies such as fire departments and rescue services.

2-8 Fire Brigade.

A plant fire brigade shall be established as indicated in Chapter 4.

Chapter 3 Fire Prevention and Administrative Controls

3-1 General.

3-1.1

This chapter sets forth the minimum requirements necessary for the administrative controls and fire prevention activities.

3-1.2*

This chapter applies to both normal operating modes and extended plant outages when fuel is removed from the reactor. However, additional requirements might be necessary during outages.

3-2 Plant Inspections.

3-2.1

The owner or his or her designated manager shall develop, implement, and update as necessary a fire prevention surveillance plan integrated with recorded rounds to all accessible sections of the plant.

3-2.2

Inspections of the plant shall be conducted in accordance with NFPA 601, *Standard on Guard Service in Fire Loss Prevention*. A prepared checklist shall be used for the inspection. Areas of primary containment and high radiation areas normally inaccessible during plant operation shall be inspected as plant conditions permit but at least during each refueling outage. The results of each inspection shall be documented and retained for two years.

Exception: For those plant areas inaccessible for periods greater than two years, the most recent inspection shall be retained.

3-3 Control of Combustible Materials.

3-3.1*

Plant administrative procedures shall specify appropriate requirements governing the storage, use, and handling of flammable and combustible liquids and flammable gases.

3-3.1.1* An inventory of all temporary flammable and combustible materials shall be made for each fire area, identifying the location, type, quantity, and form of the materials.

3-3.1.2* Temporary but predictable and repetitive concentrations of flammable and combustible materials shall be considered.

3-3.1.3 Combustibles, other than those that are an inherent part of the operation, shall be restricted to designated storage compartments or spaces.

3-3.1.4 Consideration shall be given to reducing the fire hazard by limiting the amount of combustible materials.

3-3.1.5 The storage and use of hydrogen shall be in accordance with NFPA 50A, *Standard for Gaseous Hydrogen Systems at Consumer Sites*, and NFPA 50B, *Standard for Liquefied Hydrogen Systems at Consumer Sites*.

3-3.1.6 The temporary use of wood shall be minimized. Plant administrative procedures shall specify that if wood must be used in the power block it shall be listed pressure-impregnated fire-retardant lumber.

3-3.2 Housekeeping.

3-3.2.1 Housekeeping shall be performed in such a manner as to minimize the probability of fire.

3-3.2.2 Accumulations of combustible waste material, dust, and debris shall be removed from the plant and its immediate vicinity at the end of each work shift or more frequently as necessary for safe operations.

3-3.3 Transient Combustible Loading.

3-3.3.1* Plant administrative procedures shall require that the total fire loads, including temporary and permanent combustible loading, will not exceed those quantities established for extinguishment by permanently installed fire protection systems and equipment.

Exception: Where limits are temporarily exceeded, the plant fire protection manager shall assure that appropriate fire protection measures are provided.

3-3.3.2 The fire protection manager or his or her designated representative shall conduct weekly walk-through inspections to ensure implementation of required controls. During major maintenance operations, the frequency of these walk-throughs shall be increased to daily. The results of these inspections shall be documented and the documentation retained for a minimum of two years.

3-3.3.3 When the work is completed, the plant fire protection manager shall have the area inspected to confirm that transient combustible loadings have been removed from the area. Extra equipment shall then be returned to its proper location. The results of this inspection shall be documented and retained for two years.

3-3.3.4* Only noncombustible panels or flame-retardant tarpaulins or approved materials of equivalent fire-retardant characteristics shall be used. Any other fabrics or plastic films used shall be certified to conform to the large-scale fire test described in NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*.

3-3.4 Flammable and Combustible Liquids.

3-3.4.1 Flammable and combustible liquid storage and use shall be in accordance with NFPA 30, *Flammable and Combustible Liquids Code*. Where oil-burning equipment, stationary combustion engines, or gas turbines are used, they shall be installed and used in accordance with NFPA 31, *Standard for the Installation of Oil-Burning Equipment*, or NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*, as appropriate.

3-3.4.2 Flammable and combustible liquid and gas piping shall be in accordance with ANSI B31.1, *Code for Power Piping*, or ASME *Boiler and Pressure Vessel Code*, Section III, as applicable.

3-3.4.3 Hydraulic systems shall use only listed fire-resistant hydraulic fluids.

Exception: Where unlisted hydraulic fluids must be used, they shall be protected by a fire suppression system.

3-3.4.4 The ignition of leaked or spilled liquid shall be minimized by:

(a)* Keeping the liquid from contact with hot parts of the steam system (wall temperature greater than or equal to ignition temperature), such as steam pipes and ducts, entry valve, turbine casing, reheater, and bypass valve;

(b) Using suitable electrical equipment;

(c) Sealing the insulation of hot plant components to prevent liquid saturation;

(d) Using concentric piping; and

(e) Using liquid collection systems.

3-4 Control of Ignition Sources.

Plant administrative procedures shall require an in-plant review and prior approval of all work plans to assess potential fire hazard situations. Where such conditions are determined to exist, special precautions shall be taken to define appropriate conditions under which the work is authorized.

3-4.1 Hot Work.

3-4.1.1 The owner or his or her designated manager shall develop, implement, and update as necessary a welding and cutting safety procedure using NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*, and NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*, as a guide.

3-4.1.2 Written permission from the fire protection manager or a designated alternate shall be obtained before starting activities involving cutting, welding, grinding, or other potential ignition sources.

3-4.1.3* A permit shall not be issued until:

(a) An inspection has determined that hot work can be safely conducted at the desired location,

(b) Combustibles have been moved away or safely covered,

(c) The atmosphere is nonflammable, and

(d) A trained fire watch (with equipment) is posted for the duration of the work, and for 30 min thereafter, to protect against sparks or hot metal starting fires.

3-4.1.4 All cracks or openings in floors shall be safely covered or closed.

3-4.2 Smoking.

3-4.2.1 Smoking shall be prohibited at or in the vicinity of hazardous operations or combustible and flammable materials. “No Smoking” signs shall be posted in these areas.

3-4.2.2 Smoking shall be permitted only in designated and supervised safe areas of the plant. Where smoking is permitted, safe receptacles shall be provided for smoking materials.

3-4.3 Temporary Electrical Wiring.

The ignition of flammable materials shall be minimized by requiring that all temporary electrical wiring:

(a) Be kept to a minimum;

(b) Be suitable for the location;

(c) Be installed and maintained in accordance with NFPA 70, *National Electrical Code®*, or ANSI C2, *National Electrical Safety Code*, as appropriate;

(d) Be arranged so that energy shall be isolated by a single switch; and

(e) Be arranged so that energy shall be isolated when not needed.

3-4.4 Temporary Heating Appliances.

3-4.4.1 Only safely installed, approved heating devices shall be used in all locations. Ample clearance shall be provided around stoves, heaters, and all chimney and vent connectors to prevent ignition of adjacent combustible materials in accordance with NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances* (connectors and solid fuel); NFPA 54, *National Fuel Gas Code* (fuel gas appliances); and NFPA 31, *Standard for the Installation of Oil-Burning Equipment* (liquid fuel appliances).

3-4.4.2 Refueling operations of heating equipment shall be conducted in an approved manner.

3-4.4.3 Heating devices shall be situated so that they are not likely to overturn.

3-4.4.4 Temporary heating equipment, when utilized, shall be monitored and maintained by properly trained personnel.

3-4.5

Open-flame or combustion-generated smoke shall not be used for leak testing.

3-4.6

Plant administrative procedures shall specify appropriate requirements governing the control of electrical appliances in all plant areas.

3-5 Temporary Structures.

3-5.1 Exterior Buildings.

3-5.1.1* Temporary buildings, trailers, and sheds, whether individual or grouped shall be constructed of noncombustible material and shall be separated from other structures. (*See NFPA 80A, Recommended Practice for Protection of Buildings from Exterior Fire Exposures.*)

3-5.1.2 Temporary buildings, trailers, and sheds and other structures constructed of combustible or limited-combustible material shall be separated from other structures by a minimum distance of 30 ft (9.1 m).

Exception: Where all portions of the exposed building (i.e., walls, roof, etc.) within 30 ft (9.1 m) of the exposure constitute a rated fire barrier, the minimum separation distance shall be permitted to be reduced in accordance with Table 3-5.1.2.

Table 3-5.1.2 Minimum Separation Distances

Exposed Building Fire Barrier Rating	Minimum Distance Where Exposing Building Is Without Protection	Minimum Distance Where Exposing Building Has Automatic Sprinklers
3 hr	5 ft (1.5 m)	0 ft (0 m)
2 hr	10 ft (3.0 m)	5 ft (1.5 m)
1 hr	20 ft (6.1 m)	10 ft (3.0 m)
< 1 hr	30 ft (9.1 m)	15 ft (4.6 m)

3-5.1.3 All exterior buildings, trailers, sheds, and other structures shall have the appropriate type and size of portable fire extinguishers.

3-5.2 Exterior Temporary Coverings.

Where coverings are utilized for protection of the outdoor storage of materials or equipment, the following shall apply:

(a) Only approved fire-retardant tarpaulins or other acceptable materials shall be used;

(b) All framing material used to support such coverings shall be either noncombustible or fire-retardant pressure-impregnated wood; and

(c) Covered storage shall not be located within 30 ft (9.1 m) of any building.

3-5.3 Interior Temporary Facilities.

3-5.3.1 All interior temporary structures shall be constructed of noncombustible, limited-combustible, or fire-retardant pressure-impregnated wood. Structures constructed of noncombustible or limited-combustible materials shall be protected by an automatic fire suppression system unless the fire hazard analysis determines that automatic suppression is not required. The structure shall be protected by an automatic fire suppression system if the structure is constructed of fire-retardant pressure-impregnated wood.

3-5.3.2 This use of interior temporary coverings shall be limited to special conditions where interior temporary coverings are necessary. They shall be constructed of approved fire-retardant tarpaulins.

3-5.3.3 Where framing is required, it shall be constructed of noncombustible, limited-combustible, or fire-retardant pressure-impregnated wood.

3-5.3.4 All interior temporary facilities shall have the appropriate type and size of portable fire extinguisher.

3-6 Impairments.

3-6.1*

A written procedure shall be established to address impairments to fire protection systems and features and other plant systems that directly impact the level of fire risk (e.g., ventilation systems, plant emergency communication systems, etc.).

3-6.2*

Impairments to fire protection systems shall be as short in duration as practical.

3-6.3*

Appropriate post-maintenance testing shall be performed on equipment that was impaired to ensure that the system will function properly. Any change to the design or function of the system after the impairment shall be considered in establishing the testing requirements and shall be reflected in the appropriate design documents and plant procedures.

3-7 Testing and Maintenance.

3-7.1

Upon installation, all new fire protection systems and passive fire protection features shall be preoperationally inspected and tested in accordance with applicable NFPA standards. Where appropriate test standards do not exist, inspections and test procedures described in the purchase and design specification shall be followed.

3-7.2*

Fire protection systems and passive fire protection features shall be inspected, tested, and maintained in accordance with applicable NFPA standards, manufacturers' recommendations, and requirements established by those responsible for fire protection at the plant.

3-7.3

Inspection, testing, and maintenance shall be performed using established procedures with written documentation of results and a program of follow-up actions on discrepancies.

3-7.4*

Consideration shall be given to the inspection, testing, and maintenance of nonfire protection systems and equipment that have a direct impact on the level of fire risk within the plant.

Chapter 4 Manual Fire Fighting

4-1 Prefire Plans.

4-1.1

Detailed prefire plans shall be developed for all site areas.

4-1.2*

The plans shall detail the fire area configurations and fire hazards to be encountered in the fire area along with any safety-related components and fire protection systems and features that are present.

4-1.3

Prefire plans shall be reviewed and, if necessary, updated at least every two years.

4-1.4*

Prefire plans shall be available in the control room and made available to the plant fire brigade.

4-2* On-Site Fire-Fighting Capability.

4-2.1 General.

4-2.1.1 A minimum of five plant fire brigade members shall be available for response at all times.

4-2.1.2 Fire brigade members shall have no other assigned normal plant duties that would prevent immediate response to a fire or other emergency as required.

4-2.1.3 The brigade leader and at least two brigade members shall have sufficient training and knowledge of plant safety-related systems to understand the effects of fire and fire suppressants on safe shutdown capability.

4-2.1.4 The fire brigade shall be notified immediately upon verification of a fire or fire suppression system actuation.

4-2.2 Fire Fighter Qualifications and Requirements.

4-2.2.1 Plant fire brigade members shall be physically qualified to perform the duties assigned.

4-2.2.2 Each member shall pass an annual physical examination to determine that the fire brigade member can perform strenuous activity.

4-2.2.3 The physical examination shall determine each member's ability to use respiratory protection equipment.

4-2.3

Each fire brigade member shall meet training qualifications as specified in Section 4-3.

4-3 Training and Drills.

4-3.1 Plant Fire Brigade Training.

4-3.1.1 Plant fire brigade members shall receive training consistent with the requirements contained in NFPA 600, *Standard on Industrial Fire Brigades*, or NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, as appropriate.

4-3.1.2 Fire brigade members shall be given quarterly training and practice in fire fighting. This includes radioactivity and health physics considerations to ensure that each member is thoroughly familiar with the steps to be taken in the event of a fire; this training will contribute to maintaining the best possible preparedness for such contingencies.

4-3.1.3 A written program shall detail the fire brigade training program.

4-3.1.4 Written records that include, but are not limited to, initial fire brigade classroom and hands-on training, refresher training, special training schools attended, drill attendance records, and leadership training for fire brigades shall be maintained for each fire brigade member.

4-3.2 Drills.

4-3.2.1 Drills shall be conducted quarterly for each shift to test the response capability of the fire brigade.

4-3.2.2 Fire brigade drills shall be developed to test and challenge fire brigade response including brigade performance as a team, proper use of equipment, effective use of pre-fire plans, and coordination with other groups.

4-3.2.3 Fire brigade drills shall be conducted in various plant areas, especially in those areas identified by the fire hazards analysis to be critical to plant operation and to contain significant fire hazards.

4-3.2.4 Drill records shall be maintained detailing the drill scenario, fire brigade member response, and ability of the fire brigade to perform the assigned duties.

4-3.2.5 A critique shall be held after each drill.

4-4 Fire-Fighting Equipment.

4-4.1

The plant fire brigade shall be provided with equipment that will enable them to adequately perform their assigned tasks. This would include but not be limited to protective clothing, respiratory protective equipment, radiation monitoring equipment, personal dosimeters, and fire suppression equipment such as hoses, nozzles, fire extinguishers, etc.

4-4.2

Fire brigade equipment shall be tested and maintained. Written records shall be retained for review.

4-5 Off-Site Fire Department Interface.

4-5.1 Mutual Aid Agreement.

4-5.1.1 A mutual aid agreement shall be offered to the local off-site fire department.

4-5.1.2 Where possible, the plant fire protection manager and the off-site fire authorities shall develop a plan for their interface. The fire protection manager also shall consult with the off-site fire department to make plans for fire fighting and rescue, including assistance from other organizations, and to maintain these plans.

4-5.1.3 The local off-site fire department shall be invited to participate in an annual drill.

4-5.2 Site-Specific Training.

4-5.2.1 Fire fighters from the off-site fire department who are expected to respond to a fire at the plant shall be familiar with the plant layout.

4-5.2.2 The access routes to fires in the controlled area (to which access doors are locked) shall be planned in advance.

4-5.2.3* The off-site fire department shall be offered instruction and training in radioactive materials, radiation, and hazardous materials that might be present.

4-5.3 Security and Health Physics.

4-5.3.1* Plant management shall designate a plant position to act as a liaison to the off-site fire department when they respond to a fire or other emergency at the plant.

4-5.3.2 Plant management shall ensure that the off-site fire department personnel are escorted at all times and emergency actions are not delayed.

4-6 Water Drainage.

The fire brigade shall have at their disposal the necessary equipment to assist with routing water from the affected area.

4-7 Fire-Fighting Access.

4-7.1

All plant areas shall be accessible for fire-fighting purposes.

4-7.2

Prefire plans shall identify those areas of the plant that are locked and have limited access for either security or radiological control reasons. Provisions shall be made to allow access to these areas. If necessary, this shall include having security and health physics personnel respond to the fire area along with the fire brigade. Health physics personnel shall confer with the fire brigade leader to determine the safest method of access to any radiologically controlled area.

4-8 Radiation Shielding.

4-8.1

Full advantage shall be taken of all fixed radiation shielding to protect personnel responding for fire suppression purposes.

4-8.2

Health physics personnel shall advise the fire brigade leader of the best method for affording radiological protection.

4-9* Smoke and Heat Removal.

If fixed ventilation systems are not capable of removing smoke and heat, the fire brigade shall utilize portable ventilation equipment. (*See Section 6-4.*)

Chapter 5 Nuclear Reactor Safety Considerations

5-1 General.

Ensuring the safety of the public, the environment, and plant personnel during and after a fire event is paramount to this standard. The purpose of this chapter is to define the minimum criteria necessary to ensure that the reactor and any support facilities are capable of achieving and maintaining safe plant conditions in the event of a fire and minimizing the release of radioactive material.

5-2 Fire Hazards and Safe Shutdown Analysis.

A fire safe shutdown analysis (FSSA) shall be prepared and maintained for the operating life of the reactor. The FSSA shall include as a minimum:

(a) Fire hazards analysis (FHA),

(b) Safe shutdown analysis (SSA), and

(c) Internal plant examination of external fire events for severe accident vulnerabilities.

5-2.1 Fire Hazards Analysis.

The fire hazards analysis shall include the criteria indicated in Section 2-4.

5-2.2 Safe Shutdown Analysis.

A safe shutdown analysis of the effects of a fire on those essential structures, systems, and components required to safely shut down the plant and maintain it in a safe shutdown condition shall be performed. The analysis shall include as a minimum the requirements of this section.

5-2.2.1 A safe shutdown system available/unavailable calculation or table shall be prepared and maintained for each fire area. This document shall identify all safe shutdown equipment that is operable or inoperable due to the effects of a fire in that fire area. This document shall demonstrate compliance with the requirements of Sections 5-3 and 5-4.

5-2.2.2* A shutdown logic diagram shall be available that identifies the conditions necessary to achieve and maintain safe shutdown capability in the event of a fire and those plant features necessary to realize these conditions, including auxiliary and support features.

5-2.3 Internal Plant Examination of External Fire Events for Severe Accident Vulnerabilities.

A risk assessment that estimates the potential risk from a fire in relation to the plant's core damage frequency shall be prepared.

5-2.3.1* An industry-accepted examination process shall be used for the risk assessment.

5-2.3.2* An acceptable risk assessment shall demonstrate that the probability of core damage as a result of an internal fire is less than 1×10^{-6} per reactor year.

5-2.3.3 The internal plant examination of external fire events for severe accident vulnerabilities shall be used to evaluate the level of safety of the plant and shall not be used to reduce the overall plant fire protection design basis.

5-3 Design Basis Events and Requirements.

5-3.1 Fire.

5-3.1.1 Only one fire is assumed to occur at a given time. For the purpose of a safe shutdown analysis, damage shall be assumed to occur immediately.

5-3.1.2* All components, including electrical cables, that are susceptible to fire damage in a single fire area (except primary containment and annulus areas) shall be assumed to be disabled or to be spuriously actuated, whichever is the worst case.

5-3.1.3* A fire shall not be assumed to impair safe shutdown capability inside primary containment or annulus areas.

5-3.1.4 The plant shall be assumed to be operating at 100 percent power, with all components in their normal configuration, when a postulated fire occurs. The analysis also shall consider changes in plant configurations during all normal modes of operation.

5-3.1.5 A concurrent single active component failure independent of the postulated fire shall not be assumed to occur.

5-3.1.6 Plant accidents or severe natural phenomena are not assumed to occur concurrently with a postulated fire.

Exception: For seismic/fire interaction, see 5-3.2.

5-3.1.7 A loss of off-site power shall be assumed concurrent with the postulated fire only where the safe shutdown analysis (including alternative shutdown) indicates the fire could initiate the loss of off-site power.

5-3.1.8 Fire safe shutdown components shall be capable of performing the following functions in the event of the postulated fire:

(a) Achieving and maintaining subcritical reactivity conditions in the reactor;

(b) Maintaining the reactor coolant inventory such that plant safety limits are not violated;

(c)* Establishing reactor decay heat removal to prevent fuel damage and achieve and maintain cold shutdown conditions;

(d) Providing support functions such as process cooling, lubrication, etc., necessary to permit operation of the FSSD components; and

(e) Providing direct readings of the process variables necessary to perform and control the FSSD functions.

5-3.1.9 Limiting Safety Conditions. During a postfire shutdown, the fission product boundary integrity shall be maintained within acceptable limits (e.g., fuel clad damage, rupture of any primary coolant boundary, or rupture of the primary containment boundary).

5-3.1.10 Spurious Signals.

5-3.1.10.1 An evaluation of spurious signals shall be performed based on these assumptions:

(a) All potential spurious components shall be assumed to be in their normal operating positions for the particular mode of operation being considered by the spurious signal evaluation.

(b) The fire-induced cable damage shall determine if any of the following cable failure modes are possible:

1. *Hot Short.* Individual conductors within a cable are shorted to individual conductors of a different cable such that a de-energized circuit might become energized by shorting to an external source of electrical power;

2. *Open Circuit.* The cable failure results in the loss of electrical continuity;

3. *Shorts to Ground.* Cable conductors short to grounded structures; or

4. *Short Circuit.* Individual conductors within multi-conductor cable short to each other.

5-3.1.10.2 Functional failure or damage modes of equipment and components that can spuriously operate shall be considered.

5-3.1.11 Fire-Induced Spurious Actuation. The following postulates shall be used when analyzing fire-induced spurious actuation of equipment.

5-3.1.11.1 FSSD capability shall not be adversely affected by simultaneous spurious actuation of all valves in a single high-to-low pressure interface line where the power or control circuits for the valves can be damaged by a postulated fire.

5-3.1.11.2 For other than high-to-low pressure boundaries, FSSD capability shall not be adversely affected by spurious actuation or signal.

5-3.1.11.3 Separate conditions shall be analyzed concurrent with the spurious actuation(s) or signal addressed in 5-3.1.10.1 and 5-3.1.10.2.

5-3.1.11.4 All automatic functions (signal, logic, etc.) from the circuits that can be damaged by the postulated fire shall be assumed lost or assumed to function as intended, whichever is the worst case.

5-3.1.11.5 All potential spurious signals shall be analyzed. However, only one spurious signal shall be postulated to occur at a time for purposes of analysis, except for high-low pressure interface valves.

5-3.1.12* For the purpose of analysis for cases involving high-to-low pressure interface, hot shorts involving three-phase ac circuits shall be postulated.

5-3.1.13 For ungrounded dc circuits, if it can be shown that only two hot shorts of the proper polarity without grounding could cause spurious operation, no further evaluation shall be necessary except for cases involving high-to-low pressure interfaces.

5-3.1.14* All associated circuits of concern shall be isolated from FSSD circuits by coordinated circuit breakers or fuses.

5-3.1.15* Circuits Associated by Common Enclosure.

5-3.1.15.1 Protection for circuits associated by common enclosure shall be demonstrated by ensuring that suitable electrical overcurrent protection devices are provided for all cables. Appropriate measures to prevent the propagation of fire, such as rated fire stops and seals in the raceway or enclosure, shall be provided.

5-3.1.15.2 The overcurrent protection devices shall be located outside of the fire area containing the common enclosure.

5-3.1.16 High Impedance Faults.

5-3.1.16.1 A high impedance fault shall be assumed to occur as a result of a fire.

5-3.1.16.2 Evaluation of the impact of high impedance faults on the ability to achieve and maintain safe shutdown shall be performed. This evaluation shall demonstrate that there is sufficient capacity in the electrical protective system to preclude a trip of the main source breaker to the supply.

5-3.2* Seismic/Fire Interaction.

5-3.2.1 A risk assessment that demonstrates the potential risk from a seismically induced fire in relationship to the plant's core damage frequency shall be prepared.

5-3.2.2* An industry-accepted examination process shall be used for the risk assessment.

5-3.2.3 The assessment shall be used to evaluate the level of safety of the plant. This assessment shall not be used to reduce the overall plant fire protection design basis.

5-4 Separation Criteria.

5-4.1

One safety division of systems that is necessary to achieve and maintain safe shutdown from either the control room or emergency control station(s) shall be maintained free of fire damage by a single fire, including an exposure fire.

5-4.2

One safety division of systems that is necessary to prevent the initiation of a design basis accident shall be maintained free of fire damage from a single fire that occurs outside the main control room.

5-4.3

Redundant cables, equipment, components, and associated circuits of nuclear-safety-related or safe shutdown systems shall be located in separate fire areas. The fire barrier forming these fire areas shall have a 3-hr fire rating and automatic area-wide detection shall be installed throughout these fire areas. Structural steel forming a part of or supporting such fire barriers shall be protected to provide fire resistance equivalent to that of the barrier.

Exception No. 1: Where redundant system separation inside containment cannot be achieved, other measures shall be permitted in accordance with Section 5-6 to prevent a fire from causing the loss of function of nuclear-safety-related or safe shutdown systems.

Exception No. 2: Redundant cables, equipment, components, and associated circuits of nuclear-safety-related or safe shutdown systems shall be located in separate fire areas. The fire barriers forming these fire areas shall have a minimum fire-resistive rating of 1 hr and automatic area-wide detection and suppression shall be installed throughout these fire areas. Structural steel forming a part of or supporting such fire barriers shall be protected to provide fire resistance equivalent to that of the barrier.

5-4.4

Fire areas separated by minimum 3-hr fire barriers shall be established to separate redundant safety divisions and safe shutdown functions from fire hazards in nonsafety or safe shutdown related areas of the plant.

5-4.5

Within fire areas containing components of either a nuclear-safety-related or safe shutdown system, special attention shall be given to detecting and suppressing fire that can adversely affect the system. Measures that shall be taken to reduce the effects of a postulated fire in a given fire area include limiting the amount of combustible materials (*see Section 3-3*), providing fire-rated barriers between major components and equipment to limit fire spread within a fire area (*see Section 6-1*), or installing fire de- tection (*see Section 7-8*) and fixed suppression systems (*see Section 7-6*).

5-5 Manual Actions.

5-5.1 Shutdown Procedures.

Procedures shall be developed for actions necessary to achieve FSSD.

5-5.2 Operator Actions.

5-5.2.1 Operator actions necessary to achieve FSSD of the reactor shall be kept to a minimum.

5-5.2.2* No credit shall be taken for operator actions required to effect repairs to equipment in order to achieve FSSD of the reactor.

5-5.2.3 Personnel necessary to achieve and maintain the plant in FSSD following a fire shall be provided from the normal on-site staff, exclusive of the fire brigade.

5-5.2.4 The operator training program shall include performance-based simulator training on FSSD procedures.

5-5.2.5 Walk-through of operator actions necessary to achieve FSSD of the reactor shall be performed to verify that the actions are feasible and shall be integrated into the operator training program.

5-5.2.6 Postfire shutdown and recovery plans shall be included in the station emergency preparedness plan. Drills and operator requalification training shall ensure that operations personnel are familiar with and can accomplish the necessary actions.

5-5.3 Operator Access and Equipment Operation.

5-5.3.1 Operator Access.

5-5.3.1.1* Access routes to areas containing equipment necessary for safe shutdown of the reactor shall be protected from the effects of smoke and fire.

5-5.3.1.2 Two separate access routes shall be provided from the main control room to the remote shutdown location.

5-5.3.1.3 Emergency lighting shall be provided for the access routes and the remote shutdown location (*see Section 6-6*).

5-5.3.2 Equipment Operation.

5-5.3.2.1* Operator safety shall not be threatened by fire conditions while implementing FSSD of the reactor.

5-5.3.2.2* Operation of equipment required to effect FSSD of the reactor shall not require any extraordinary actions by the operator.

5-5.3.2.3 Operators (e.g., handwheels of valves that require manual manipulation for FSSD) shall be readily accessible. If the handwheel is located more than 5 ft (1.5 m) above the floor, it shall be provided with either a chain operator or a permanent platform. The platform shall be of sufficient size to allow the operator to safely perform the manual action.

5-6 Alternative Shutdown Capability.

5-6.1

Alternative shutdown capability provided for a specific fire area shall include achieving and maintaining subcritical reactivity conditions in the reactor, maintaining the reactor coolant inventory, achieving safe shutdown, and maintaining safe shutdown following the fire event.

5-6.2

During the postfire shutdown, the reactor coolant system process variables shall be maintained within those predicted for a loss of normal ac power, and the fission product boundary integrity shall not be affected.

5-6.3

Performance goals for reactor shutdown functions shall be the same as those required by 5-3.1.8.

5-6.4

The safe shutdown circuits for each fire area shall be known to be isolated from associated circuits in the fire area so the hot shorts, shorts to ground, open circuits, or short circuits will not prevent the operation of the safe shutdown equipment. Isolation of associated circuits from the safe shutdown equipment shall be such that a postulated fire involving the associated circuits will not prevent safe shutdown or damage the safe shutdown components.

Chapter 6 General Plant Design

6-1 Plant Arrangement.

6-1.1 Building Separation.

6-1.1.1 In multi-unit plants, each unit shall be separated from adjacent units by either an open space of at least 50 ft (15.2 m), or at least a 3-hr-rated fire barrier.

6-1.1.2 Buildings or portions thereof containing nuclear-safety-related systems shall be separated from buildings or portions thereof not related to nuclear safety by barriers having a designated fire resistance rating of 3 hr.

Exception: Buildings containing nuclear-safety-related systems shall be permitted to be separated from buildings not related to nuclear safety by an open space of at least 50 ft (15.2 m).

6-1.2 Fire Areas.

Advanced light water reactor (ALWR) electric generating plants shall be subdivided into separate fire areas to minimize the risk of fire spread and the resultant consequential damage from fire gases, smoke, heat, radioactive contamination, and fire-fighting activities. In addition, the subdivision into fire areas shall allow adequate access for manual fire suppression activities.

6-1.2.1 A listed fire barrier having a fire resistance rating of at least 3 hr, and with listed 3-hr-rated penetration seals, shall be provided as follows:

(a) To separate all contiguous buildings or portions thereof serving different purposes, such as reactor containment, auxiliary, turbine, rad waste, control, service, administration, and other occupancy areas as dictated by reactor design;

(b) To separate safety-related standby emergency diesel generators and combustion turbines from each other and the rest of the plant;

(c) To separate the turbine generator lube oil conditioning system and lube oil storage from the turbine building and adjacent areas;

(d) To separate diesel fire pumps and associated equipment from other pumps in the same pump house;

(e) To separate all areas with heavy concentrations of cables, such as cable spreading rooms, cable tunnels, cable penetration areas, and cable shafts or chases, including those within the reactor containment, from adjacent areas;

(f) To separate auxiliary boiler rooms from adjacent areas; and

(g) Wherever so determined by the fire hazards analysis.

6-1.2.2 To prevent vertical spread of fire, stairways, elevator shafts, trash chutes, and other vertical shafts and plenums shall be enclosed with barriers having a fire resistance rating of at least 2 hr. Openings in such barriers shall be protected with listed automatic or self-closing fire doors having a fire protection rating of at least $1^1/_2$ hr.

6-1.3 Openings in Fire Barriers.

6-1.3.1 All openings in fire barriers shall be provided with fire door assemblies, fire dampers, penetration seals (fire stops), or other approved means having a fire protection rating consistent with the designated fire resistance rating of the barrier.

Exception: The use of assemblies that are not listed or approved due to nuclear safety or security requirements shall be demonstrated to be equivalent.

6-1.3.2 Fire door assemblies, fire dampers, and fire shutters used in 2-hr-rated fire barriers shall be listed as not less than $1^1/_2$ hr rated and shall meet the requirements of NFPA 80, *Standard for Fire Doors and Fire Windows*, for fire door requirements and NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, for fire damper requirements.

Exception: Where approved full-scale fire tests indicate that opening protection is not necessary, opening protection shall not be required.

6-1.3.2.1 Windows in fire barriers, such as for a control room or computer room, shall be provided with a listed or approved fire shutter or automatic wall curtain.

6-1.3.2.2 Cable openings, piping openings, and building joints shall be provided with fire-rated penetration seals. The sealing material shall be of limited-combustible or noncombustible material and shall meet the requirements of ASTM E 814, *Fire Tests of Through-Penetration Fire Stops*, or UL 1479, *Standard for Safety Fire Tests of Through-Penetration Firestops*.

6-1.3.2.3 Internal Conduit Seals. All conduits shall be sealed at the barrier with a fire-rated seal, if accessible. Alternatively, internally sealing with a fire-rated seal at the first break in the conduit on both sides of the barrier shall be acceptable. For the above configuration, the fire rating of the internal conduit seal shall be equivalent to the rating of the fire barrier being penetrated.

Exception: Where approved full-scale fire tests indicate that internal conduit seals are not necessary, internal conduit seals are not required.

6-1.3.2.4 All fire-rated assemblies shall be tested with a positive pressure in the furnace.

6-1.3.2.5 Normally closed fire doors in fire barriers shall be identified with a sign indicating, "Fire Door — Keep Closed."

6-1.3.3 Design features that provide for monitoring and control of fire doors to assure fire door operability and fire barrier integrity shall be provided.

Exception: Administrative procedures instead of design features shall be permitted.

6-2 Life Safety.

6-2.1*

NFPA *101*,® *Life Safety Code*,® shall be the standard for life safety from fire in the design and operation of the ALWR, except where modified by this standard.

6-2.2*

The majority of the areas involved in the transfer of nuclear energy to electrical energy shall be considered as special-purpose industrial occupancies and special structure, windowless buildings, as defined in NFPA *101*, *Life Safety Code*.

6-2.3

In determining the exits for an ALWR plant, the actual number of personnel and occupancy hazards during maintenance, refueling, and testing shall determine the exit requirements and occupant load based upon NFPA *101*, *Life Safety Code*.

6-2.4

Cafeterias, lunchrooms, conference rooms, and assembly rooms having an occupant load greater than 50 shall conform to the new assembly occupancy requirements in NFPA *101*, *Life Safety Code*.

6-2.5

General office areas, office buildings, and training facilities shall conform to the business occupancy requirements in NFPA *101*, *Life Safety Code*.

6-2.6

Warehouses and storage areas shall conform to the storage occupancy requirements in NFPA *101*, *Life Safety Code*.

6-3 Building and Construction Materials.

6-3.1

Construction materials for the ALWR plant shall be classified by at least one of the following test methods appropriate to the end-use configuration of the material:

(a) NFPA 220, *Standard on Types of Building Construction*;

(b) ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*;

(c) NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials* (ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*);

(d) NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*;

(e) NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials* (ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*);

(f) NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*; or

(g) NFPA 259, *Standard Test Method for Potential Heat of Building Materials*.

6-3.2*

All walls, floors, and structural components, except interior finish materials, shall be of noncombustible construction.

6-3.2.1 Interior wall or ceiling finish classification shall be in accordance with NFPA *101*, *Life Safety Code*, requirements for Class A material.

6-3.2.2 Interior floor finish classification shall be in accordance with NFPA *101*, *Life Safety Code*, requirements for Class I interior floor finish.

6-3.3

Thermal insulation materials, radiation shielding materials, ventilation duct materials, soundproofing materials, and suspended ceilings, including light diffusers and their supports, shall be noncombustible or limited combustible.

6-3.4

Electrical wiring above suspended ceilings shall be kept to a minimum. Electrical wiring shall be listed for plenum use, or armor-metal-jacketed, or routed in metallic conduits, or trays having both solid metallic bottoms and covers.

6-3.5

Roof coverings shall be Class A as determined by tests described in NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.

6-3.6

Metal roof deck construction shall be Class I as listed by Factory Mutual or fire acceptable as listed by Underwriters Laboratories Inc.

6-3.7

Bulk flammable gas storage, either compressed or cryogenic, shall not be permitted inside structures housing safety-related systems.

6-3.7.1 Storage of flammable gas, such as hydrogen, shall be located outdoors or in separate detached buildings, so that a fire or explosion will not adversely affect any safety-related systems or equipment.

6-3.7.2* Outdoor high pressure flammable gas storage containers shall be located so that the long axis is not pointing at the building walls.

6-3.8

Bulk storage of flammable and combustible liquids shall not be permitted inside structures housing safety-related systems. As a minimum, the storage and use shall comply with the requirements of NFPA 30, *Flammable and Combustible Liquids Code*.

6-4* Ventilation.

6-4.1*

The design, installation, and operation of ventilation systems necessary for normal and emergency operation of the plant shall be in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems.*

6-4.2*

Automatic damper closure or shutdown of ventilation systems shall be consistent with nuclear safety and safety of on-site personnel.

6-4.3

Smoke removal shall be provided for nuclear-safety-related areas of the plant. Equipment shall be suitable for removing smoke without damage to equipment. The release to the environment of smoke containing radioactive materials shall be monitored in accordance with emergency plans.

Exception: For those plants provided with complete automatic sprinkler protection, fixed ventilation systems for the removal of smoke is not required.

6-4.3.1 Smoke and heat removal systems shall be provided for other fire areas based upon the fire hazards analysis.

Exception: For those plants provided with complete automatic sprinkler protection, fixed ventilation systems for the removal of smoke is not required.

6-4.3.2 Smoke from nonnuclear areas shall be discharged directly outside to an area that will not adversely affect nuclear-safety-related areas.

6-4.3.3 Any ventilation system designed to exhaust potentially radioactive smoke or heat shall be evaluated to ensure that inadvertent operation or single failures will not violate the radiologically controlled areas of the plant. This includes containment functions for protecting the public and maintaining habitability for operations personnel.

6-4.4

To facilitate manual fire fighting, smoke control shall be provided in high-density cable-use areas, switchgear rooms, diesel fuel oil storage areas, turbine buildings, and other areas where potential exists for heavy smoke and heat conditions as determined by the fire hazards analysis.

6-4.5

The power supply and controls for mechanical ventilation systems used for smoke removal shall be routed outside the fire area served by the system or protected from fire damage.

6-4.6

The fresh air supply intakes to plant areas shall be located remote from the exhaust air outlets and smoke vents of other fire areas to minimize the possibility of contaminating the air intake with the products of combustion.

6-4.7

Enclosed stairwells shall be designed to minimize smoke infiltration during a fire.

6-4.8

Where natural-convection ventilation is used, a minimum ratio of vent area to floor area shall be at least 1 to 200, except in oil hazard areas, where at least a 1- to-100 ratio shall be provided.

6-4.9 Duct Systems.

6-4.9.1 Combustible ducts, including fire-retardant types, shall not be used for ventilation systems.

6-4.9.2 Interconnections of individual fire areas via the ventilation system shall be kept to a minimum.

6-4.9.3 Fire dampers shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*. Consideration shall be given to the velocity in the duct.

Exception No. 1: Where full-scale fire tests that are conducted by testing laboratories indicate that fire dampers are not necessary to prevent fire spread through a fire-rated barrier, fire dampers can be omitted from the fire barrier.

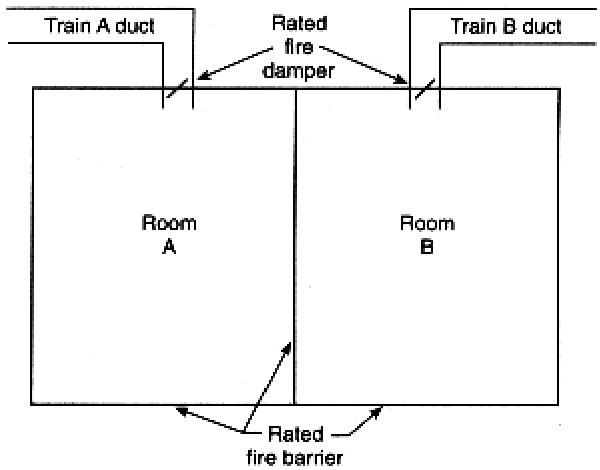
Exception No. 2: As an alternative to fire dampers, the duct system can be enclosed or constructed to provide the required fire barrier through adjacent areas. (Refer to Figure 6-4.9.)

6-4.9.4 Listed fire dampers having a rating of $1^1/_2$ hr shall be installed where ventilation ducts penetrate fire barriers having a required fire resistance rating of 2 hr. Where ventilation ducts penetrate required 3-hr fire barriers, approved fire dampers having a fire protection rating of 3 hr shall be installed.

6-4.9.5 Fire dampers shall be equipped for automatic closure by thermal release elements. The fire damper shall be mounted directly into the separating wall or the duct can be protected between the wall and the damper according to the fire resistance of the separating wall structure.

6-4.9.6 Fire dampers shall be designed and installed so that the air velocity in the ducts assists in closing fire dampers and does not preclude proper damper closure.

6-4.9.7 Ventilation ducts containing fire dampers shall be provided with access ports for ease of inspection and for replacement of the thermal element.



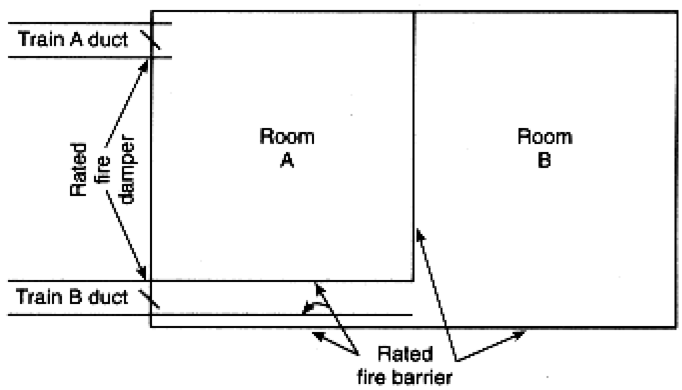


Figure 6-4.9 Typical air duct fire damper configuration.

6-4.10 Filters.

6-4.10.1 Air entry filters shall have approved noncombustible filter media that produce a minimum amount of smoke (UL Class 1) when subjected to heat.

6-4.10.2 In order to decrease the fire hazard of these filters and of oil-bath-type filters, only approved fire-resistive adhesives and oils with the Cleveland open-cup flash point (ASTM D 92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup*) equal to or greater than 464°F (240°C) and that do not produce appreciable smoke shall be used.

6-4.10.3 High-efficiency particulate air filters (HEPA) shall meet the requirements of UL 586, *Standard for Test Performance of High-Efficiency Particulate Air Filter Units*.

6-4.10.4 Fixed water spray systems shall be provided for charcoal adsorber beds containing more than 100 lb (45.4 kg) of charcoal.

6-4.10.5 Fire suppression systems shall be installed to protect filters that collect combustible material.

6-5 Drainage.

6-5.1*

Drainage shall be provided in all areas of the plant for the removal of all liquids directly to safe areas, or for containment in the area without adverse flooding of equipment and without endangering other areas.

6-5.2

Drainage and the prevention of equipment water damage shall be accomplished by one or more of the following:

(a) Floor drains,

(b) Floor trenches,

(c) Open doorways or other wall openings,

(d) Curbs for containing or directing drainage,

(e) Equipment pedestals, or

(f) Pits, sumps, and sump pumps.

6-5.3

Drainage and any associated drainage facilities for a given area shall be sized to accommodate the volume of liquid produced by all of the following:

(a) The spill of the largest single container of any flammable or combustible liquids in the area;

(b) Where automatic suppression is provided throughout, the credible volume of discharge (as determined by the fire hazards analysis) for the suppression system operating for a period of 30 min;

(c) Where automatic suppression is not provided throughout, the volume shall be based on a manual fire-fighting flow rate of 500 gal/min (1892.5 L/min) for a duration of 30 min, unless the fire hazards analysis demonstrates a different flow rate and duration;

(d)* Where automatic suppression is not provided throughout, the contents of piping systems and containers that are subject to failure in a fire; and

(e) Where the installation is outside, credible environmental factors such as rain and snow.

6-5.4

Floor drainage from areas containing flammable or combustible liquids shall be trapped to prevent the spread of burning liquids beyond the fire area.

6-5.5

Where gaseous fire suppression systems are installed, floor drains shall be provided with adequate seals, or the fire suppression system shall be sized to compensate for the loss of fire suppression agent through the drains.

6-5.6

Drainage facilities shall be provided for outdoor oil-insulated transformers, or the ground shall be sloped such that oil spills flow away from buildings, structures, and adjacent transformers.

6-5.6.1 Unless drainage from oil spills is accommodated by sloping the ground around transformers away from structures or adjacent equipment, consideration shall be given to providing curbed areas or pits around transformers.

6-5.6.2 If a layer of uniformly graded stone is provided in the bottom of the curbed area or pit as a means of minimizing ground fires, the following shall be assessed:

(a) The sizing of the pit shall allow for the volume of the stone, and

(b) The design shall address the possible accumulation of sediment or fines in the stone.

6-5.7

For facilities consisting of more than one generating unit, a curb or trench drain shall be provided on solid floors where the potential exists for an oil spill, such that oil released from the incident on one unit will not expose an adjacent unit.

6-5.8

Water drainage from areas that might contain radioactivity shall be collected, sampled, and analyzed before discharge to the environment.

6-5.9

Water released during fire suppression operations in areas containing radioactivity shall be drained to a location that would be acceptable for the containment of radioactive materials.

6-6 Emergency Lighting.

6-6.1

Emergency lighting units shall provide adequate lighting levels. The lighting units shall be sized to provide a duration of operation that will adequately illuminate the egress and access routes to areas containing safe shutdown equipment and the equipment operation until normal or emergency plant lighting can be re-established.

6-6.2

The illumination of means of egress shall be in accordance with NFPA *101, Life Safety Code*. The illumination shall include emergency lighting and marking of the means of egress.

6-6.3

The floor of the means of egress and the safe shutdown operations shall be illuminated at all points including angles, intersections of corridors, passageways, stairways, landings of stairways, exit doors, safe shutdown equipment, and access and egress routes to safe shutdown equipment to values of not less than 1 foot-candle measured at the floor and at safe shutdown equipment.

6-6.4

The required illumination shall be so arranged that the failure of any single lighting unit, such as the burning out of a single light bulb, will not leave any area in darkness.

6-6.5

Suitable battery-powered hand lights shall be provided for emergency use by the fire brigade and other operations personnel required to achieve safe plant shutdown.

6-7 Lightning Protection.

The plant shall be provided with a lightning protection system in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

6-8 Electrical Cabling.

6-8.1

As a minimum, combustible cable insulation and jacketing material shall meet the fire and flame test requirements of IEEE 383, *Standard for Type Test of Class IE Electric Cables, Field Splices and Connections for Nuclear Power Generating Stations*. Meeting the requirements of IEEE 383 shall not eliminate the need for protection as specified in this standard and the fire hazards analysis.

6-8.2

Fiber optic cable insulation and jacketing material shall meet the fire and flame test requirements of IEEE 383, *Standard for Type Test of Class IE Electric Cables, Field Splices and Connections for Nuclear Power Generating Stations*.

6-8.3

Group cabling shall be routed away from exposure hazards or protected as specified in this standard. Specifically, group cabling shall not be routed near sources of ignition or flammable and combustible liquid hazards.

6-8.4

Cable raceways shall be used only for cables.

6-8.5

Only metal shall be used for cable trays.

6-8.6

Only metallic tubing shall be used for conduit.

Exception: Nonmetallic conduit shall be permitted to be used with concrete encasement or for direct burial runs.

6-8.6.1 Thin-wall metallic tubing shall not be used.

6-8.6.2 Flexible metallic tubing shall only be used in lengths less than 5 ft (1.5 m) to connect components to equipment.

6-8.6.3 Other raceways shall be made of noncombustible materials.

6-9* Exposure Protection.

Buildings shall be protected from exposure fires by any one of the following:

(a) A listed 3-hr fire barrier with automatic or self-closing fire doors having a fire protection rating of 3 hr and listed penetration protection of 3-hr rating,

(b) A spatial separation of at least 50 ft (15.2 m), or

(c) Exterior exposure protection.

6-10 Electrical Systems for the Plant.

The electrical design and installation of electrical generating, control, transmission, distribution, and metering of electrical energy shall be provided in accordance with NFPA 70, *National Electrical Code*, or ANSI C2, *National Electrical Safety Code*, as applicable.

6-11 Communications.

6-11.1

The plant-approved voice/alarm communication system in accordance with NFPA 72, *National Fire Alarm Code*, shall be available on a priority basis for fire announcements, directing plant fire brigade, and fire evacuation announcements.

6-11.2*

A portable radio communication system shall be provided for use by the fire brigade and other operation personnel required to achieve safe shutdown.

6-11.3

The radio communication system shall not interfere with the communication capabilities of the plant security force.

6-11.4

The impact of fire damage on the communication systems shall be considered when installing fixed repeaters to permit the use of portable radios. Repeaters shall be located such that a fire-induced failure of the repeater will not also cause failure of the other communication systems relied upon for safe shutdown.

6-11.5*

Plant control equipment shall be designed so that the control equipment is not susceptible to radio frequency interferences from portable radios.

6-11.6

Preoperational tests and periodic testing shall demonstrate that the frequencies used for portable radio communications will not affect actuation of protective relays or other electrical components.

Chapter 7 General Fire Protection Systems and Equipment

7-1 General.

7-1.1*

A fire hazards analysis shall be conducted to determine the fire protection requirements for the facility.

7-1.2*

All fire protection systems, equipment, and installations shall be dedicated to fire protection purposes.

Exception No. 1: Except when in accordance with 7-4.9.

Exception No. 2: Fire protection systems shall be permitted to be used to provide redundant backup to nuclear-safety systems provided the fire protection systems meet the design basis requirements of the nuclear-safety systems. Fire protection systems used in this manner shall be designed to handle both functions.

7-1.3

All fire protection equipment shall be listed or approved for its intended service.

7-2 Water Supply.

7-2.1*

The fire water supply shall be calculated on the basis of the largest expected flow rate for a period of 2 hr, but shall not be less than 300,000 gal (1 135 500 L). This flow rate shall be based on 500 gal/min (1892.5 L/min) for manual hose streams plus the largest design demand of any sprinkler or fixed water spray system as determined in accordance with this standard, NFPA 13, *Standard for the Installation of Sprinkler Systems*, or NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*. The fire water supply shall be capable of delivering this design demand with the hydraulically least demanding portion of fire main loop out of service.

7-2.2*

Two 100 percent [minimum of 300,000 gal (1 135 500 L) each] system capacity tanks shall be installed. The tanks shall be interconnected such that fire pumps can take suction from either or both. A failure in one tank or its piping shall not cause both tanks to drain. The tanks shall be designed in accordance with NFPA 22, *Standard for Water Tanks for Private Fire Protection*.

Exception: Refill times for filling the water tanks do not apply.

7-2.3*

The tanks shall not be supplied by an untreated, raw water source.

7-2.4 Fire Pumps.

7-2.4.1 Fire pumps shall meet the requirements of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and shall be automatic starting.

7-2.4.2* Fire pumps shall be provided to ensure that 100 percent of the flow rate capacity will be available assuming failure of the largest pump.

7-2.4.3 Individual fire pump connections to the yard fire main loop shall be separated with sectionalizing valves between connections. Each pump and its driver and controls shall be located in a room separated from the remaining fire pumps by a fire wall with a minimum rating of 3 hr. The fuel for the diesel fire pump(s) shall be separated so that it does not provide a fire source exposing safety-related equipment.

7-2.4.4 A method of automatic pressure maintenance of the fire protection system shall be provided independent of the fire pumps.

7-2.4.5 Supervisory signals and visible indicators required by NFPA 20 shall be received in the control room.

7-3 Valve Supervision.

All fire protection water supply and system control valves shall be under a periodic inspection program (*see Chapter 3*) and shall be supervised by one of the following methods:

(a) Electrical supervision with audible and visual signals in the main control room or another constantly attended location and monthly valve inspections;

(b) Locking valves in their normal position and monthly valve inspections. Keys shall be made available only to authorized personnel; or

(c) Sealing valves in their normal positions and weekly valve inspections. This option shall be utilized only where valves are located within fenced areas or under the direct control of the property owner.

7-4 Yard Mains, Hydrants, and Building Standpipes.

7-4.1

The underground yard fire main loop shall be installed to furnish anticipated water requirements. NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*, gives necessary guidance for such installation. It references other design codes and standards developed by such organizations as the American National Standards Institute (ANSI) and the American Water Works Association (AWWA). The type of pipe and water treatment shall be design considerations, with tuberculation as one of the parameters. Means for inspecting and flushing the systems shall be provided.

7-4.2

Approved visually indicating sectional control valves such as post-indicator valves shall be provided to isolate portions of the main for maintenance or repair without simultaneously shutting off the supply to both primary and backup fire suppression systems.

7-4.3

Valves shall be installed to permit isolation of outside hydrants from the fire main for maintenance or repair without interrupting the water supply to automatic or manual fire suppression systems.

7-4.4

A common yard fire main loop may serve multi-unit nuclear power plant sites if it is cross-connected between units. Sectional control valves shall permit maintaining independence of the individual loop around each unit. For such installations, common water supplies shall also be permitted to be utilized. For multiple-reactor sites with widely separated plants [approaching 1 mi. (1.6 km) or more], separate yard fire main loops shall be used.

7-4.5

Outside manual hose installation shall be sufficient to provide an effective hose stream to any on-site location. Hydrants with individual hose gate valves shall be installed approximately every 250 ft (76 m) apart on the yard main system. A hose house equipped with hose and combination nozzle and other auxiliary equipment specified in NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*, shall be provided at intervals of not more than 1000 ft (305 m) along the yard main system.

Exception: Mobile means of providing hose and associated equipment, such as hose carts or trucks, shall be permitted in lieu of hose houses. Where provided, such mobile equipment shall *be equivalent to the equipment supplied by three hose houses.*

7-4.6

Threads compatible with those used by local fire departments shall be provided on all hydrants, hose couplings, and standpipe risers, or the fire departments shall be provided with adapters that allow interconnection between plant equipment and the fire department equipment.

7-4.7

Sprinkler systems and manual hose station standpipes shall have connections to the plant underground water main so that a single active failure or a crack in a moderate-energy line can be isolated so as not to impair both the primary and backup fire suppression systems. Alternatively, headers fed from each end are permitted inside buildings to supply both sprinkler and standpipe systems, provided steel piping and fittings meeting the requirements of ANSI B31.1, *Code for Power Piping*, are used for the headers (up to and including the first valve) supplying the sprinkler systems where such headers are part of the seismically analyzed hose standpipe system. Where provided, such headers are considered an extension of the yard main system. Each sprinkler and standpipe system shall be equipped with an outside screw and yoke (OS&Y) gate valve or other approved shutoff valve.

7-4.8

For all power block buildings, Class III standpipe and hose systems shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*. For all other buildings on site, the requirements for standpipe and hose systems shall be appropriate for the hazard being protected.

7-4.9*

The proper type of hose nozzle to be supplied to each area shall be based on the fire hazards analysis. The usual combination spray/straight-stream nozzle shall not be used in areas where the straight stream can cause unacceptable damage. Approved, electrically safe fixed fog nozzles shall be provided at locations where high-voltage shock hazards exist. All hose nozzles shall have shutoff capability.

7-4.10 Seismic Fire Suppression Capabilities.

7-4.10.1* Provisions shall be made to supply water at least to standpipes and hose stations for manual fire suppression in all areas containing nuclear-safety-related systems and components for safe shutdown in the event of a safe shutdown earthquake (SSE).

7-4.10.2 The piping system serving these hose stations shall be analyzed for safe shutdown and earthquake loading, and shall be provided with supports that ensure pressure boundary integrity. The piping and valves for the portion of hose standpipe system affected by this functional requirement shall, as a minimum, satisfy the requirements of ANSI B31.1, *Code for Power Piping*.

7-4.10.3 The system shall be designed to flow a minimum of one Class III standpipe station in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

7-4.10.4 Where the seismic required hose stations are cross-connected to essential seismic Category I water systems, the fire flow shall not degrade the essential water system requirements.

7-5 Portable Fire Extinguishers.

7-5.1

Portable and wheeled fire extinguishers shall be installed, inspected, maintained, and tested in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

Exception: Where placement of extinguishers would result in required activities that are contrary to personnel radiological exposure concerns or nuclear-safety-related concerns, fire extinguishers shall be permitted to be inspected at intervals greater than those specified in NFPA 10, Standard on Portable Fire Extinguishers, or consideration shall be given to locating the extinguishers outside high radiation areas.

7-6 Fire Suppression Systems.

7-6.1

Automatic suppression systems shall be provided in all areas of the plant as required by the fire hazards analysis. Except as modified in this chapter, the following NFPA standards shall be used:

(a) NFPA 11, *Standard for Low-Expansion Foam;*

(b) NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems;*

(c) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems;*

(d) NFPA 13, *Standard for the Installation of Sprinkler Systems;*

(e) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection;*

(f) NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems;*

(g) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*;

(h) NFPA 214, *Standard on Water-Cooling Towers*; and

(i) NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*.

7-6.2

The extinguishing systems chosen shall be based upon the design parameters required as a result of the fire hazards analysis.

7-6.3

Selection of extinguishing agent shall be based upon:

(a) Type or class of hazard;

(b) Effect of agent discharge on critical equipment such as thermal shock, continued operability, water damage, overpressurization, cleanup, etc.; and

(c) Health hazards.

7-6.4

Each fire suppression system shall be equipped with approved alarming devices and annunciate in a constantly attended area.

7-7 Fire Alarm Systems.

7-7.1

Fire signaling systems shall be provided in all areas of the plant as required by the fire hazards analysis. The requirements of this chapter constitute the minimum acceptable protective signaling system functions when used in conjunction with NFPA 72, *National Fire Alarm Code*.

7-7.2*

The signaling system's initiating device and signaling line circuits shall provide emergency operation for fire detection, fire alarm, and water flow alarm during a single break or a single ground fault.

7-7.3

The fire signaling equipment used for fixed fire suppression systems shall give audible and visual alarm and system trouble annunciation in the plant control room for the power block buildings. Local alarm shall be provided. Other fire alarm signals from other buildings shall be permitted to annunciate at the control room or other locations that are constantly attended.

7-7.4*

Audible signaling appliances shall produce a distinctive sound, used for no other purpose. (*See NFPA 72, National Fire Alarm Code*.) Audible signaling devices shall be located and installed so that the alarm can be heard above ambient noise levels.

7-7.5

Plant control room or plant security personnel shall be trained in the operation of all fire signaling systems used in the plant. This training shall include the ability to identify any alarm zone or fire protection system that is operating.

7-7.6

Fire signaling equipment and actuation equipment for the release of fixed fire suppression systems shall be connected to power supply sources in accordance with the requirements of NFPA 72, *National Fire Alarm Code*, and shall be routed outside the area to be protected.

7-7.7

Manual fire alarm boxes shall be installed as required by the fire hazards analysis. (*See NFPA 72, National Fire Alarm Code*.) Where manual release devices are installed for the purpose of releasing an extinguishing agent in a fixed fire suppression system, the manual releases shall be clearly marked for that purpose. The manual release device circuits shall be routed outside the area protected by the fixed extinguishing system.

7-7.8

All signals shall be permanently recorded in accordance with NFPA 72, *National Fire Alarm Code*.

7-8 Fire Detectors.

Automatic fire detectors shall be selected and installed in accordance with:

(a) NFPA 72, *National Fire Alarm Code*;

(b) The design parameters required as a result of the fire hazards analysis of the plant area; and

(c) The additional requirements of this standard.

Chapter 8 Identification of and Protection Against Hazards

8-1* General.

The identification and selection of fire protection systems shall be based on the fire hazards analysis. This chapter identifies fire and explosion hazards in advanced light water reactor plants and specifies the protection criteria that shall be used unless the fire hazards analysis indicates otherwise.

8-2 Primary and Secondary Containments.

8-2.1 Normal Operation.

Fire protection for the primary and secondary containment areas shall be provided for hazards identified by the fire hazards analysis.

8-2.1.1 Operation of the fire protection systems shall not compromise the integrity of the containment or other safety-related systems. Fire protection systems in the containment areas shall function in conjunction with total containment requirements such as ventilation and control of containment liquid and gaseous release.

8-2.1.2 Inside primary containment, fire detection systems shall be provided for each fire hazard identified in the fire hazards analysis. The type of detection used and the location of the detectors shall be the most suitable for the particular type of fire hazard identified by the fire hazards analysis.

8-2.1.3 A general area fire detection capability shall be provided in the primary containment as a backup for the hazard detection described above. To accomplish this, suitable smoke or heat detectors compatible with the radiation environment shall be installed in accordance with NFPA 72, *National Fire Alarm Code*.

8-2.1.4 Standpipe and hose stations shall be installed inside containment. Standpipe and hose stations inside containment shall be permitted to be connected to a high quality water supply of sufficient quantity and pressure other than the fire main loop if plant-specific features prevent extending the fire main supply inside containment.

Exception: For inerted primary containment, standpipe and hose stations shall be permitted to be placed outside the primary containment, with hose no longer than 100 ft (30.5 m), to reach any location inside the primary containment with a 30-ft (9.1-m) effective hose stream.

8-2.1.5 Reactor coolant pumps with an external lubrication system shall be provided with an oil collection system. The oil collection system shall be so designed, engineered, and installed that failure of the oil collection system will not lead to a fire during normal operations, or off-normal conditions such as accident conditions, or earthquakes.

8-2.1.6 The oil collection systems shall be capable of collecting oil from all potential pressurized and unpressurized leakage sites in the reactor coolant pump oil systems. Leakage shall be collected and drained to a vented closed container that can hold the entire oil system inventory.

A flame arrester is required in the vent if the flash point characteristics of the oil present the hazard of fire flashback. Leakage points to be protected shall include the lift pump and piping, overflow lines, oil cooler, oil fill and drain lines and plugs, flanged connections on oil lines, and oil reservoirs where such features exist on the reactor coolant pumps. The drain line shall be large enough to accommodate the largest potential oil leak.

8-2.2 Refueling and Maintenance.

8-2.2.1* Management procedures and controls necessary to ensure adequate fire protection for fire hazards introduced during maintenance and refueling shall be provided. Adequate backup fire suppression shall be provide so that total reliance is not placed on a single fire suppression system.

8-2.2.2 Adequate self-contained breathing apparatus shall be provided near the containment entrance for fire-fighting and damage control personnel. These units shall be independent of any breathing apparatus or air supply systems provided for general plant activities and shall be clearly marked as emergency equipment.

8-3 Control Room Complex.

8-3.1

The control room complex (including kitchen, office spaces, etc.) shall be protected against disabling fire damage and shall be separated from other areas of the plant by floors, walls, ceilings, and roofs having a minimum fire resistance rating of 3 hr. Peripheral rooms in the control room complex shall have an automatic water-based suppression system, where required by the fire hazards analysis, and shall be separated from the control room by noncombustible construction with a minimum fire resistance rating of 1 hr. Ventilation system openings between the control room and the peripheral rooms shall have automatic smoke dampers installed that close on operation of the fire detection and fire suppression systems.

8-3.2

Manual fire-fighting capability shall be provided for both:

(a) Fires originating within a cabinet, console, or connecting cables; and

(b) Exposure fires involving combustibles in the general room area.

8-3.3

Portable Class A and Class C fire extinguishers shall be located in the control room. A fire hose station shall be installed immediately outside of the control room.

8-3.4

Nozzles that are compatible with the hazards and the equipment in the control room shall be provided for the fire hose stations. The choice of nozzles shall satisfy fire-fighting requirements and electrical safety requirements, and shall minimize physical damage to electrical equipment from hose stream impingement.

8-3.5

Smoke detectors shall be provided in the control room complex, the electrical cabinets, and consoles. If redundant safe shutdown equipment is located in the same control room cabinet or console, the cabinet or console shall be provided with internal separation (noncombustible barriers) to limit the damage to one safety division.

8-3.6

Breathing apparatus for the control room operators shall be readily available.

8-3.7

The outside air intakes for the control room ventilation system shall be provided with smoke detection capability to alarm in the control room and enable manual isolation of the control room ventilation system, thus preventing smoke from entering the control room.

8-3.8

Venting of smoke produced by a fire in the control room by means of the normal ventilation system is acceptable; however, provision shall be made to permit isolation of the recirculation portion of the normal ventilation system. Manually operated venting of the control room shall be available to the operators.

8-3.9

All cables that enter the control room shall terminate in the control room. No cabling shall be routed through the control room from one area to another. Cables in spaces underfloor and in above-ceiling spaces shall meet the separation criteria necessary for fire protection.

8-3.10

Air-handling functions shall be ducted separately from cable runs in such spaces (i.e., if cables are routed in underfloor or ceiling spaces, these spaces shall not be used as air plenums for ventilation of the control room). Fully enclosed electrical raceways located in such underfloor and ceiling spaces, if over 1 ft^3 (0.09 m^2) in cross-sectional area, shall have automatic fire suppression inside. Area automatic fire suppression shall be provided for underfloor and ceiling spaces if used for cable runs unless all cable is run in 4-in. (101.6-mm) or smaller steel conduit or cables are in fully enclosed raceways internally protected by automatic fire suppression.

8-4 Cable Concentrations.

8-4.1 Cable Spreading Room.

8-4.1.1 The cable spreading room shall have an automatic water-based suppression system. The location of sprinklers or spray nozzles shall consider cable tray arrangements to ensure adequate water coverage for areas that could present exposure fire hazards to the cable raceways. Automatic sprinkler systems shall be designed for a density of 0.30 gal/min/ft^2 (12.2 L/min/m^2) over the most remote 2500 ft^2 (232.2 m^2).

8-4.1.2 Suppression systems shall be zoned to limit the area of protection to that which the drainage system can handle with any two adjacent systems actuated. Deluge and water spray systems shall be hydraulically designed with each zone calculated with the largest adjacent zone flowing.

8-4.1.3 Cable spreading rooms shall have:

(a) At least two remote and separate entrances for access by the fire brigade personnel,

(b) An aisle separation between tray stacks at least 3 ft (0.9 m) wide and 8 ft (24 m) high,

(c) Hose stations and portable fire extinguishers installed immediately outside the room, and (d)* Area smoke detection.

8-4.2 Cable Tunnels.

8-4.2.1* **Detection Systems.** Cable tunnels shall be provided with smoke detection.

8-4.2.2 Suppression Systems.

8-4.2.2.1 Cable tunnels shall be provided with automatic fixed suppression systems. Automatic sprinkler systems shall be designed for a density of 0.30 gal/min/ft^2 (12.2 L/min/m^2) for the most remote 100 linear ft (30.5 m) of cable tunnel up to the most remote 2500 ft^2 (232.2 m^2).

8-4.2.2.2 The location of sprinklers or spray nozzles shall consider cable tray arrangements and possible transient combustibles to ensure adequate water coverage for areas that could present exposure fire hazards to the cable raceways.

8-4.2.2.3 Deluge sprinkler systems or deluge spray systems shall be zoned to limit the area of protection to that which the drainage system can handle with any two adjacent systems actuated. The systems shall be hydraulically designed with each zone calculated with the largest adjacent zone flowing.

8-4.2.3 Cables shall be designed to allow wetting undamaged cables with water supplied by the fire suppression system without electrical faulting.

8-4.2.4 Cable tunnels over 50 ft (15.2 m) long shall have:

(a) At least two remote and separate entrances for access by the fire brigade personnel,

(b) An aisle separation between tray stacks at least 3 ft (0.9 m) wide and 8 ft (2.4 m) high, and

(c) Hose stations and portable fire extinguishers installed immediately outside the tunnel.

8-4.3 Cable Shafts and Risers.

Cable tray fire breaks shall be installed every 20 ft (6.1 m) for vertical cable trays that rise over 30 ft (9.1 m). Access to cable shafts shall be provided every 40 ft (12.2 m) with the topmost access within 20 ft (6.1 m) of the cable shaft ceiling. Automatic sprinkler protection and smoke detection shall be provided at the ceiling of the vertical shaft.

8-5 Plant Computer and Communication Rooms.

Computer and communication rooms shall meet the applicable requirements of NFPA 75, *Standard for the Protection of Electronic Computer/Data Processing Equipment*.

8-6 Switchgear Rooms and Relay Rooms.

8-6.1*

Smoke detection shall be provided and shall alarm in both the control room and locally. Cables entering the safety-related switchgear rooms shall terminate in the switchgear room. The safety-related switchgear rooms shall not be used for other purposes. Fire hose stations and portable fire extinguishers shall be readily available outside the area.

8-6.2

Equipment shall be located to facilitate fire fighting. Drains shall be provided to prevent water accumulation from damaging safety-related equipment. Remote manually actuated ventilation shall be provided for smoke removal when manual fire suppression is needed. (*See Section 6-4*.)

8-7 Battery Rooms.

8-7.1*

Battery rooms shall be provided with ventilation to limit the concentration of hydrogen to 2 percent by volume. Loss of ventilation shall alarm in the control room.

8-7.2

Safety-related battery rooms shall be protected against fires and explosions. Battery rooms shall be separated from other areas of the plant by fire barriers having a 1-hr minimum rating. Direct current switchgear and inverters shall not be located in these battery rooms. Fire detection shall be provided. Fire hose stations and portable fire extinguishers shall be readily available outside the room.

8-8 Turbine Building.

8-8.1*

The turbine building shall be separated from adjacent structures containing safety-related equipment by fire-resistive barriers having a minimum 3-hr rating. The fire barriers shall be designed so that the barrier will remain in place even in the event of a complete collapse of the turbine structure. Openings and penetrations shall be minimized in the fire barrier and shall not be located where turbine oil systems or generator hydrogen cooling systems create a direct fire exposure hazard to the fire barrier. Smoke and heat removal systems shall be provided in accordance with 6-4.3.

Exception: For those plants provided with complete automatic sprinkler protection at the roof level, smoke and heat removal systems are not required.

8-8.2 Beneath Turbine Generator Operating Floor.

8-8.2.1* All areas beneath the turbine generator operating floor shall be protected by an automatic sprinkler or foam-water sprinkler system. The sprinkler system beneath the turbine generator shall take into consideration obstructions from structural members and piping and shall be designed to a minimum density of 0.30 gal/min/ft^2 (12.2 L/min/m^2) over a minimum application of 5000 ft^2 (464.5 m^2).

8-8.2.2 Foam-water sprinkler systems installed in place of automatic sprinklers described above shall be designed in accordance with NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, or NFPA 16A, *Standard for the Installation of Closed-Head Foam-Water Sprinkler Systems*, and the design densities specified above.

8-8.2.3 Electrical equipment in the area covered by a water or foam system shall be of the enclosed type or otherwise protected to minimize water damage in the event of system operation.

8-8.3* Turbine Generator Bearings.

8-8.3.1 Automatic fixed suppression systems shall be provided for all turbine generator and exciter bearings. If closed-head water spray systems utilizing directional nozzles in accordance with NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, are provided, bearing protection shall be provided for a minimum density of 0.30 gal/min/ft^2 (12.2 L/min/m^2) over the protected area.

8-8.3.2 Accidental water discharge on bearing points and hot turbine parts shall be considered. If necessary, these areas shall be permitted to be protected by shields and encasing insulation with metal covers.

8-8.4

Lubricating oil lines above the turbine operating floor shall be protected with an automatic sprinkler system covering those areas subject to oil accumulation, including the area within the turbine lagging (skirt). The automatic sprinkler system shall be designed to a minimum density of 0.30 gal/min/ft^2 (12.2 L/min/m^2).

8-8.5

Lubricating oil reservoirs and handling equipment shall be protected in accordance with 8-8.2.1. If the lubricating oil reservoir is elevated, sprinkler protection shall be extended to protect the area beneath the reservoir.

8-8.6

If shaft-driven ventilation systems are not used, the area inside a directly connected exciter housing shall be protected with an automatic fire suppression system. If shaft-driven ventilation systems are used, an automatic preaction sprinkler system providing a density of 0.30 gal/min/ft^2 (12.2 L/min/m^2) over the entire area shall be provided.

8-8.7

Clean or dirty oil storage areas shall be protected based on the fire risk evaluation. This area generally represents the largest concentrated oil storage area in the plant. The designer shall consider, as a minimum, the installation of fixed automatic fire protection systems and the ventilation and drainage requirements in Chapter 6.

8-8.8 Hydrogen Systems.

8-8.8.1 General.

8-8.8.1.1 For hydrogen storage systems, see NFPA 50A, *Standard for Gaseous Hydrogen Systems at Consumer Sites*, or NFPA 50B, *Standard for Liquefied Hydrogen Systems at Consumer Sites*.

8-8.8.1.2 Bulk hydrogen systems supplying one or more generators shall have automatic valves located at the supply and operable by “dead man”-type controls at the generator fill point(s) or operable from the control room. This will minimize the potential for a major discharge of hydrogen in the event of a leak from piping inside the plant. Alternatively, vented guard piping shall be permitted to be used inside the building to protect runs of hydrogen piping.

8-8.8.1.3 A flanged spool piece or equivalent arrangement shall be provided to facilitate the separation of hydrogen supply when the generator is open for maintenance.

8-8.8.1.4 For electrical equipment in the vicinity of the hydrogen handling equipment, including detraining equipment, seal oil pumps, valves etc., see Article 500 of NFPA 70, *National Electrical Code*, and Section 127 of ANSI C2, *National Electrical Safety Code*.

8-8.8.1.5 Control room alarms shall be provided to indicate abnormal gas pressure, temperature, and percentage of hydrogen in the generator.

8-8.8.1.6 The generator hydrogen dump valve and hydrogen detraining equipment shall be arranged to vent directly to a safe outside location. The dump valve shall be remotely operable from the control room or from an area accessible during a machine fire.

8-8.8.1.7* An excess-flow check valve shall be provided for the bulk supply hydrogen piping.

8-8.8.2 Hydrogen Seal Oil Pumps.

8-8.8.2.1 Redundant hydrogen seal oil pumps with separate power supplies shall be provided for adequate reliability of seal oil supply.

8-8.8.2.2 Where feasible, electrical circuits to redundant pumps shall be run in buried conduit or provided with fire-retardant coating if exposed in the area of the turbine generator to minimize the possibility of loss of both pumps as a result of a turbine generator fire.

8-8.8.2.3 Hydrogen seal oil units shall be protected in accordance with 8-8.2. Hydrogen seal oil units shall be protected by an automatic, open-head water spray system providing a density of 0.30 gal/min (1.13 L/min) over the hydrogen seal area.

8-8.8.2.4 Curbing or drainage or both shall be provided for the hydrogen seal oil unit in accordance with Section 6-5.

8-8.8.3 Hydrogen in Safety-Related Areas.

8-8.8.3.1 Hydrogen lines in safety-related areas shall be either designed to seismic Class I requirements or sleeved such that the outer pipe is directly vented to the outside, or shall be equipped with excess-flow valves so that, in case of a line break, the hydrogen concentration in the affected areas will not exceed 2 percent.

8-8.8.3.2 Hydrogen lines or sensing lines containing hydrogen shall not be piped into or through the control room.

8-8.9 Hydraulic Control Systems.

The hydraulic control system shall use a listed fire-resistant fluid.

8-8.10* Lubricating Oil Systems.

8-8.10.1 Turbine lubricating oil reservoirs shall be provided with vapor extractors, which shall be vented to a safe outside location.

8-8.10.2 Curbing or drainage or both shall be provided for the turbine lubricating oil reservoir in accordance with Section 6-5.

8-8.10.3 All oil pipe serving the turbine generator shall be designed and installed to minimize the possibility of an oil fire in the event of severe turbine vibration.

8-8.10.4* Piping design and installation shall consider the following measures:

(a) Welded construction,

(b) Guard pipe construction with the pressure feed line located inside the return line or in a separate shield pipe drained to the oil reservoir,

(c) Route oil piping clear of or below steam piping or metal parts, and

(d) Insulate with impervious lagging for steam piping or hot metal parts under or near oil piping or turbine bearing points.

8-8.10.5 Cable for operation of the lube oil pumps shall be protected from fire exposure. Where feasible, electrical circuits to redundant pumps shall be run in buried conduit. Protection shall be permitted to consist of separation of cables for ac and dc oil pumps or 1-hr fire-resistive coating (derating of cable shall be considered).

8-9 Standby Emergency Diesel Generators and Combustion Turbines.

8-9.1

The installation and operation of standby emergency diesel generators and combustion turbines shall be in accordance with NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*.

Exception: Automatic shutdown and remote shutdown features, which shall be governed by nuclear-safety requirements.

8-9.2

Standby emergency diesel generators and combustion turbines located within main plant structures shall be protected by automatic sprinkler, water spray, or foam-water sprinkler systems. Sprinkler and water spray protection systems shall be designed for a 0.25-gal/min/ft^2 (10.19-L/min/m^2) density over the entire area.

8-9.3

Fire detection shall be provided to alarm and annunciate in the control room and to alarm locally. Fire hose stations and portable fire extinguishers shall be readily available outside the area. Drainage for fire-fighting water and means for local manual venting of smoke shall be provided.

8-9.4

A day tank is permitted in standby emergency diesel generator and combustion turbine rooms if the day tank is located in a diked enclosure that has sufficient capacity to hold 110 percent of the contents of the day tank or is drained to a safe location.

8-10 Diesel Fuel Storage and Transfer Areas.

8-10.1

Diesel fuel oil storage tanks shall not be located inside buildings containing other nuclear-safety-related equipment. If aboveground tanks are used, they shall be located at least 50 ft (15.2 m) from any building, or if within 50 ft (15.2 m), they shall be separated from the building by a fire barrier having a minimum 3-hr rating. Potential oil spills shall be confined or directed away from buildings containing safety-related equipment. Underground tanks are acceptable outside or under buildings. (*See NFPA 30 for additional guidance*.)

8-10.2

Aboveground tanks shall be provided with automatic fire suppression systems.

8-11 Nuclear-Safety-Related Pump Rooms.

These rooms shall be protected by fire detection systems. Automatic fire suppression systems shall be provided unless the fire hazards analysis determines that fire suppression is not required.

Fire hose stations and fire extinguishers shall be readily accessible.

8-12 New Fuel Area.

8-12.1

Fire extinguishers shall be located within the new fuel area. Fire hose stations shall be located as determined by the fire hazards analysis to facilitate access and use for fire-fighting operations. Fire detection systems shall be provided. Combustible material shall be limited to the minimum necessary for operation in the new fuel area.

8-12.2

The storage configuration of new fuel shall always be maintained as to preclude criticality for any water density that might occur during fire water application.

8-13 Spent Fuel Pool Area.

Protection for the spent fuel pool area shall be provided by fire hose stations and fire extinguishers. Fire detection shall be provided in the area.

8-14 Rad Waste and Decontamination Areas.

Fire barriers, fire detection, and automatic fire suppression shall be provided as determined by the fire hazards analysis. Manual ventilation control to assist in smoke removal shall be provided if necessary for manual fire fighting.

8-15 Safety-Related Water Tanks.

Storage tanks that supply water for fire-safe shutdown shall be protected from the effects of an exposure fire. Combustible materials shall not be stored next to these tanks.

8-16 Record Storage Areas.

Record storage areas shall be located and protected in accordance with NFPA 232, *Standard for the Protection of Records*. Record storage areas shall not be located in safety-related areas and shall be separated from safety-related areas by fire barriers having a minimum 3-hr rating.

8-17 Cooling Towers.

Cooling towers shall be of noncombustible or limited-combustible construction and located such that a fire in the cooling tower will not adversely affect safety-related systems or equipment. Cooling towers shall be of noncombustible construction when the basin is used as the ultimate heat sink.

Exception: If combustible construction is used, the cooling towers shall be protected by automatic sprinklers or water spray systems in accordance with NFPA 214, Standard on Water Cooling Towers, and shall be located so that they do not affect safety-related systems or equipment in the event of a fire.

8-18 Acetylene-Oxygen Fuel Gases.

Gas cylinder storage locations or the fire protection systems that serve those safety-related areas shall not be in areas that contain or expose safety-related equipment.

8-19 Storage Areas for Ion Exchange Resins.

Unused ion exchange resins shall not be stored in areas that contain or expose safety-related systems or equipment.

8-20 Storage Areas for Hazardous Chemicals.

Hazardous chemicals shall not be stored in areas that contain or expose safety-related systems or equipment.

8-21 Warehouses.

Automatic sprinkler protection shall be provided for warehouses that contain high-value equipment or combustible materials.

8-22 Fire Pump Room/House.

Rooms housing diesel-driven fire pumps shall be protected by automatic sprinkler, water spray, or foam-water sprinkler systems. If sprinkler and water spray systems are provided for fire pump houses, they shall be designed for a minimum density of 0.25 gal/min/ft^2 (10.19 L/min/m^2) over the entire fire area.

8-23 Transformers.

8-23.1

Buildings shall be protected from exposure fires involving oil-filled transformers by locating the transformer casing, conservator tank, and cooling radiators at least 50 ft (15.2 m) from buildings or by providing a minimum 2-hr fire barrier between transformers and exposed buildings [*see Figures 8-23.1(a) and (b)*]. A minimum 1-hr fire barrier or a distance of 30 ft (9.1 m) shall be provided between adjacent transformers. Means shall be provided to contain oil spills.

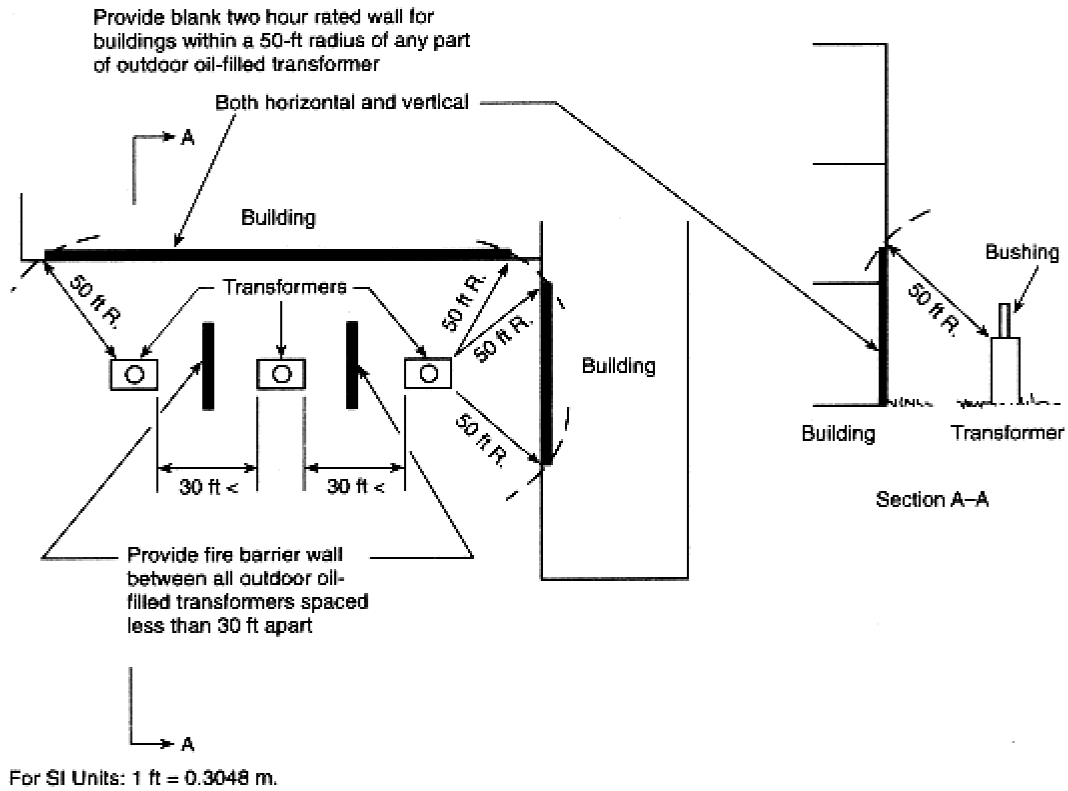

Figure 8-23.1(a) Transformer spacing.

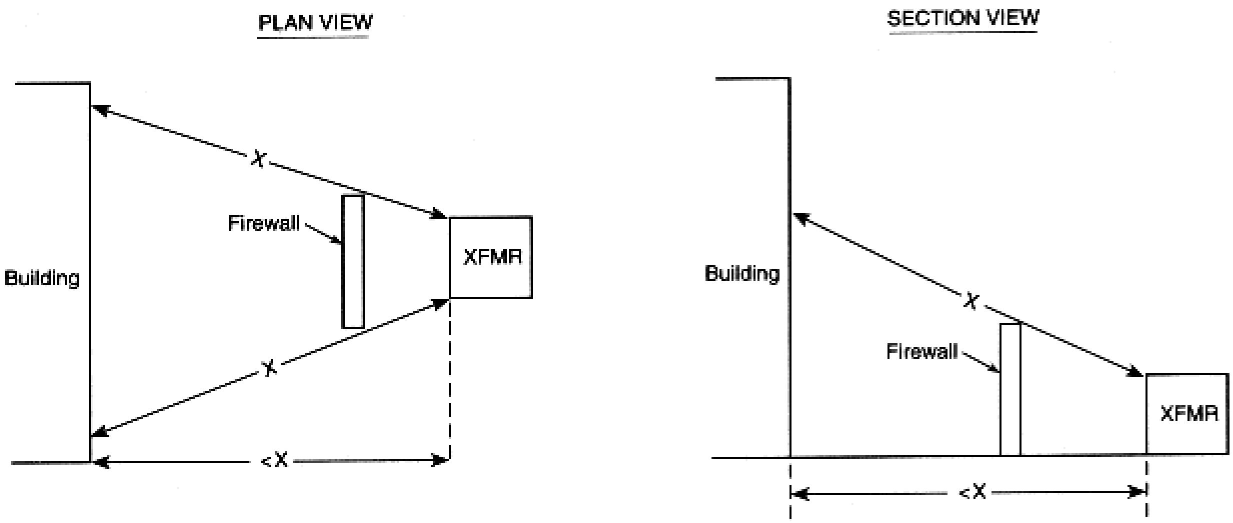
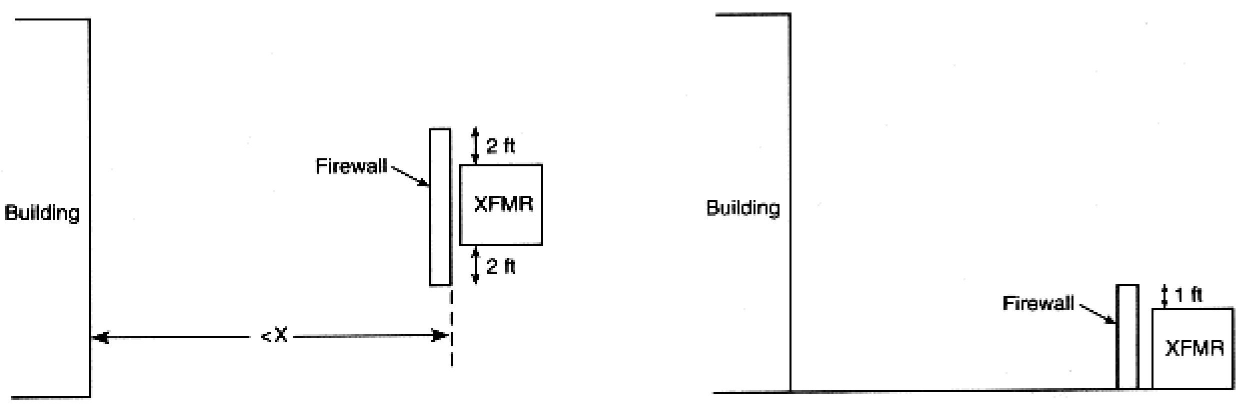
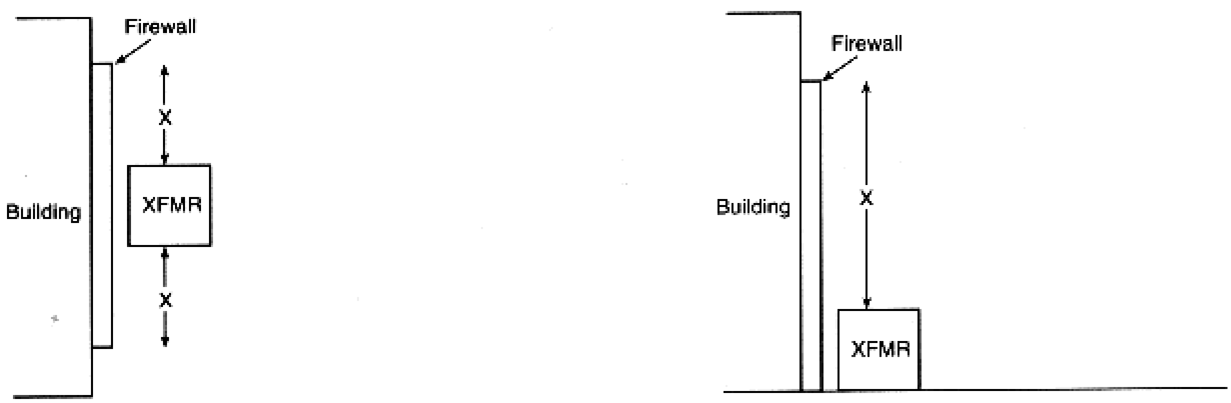


Generic case



Example 1



Example 2

Figure 8-23.1(b) Transformer spacing.

Table 8-23.1 Transformer Spacing Separation Distances

Transformer Oil Capacity	Minimum (Line-of-Sight) Separation without Firewall
Less than 5000 gal (18 925 L)	25 ft (7.6 m)
Over 5000 gal (18 925 L)	50 ft (15.2 m)

8-23.2

Oil-filled main, station service, and start-up transformers shall be protected with automatic water spray systems in accordance with NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, or foam-water spray systems in accordance with NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*.

8-23.3

Transformers installed inside fire areas containing safety-related systems or equipment shall be of the dry type or insulated and cooled with noncombustible liquid.

Exception: Transformers filled with combustible fluid that are located indoors shall be enclosed in a transformer vault [see Article 450(c) of NFPA 70].

8-24 Auxiliary Boilers.

8-24.1

Auxiliary boilers, their fuel burning systems, combustion product removal systems, and related control equipment shall be installed and operated in accordance with NFPA 8501, *Standard for Single Burner Boiler Operation*, and NFPA 8502, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boilers*.

8-24.2

Oil-fired boilers or boilers using oil ignition within the main plant shall be protected with automatic sprinkler, water spray, or foam-water sprinkler systems covering the boiler area. Sprinkler and water spray systems shall be designed for a minimum density of 0.25 gal/min/ft^2 (10.19 L/min/m^2) over the entire area.

8-25 Offices, Shops, and Storage Areas.

Automatic sprinklers shall be provided for storage rooms, offices, and shops containing combustible materials that present an exposure to surrounding areas that are critical to plant operation, and shall be so located and protected that a fire or the effects of a fire, including smoke, will not adversely affect any safety-related systems or equipment.

8-26 Simulators.

Simulators shall be provided with a fixed automatic suppression system. Simulators and supporting equipment shall be separated from other areas by a fire barrier with a minimum 1-hr rating.

8-27 Technical Support and Emergency Response Centers.

Technical support centers shall be separated from all other areas by fire barriers, or separated from all other buildings by at least 50 ft (15.2 m), and protected by an automatic fixed suppression system as required by the fire hazards analysis.

8-28 Intake Structures.

Intake structures shall be of noncombustible construction and shall be provided with automatic sprinkler protection.

Chapter 9 Fire Protection for the Construction Site

9-1 General.

9-1.1*

Although many of the activities on nuclear power generating plant construction sites are similar to the construction of other large industrial plants, an above-average level of fire protection is justified due to life safety consideration of the large number of on-site personnel, the high value of materials, and the duration of the construction period. Consideration of fire protection shall include safety to life and potential for delays in construction schedules and plant startup, as well as protection of property. An example of a multi-million dollar fire that resulted in significant property damage, construction delays, and other complications is included in the appendix.

9-1.2

Major construction projects in existing plants present many of the hazards associated with new construction, while presenting additional exposures to an existing nuclear power plant facility. The availability of the existing plant fire protection equipment and the reduction of fire exposure by construction activities are particularly important.

9-1.3

For fire protection for plants and areas under construction, see NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*. This chapter addresses concerns not specifically considered in NFPA 241.

9-2 Administration.

9-2.1

The responsibility for fire protection for the entire site during the construction period shall be clearly defined. The administrative responsibilities shall be to develop, implement, and periodically update as necessary the measures outlined in this standard.

9-2.2

The responsibility for fire protection programs among various organizations on-site shall be clearly delineated. The fire protection program to be followed and the owner’s right to administration and enforcement shall be established.

9-2.3

The fire protection program shall include a fire risk evaluation of the construction site and construction activities.

9-2.4

Written procedures shall be established for the new construction site, including major construction projects in existing plants. Such procedures shall be in accordance with Chapter 3.

9-2.5*

Security guard service, including recorded rounds, shall be provided through all areas of construction during times when construction activity is not in progress (*see NFPA 601*, *Standard on Guard Service in Fire Loss Prevention*).

9-2.6

Construction schedules shall be coordinated so that the planned permanent fire protection systems are installed and placed in service as soon as possible.

9-2.7

Construction and installation of fire barriers and fire doors shall be given priority in the construction schedule.

9-3 Site Clearing and Construction Equipment.

9-3.1 Site Clearing.

9-3.1.1 Prior to clearing forest and brush-covered areas, the owner shall ensure that a written fire control plan is prepared and that fire-fighting tools and equipment are made available as required by NFPA 295, *Standard for Wildfire Control*. Contact shall be made with local fire and forest agencies for current data on restrictions and fire potential, and to arrange for necessary permits.

9-3.1.2 All construction vehicles and engine-driven portable equipment shall be equipped with effective spark arresters. Vehicles equipped with catalytic converters shall be prohibited from wooded and heavily vegetated areas.

9-3.1.3 Fire tools and equipment shall be distinctly marked and used for fire emergencies only.

9-3.1.4 Each site utility vehicle shall be equipped with at least one fire-fighting tool, portable fire extinguisher, or backpack pump filled with 4 gal to 5 gal (15 L to 19 L) of water.

9-3.1.5 Cut trees, brush, and other combustible spoil shall be disposed of promptly.

9-3.1.6* Where it is necessary to dispose of combustible waste by on-site burning, designated burning areas shall be established with approval of the owner and shall be in compliance with federal, state, and local regulations and guidelines. The contractor shall coordinate burning with the agencies responsible for monitoring fire danger in the area and shall obtain all appropriate permits prior to the start of work.

9-3.2 Construction Equipment.

Construction equipment shall meet the requirements of NFPA 512, *Standard for Truck Fire Protection*.

9-4 Construction Warehouses, Shops, and Offices.

9-4.1

All structures that are to be retained as part of the completed plant shall be constructed of materials as indicated in Chapter 6 and in accordance with other applicable sections in this standard.

9-4.2*

Construction warehouses, offices, trailers, sheds, and other facilities for the storage of tools and materials shall be located with consideration of their exposure to major plant buildings or other important structures.

9-4.3*

A fire risk evaluation shall be performed.

9-4.4

Warehouses that contain high-value equipment (as defined by the individual responsible for fire prevention and fire protection), or where the loss of or damage to contents would cause a delay in start-up dates of the completed plant, shall be arranged and protected as indicated below. Although some of these structures are considered to be temporary and will be removed upon completion of the plant, the fire and loss potential shall be thoroughly evaluated and protection provided where warranted.

9-4.4.1 Building construction materials shall be noncombustible or limited combustible.

9-4.4.2 Automatic sprinkler systems shall be designed and installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*. Waterflow alarms shall be provided and located so as to be monitored at a constantly attended location as determined by the individual responsible for fire protection.

9-4.4.3* Air-supported structures shall only be used for the storage of noncombustibles.

9-4.5

Temporary enclosures, including trailers, inside permanent plant buildings shall be prohibited except where permitted by the individual responsible for fire prevention and fire protection. Where the floor area of a combustible enclosure exceeds 100 ft^2 (9.29 m^2) or where the occupancy presents a fire exposure, the enclosure shall be protected with an approved automatic fire suppression system.

9-4.6

Storage of construction materials, equipment, or supplies that are either combustible or in combustible packaging shall be prohibited in main plant buildings unless the following conditions exist:

(a) An approved automatic fire suppression system is in service in the storage area; or

(b) Where loss of the materials or loss to the surrounding plant area would be minimal, as determined by the individual responsible for fire prevention and fire protection.

9-4.7

Construction areas comprised of mobile buildings arranged with the buildings adjoining each other to form one large fire area shall be avoided. If buildings cannot be adequately separated, fire walls shall be installed between units or automatic sprinklers shall be provided throughout the buildings.

9-4.8

Fire alarms shall be connected to a constantly attended central location.

9-4.9

The handling, storage, and dispensing of flammable liquids and gases shall meet the requirements of NFPA 30, *Flammable and Combustible Liquids Code*; NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*; and NFPA 395, *Standard for the Storage of Flammable and Combustible Liquids at Farms and Isolated Sites*.

9-4-10

Vehicle repair facilities shall meet the requirements of NFPA 88B, *Standard for Repair Garages*.

9-5 Construction Site Lay-Down Areas.

9-5.1

Fire hydrant systems with an adequate water supply shall be provided in lay-down areas where the need is determined by the individual responsible for fire prevention and fire protection.

9-5.2

Combustible materials shall be separated by a clear space to allow access for manual fire-fighting equipment. Access shall be provided and maintained to all fire-fighting equipment including fire hoses, extinguishers, and hydrants.

9-6 Temporary Construction Materials.

9-6.1*

Noncombustible or fire-retardant scaffolds, formwork, decking, and partitions shall be used both inside and outside of permanent buildings where a fire could cause substantial damage or delay construction schedules.

9-6.2*

The use of listed pressure-impregnated fire-retardant lumber or listed fire-retardant coatings shall be provided.

9-6.3

Tarpaulins (fabrics) and plastic films shall be certified to conform to the weather-resistant and fire-retardant materials described in NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*.

9-6.4

Where it is necessary to store new nuclear fuel in areas other than the permanent storage facilities, a written procedure shall be developed to address separation from combustible materials, security, nuclear criticality, packing material, noncombustible or limited-combustible building materials, standpipe, portable fire extinguishers, and hydrant protection.

9-7 Water Supplies, Supply Mains, and Hydrants.

9-7.1* General.

The permanent underground yard system, fire hydrants, and water supply (at least one water source), as indicated in Chapter 6, shall be installed during the early stages of construction. Where provision of all or part of the permanent underground system and water supply is not practical, temporary systems shall be provided. Temporary water supplies shall be hydrostatically tested, flushed, and arranged to maintain a high degree of reliability, including protection from freezing and loss of power.

9-7.2

Hydrants shall be installed, as indicated in Chapter 6, in the vicinity of main plant buildings, important warehouses, office or storage trailer complexes, and important outside structures with combustible construction or combustible concrete formwork (e.g., cooling towers). The underground main shall be arranged to minimize the possibility that any one break will remove from service any fixed water extinguishing system or leave any area without accessible hydrant protection.

9-7.3

A fire protection water supply shall be provided on the construction site and shall be capable of furnishing the largest of the following for a minimum 2-hr duration:

(a) 500 gal/min (1892.5 L/min), or

(b) The in-service fixed water extinguishing system with the highest water demand and 500 gal/min (1892.5 L/min) for hose streams.

9-7.3.1 The highest water demand shall be determined by the hazards present at the stage of construction, which might not correspond with the highest water demand of the completed plant.

9-7.3.2 As fixed water extinguishing systems are completed, they shall be placed in service, even when the available construction phase fire protection water supply is not adequate to meet the designed system demand. The extinguishing system will provide at least some degree of protection, especially where the full hazard is not yet present. However, when the permanent hazard is introduced, the water supply shall be capable of providing the designed system demand. Where using construction water in permanent systems, adequate strainers shall be provided to prevent clogging of the system by foreign objects and dirt.

9-7.3.3 The water supply shall be sufficient to provide adequate pressure for hose connections at the highest elevation.

9-8 Manual Fire-Fighting Equipment.

9-8.1*

Fire-fighting equipment shall be provided in accordance with NFPA 600, *Standard on Industrial Fire Brigades*, and NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

9-8.2

Portable fire extinguishers of suitable capacity shall be provided in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*, where:

(a) Flammable liquids are stored or handled,

(b) Combustible materials are stored,

(c) Temporary oil- or gas-fired equipment is used,

(d) A tar or asphalt kettle is used, or

(e) Welding or open flames are in use.

9-8.3

A standpipe system shall be provided in any permanent building that has two-floor equivalent wall heights erected. Additional standpipe hose connections shall be added to each floor level as soon as sufficient landings are available to fight fires from that level. Protection from freezing shall be provided. (*See NFPA 14, Standard for the Installation of Standpipe and Hose Systems*.)

9-8.4

Hoses and nozzles shall be available at strategic locations, such as inside hose cabinets or hose houses or on dedicated fire response vehicles.

9-8.5

If fire hose connections are not compatible with local fire-fighting equipment, adapters shall be made available.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for information purposes only.

A-1-1

This standard does not address water-moderated or -cooled nuclear reactors used for training, testing, experimental purposes, or the production of special nuclear materials as defined in the Atomic Energy Act of 1954, as amended. Refer to NFPA 802, *Recommended Fire Protection Practice for Nuclear Research and Production Reactors*.

This standard does not address light water nuclear power plants with construction permits issued prior to January 1, 1979. Refer to NFPA 803, *Standard for Fire Protection for Light Water Nuclear Power Plants*.

A-1-4 Advanced Light Water Reactors.

Principal examples of evolutionary plant design include the General Electric advanced boiling water reactor (ABWR), the Westinghouse advanced pressurized water reactor (APWR), and the Asea Brown Boveri-Combustion Engineering System 80+ reactor. Principal examples of revolutionary plant design include the General Electric simplified boiling water reactor (SBWR) and the Westinghouse AP-600.

A-1-4 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4 Fire Area.

Where an exterior wall forms a part of the fire area boundary, it should be evaluated to determine if it is required to be fire rated based on potential exposures.

A-1-4 Fire Area Subdivision.

The phrase “fire zone” typically has been used to address both portions of fire areas and divisions of suppression and detection systems. To provide clarity, this standard has created two separate phrases: “fire area subdivision” and “fire zone.” It should be noted that there might be cases in which these two terms could be describing the same location. An example might include a pump bay with concrete barriers (but without all penetrations sealed), which is protected by its own sprinkler system, and detection that annunciates an alarm specifically for the pump bay. It is acceptable to describe such a location as both a fire area subdivision and a fire zone.

A-1-4 Fire Brigade.

Fire brigades can be staffed by shift personnel with collateral responsibilities or by personnel whose primary responsibility is fire-fighting activities (a plant fire department).

A-1-4 Fire-Rated Cables.

At this time, there is no nationally recognized standard to test and qualify fire-rated cables. The cables should be tested in accordance with the time-temperature curve in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. The cables should remain functional for the required rating period.

A-1-4 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-4

Where any of the analyses in Section 2-4 have been performed elsewhere, they need only be referenced as part of the fire hazards analysis.

A-2-4(b) A subdivision inventory or table should be prepared and maintained for each fire area. All in situ combustible and flammable materials and their configurations should be identified. Where the in situ combustibles present an exposure to nuclear-safety-related systems and components, they should be uniquely identified. Transient combustibles that are expected to be in place during normal plant operating modes also should be identified. The combustible storage areas should not present a threat to nuclear-safety-related systems and components.

A-2-6.1(b) Inspections, tests, administrative controls, fire drills, and training that govern the fire protection program should be prescribed by documented instructions, procedures, or drawings and should be accomplished in accordance with these documents.

A-2-6.1(c) Measures should be established to ensure that purchased material, equipment, and services conform to the procurement documents.

A-2-6.1(d) A program for independent inspection of activities affecting fire protection should be established and executed by or for the organization performing the activity to verify conformance with documented installation drawings and test procedures for accomplishing the activities.

A-2-6.1(e) A test program should be established and implemented to ensure that testing is performed and verified by inspection and audit to demonstrate conformance with design and system readiness requirements. The tests should be performed in accordance with written test procedures; test results should be properly evaluated and acted on.

A-2-6.1(f) Measures should be established to provide for the identification of items that have satisfactorily passed necessary tests and inspections.

A-2-6.1(g) Measures should be established to control items that do not conform to specified requirements to prevent inadvertent use or installation.

A-2-6.1(h) Measures should be established to ensure that conditions adverse to fire protection, such as failures, malfunctions, deficiencies, deviations, defective components, uncontrolled combustible material, and nonconformances, are promptly identified, reported, and corrected.

A-2-6.1(i) Records should be prepared and maintained to furnish evidence that the criteria enumerated in 2-6.1 are being met for activities affecting the fire protection program.

A-2-6.1(j) Audits should be conducted and documented to verify compliance with the fire protection program, including design and procurement documents, instructions, procedures and drawings, and inspection and test activities.

A-3-1.2

Plant outages can create conditions not specifically addressed by the administrative controls and fire prevention practices established in Chapter 3. Fire protection personnel should participate in outage planning to determine if unusual challenges will be presented to the fire protection program. Plans should be developed to address conditions not already covered by existing procedures. In addition, extra vigilance to adherence to administrative controls is important during outages. The amount of work activities occurring during outages increases the risk of fire during this time.

A-3-3.1

Combustible materials in both large and small concentrations will be present in nuclear power plants, as in most other industrial plants, and it should be assumed that outbreaks of fire occur for a variety of reasons.

A-3-3.1.1 Typical examples of flammable and combustible materials found in a nuclear power plant are:

(a) Conventional fuels for emergency power units, auxiliary boilers, etc.;

(b) Lubricants and hydraulic oils;

(c) Insulating materials (thermal and electric);

(d) Building materials (including PVC and other plastics);

(e) Filtering materials (e.g., oil-bath filters, charcoal, etc.);

(f) Cleansing materials;

(g) Paints and solvents;

(h) Packaging materials (e.g., bitumen, etc.);

(i) Neutron shields (if organic materials); or

(j) Clothing.

Typical examples of flammable gases found in a nuclear power plant are:

(a) Hydrogen for generator cooling, for coolant conditioning of pressurized water and gas-cooled reactors, and from battery charging;

(b) Propane or other fuel gases;

(c) Hydrogen (H_2) by radiolysis in the core and addition of H_2 for improved recombination;

(d) Gas for cutting and welding; and

(e) Oxygen (O_2) (while not a flammable gas, it is an oxidizer and requires similar controls).

Typical examples of radioactive substances external to the reactor are:

(a) Sealed radioactive materials, such as irradiated or plutonium containing fuel elements, or both, irradiated control rods, neutron sources, etc.;

(b) Unsealed radioactive material, such as ion exchanger fillings and filter cartridges that have become loaded with radioactive substances, rad waste materials, etc.; and

(c) Dry low-level radioactive waste.

A-3-3.1.2 Typical examples are:

(a) Replacement of lubricating or hydraulic oils,

(b) Repainting equipment or structures,

(c) Replacement of combustible filter materials,

(d) Scaffolding or dunnage necessary to maintain or replace equipment, or

(e) Spare equipment in shipping crates or boxes awaiting installation.

A-3-3.3.1 The control of temporary fire loads in the plant is essential to provide defense in depth protection. This includes controlling the use of temporary buildings including trailers, shacks, or shanties within the confines of the plant; the use of noncombustible scaffolds, formwork, decking, and partitions both inside and outside permanent buildings; and the use of noncombustible tarpaulins.

All combustible packing containers should be removed from the area immediately following unpacking. No such combustible material should be left unattended during lunch breaks, shift changes, or other similar periods. Loose combustible packing material such as wood or paper excelsior, polyethylene sheeting, or expanded polystyrene should be placed in metal containers with tight-fitting, self-closing metal covers.

A-3-3.3.4 Particular attention should be given to the control of halogenated plastics.

A-3-3.4.4(a) Oil pipes should be located below steam lines.

A-3-4.1.3 If welding operations have been conducted during the previous work period, the oncoming watchperson should be alerted to check the location where welding was done as part of his or her regular rounds. Where watch service is not provided, use of gas-operated welding or cutting equipment should be discontinued a minimum of 1 hr before quitting time. Where practical, work should be moved to a safe location to be welded. Torches should not be used to cut holes in walls, floors, ceilings, or roofs containing combustible insulation, framing, sheathing, or finished material.

A-3-5.1.1 Grouped noncombustible buildings, trailers, and sheds with separation between individual units less than that specified by NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*, or grouped combustible or limited-combustible buildings, trailers, or sheds with separation between individual units less than 30 ft (9.1 m) should be considered as a single building.

A-3-6.1

The impairment procedure should include the following:

(a) Identification of equipment that is not available for service;

(b) List of those to be notified of impairments (e.g., operations personnel, plant fire brigade personnel, the insurance company, etc.);

(c) Compensatory measures (e.g., increased surveillance on other systems, fire watch patrols);

(d) Target durations for impaired equipment (i.e., escalation of management attention to impaired equipment to ensure prompt corrective action); and

(e) Consideration of plant status (i.e., compensatory measures can be relaxed for impairment of certain systems during outage conditions).

This list can be modified as needed to include any site-specific actions or regulatory commitments.

While impairments to fire protection systems protecting both safe shutdown areas and balance of plant areas are to be included in the procedure, there might be differences in various aspects of the programs (e.g., compensatory measures might be more stringent for impaired systems protecting safe shutdown equipment).

A-3-6.2

When impairments are planned, the necessary equipment and personnel for the repair or service should be staged in advance. When the impairment is unplanned, those responsible for fire protection should ensure that the repair is given the appropriate priority and should bring delays in repair to management’s attention.

A-3-6.3

Post-maintenance testing of a system prior to return to service after an impairment is critical to ensure proper functioning. This is not necessary in cases where there was no actual repair or modification work performed on the impaired system. The appropriate level of testing should be established by those most knowledgeable of the impaired system. Section 3-7 and the appropriate NFPA standard addressing the type of system impaired should be used when considering the type of post-maintenance testing that is necessary.

A-3-7.2

Normally NFPA standards are used to determine the frequency and type of inspection, testing, and maintenance performed on systems installed for fire protection. Table A-3-7.2 is provided as a reference for this purpose. However, there are considerations and configurations at nuclear power plants that might make it difficult or impracticable to follow the exact requirements of the NFPA standard. In these situations, those responsible for fire protection at the plant need to establish the appropriate inspection, testing, and maintenance frequency and type. For example, fire protection systems installed in containment or high radiation areas might only be accessible during outages. Water disposal considerations might limit certain sprinkler system tests within radioactive controlled areas.

Table A-3-7.2 Reference Guide for Fire Equipment Inspection, Testing, and Maintenance

Item	NFPA Document
Supervisory and Fire Alarm Circuits	72
Fire Detectors	72
Manual Fire Alarms	72
Sprinkler Water Flow Alarms	25, 72
Sprinkler and Water Spray Systems	15, 25
Foam Systems	11A, 11C, 16
Halogenated Agent, Chemical, and CO_2 Systems	12, 12A, 17
Fire Pumps and Booster Pumps	20
Water Tanks and Alarms	22, 25, 72
PIV's and OS&Y Valves	25, 72
Fire Hydrants and Associated Valves	24, 25
Fire Hose and Standpipes	14, 1962
Portable Fire Extinguishers and Hose Nozzles	10, 1962
Fire Brigade Equipment	1972
Fire Doors	80
Smoke Vents	204M

Emergency Lighting	70
Radio Communication Equipment	1221
Audible and Visual Signals	72

A-3-7.4

Certain plant systems and equipment, including the turbine generator, transformers, large pumps, etc., will have a large impact on the level of fire risk at a plant. While typically there are programs in place to perform inspections, tests, and maintenance of these systems, those responsible for fire protection should ensure that this testing is adequate to minimize the fire risk.

A-4-1.2

Water drainage methods should be reviewed and included in that area's prefire plans.

A-4-1.4

Consideration should be given to providing prefire plans to public fire departments that might respond to the site to assist them in the development of their own prefire plans.

A-4-2

The focus of the plant fire brigade is to respond to fires that could impair the ability to safely shut down the plant. Response by the fire brigade to fires and alarms on the owner-controlled property but outside the power block is acceptable. Considerations should be given to such factors as:

(a) Proximity and response capability of local fire department;

(b) Monetary value of other on-site facilities;

(c) Potential for off-site radioactive material release (low level radioactive waste facilities, for example); and

(d) Potential for impact on plant operations due to fire loss (low lead time items in warehouse, for example).

Prefire plans should detail radiologically hazardous areas and radiation protection barriers. Methods of smoke and heat removal should be identified for all fire areas in the prefire plans. This may include the use of dedicated smoke and heat removal systems or the use of the structure's HVAC system if it can operate in the 100 percent exhaust mode.

A-4-5.2.3 Training of the plant fire brigade should be coordinated with the local fire department so that responsibilities and duties are delineated in advance. This coordination should be part of the training course and should be included in the training of the local fire department staff.

Local fire departments should be provided training in operational precautions when fighting fires on nuclear power plant sites and should be made aware of the need for radiological protection of personnel and the special hazards associated with a nuclear power plant site.

A-4-5.3.1 Duties of the person in this position should include overseeing the issuance of security badges, film badges, and dosimetry to the responding public fire-fighting forces, and ensuring that the responding off-site fire department(s) are escorted to the designated point of entry to the plant.

A-4-9

Methods of manual smoke and heat removal should consider the use of portable ventilation equipment as well as the natural migration of smoke and heat due to either natural or mechanical air movement within the building or buildings.

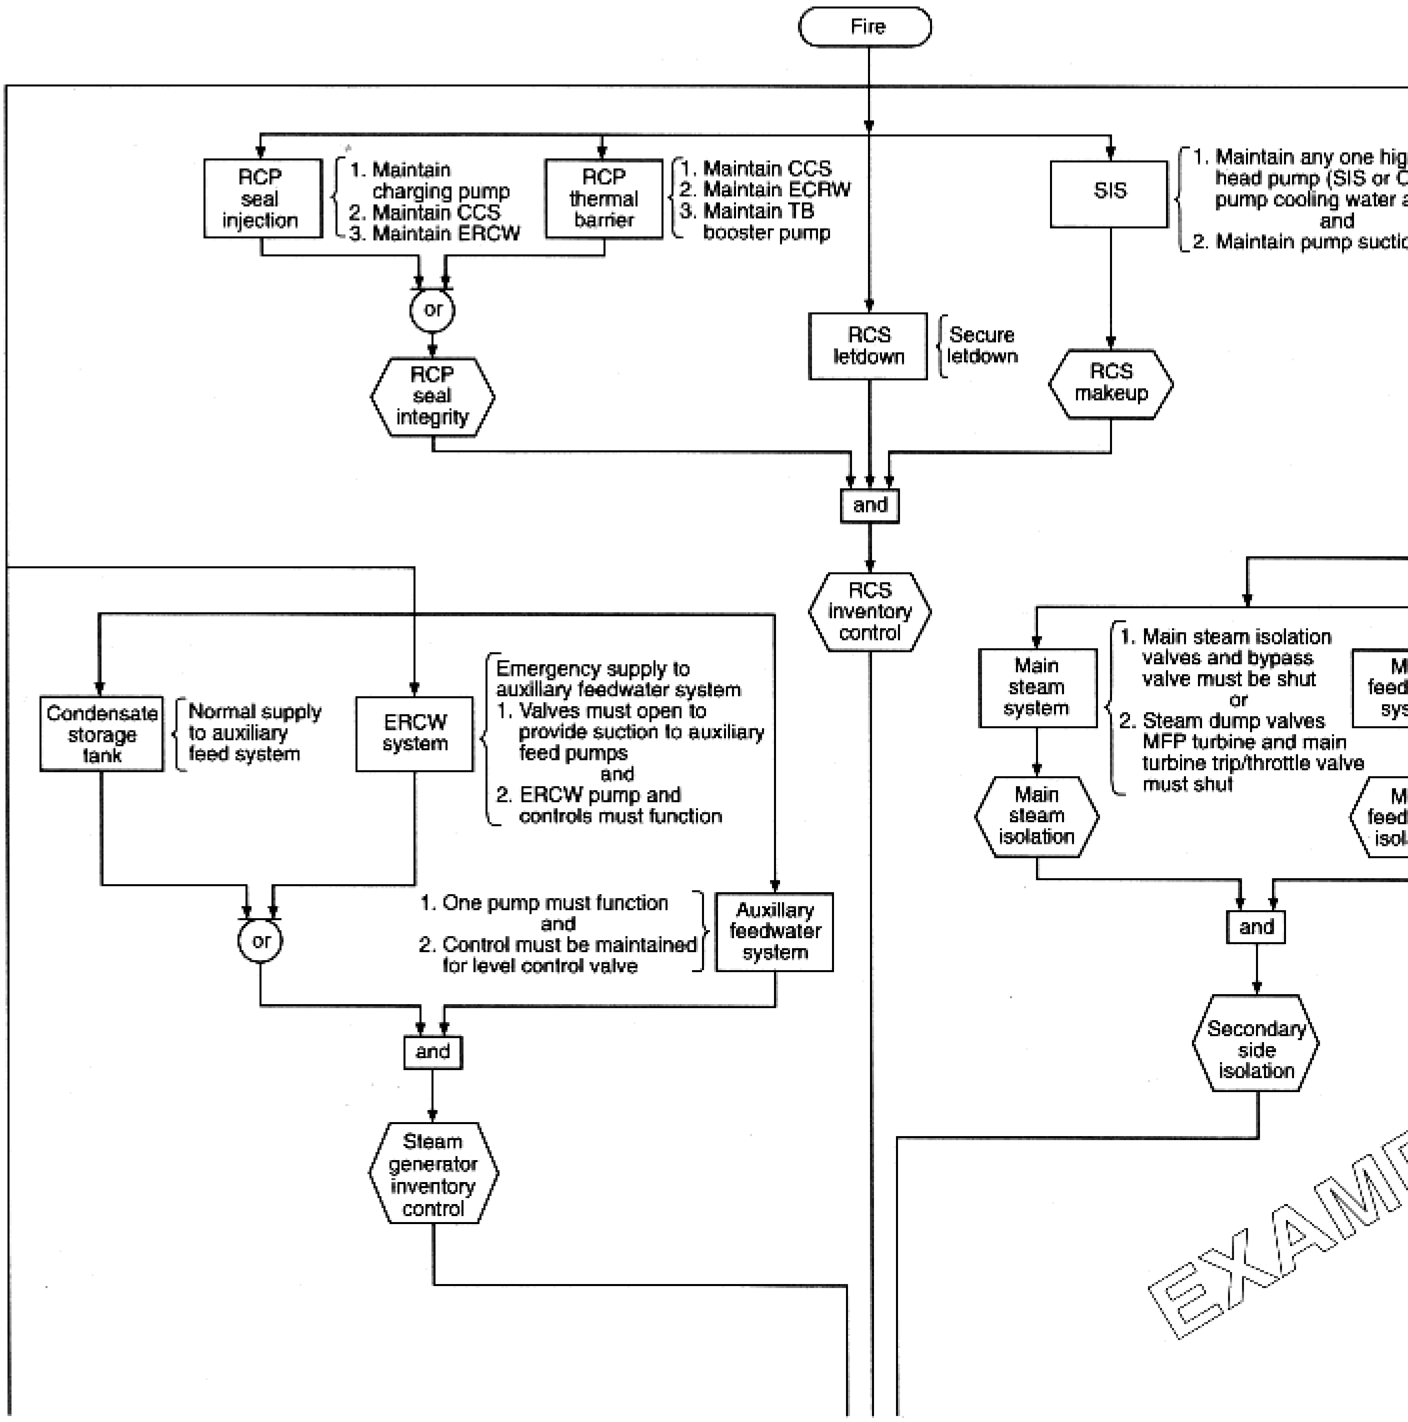

Figure A-5-2.2.2 Typical shutdown logic diagram — fire (Source: ANS-59.4-1979) (continued on next page).

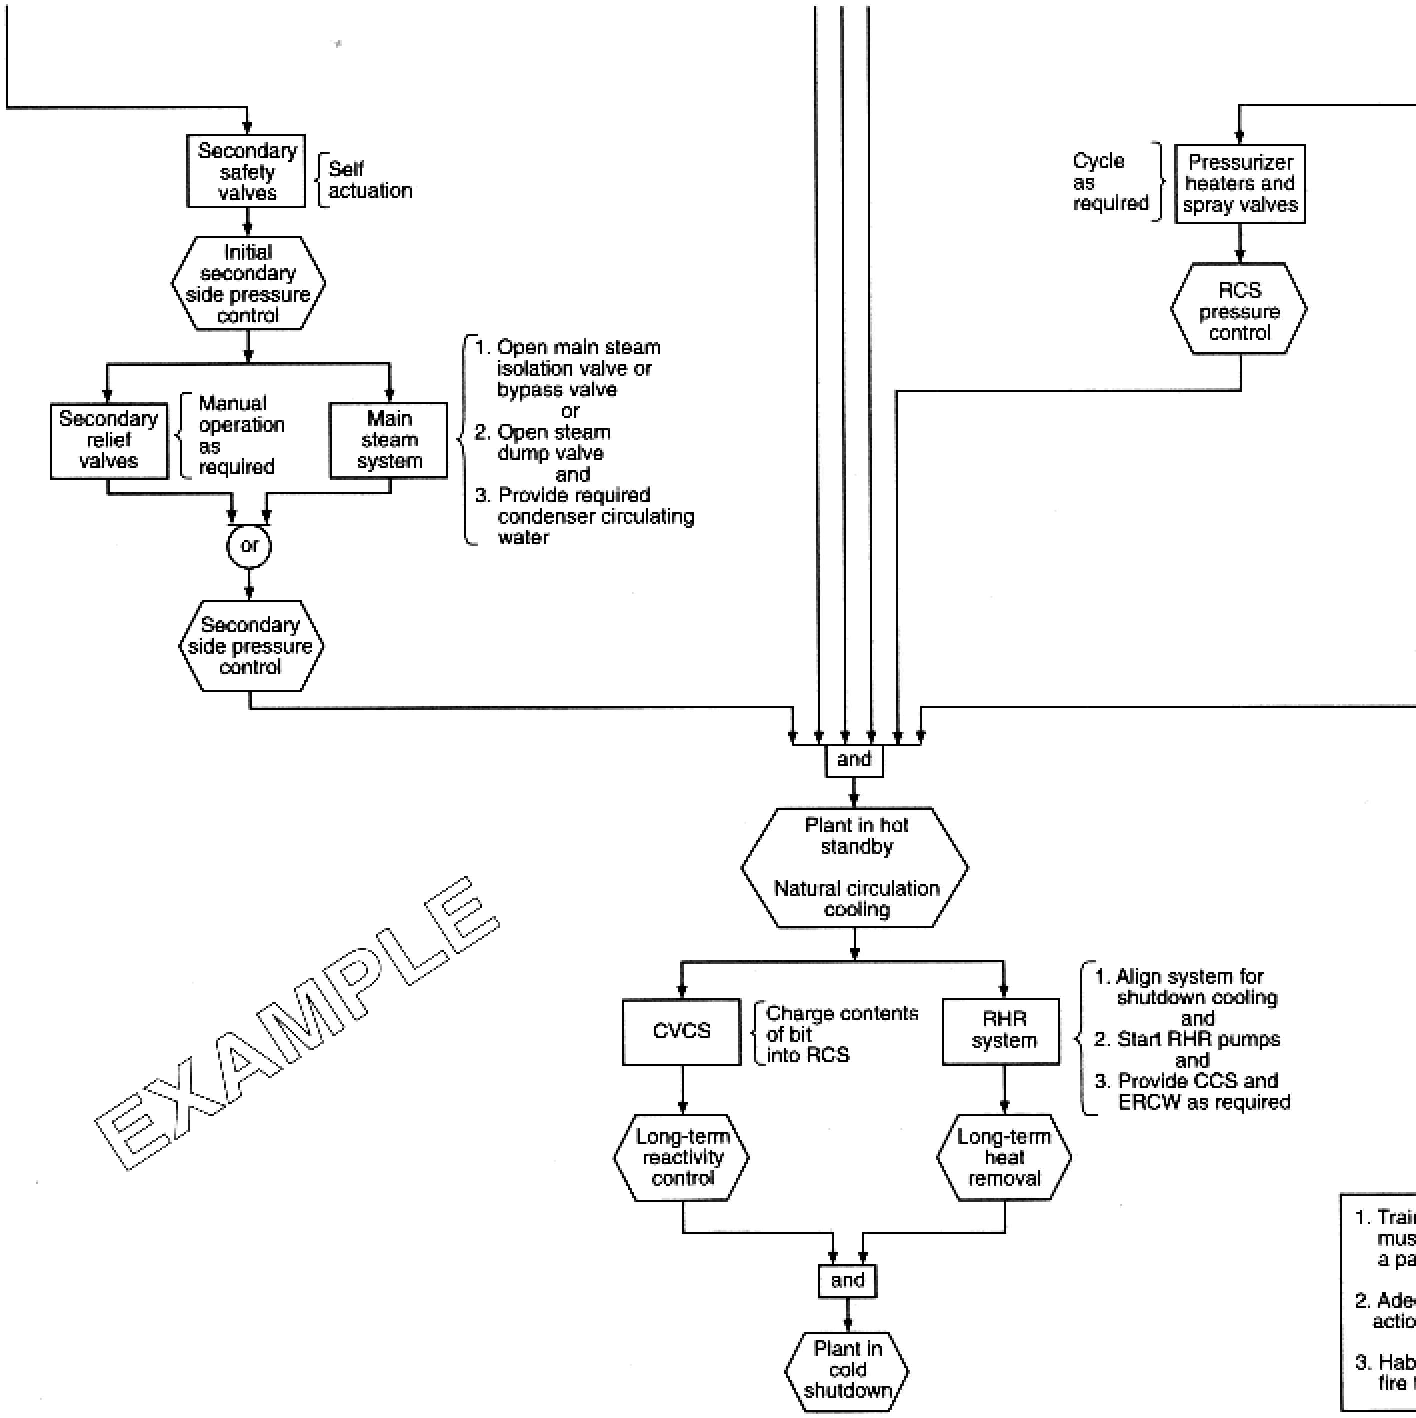

Figure A-5-2.2.2 Typical shutdown logic diagram — fire (Source: ANS-59.4-1979) (continued).

A-5-2.3.1 Currently the fire-induced vulnerability evaluation (FIVE) methodology and fire probabilistic risk assessment (PRA) are available.

A-5-2.3.2 The value of 1×10^{-6} per reactor year is based on NRC Generic Letter 88-20, Supplement 4.

A-5-3.1.2 These components include nuclear-safety-related and safe shutdown components. Components outside the fire area that are electrically or mechanically dependent upon fire-damaged components within the fire area should be considered within the analysis.

A-5-3.1.3 This can be accomplished by the use of rated barriers, fire-rated cables, an electrical raceway fire barrier system, physical separation, or a combination of these methods.

A-5-3.1.8(c) Due to their design, revolutionary plants will achieve and maintain cold shutdown conditions only after an extended period of time.

A-5-3.1.12 For three-phase ac circuits, the probability of getting a hot short on all three phases in the proper sequence to cause spurious operation of a motor is considered sufficiently low and additional evaluation, except for the case involving high-to-low pressure interface, is not necessary.

A-5-3.1.14 These devices protect the function of the safety circuit in the event of fire damage to the associated circuits of concern.

A-5-3.1.15 Associated circuits of concern not necessary to achieve safe shutdown might be found to share a common enclosure. Fire-initiated electrical fault currents could be generated on unprotected nonsafe shutdown cables. If a fault current is of sufficient magnitude, a secondary fire might be initiated in the common enclosure shared with shutdown cable.

A-5-3.2

Review of seismic-induced fire experience data performed by the Electric Power Research Institute (EPRI), the Seismic Qualification Utilities Group (SQUG), and others suggests there is minimal threat of seismic-induced fires in nuclear power plants. Review of more than 100 power plant and industrial sites in 18 strong ground-motion earthquakes revealed only 4 instances of seismic-induced fires. The causes of these fires were attributed to arcing of high voltage equipment, chemical laboratory fire, and oil-soaked insulation on piping. This low incidence of approximately 4 percent represents installations primarily in high seismic hazard regions, designed to commercial and industrial codes and standards.

A-5-3.2.2 Guidance is provided in NRC Generic Letter 88-20, Supplement 4, “Sandia Risk Scoping Items.”

A-5-5.2.2 Repairs such as lifting leads or pulling of fuses should not be necessary to achieve shutdown of the reactor.

A-5-5.3.1.1 Stairwells in such routes should be enclosed in masonry or concrete towers with a minimum fire rating of 2 hr and should be provided with self-closing, Class B fire doors. The stairwells should be designed with smoke-control features.

A-5-5.3.2.1 Operators should not be required to perform any unsafe physical actions.

A-5-5.3.2.2 Operators should not be required to perform any physical operations that are outside of their normal physical abilities.

A-6-2.1

Conformance with the NFPA *101*, *Life Safety Code*, satisfies OSHA requirements for means of egress.

A-6-2.2

The operation and maintenance of an ALWR plant involves unique operations and materials in process.

A-6-3.2

Many plastic materials, including flame- and fire-retardant materials, will burn with an intensity and energy production in the range similar to that of ordinary hydrocarbons. When burning, they produce heavy smoke that obscures visibility and can plug air filters, especially charcoal and HEPA filters. The halogenated plastics also release free chloride and hydrogen chloride when burning, which are toxic to humans and corrosive to equipment.

A-6-3.7.2 This will minimize the possibility of wall penetration in the event of a container failure.

A-6-4

Suitable design of the ventilation system can limit the consequences of a fire by preventing the spread of the products of combustion to other fire areas. The design of the ventilation system should provide a means to ventilate, exhaust, or isolate the fire area as necessary, and consideration should be given to the consequences of failure of the ventilation system due to fire causing loss of control for ventilating, exhausting, or isolating a given fire area. The capability to ventilate, exhaust, or isolate is particularly important to ensure the habitability of rooms and spaces that should be attended in the fire emergency. In the design, provisions should be made for personnel access to and escape routes from each fire area.

A-6-4.1

For further information, see NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 204M, *Guide for Smoke and Heat Venting*.

A-6-4.2

The need for automatic dampers or shutdown can be avoided by installing separate ventilation systems for each fire area, or by installing fire-resistive ducting enclosures. Additional filter protection might be necessary.

A-6-5.1

Refer to Appendix A of NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, for additional information on drainage.

A-6-5.3(d) Brazed, soldered, and clamp-type fittings as well as nonferrous and plastic piping are susceptible to melting under fire conditions. Ferrous piping, where internal liquids are confined, is subject to bursting under fire conditions.

A-6-9

See NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*.

A-6-11.2

Multi-channel portable radios are used for communications at nuclear power plants.

Subsections 6-11.2 and 6-11.3 do not prohibit sharing of radio channels by various station groups. The use and assignment of channels should ensure that the fire brigade, operations, and security all can use the radios to carry out their functions during a fire emergency.

A-6-11.5

In unique or unusual circumstances where equipment cannot be designed to prevent radio frequency interference, the authority having jurisdiction can permit the area around the sensitive equipment where portable radios cannot be used to be identified and marked so that fire fighters can readily recognize the condition. Training in this recognition also should be provided.

A-7-1.1

Automatic sprinkler protection provides the best means for controlling fires and should be provided. Special hazards might necessitate additional fixed protection systems as indicated by the fire hazards analysis.

A-7-1.2

Mitigating severe accident events that can result in fuel-clad damage is a top priority. Since fires and other severe plant accidents are not assumed to occur simultaneously, fire protection systems do not need to be designed to handle both demands simultaneously.

A-7-2.1

The water supply for the permanent fire protection water system should be based on providing a 2-hr water supply for both items (a) and (b) as follows:

(a) Either of items (1) or (2) below, whichever is larger:

1. The largest fixed fire suppression system demand; or

2. Any fixed fire suppression system demand that could be reasonably expected to operate simultaneously during a single event (e.g., turbine underfloor protection in conjunction with other fire protection systems in the turbine area).

(b) The hose stream demand of not less than 500 gal/min (1892.5 L/min).

A-7-2.2

Due to the 100 percent redundancy feature of two tanks, refill times in excess of 8 hr are acceptable.

A-7-2.3

The intent of this section is to provide a water supply that will not be susceptible to biofouling, scaling, microbiologically induced corrosion (MIC), or sedimentation.

A-7-2.4.2 For maximum reliability, three fire pumps should be provided so that two pumps meet the maximum demand plus hose streams. Two fire pumps could be an acceptable alternate, provided either of the fire pumps can supply the maximum demand plus hose streams within 120 percent of its rated capacity.

A-7-4.9

Guidance on safe distances for water application to live electrical equipment can be found in the *NFPA Fire Protection Handbook*.

A-7-4.10.1 The water supply for this condition is permitted to be obtained by manual operator actuation of valves in a connection to the hose standpipe header from a normal seismic Category 1 water system such as the essential service water system.

A-7-7.2

This is also referred to as a Class A system.

A-7-7.4

Visual signaling appliances can be used to supplement audible appliances in the protected area.

A-8-1

Examples of such hazards include lubricating oil or hydraulic fluid systems for the primary coolant pumps, cable tray arrangements and cable penetration, and charcoal filters. Because of the general inaccessibility of the primary containment during normal plant operation, protection should be provided by automatic fixed suppression systems. The effects of postulated fires within the primary containment should be evaluated to ensure that the integrity of the primary coolant system and the containment are not jeopardized assuming no manual action is taken to fight the fire.

A-8-2.2.1 Refueling and maintenance operations in containment might introduce additional hazards such as containment control materials, decontamination supplies, wood planking, temporary wiring, welding, and flame cutting (with portable compressed-gas fuel supply). Possible fires would not necessarily be in the vicinity of the installed fire detector and suppression systems.

A-8-4.1.3(d) It might be beneficial to provide continuous line-type heat detectors in the cable trays where the cable trays are stacked more than three cable trays high or over 18 in. (457.2 mm) wide, in addition to the area smoke detection systems.

A-8-4.2.1 It might be beneficial to provide continuous line-type heat detectors in the cable trays where the cable trays are stacked more than three cable trays high or over 18 in. (457.2 mm) wide, in addition to the area smoke detection systems.

A-8-6.1

Switchgear should be raised off the floor.

A-8-7.1

For further information refer to IEEE 484, *Recommended Practice for Installation Design and Installation of Large Lead Batteries for Generating Stations and Substations*.

A-8-8.1

Smoke and heat vents or sprinkler protection at the roof level is necessary to protect the turbine building structure.

A-8-8.2.1 To avoid water application to hot parts or other water-sensitive areas and to provide adequate coverage, designs that incorporate items such as fusible element operated spray nozzles might be necessary.

A-8-8.3

Additional information concerning turbine generator fire protection can be found in EPRI Research Report 1843-2, “Turbine Generator Fire Protection by Sprinkler System,” July 1985.

A-8-8.8.1.7 The preferable arrangement from a fire risk standpoint is to keep the bulk storage isolated from the generator by shutting the block valve outdoors. Makeup should be done manually as necessary, logging hydrogen usage to track consumption. This procedure allows for ongoing indication of what is being used, and it prevents the system from feeding hydrogen during a fire emergency if there is a failure at one of the generator shaft seals.

A-8-8.10

It is desirable to provide for remote operation, preferably from the control room, of the condenser vacuum break valve and the lubricating pumps. Breaking the condenser vacuum markedly reduces the rundown time for the turbine generator and thus limits oil discharge in the event of a leak.

A-8-8.10.4 On some turbine generators employing the guard pipe principle, the guard piping arrangement terminates under the machine housing where feed and return piping run to pairs of bearings. Such locations are vulnerable to breakage with attendant release of oil in the event of excessive vibration and should be protected.

A-9-1.1

A 1971 fire occurred in the primary auxiliary building of a U.S. nuclear power plant under construction. The fire originated in a combustible construction shed. At the time of the fire, nuclear fuel had been loaded and the reactor vessel head was removed. The fire spread to the cable system and caused considerable damage to three motor control centers, which provided power to many of the engineered safety features. The two-hour fire was fought by the off-site fire departments from three local communities. Arson was suspected to have been the cause of this $2,100,000 fire, which delayed the startup of the plant.

A-9-2.5

The first round should be conducted one-half hour after the suspension of work for the day. Thereafter, rounds should be made every hour. Where partial construction activities occur on second and third shifts, the guard service rounds can be modified to include only unattended or sparsely attended areas. In areas where automatic fire detection or extinguishing systems are in service, with alarm annunciation at a constantly attended location, or in areas of limited combustible loading, rounds can be omitted after the first round.

A-9-3.1.6 Local conditions might require the establishment of fire breaks by clearing or use of selective herbicides in areas adjacent to property lines and access roads.

A-9-4.2

For guidance in separation and protection see NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*.

A-9-4.3

Large central office facilities might be of substantial value and contain high-value computer equipment, irreplaceable construction records, or other valuable contents, the loss of which can result in significant construction delays.

This evaluation might indicate a need for automatic sprinkler systems or other protection or the desirability of subdividing the complex to limit values exposed by one fire.

A-9-4.4.3 Air-supported structures sometimes are used to provide temporary warehousing space.

Although the fabric envelope might be a fire-retardant material, the combustibility of contents and the values should be considered, as with any other type of warehouse. Because it is impractical to provide automatic sprinkler protection for them, air-supported structures should be used only for noncombustible storage. An additional consideration is that relatively minor fire damage to the fabric envelope might leave the contents exposed to the elements.

A-9-6.1

The use of noncombustible or fire-retardant concrete formwork is especially important for large structures (e.g., reactor building and turbine generator pedestal) where large quantities of forms are used.

A-9-6.2

Pressure-impregnated fire-retardant lumber should be used in accordance with its listing and the manufacturer's instructions. Where exposed to the weather or moisture (e.g., concrete forms), the fire retardant used should be suitable for this exposure. Fire-retardant coatings are not acceptable on walking surfaces or surfaces subject to mechanical damage.

A-9-7.1

The necessary reliability of construction water supplies, including redundant pumps, arrangement of power supplies, and use of combination service water and construction fire protection water, should be determined by the individual responsible for fire protection.

A-9-8.1

Mobile fire-fighting equipment can be utilized to provide necessary fire-fighting equipment.

NFPA 820

1995 Edition

Standard for Fire Protection in Wastewater Treatment and Collection Facilities

1995 Edition

This edition of NFPA 820, *Standard for Fire Protection in Wastewater Treatment and Collection Facilities,* was prepared by the Technical Committee on Wastewater Treatment Plants and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May

22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 820 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 820

The Committee on Wastewater Treatment Plants was organized in 1983 to have primary responsibility for documents on safeguarding against the fire and explosion hazards specific to wastewater treatment plants and associated collection systems. This includes the hazard classification of specific areas and processes. The need to develop NFPA 820 was based on fire or explosion incidents that, while infrequent, are relatively severe when they do occur. Initial work on the document was begun early in 1985 and resulted in the first edition being issued in 1990. Extensive changes were made between the first edition and the 1992 edition, with the most notable revision being the document title, which was changed from Recommended Practice for Fire Protection in Wastewater Treatment Plants to Recommended Practice for Fire Protection in Wastewater Treatment and Collection Facilities. In addition, the document scope was revised to include storm sewer systems and their appurtenances.

In 1995 the document was changed from a recommended practice to a standard, which contains mandatory requirements. This was done because NFPA 820 was widely referenced by various jurisdictions.

Technical Committee on Wastewater Treatment Plants

James F. Wheeler, *Chair*
U.S. Environmental Protection Agency, DC

Alphonse A. Abadir, U.S. Dept. of Labor, DC

John R. Anderson, Marshfield, MA

Alonza W. Ballard, Crouse-Hinds ECM, NY
Rep. Nat'l Electrical Mfrs. Assn.

Alan J. Callier, Burns & McDonnell, MO
Rep. Water Environment Federation

Smith Choi, Metropolitan Water District of S California, CA

Michael P. Dyrness, Johnson and Higgins, WA

Casey C. Grant, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on criteria for safeguarding against the fire and explosion hazards specific to wastewater treatment plants and associated collection systems, including the hazard classification of specific areas and processes.

NFPA 820

Standard for
Fire Protection in Wastewater Treatment and Collection Facilities

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 9 and Appendix F.

Chapter 1 Introduction

1-1 Scope.

1-1.1 General.

1-1.1.1* This standard provides the minimum requirements for protection against fire and explosion hazards in wastewater treatment plants and associated collection systems, including the hazard classification of specific areas and processes.

1-1.1.2 This standard covers the following:

(a) Collection sewers,

(b) Trunk sewers,

(c) Intercepting sewers,

(d) Combined sewers,

(e) Storm sewers,

(f) Pumping stations,

(g) Wastewater treatment plants,

(h) Sludge-handling facilities,

(i) Chemical-handling facilities,

(j) Treatment facilities, or

(k) Ancillary structures (*see definition*).

1-1.1.3 This standard does not cover the following:

(a) Collection, treatment, or disposal of industrial wastes or manufactured by-products that are treated on-site and not discharged to a public or privately operated municipal facility;

(b) On-site treatment systems (*see definition*);

(c) Pressure sewer systems (*see definition*);

(d) Building drain systems and appurtenances (*see definition*);

(e) Industrial sewer systems and appurtenances (*see definition*);

(f) Personnel safety from toxic and hazardous materials or products of combustion; or

(g) Separate nonprocess related structures (*see definitions*).

1-1.2 Alternative Methods.

Nothing in this standard is intended to prevent or discourage the use of alternative methods, materials, practices, or devices, provided that sufficient technical data are submitted to the authority having jurisdiction to demonstrate that the alternative method, material, practice, or device is equivalent to or superior to the requirements of this standard.

1-1.3

A fire risk evaluation shall be initiated early in the facility design or alteration to integrate the fire prevention and fire protection requirements as described in this document.

1-2 Purpose.

1-2.1 General.

The purpose of this standard is to provide a reasonable degree of fire and explosion protection for life, property, continuity of mission, and protection of the environment. This standard intends to reduce or eliminate effects of fire or explosion by maintaining structural integrity, controlling flame spread and smoke generation, preventing the release of toxic products of combustion, and maintaining serviceability and operation of the facility.

1-2.2 Toxicity and Biological Hazards.

This standard addresses the fire and explosion hazards of various substances associated with wastewater treatment and conveyance. This standard does not cover toxicity and biological hazards.

CAUTION: It is recognized that, from a personnel safety standpoint, these hazards can be present in life-threatening concentrations while no threat of fire or explosion exists.

1-2.3 Ventilation Practices.

Ventilation rates required by this standard are intended to minimize fire and explosion hazards but might be insufficient to protect personnel from exposure to toxic and biological hazards.

1-2.4 Materials Selection.

The fire risk evaluation shall include consideration for flame spread, smoke generation, and the impact that a fire or explosion will have on the structural integrity of the facility when conditions or applications warrant the selection of materials that are combustible, limited combustible, or low flame spread.

CAUTION: Since many of the corrosion-resistant materials and coatings are combustible or limited-combustible and might represent a considerable fuel load during fire events, the design and fire risk evaluation shall consider any additional hazards imposed by the use of these materials.

1-3 Application.

1-3.1*

The requirements of this standard are intended for new installations. When additions or modifications are made to existing facilities, the modifications shall reflect the requirements of this document. In any event, the requirements of this standard shall be used by owners in a risk assessment to identify areas of a treatment plant that are vulnerable to fire or other loss.

1-3.2

This document is divided into 9 chapters. Chapters 1, 5, 6, 7, 8, and 9 apply generally. Chapters 2, 3, and 4 apply to specific processes and functions. The appendixes provide explanatory information, and the paragraph designations used in Appendix A coincide with the paragraph numbers used in Chapters 1 through 8 to which the clarification is provided. Appendix B provides a general overview and layout of the unit processes found at a typical wastewater treatment plant, although the arrangement of the unit processes will vary from plant to plant.

1-3.3* National Electrical Code® Criteria.

This standard is based on the criteria established by Article 500 of NFPA 70, *National Electrical Code*, but is not intended to supersede or conflict with the requirements therein. Once an area is properly classified, the *National Electrical Code* specifies the types of equipment and the wiring methods that shall be used.

1-4 Metric Units of Measurement Guidance.

Metric units of measurement used within this standard are in accordance with the modernized metric system known as the International System of Units (SI). Values of measurement are followed by an approximate equivalent value in SI units. For metric conversion practices, see ANSI/IEEE 268, *Metric Practices.*

1-5 Definitions.

Activated Carbon. Adsorptive carbon particles or granules usually obtained by heating carbonaceous material in the absence of air or in steam and possessing a high capacity to selectively remove trace and soluble components from solution.

Activated Sludge. A microbial mass grown in aeration tanks, subsequently separated from treated wastewater by sedimentation, and wasted or returned to the process as needed.

Adjacent. Adjacent, as used in this document, means sharing a common wall, partition, or barrier.

Advanced (Tertiary) Wastewater Treatment. Any physical, chemical, or biological treatment process used to accomplish a degree of treatment greater than that achieved by secondary treatment. (*See Secondary Wastewater Treatment.*)

Anaerobic Digestion. A unit process designed to biologically convert organic matter (sludge) through the action of microorganisms in the absence of elemental oxygen. Process by-products include a gas containing methane, carbon dioxide, and small quantities of hydrogen sulfide. The digestion tank can have a fixed or floating roof system.

Anaerobic Waste Treatment. A unit process providing treatment of the liquid stream by action of microorganisms in the absence of elemental oxygen. Process by-products include a gas containing methane, carbon dioxide, and small quantities of hydrogen sulfide.

Ancillary Structure. A structure that is an integral part of the wastewater treatment or collection process.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Belt Filter. A sludge dewatering or concentrating device having continuous bands or belts of filtering media that pass around rollers and from which the material caught on the media is usually removed by gravity and pressure.

Building. A structure used or intended for supporting or sheltering any use or occupancy. Personnel might occupy buildings continuously or intermittently.

Building Drain. In plumbing, the part of the lowest horizontal piping of a drainage system that receives the discharge from soil, waste, and other drainage pipes inside the walls of the building and conveys it to the building sewer (house connection or lateral).

Centrifuge. A mechanical device in which centrifugal force is used to separate solids from liquids or to separate liquids of different densities.

Combustible. Any material that does not comply with the definition of either noncombustible or limited-combustible.

Combustible Gas Detectors. Devices used to detect the presence of flammable vapors and gases and warn when concentrations in air approach the explosive range.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code*.)

Combustible or Explosive Dust. A dust capable of spontaneous combustion or of exploding or burning when subjected to a source of ignition.

Compost. The product of thermophilic biological oxidation of sludge or other organic materials.

Digester Gas. See Sludge Gas.

Dissolved Air Flotation. A separation process in which air bubbles emerging from a supersaturated solution become attached to suspended solids in the liquid undergoing treatment and float them up to the surface.

Domestic Wastewater. Wastewater derived principally from dwellings, commercial establishments, institutions, and the like. It might or might not contain small amounts of ground water, surface water, or storm water.

Dry Well. That portion of a pumping station designed to provide isolation and shelter or accommodations for controls or equipment associated with pumping of wastewater. Dry wells are designed to completely and permanently exclude wastewater or wastewater-derived atmospheres. Dry wells can contain accidental leakage of wastewater from shaft seals or occasional spills. A dry well might contain equipment such as pumps, motors, fans, wiring, controls, lights and associated wiring devices, and other accessories.

Drying Beds. Confined, underdrained, shallow layers of sand or gravel on which digested sludge is distributed for draining and air drying. Also applied to underdrained, shallow, diked earthen structures used for drying sludge.

Enclosed. The interior of any tank or unit process that is closed to the atmosphere (excluding vents or pressure relief), or the area around any open tank or unit process surrounded by a building or other structure constructed with a roof and solid walls.

Equipment. A general term including material, fittings, devices, appliances, fixtures, apparatus, and the like used as part of, or in connection with, a mechanical, instrumentation, or electrical installation.

Equipment Enclosure. The housing that covers, protects, or guards a piece of equipment and is not intended for personnel occupancy, but can provide for access to the equipment.

Explosionproof Apparatus. Apparatus, enclosed in a case, that is capable of withstanding an explosion of a specified gas or vapor that might occur within it and of preventing the ignition of a specified gas or vapor surrounding the enclosure by sparks, flashes, or explosion of the gas or vapor within and that operates at such an external temperature that a surrounding flammable atmosphere will not be ignited thereby.

Explosive Limits. The minimum concentration of a gas-air or vapor-air mixture that supports flame, if ignited, is known as the lower explosive limit (LEL). The maximum concentration of a gas-air or vapor-air mixture that, if ignited, supports flame is known as the upper explosive limit (UEL). Above the UEL and below the LEL, ignition cannot take place. (These values might change in oxygen-enriched atmospheres.)

Filter (Pressure or Gravity). A device used to pass liquid through a medium to remove suspended solids.

Filter Press. A unit process using a plate and frame press, that is operated hydraulically and mechanically, to produce a semisolid sludge cake from a slurry.

Fire Barrier. A continuous membrane, either vertical or horizontal, such as a wall or floor assembly, that is designed and constructed with a specified fire resistance rating to limit the spread of fire and that will also restrict the movement of smoke. Such barriers might have protected openings.

Fire Loading. The amount of combustibles present in a given area, expressed in Btu/ft^2 (kJ/m^2).

Fire Prevention. Measures directed toward avoiding the inception of fire.

Fire Protection. Methods of providing for fire control or fire extinguishment.

Fire-Rated Penetration Seal. An opening in a fire barrier for the passage of pipe, cable, duct, etc., that has been sealed so as to maintain a barrier rating.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with the test procedures of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. This definition applies to the materials used in the construction of buildings but does not apply to furnishings or the contents of buildings or to the fire hazard evaluation of materials.

Fire Stop. A through-penetration fire stop is a specific construction consisting of the materials that fill the opening around penetrating items such as cables, cable trays, conduits, ducts, and pipes and their means of support through the wall or floor opening to prevent spread of fire. Its rating is established in accordance with test procedures in ASTM E 814, *Standard Method of Fire Tests of Through-Penetration Fire Stops.*

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psia (276 kPa) absolute pressure at 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code*.)

Flash Dryer. A device for vaporizing water from partly dewatered and finely divided sludge through contact with a current of hot gas or superheated vapor. It includes a squirrel-cage mill for separating the sludge cake into fine particles.

Flash Mixer. A device for quickly dispersing chemicals uniformly throughout a liquid or semisolid.

Flocculator. A unit process for the formation of floc in wastewater.

Fluidized Bed Reactor. A pressure vessel or tank that is designed for liquid-solid or gas-solid reaction; the liquid or gas moves upward through the solids particles at a velocity sufficient to suspend the individual particles in the fluid. Applications include ionexchange, granular activated carbon adsorbers, and some types of furnaces, kilns, and biological contactors.

Force Main (Pressure Main). A pressure pipe connecting the pump discharge of a wastewater pumping station under pressure to a point of discharge.

Fuel Gases. Any gas used as a fuel source including natural gas, manufactured gas, sludge gas, liquefied petroleum gas-air mixtures, liquefied petroleum gas in the vapor phase, and mixtures of these gases. (*See NFPA 54, National Fuel Gas Code*.)

Galleries. Long tunnels or walkways connecting separate buildings or structures. Galleries are generally underground, without windows, and with limited entrances and exits. Galleries frequently contain gas, water, wastewater, sludge piping, electrical wiring, and mechanical or electrical equipment.

Gas-Handling Equipment. Gas-handling equipment includes equipment for removal of gas evolved from the anaerobic digestion process and the compression, conditioning, or treatment of this gas. This equipment includes gas compressors, sediment traps, drip traps, gas scrubbers, and pressure regulating and control valves. Gas-handling equipment does not include equipment or devices for the utilization of the gas, such as boilers, engines, and waste gas burners.

Grit Chamber. A detention chamber or an enlargement of a sewer designed to reduce the velocity of flow of the liquid to permit the separation of mineral from organic solids by differential sedimentation.

Hazardous (Classified) Location. Locations are classified depending on the properties of the flammable vapors, liquids, or gases or combustible dusts or fibers that might be present and the likelihood that a flammable or combustible concentration or quantity is present. Each room, section, or area is considered individually in determining its classification.

Hazardous Waste. Any waste that is potentially damaging to the environment or human health because of toxicity, ignitibility, corrosivity, chemical reactivity, or other reason.

Heat Treatment. A sludge-conditioning process combining high temperature, time, and pressure to improve the dewaterability of organic sludge.

Hydrogen Sulfide (H_2S). A toxic and lethal gas produced in sewers and digesters by anaerobic decomposition of wastewater solids or other anaerobic wastewater or sludge treatment processes.

Identified (as applied to equipment). Recognizable as suitable for the specific purpose, function, use, environment, application, etc., where described in a particular code requirement. Suitability of equipment for a specific purpose, environment, or application can be determined by a qualified testing laboratory, inspection agency, or other organization concerned with product evaluation. Such identification can include labeling or listing. (*See Labeled and Listed*.)

Imhoff Tank. A deep, two-story wastewater treatment tank. It consists of an upper continuous-flow sedimentation chamber and a lower sludge-digestion chamber. The upper chamber floor slopes steeply to trapped slots through which solids can slide into the lower chamber. The lower chamber receives no fresh wastewater directly but is provided with gas vents and with means for drawing digested sludge from near the bottom.

Incineration. Combustion or controlled burning of volatile organic matter in sludge and solid waste that reduces the volume of the material while producing heat, dry inorganic ash, and gaseous emissions.

Industrial Waste. Generally liquid, solid, or gaseous wastes originating from the manufacture of specific products. Such wastes are usually more concentrated, are more variable in content and rate, and require more extensive or different treatment than municipal waste.

Inspection. A visual examination of a system or portion thereof to verify that it appears to be in operating condition and is free of physical damage.

Intrinsically Safe. Intrinsically safe equipment and wiring are not capable of releasing sufficient electrical or thermal energy under normal or abnormal conditions to cause ignition of a specific flammable or combustible atmospheric mixture in its most easily ignitable concentration. Abnormal conditions include accidental damage to any field-installed wiring, failure of electrical components, application of overvoltage, adjustment and maintenance operations, and other similar conditions. (*See ANSI/ISA RP 12.67, Installation of Intrinsically Safe Instrument Systems in Class I Hazardous Locations*.)

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Limited-Combustible. As applied to a building construction material, a material not complying with the definition of noncombustible material that in the form in which it is used has a potential heat value not exceeding 3500 Btu/lb (8.14×10^6 J/kg) (*see NFPA 259, Standard Test Method* *for Potential Heat of Building Materials*) and complies with one of the following paragraphs (a) or (b):

(a) Materials having a structural base of noncombustible material with a surfacing not exceeding a thickness of $^1/_8$ in. (3.175 mm) that has a flame spread rating not greater than 50.

(b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread rating greater than 25 nor evidence of continued progres- sive combustion and of such composition that surfaces that would be exposed by cutting through a material on any plane would have neither a flame spread rating greater than 25 nor evidence of continued progressive combustion as tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

NOTE: Materials subject to increase in combustibility or flame spread rating beyond the limits herein established through the effects of age, moisture, or other atmospheric condition should be considered combustible. This definition applies to the materials used in the construction of buildings but does not apply to furnishings or the contents of buildings or to the fire hazard evaluation of materials.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Low Flame Spread. A material with a flame spread rating of 25 or less when classified in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Maintenance. Work performed to keep equipment operable or to make repairs.

Maintenance Hole. A structure atop an opening in a gravity sewer to permit personnel entry, or an opening in the top or side of an enclosed vessel to permit personnel entry. Also referred to as manhole or manway.

Methane (CH_4). A colorless, odorless, flammable gaseous hydrocarbon present in natural gas and formed by the anaerobic decomposition of organic matter. (*See also Anaerobic Digestion.*)

Nitrification Tank. A unit process for the oxidation of ammonia and nitrogen into nitrates through biochemical actions.

Noncombustible. A material that in the form in which it is used and under the conditions anticipated will not aid combustion or add appreciable heat to an ambient fire. Materials when tested in accordance with ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C (1382°F)*, and conforming to the criteria contained in Section 7 of the referenced standard shall be considered as noncombustible. This definition applies to the materials used in the construction of buildings but does not apply to furnishings or the contents of buildings or to the fire hazard evaluation of materials.

Nonenclosed. Any tank or unit process open to the atmosphere, or the area around any open tank or unit process housed in a building or other structure constructed with a roof and having at least 50 percent of the wall area open to the atmosphere. Fixed open louvered panels with effective openings greater than 50 percent of the wall area and evenly distributed over the wall area are considered open to the atmosphere.

On-Site Treatment System. A self-contained system, including pumping equipment, that provides both treatment and disposal of wastewater on or immediately adjacent to a single residence or group of residences or small commercial establishments.

Oxygen-Enriched Atmosphere. Any atmosphere with an oxygen concentration greater than ambient by volume at normal atmospheric pressure, for example in oxygen-activated sludge systems, ozonation units, or high-pressure oxidation units.

Ozonation. The process of contacting wastewater or air with ozone for the purpose of disinfection, oxidation, or odor control.

Physically Separated. Physically separated, as used in this document, means a gastight partition between two adjacent spaces, or two nonadjacent spaces, with no means of gas communication between the spaces. Personnel entry to the separate spaces is by individual, grade-level exterior access ports with no physical connection between the two.

Primary Wastewater Treatment. The first major treatment in a wastewater treatment plant, generally consisting of one or more of the following unit processes: screening, comminution or grinding, grit removal, sedimentation, and skimming.

Pumping Station. A structure that contains pumps and appurtenant piping, valves, and other mechanical and electrical equipment for pumping wastewater or other liquid. Also called lift station.

Pyrolysis. The destructive distillation of organic compounds in an oxygen-free environment that converts the organic matter into gases, liquids, and char.

Residential Wastewater. Wastewater derived from areas consisting of single- and multiple-family residences.

Rotating Biological Contactor (RBC). A unit process for wastewater treatment that is composed of large, closely spaced plastic discs that are rotated about a horizontal shaft (usually a secondary biological treatment process).

Screening Chamber. A chamber or enlargement of a sewer where large suspended or floating solids or material is removed from raw wastewater by a screen.

Scum or Skimmings. Grease, solids, liquids, and other floatable material removed from settling tanks.

Secondary Wastewater Treatment. Wastewater treatment unit processes usually consisting of primary treatment and biological oxidation using activated sludge or trickling filtration, followed by clarification.

Sedimentation. The unit process of subsidence of suspended matter carried by water, wastewater, or other liquids, by gravity. It is usually accomplished by reducing the velocity of the liquid below the point at which it can transport the suspended material. Also called settling, it can be enhanced by chemical addition, coagulation, and flocculation.

Separate Nonprocess-Related Structures. Structures that are physically separated and do not contain any process-related equipment associated with the collection and treatment of wastewaters and solids derived from wastewater treatment processes.

Sewer. A single pipe or system of pipes or conduits that carries wastewater or drainage water. See definitions below for different types of sewers.

Branch. A sewer that receives wastewater from a relatively small area and discharges into a main sewer serving more than one branch-sewer area.

Building. In plumbing, the extension from the building drain to the public sewer or other place of disposal (also called house connection or lateral).

Collector. A pipe or conduit that receives wastewater from a relatively small area from two or more lateral sewers and that subsequently discharges into a trunk sewer.

Combined. A sewer intended to receive both wastewater and storm or surface water.

Industrial. A sewer intended to receive only industrial wastewater or other liquid or water-carried wastes (also see sanitary sewer, storm sewer, and combined sewer).

Interceptor. A sewer that receives dry-weather flow and frequently additional predetermined quantities of storm water (if from a combined system) from a number of transverse sewers or outlets and conducts such waters to a point for treatment or disposal (also called main sewer).

Outfall. A sewer that receives wastewater from a collecting system or from a treatment plant and carries it to a point of final discharge.

Pressure. A collection sewer that incorporates a wastewater grinder pump or septic tank effluent pump to convey wastewater from a single residence or group of residences or small commercial establishments to a private or public sewer system or on-site disposal system.

Private. A sewer privately owned and used by one or more properties or owners.

Relief. A sewer built to carry the flows in excess of the capacity of an existing sewer. Also a sewer intended to carry a portion of the flow from a district in which the existing sewers are of insufficient capacity.

Residential. A sewer intended to receive only residential wastewater (also see combined sewer, sanitary sewer, and storm sewer).

Sanitary. A sewer that carries liquid and water-carried wastes from residences, commercial buildings, industrial plants, and institutions together with minor quantities of storm, surface, and ground waters that are not admitted intentionally.

Storm. A pipe or conduit that carries storm water and surface water, street wash, and other wash water, or drainage, but excludes domestic wastewater and industrial wastes (also called storm drain).

Trunk. The principal pipe or conduit to which one or more collector sewers or branch sewers are tributaries (also called main sewer).

Sewer Gas. Gas resulting from decomposition of organic matter in wastewater in sewers. Also, gas resulting from the incidental uncontrolled release of hydrocarbons or decomposition of organic matter in stagnant liquid and septic sludge in wastewater treatment plants. The gas might contain trace quantities of methane and hydrogen sulfide and might be low in oxygen. It might be both a fire and life safety hazard.

Shall. Indicates a mandatory requirement.

Sludge. A semiliquid mass of accumulated settled solids deposited from wastewater, raw or treated, in tanks or basins. Also referred to as biosolids.

Sludge Cake. A semisolid product of a sludge dewatering process.

Sludge Dewatering. The process of removing a part of the water in sludge by any physical or mechanical method without heat, such as draining, pressing, vacuum filtration, centrifuging, or passing between rollers.

Sludge Drying Systems. Sludge processes using physical or mechanical evaporation techniques with or without the application of heat to achieve solids concentrations greater than 85 percent.

Sludge Gas. Gas obtained as a by-product of the anaerobic sludge digestion unit process from the decomposition of organic matter. It has a high content of methane, varying amounts of carbon dioxide and hydrogen sulfide, and a small amount of nitrogen. It can be both a fire and life safety hazard.

Sludge Gas Vent. A passage to permit the controlled release of gases from anaerobic treatment processes or gas storage facilities.

Sludge Thickening. A sludge treatment process designed to concentrate wastewater sludges by gravity, mechanical means, or air flotation.

Sludge Treatment. The processing of wastewater sludges to render them stable. This can be done by aerobic or anaerobic digestion followed by drying on sand beds, filtering and incineration, filtering and drying, or wet air oxidation.

Standard. A document, the main text of which contains only mandatory provisions using the word “shall” to indicate requirements, which is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions shall be located in an Appendix, footnote, or fine-print note and are not to be considered a part of the requirements of a standard.

Structure. Structure, as used in this document, includes all construction designed to carry gravity loads and intended to contain wastewater, sludge, sludge gas, piping, or equipment. Structures can provide access but are not intended for continuous personnel occupancy.

Trickling Filter. A treatment unit process consisting of stone, plastic, redwood, or similar media over which wastewater is distributed and through which wastewater trickles to the underdrains and is treated by the microbial slimes formed on the surface of the media.

Utilization Equipment. Equipment that utilizes electric energy for mechanical, chemical, heating, lighting, or similar purposes.

Vacuum Filter. A unit process used to dewater wastewater sludge and consisting of a cylindrical drum mounted on a horizontal axis, covered with a media, and subjected to an internal vacuum.

Vault. An enclosed structure, usually underground, used to permit personnel access to various types of equipment and instrumentation.

Ventilation Rate. Ventilation rate, as used in this document, is based on air changes per hour and is calculated by the use of 100 percent outside air for the supply air that is exhausted. Air change per hour is calculated on the basis of the maximum aggregate volume (under normal operating conditions) of the space to be ventilated.

Volatile Liquid. A liquid that evaporates readily at normal temperature and pressure.

Wastewater. The spent water of a community. Combination of the liquid and water-carried wastes from residences, commercial buildings, industrial plants, and institutions, together with any ground water, surface water, and storm water that might be present.

Wet Well. That portion of the pumping station that receives and temporarily stores wastewater for the purpose of pumping. A wet well might or might not contain electrical equipment such as pumps, motors, fans, wiring and wiring devices, controls, lights, and other accessories.

Chapter 2 Collection Systems

2-1* General.

This chapter provides minimum criteria for protection against fire and explosion hazards in the collection and transportation of municipal wastewater. This chapter does not address on-site systems, force mains, or those sewers that convey principally industrial wastes. Table 2 summarizes the various components associated with wastewater collection and transport systems.

2-2* Design and Construction.

The design and construction of collection system facilities shall conform to Table 2.

Table 2 Collection Systems

		A	B	C	D	E	F	G
		Location and Function	Fire and Explosion Hazard	Ventilation	Extent of Classified Area	NEC-Area Electrical Classification (All Class I, Group D)	Material of Construction for Buildings or Structures	Fire Protection Measures
1		MATERIALS USED IN REHABILITATION, RECONSTRUCTION, OR SLIP-LINING OF SEWERS	NA	NA	NA	NA	In accordance with 6-3.1	NA
2		INDUSTRIAL SEWER Sewer transporting industrial wastewater only. (No sanitary wastewater.)	Not included within the scope of this document					
3		STORM SEWER Sewer transporting storm water only. (No sanitary wastewater.)	Possible ignition of flammable gases and floating flammable liquids	NNV	Inside of sewer	Division 2	In accordance with 6-3.1	NR
4		STORM WATER PUMPING STATION WET WELLS Liquid side of pumping station serving only a storm sewer system.	Possible ignition of flammable gases and floating flammable liquids	NNV	Entire room or space	Division 2	NC, LC, or LFS	CGD if enclosed
5	a	STORM WATER PUMPING STATION DRY WELLS Dry side of a pumping station serving only a storm sewer system and physically separated from wet well.	Buildup of vapors from flammable or combustible liquids	D	Entire dry well	Division 2, or unclassified, if space provided with pressurization in accordance with NFPA 496	NC, LC, or LFS	FE
	b			C		Unclassified		
6		PRESSURE SEWER- (Force main) Sewer under pressure. (Flooded discharge pipe from pump or tank.)	Not included within the scope of this document					
7		BUILDING SEWER (Lateral sewer or drain) Sewer serving a house or single building (plumbing).	Not included within the scope of this document					
8		INDIVIDUAL RESIDENTIAL SEWER Sewer serving one but not more than five dwellings.	NA	NNV	Within enclosed space	Unclassified	NR	NR
9		INDIVIDUAL RESIDENTIAL PUMPING UNITS Pumping units serving one but not more than five dwellings (e.g., grinder pumps, septic tank effluent pumps, ejector pumps).	NA	NNV	Within enclosed space	Unclassified	NR	NR

A — No ventilation, or ventilated at less than 12 air changes per hour
B — Continuously ventilated at 12 air changes per hour or in accordance with Chapter 7
C — Continuously ventilated at 6 air changes per hour or in accordance with Chapter 7
CGD — Combustible gas detection system
FE — Portable fire extinguisher
FSS — Fire suppression system (automatic sprinkler, water spray, foam, gaseous, or dry chemical)
H — Hydrant protection in accordance with 5-2.4
LC — Limited-combustible material
LFS — Low flame spread material
NA — Not applicable
NR — No requirement

Chapter 3 Liquid Stream Treatment Processes

3-1* General.

This chapter provides minimum criteria for protection against fire and explosion hazards associated with liquid stream treatment processes. This chapter does not address treatment systems serving individual structures or treatment systems that treat principally industrial wastes. Table 3 summarizes the various components associated with liquid stream treatment processes.

3-2* Design and Construction.

The design and construction of liquid stream treatment processes shall conform to Table 3.

Table 3 Liquid Stream Treatment Processes

		A	B	C	D	E	F	G
		Location and Function	Fire and Explosion Hazard	Ventilation	Extent of Classified Area[3]	NEC-Area Electrical Classification (All Class I, Group D)	Material of Construction for Buildings or Structures	Fire Protection Measures
1	a	COARSE AND FINE SCREEN FACILITIES Removal of screenings from raw wastewater.	Possible ignition of flammable gases and floating flammable liquids	A	Enclosed — entire space	Division 1	NC	FE, H, and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1,2]			
2		PUMPING STATIONS (*See Collection Systems, Table 2.*)						
3	a	FLOW EQUALIZATION TANKS Storage of raw or partially treated wastewater.	Possible ignition of flammable gases and floating flammable liquids	A	Enclosed — entire space	Division 1	NC	FE, H, and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1,2]			
4	a	GRIT REMOVAL TANKS Separation of grit from raw wastewater.	Possible ignition of flammable gases and floating flammable liquids	A	Enclosed — entire space	Division 1	NC	FE, H, and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1,2]			
5	a	PRE-AERATION TANKS Conditioning of wastewater prior to further treatment.	Possible ignition of flammable gases and floating flammable liquids	A	Enclosed — entire space	Division 1	NC	H and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1]			
6	a	PRIMARY SEDIMENTATION TANKS Separation of floating or settleable solids from raw wastewater.	Possible ignition of flammable gases and floating flammable liquids	A	Enclosed — entire space	Division 1	NC	H and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Interior of the tank from the minimum operating water surface to the top of the tank wall. Envelope 18 in. (0.46 m) above the top of the tank and extending 18 in. (0.46 m) beyond the exterior wall. Envelope 18 in. (0.46 m) above grade extending 10 ft (3 m) horizontally from the exterior tank walls.			
7		AERATION BASIN, POND, LAGOON, OXIDATION DITCH, AEROBIC SUSPENDED GROWTH SYSTEMS, SEQUENCING BATCH REACTORS Aerobic treatment of wastewater open to the atmosphere.		NA		Unclassified (If process is not preceded by primary sedimentation, refer to primary sedimentation in Table 3 for classification.)	NR	H

NOTE 1: Area beyond envelope is unclassified.
NOTE 2: Where liquid turbulence is not induced by aeration or other factors, the following criteria apply: interior of the tank from the minimum operating water surface to the top of the tank wall; envelope 18 in. (0.46 m) above the top of the tank and extending 18 in. (0.46 m) beyond the exterior wall; and envelope 18 in. (0.46 m) above grade extending 10 ft (3 m) horizontally from the exterior tank walls.
NOTE 3: Open channels and open structures upstream from the unit processes are to be classified the same as the downstream process they supply.

A — No ventilation, or ventilated at less than 12 air changes per hour

with Chapter 7
CGD — Combustible gas detection system
D — No ventilation, or ventilated at less than 6 air changes per hour
FAS — Fire alarm system
FDS — Fire detection system
FE — Portable fire extinguisher

FSS — Fire suppression system (automatic sprinkler, water spray, foam,
LFS — Low flame spread material
NA — Not applicable
NC — Noncombustible material
NEC — In accordance with NFPA 70, *National Electrical Code*
NNV — Not normally ventilated
NR — No requirement

NOTE 3: Open channels and open structures upstream from the unit processes are to be classified the same as the downstream process they supply.

A — No ventilation, or ventilated at less than 12 air changes per hour
B — Continuously ventilated at 12 air changes per hour or in accordance with Chapter 7
C — Continuously ventilated at 6 air changes per hour or in accordance with Chapter 7
CGD — Combustible gas detection system
D — No ventilation, or ventilated at less than 6 air changes per hour
FAS — Fire alarm system
FDS — Fire detection system
FE — Portable fire extinguisher
FSS — Fire suppression system (automatic sprinkler, water spray, foam, gaseous, or dry chemical)
H — Hydrant protection in accordance with 5-2.4
LC — Limited-combustible material
LFS — Low flame spread material
NA — Not applicable
NC — Noncombustible material
NEC — In accordance with NFPA 70, *National Electrical Code*
NNV — Not normally ventilated
NR — No requirement

Chapter 4 Solids Treatment Processes

4-1* General.

This chapter provides minimum criteria for protection against fire and explosion hazards associated with solids treatment processes. This chapter does not address treatment of solids from industrial waste treatment processes. Tables 4(a) and 4(b) summarize the various components associated with solids treatment processes.

4-2* Design and Construction.

The design and construction of solids treatment processes shall conform to Table 4(a) and 4(b).

Table 4(a) Solids Treatment Processes

		A	B	C	D	E	F	G
		Location and Function	Fire and Explosion Hazard	Ventilation	Extent of Classified Area	NEC-Area Electrical Classification (All Class I, Group D)	Material of Construction for Buildings or Structures	Fire Protection Measures
1		COARSE AND FINE SCREENINGS HANDLING BUILDINGS Storage, conveying, or dewatering of screenings. (No exposed flow of wastewater through this building or area.)	NA	NR	NA	Unclassified	NC, LC, or LFS	H, FE, and FAS
2		GRIT-HANDLING BUILDING Storage, conveying, and dewatering of heavy small screenings and grit. (No exposed flow of wastewater through this building or area.)	NA	NR	NA	Unclassified	NC, LC, or LFS	H, FE, and FAS
3	a	SCUM-HANDLING BUILDING OR AREA Holding, dewatering, or storage.	Possible grease or flammable liquids carryover	A	Enclosed space	Division 2	NC, LC, or LFS	H, FE, and CGD if enclosed
	b			B		Unclassified		
	c			Not enclosed, open to atmosphere	NA			
4	a	SCUM PITS	Buildup of vapors from flammable or combustible liquids	A	Enclosed—entire space	Division 1	NC	H, FE, and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1]			
5	a	SCUM-PUMPING AREAS Pumping of scum, wet side of pumping station.	Carryover of floating flammable liquids	A	Enclosed—entire space	Division 1	NC	H, FE, and CGD if enclosed
	b			B		Division 2	NC, LC, or LFS	
	c			Not enclosed, open to atmosphere	Within 10 ft (3 m) envelope around equipment and open channel[1]			
6	a	SCUM-PUMPING AREAS Pumping of scum, dry side of pumping station.	Not significant	D	Enclosed space	Division 2, or unclassified if adequate positive pressure ventilation from clean air is provided with effective safeguards against ventilation failure	NC, LC, or LFS	FE
	b			C		Unclassified		
	c			Not enclosed, open to atmosphere	NA			
7		SCUM INCINERATORS[2] Elimination of scum through burning.	Firebox explosion from possible carryover of flammable scum	NR	Incinerator area if separated from scum storage	Unclassified	NC, LC, or LFS	FSS (if indoors), H, and FE

NOTE 1: Area beyond envelope is unclassified.
NOTE 2: See NFPA 54, NFPA 82, NFPA 8501, and NFPA 8502.

A — No ventilation, or ventilated at less than 12 air changes per hour
B — Continuously ventilated at 12 air changes per hour or in accordance with Chapter 7
C — Continuously ventilated at 6 air changes per hour or in accordance with Chapter 7
FSS — Fire suppression system (automatic sprinkler, water spray, foam, gaseous, or dry chemical)
H — Hydrant protection in accordance with 5-2.4
LC — Limited-combustible material
LFS — Low flame spread material

[illegible]de
FDS — Fire detection system
FE — Portable fire extinguisher
NNV — Not normally ventilated
NR — No requirement

Chapter 5 Fire and Explosion Prevention and Protection

5-1* Scope.

This chapter establishes minimum requirements for overall protection against fire and explosion hazards in wastewater facilities and associated collection systems. The conditions created by the existence of gases, liquids, and solids can be grouped into two categories: flammable/combustible and injurious to life. While this standard deals primarily with the flammability aspects of a particular substance, process, or area within a plant, additional requirements to protect against other safety and health hazards are contained in NFPA *101*®, *Life Safety Code*®, and NFPA 70E, *Standard for Electrical Safety Requirements for Employee Workplaces*, and shall be considered part of NFPA 820.

5-2 Fire Protection Measures.

5-2.1 General.

5-2.1.1 Collection systems, liquid stream treatment processes, and solids handling processes shall be provided with fire protection appropriate to the fire hazard as described in Tables 2 through 4(a) and (b).

5-2.1.2 In addition to the fire protection specified in Chapter 6, buildings, structures, and process elements under some conditions shall be provided with automatic extinguishing systems in accordance with Chapter 5.

5-2.2 Automatic Sprinkler Systems.

5-2.2.1 An automatic sprinkler system where required by this standard or by referenced publications shall conform to NFPA 13, *Standard for the Installation of Sprinkler Systems*, and shall be approved by the authority having jurisdiction.

Exception: In certain areas of the wastewater treatment plant, such as chemical storage, underground tunnels or structures, areas where electrical hazard is a principal concern, or where water damage would seriously impair the integrity of the treatment plant, other automatic *extinguishing systems shall be permitted.*

5-2.3 Other Automatic Extinguishing Systems.

Where required or used in place of automatic sprinkler systems, special hazard extinguishing systems and nonwater automatic extinguishing systems shall be designed, installed, and maintained in accordance with the following standards, as applicable:

(a) NFPA 11, *Standard for Low-Expansion Foam*;

(b) NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*;

(c) NFPA 11C, *Standard for Mobile Foam Apparatus*;

(d) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*;

(e) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*;

(f) NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*;

(g) NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*;

(h) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*; and

(i) NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*.

5-2.4 Water Supplies, Standpipes, Hose Systems, and Hydrants.

5-2.4.1 Water supplies shall be capable of delivering the total demand of sprinklers, hose streams, and foam systems. In areas where there is no public water supply or where the supply is inadequate, treatment plant effluent shall be permitted for fire protection use. Where connections are made from public water supplies, it might be necessary to guard against possible contamination of the public supply. The requirements of the public health authority having jurisdiction shall be determined and followed.

5-2.4.2 Water supplies and hydrants shall be installed in accordance with the following standards, as applicable:

(a) NFPA 22, *Standard for Water Tanks for Private Fire Protection*;

(b) NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*; and

(c) NFPA 1231, *Standard on Water Supplies for Suburban and Rural Fire Fighting*.

5-2.4.3 Standpipes and hose systems, where provided, shall be installed and inspected in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

5-2.4.4 Where fire pumps are used as a separate and sole source of supply, the system shall provide sufficient capacity to meet fire water flow requirements and shall be equipped with a standby power supply. Pumps shall be automatic starting and manual shutdown. Pumps shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

5-2.5 Portable Fire Extinguishers.

Portable fire extinguishers shall be installed, located, and maintained in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

Exception: In areas of the treatment plant not commonly occupied, such as basement and underground pipe galleries connecting buildings, the requirement for the permanent installation of portable fire extinguishers might not be appropriate. In these cases, the provision of portable fire extinguishers adequate for the hazards involved and acceptable to the authority having jurisdiction during all times the areas are occupied shall meet the intent of this standard.

5-3 Fire Detection and Alarm Systems.

5-3.1

Fire detection and alarm systems of a type appropriate to each treatment plant area shall be provided as identified in Tables 2, 3, and 4(a) and (b) or by referenced publications.

5-3.2

Fire detection and alarm systems, where required, shall be installed and maintained in accordance with the NFPA 72, *National Fire Alarm Code*.

5-4 Combustible Gas Detection.

5-4.1*

Combustible gas detectors shall be located in accordance with Tables 2, 3, and 4(a).

5-4.2*

The selection of combustible gas detector types and their placement shall be determined by a qualified person.

5-4.3

Combustible gas detectors shall be listed. The installation of combustible gas detectors shall be in accordance with their listing requirements and the manufacturer's instructions.

5-4.4

Combustible gas detection equipment located in hazardous (classified) locations, as defined in accordance with NFPA 70, *National Electrical Code*, shall be listed for use in such atmospheres. The detectors shall be set at 10 percent of the lower explosive limit in accordance with the manufacturer's calibration instructions and shall be connected to alarm signaling systems.

Exception: Alarm limits shall be permitted to be set at a higher percentage of the explosive limit where experience indicates ambient levels are too high and spurious alarms might be the result.

5-5 Ventilation Monitoring and Signaling Systems.

5-5.1

All continuous ventilation systems shall be fitted with flow detection devices connected to alarm signaling systems to indicate ventilation system failure.

5-5.2

Local and remote alarms for both ventilation system failure and combustible gas detection shall be provided for all hazardous areas classified in accordance with the following:

(a) Article 500 of NFPA 70, *National Electrical Code*;

(b) Any space pressurized in accordance with Chapters 2, 3, and 4; or

(c) Chapter 7 and NFPA 496, *Standard for Purged and Pressurized Enclosures for Electrical Equipment*.

5-5.3*

The alarms required in 5-5.2 shall be displayed in accordance with Table 5-5.3.

Table 5-5.3 Ventilation System Alarm Devices for Areas Indicated in 5-5.2

Location/Supervision	Alarm Devices and Supervision
1. Entrance(s) to such spaces[1]	Visual and audible alarm or equivalent
2. Within such spaces	Visual and audible alarm
3. Local (within treatment plant or building)	Visual and audible alarm
4. Remote (for distant supervision)[2]	Visual and audible alarm

[1]Where locations are not constantly attended, the use of a nonaudible signal is permissible if a dual light system or equivalent is used. A dual light system shall include a "go"/"no go" or green light/red light type of warning system instead of the audible alarm.

[2]In appropriate situations and where this is impractical, a telephone dialer shall be considered to meet the intent of this portion of the table.

5-5.4

Signaling systems shall be in accordance with the requirements for supervised signaling systems as set forth in NFPA 72, *National Fire Alarm Code*.

5-6 Laboratories.

Fire protection for laboratories shall be in accordance with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*.

5-7 Special Fire Protection Measures.

5-7.1 Fire Protection During Construction.

Fire protection measures during construction at both new and existing wastewater facilities shall be provided in accordance with NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*, and NFPA 395, *Standard for the Storage of Flammable and Combustible Liquids at Farms and Isolated Sites*.

5-7.2 Lightning Protection.

Lightning protection shall be provided in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems.*

5-7.3 Drainage.

5-7.3.1 Provisions shall be made in all fire areas of the plant for removal of all liquids directly to safe areas or for containment in the fire area without flooding of equipment and without endangering other areas. Caution shall be taken to avoid washing hazardous or toxic products of combustion into the drainage system.

5-7.3.2 The provisions for drainage and any associated drainage facilities shall be sized to accommodate all three of the following simultaneously:

(a) The spill of the largest single container of any flammable or combustible liquids in the area,

(b) The maximum expected number of fire hose lines [500 gal/min (31.5 L/sec) minimum] operating for a minimum of 10 min, and

(c) The maximum design discharge of fixed fire suppression systems operating for a minimum of 10 min.

Chapter 6 Materials of Construction

6-1 General.

6-1.1

This chapter provides minimum criteria for selecting materials of construction for buildings, structures, and process elements for protection against fire and explosion in wastewater treatment plants and associated collection systems. In general, materials of construction and interior coatings and finishes shall provide a maximum degree of fire resistance with the minimum amount of flame spread and smoke generation for a particular application.

6-1.2

Materials shall be selected that reduce or eliminate the effects of fire and explosion by maintaining structural integrity, controlling flame spread and smoke generation, minimizing the release of toxic products of combustion, and maintaining serviceability and operation of critical processes. The criteria for selecting materials of construction is not intended to provide sufficient protection of personnel from the risk of exposure to an asphyxiating or toxic atmosphere generated during a fire event.

Exception: In general, criteria for selecting materials of construction do not apply to nonprocess contents of the building, structure, or assembly where such contents are not a part of the building, structure, or assembly, including, but not limited to, equipment or equipment enclosures, grating, walkways, ladders, railings, weirs, process piping and appurtenances, process media, aeration devices, slide and sluice gates, pump packing and seal material, electrical conduit, hardware, liners for basins that are open to the atmosphere, or materials used in rehabilitation or for lining existing sewer pipes.

6-1.3

In areas where corrosive environments are present, including classified areas, special attention shall be given to mitigation of corrosion problems in the selection and use of materials for nonstructural assemblies, including the use of corrosion-resistant metallic or nonmetallic grating, railings, steps and stairs, conduit, and electric equipment enclosures.

6-1.4

Other local approving authorities and governing codes shall dictate more stringent material selection requirements, when appropriate.

6-2 Materials Selection.

6-2.1

Materials shall be selected based on criteria for a particular application. Selection criteria shall include:

(a) Structural requirements,

(b) Location and operating environment,

(c) Fire rating,

(d) Flame spread value,

(e) Smoke density generation factors,

(f) Products of combustion, and

(g) Corrosion resistance.

6-2.2

For the purpose of this document, materials of construction are divided into four basic categories: (a) combustible, (b) noncombustible, (c) limited-combustible, and (d) low flame spread.

6-2.3

Materials of construction being considered for unit processes located in areas with an electrical classification of Class I, Division 1 or Division 2, and Class II shall be selected based on an overall evaluation including fire risk of the material attributes, the economic impacts of replacing the unit process, and the potential environmental dangers caused by having the unit process out of service for an extended period of time due to fire or explosion.

6-3 Applications.

6-3.1* Sewers and Appurtenances.

Materials of construction for sewers and appurtenances such as maintenance holes, junction chambers, and catch basins shall be based on the results of a written materials risk assessment.

6-3.2 Pumping Facilities.

Materials selected for wastewater pumping facilities shall be in accordance with Table 2.

Exception No. 1: When conditions or applications warrant the selection of combustible materials for pumping facilities, consideration to flame spread, smoke generation, corrosion resistance, products of combustion, and the impact that a fire or explosion will have on the structural integrity, operability of the pumping facility, and the economic and environmental consequences of having the pumping facility out of service shall be included in the fire risk evaluation.

Exception No. 2: Small aboveground pumping facilities with a floor area of 100 ft^2 (9.3 m^2) or less and physically separated from the wet well and that do not present a fire hazard to other buildings or structures shall be permitted to be constructed of any appropriate materials.

6-3.3 Buildings and Structures.

6-3.3.1 General. Buildings and structures, including domes and covers, shall be constructed of materials in accordance with Tables 2, 3, and 4(a) and (b).

Exception No. 1: When conditions or applications warrant the selection of combustible materials for buildings and structures, consideration to flame spread, smoke generation, corrosion resistance, products of combustion, and the impact that a fire or explosion will have on the structural integrity, operability of the facility, and the economic and environmental consequences of having the facility out of service shall be included in the fire risk evaluation.

Exception No. 2: Small aboveground buildings and structures, including domes and covers, with a floor or surface area of 100 ft^2 (9.3 m^2) or less and physically separated from other buildings or structures and that do not present a fire hazard to other buildings or structures shall be permitted to be constructed of any appropriate materials.

Exception No. 3: Materials other than those required by Tables 2, 3, and 4(a) and (b) shall be permitted in buildings or structures that are fully sprinklered in accordance with NFPA 13, Standard for the Installation of Sprinkler Systems.

6-3.3.2 Critical Unit Processes.

6-3.3.2.1 Buildings and structures, including domes and covers, containing unit processes that are considered critical to maintaining the integrity of the treatment plant (e.g., headworks, main pumping facility, primary clarifiers, etc.), and that if out of service for even a few hours could permanently or unacceptably damage the environment or endanger public health by allowing the release of raw wastewater or sludge, shall be constructed of materials meeting the definition of noncombustible.

Exception: Except as indicated by the Exceptions to 6-3.3.1.

6-3.3.2.2 Where structural assemblies and partitions are required in these areas for fire separation in accordance with the fire risk evaluation, they shall have a minimum 3-hr fire rating.

6-3.3.2.3 Nonstructural assemblies such as ventilation ducts and piping shall be constructed of noncombustible, limited-combustible, or low flame spread materials.

6-3.3.3 Essential Unit Processes.

6-3.3.3.1 Buildings or structures, including domes and covers, containing unit processes that are considered essential to maintain the integrity of the treatment plant (e.g., secondary biological treatment, secondary clarifiers, disinfection facilities, etc.), and that if out of service for short periods of time would not permanently or unacceptably damage the environment or endanger public health but would become critical if continued for several days, shall be constructed of materials meeting the definition of noncombustible, limited-combustible, or low flame spread.

Exception: Except as indicated by the Exceptions to 6-3.3.1.

6-3.3.3.2 Where structural assemblies and partitions are used in these areas for fire separation, they shall have a minimum 2-hr fire rating.

6-3.3.3.3* Nonstructural assemblies such as ventilation ducts and piping shall be constructed of noncombustible, limited-combustible, or low flame spread materials.

6-3.3.4 Other Unit Processes.

6-3.3.4.1 Buildings and structures containing unit processes, including most sludge processing operations, that are not considered to be critical or essential to maintaining the integrity of the treatment plant, and where being out of service for long periods of time (a week or more) would not permanently or unacceptably damage the environment or endanger public health, shall be constructed of materials considered applicable by the authority having jurisdiction.

Exception: Except as indicated by the Exceptions to 6-3.3.1.

6-3.3.4.2 Where structural assemblies and partitions are used in these areas for fire separation, they shall have a minimum fire rating of 1 hr.

6-3.3.4.3 Nonstructural assemblies such as ventilation ducts and piping shall be constructed of materials meeting the definition of noncombustible, limited-combustible, or low flame spread.

6-3.3.5 Combustible Gas Generation and Combustion Processes. Buildings and structures containing unit processes that generate, process, or utilize combustible gases (e.g., anaerobic wastewater treatment processes, anaerobic digesters, compressors, storage spheres, piping, waste gas burners, gas-fired equipment including sludge incinerators, etc.) shall be constructed of materials meeting the definition of noncombustible.

Exception: Except as indicated by the Exceptions to 6-3.3.1.

6-3.3.6 Air Supply and Exhaust. Noncombustible, limited-combustible, or low flame spread materials shall be used for air supply and exhaust systems. Systems supplying or exhausting air at a rate greater than 2000 ft^3/min (56.6 m^3/min) shall include listed smoke dampers, listed fire dampers, and smoke detection and shall cause the ventilation system to shut down upon detection of smoke. Separate smoke ventilation systems shall be used where applicable.

Exception: Smoke venting shall be permitted to be integrated into normal ventilation systems using automatic or manually positioned dampers and motor speed control in accordance with NFPA 90A, Standard for the Installation of Air Conditioning and Ventilating Systems. (Also see NFPA 204M, Guide for Smoke and Heat Venting. Smoke venting also can be accomplished through the use of portable smoke ejectors.)

6-3.3.7 Miscellaneous Materials. Cellular or foamed plastic materials shall only be used in accordance with NFPA *101*, *Life Safety Code*. Roof covering shall be Class A in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*. Metal roof deck construction, where used, shall be Class I or fire classified.

Exception: Class II metal roof deck construction shall be permitted in buildings or structures that are fully sprinklered in accordance with Chapter 5.

Chapter 7 Ventilation

7-1 General.

7-1.1 Scope.

7-1.1.1 Minimum criteria for adequate ventilation for protection against fire and explosion of wastewater treatment and pumping facilities shall be in accordance with Chapters 2, 3, and 4 for the designated electrical classifications.

7-1.1.2 Ventilation criteria not addressed by Chapters 2, 3, and 4 shall meet the requirements of Table 7-3.

7-1.1.3 An “NR” designation in column C of Tables 2, 3, and 4(a) and (b) indicates that no ventilation requirements are established for the space and, therefore, Table 7-3 also has no requirements.

7-1.2

Where this standard requires certain ventilation practices, they are intended to minimize fire and explosion hazards; these ventilation standards might be insufficient to protect personnel from the toxic effects of exposure to gases present.

7-1.3

This chapter is limited to ventilation of enclosed wastewater pumping and process-related areas. It does not establish criteria applicable to spaces devoted to administrative areas, laboratories, or other ancillary spaces.

7-1.4

This chapter does not apply to at- or above-grade unroofed structures less than 2 ft (0.6 m) deep or 2 ft (0.6 m) to the normal water line or to at- or above-grade roofed structures where (a) the roof is at least 10 ft (3 m) above surrounding finished grade, and (b) the structure is open on at least three sides.

7-1.5

Because of the unpredictable nature of materials and events that can be encountered in the operation of wastewater systems, ventilation criteria established in this standard might not be adequate for protection against all hazards that might be encountered.

7-1.6

Hazardous classifications as established in Tables 2, 3, and 4(a) and (b) shall be permitted to be reduced to a lower classification (including unclassified) with positive pressurization as provided under Article 500 of NFPA 70, *National Electrical Code*. Positive pressurization shall be as described in NFPA 496, *Standard for Purged and Pressurized Enclosures for Electrical Equipment*.

7-2 Installation.

7-2.1

Ventilation systems serving spaces governed by this standard shall be designed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, unless superseded by more restrictive provisions of this standard.

7-2.2

Ventilation systems serving hazardous areas classified under the provisions of Article 500 of NFPA 70, *National Electrical Code*, shall incorporate fans fabricated in accordance with AMCA Type A or B spark-resistant construction.

7-2.3

All mechanically ventilated spaces shall be served by both supply and exhaust fans.

Exception No. 1: For covered process facilities that are not routinely entered by personnel and where mechanically ventilated, the space is permitted to be ventilated by exhaust fans only. In determining the area classification, the induced supply (outside) air shall meet the ventilation *rate specified in the applicable chapter.*

Exception No. 2: Above-grade spaces with floor areas of 100 ft^2 (9.3 m^2) or less meeting the requirements of Exception No. 2 to 6-3.3.1 shall be permitted to be ventilated by a supply fan only.

7-2.4

Ventilation systems serving unclassified areas adjacent to classified areas shall maintain a differential pressure relative to ambient air pressure of 0.1 in. water column (25 Pa) under all operating conditions.

7-2.5

Ventilation systems serving classified areas shall maintain a differential pressure relative to ambient air pressure of 0.1 in. water column (25 Pa) under all operating conditions.

7-2.6

Ventilation systems for hazardous areas designed to operate intermittently or only when the space is occupied are not considered adequate for the purpose of downgrading the electrical classification of areas. (*See Chapters 2, 3, and 4.*)

7-2.7

Air shall be introduced into and exhausted from such spaces in a manner that will encourage scavenging of all portions of the spaces to avoid short-circuiting and to promote the effective removal of both heavier-and lighter-than-air gases and vapors.

7-2.8

Ventilation systems shall not transfer air between unclassified interior spaces and classified interior spaces.

7-2.9

Ventilation systems serving areas governed by this standard shall receive power from electrical equipment that receives power from a primary power source and that also has the means to accept power from alternate power sources. Minimum requirements for the means to accept the alternate source of power include connectors that are designed to connect to devices such as standby generators, portable generators, uninterruptible power supplies, etc. Automatic or manual switching to a permanent alternate source of power is also acceptable. Power failure of the primary source shall be alarmed so that appropriate emergency procedures can be started.

7-3 Ventilation Criteria.

7-3.1

Ventilation rates are based on air changes per hour and shall be calculated on the basis of the maximum aggregate volume (under normal operating conditions) of the space to be ventilated. Air changes per hour shall be based upon 100 percent outside supply air, which shall be exhausted. Ventilation rates shall conform to those listed in Table 7-3 in order to obtain the lowest area electrical classification possible in accordance with NFPA 70, *National Electrical Code*.

Table 7-3 Minimum Ventilation Rates

		Ventilation Rate, Air Changes per Hour, or Velocity as Noted		
	Description	Class I, Div. 1	Class I, Div. 2	Unclassified
1	Wet wells, screen rooms, and other enclosed spaces with wastewater exposed to the room atmosphere.	$<$ 12 air changes per hour	$\geq$ 12 air changes per hour	
2	Below-grade spaces (such as dry wells, equipment rooms, tunnels, or galleries)			
(a)	With equipment using or processing flammable gas; or	$<$ 12 air changes per hour, or $<$ 74 ft/min (22.2 m/min) velocity in tunnels or galleries	$\geq$ 12 air changes per hour, or $\geq$ 74 ft/min (22.2 m/min) velocity in tunnels or galleries	
(b)	With gas piping; or		$<$ 6 air changes per hour, or $<$ 37 ft/min (11 m/min) velocity in tunnels or galleries	$\geq$ 6 air changes per hour, or $\geq$ 37 ft/min (11 m/min) velocity in tunnels or galleries
(c)	Without gas piping.		$<$ 6 air changes per hour for dry wells	$\geq$ 6 air changes per hour for dry wells
			NR for tunnels and galleries	
3	Above-grade spaces (such as equipment rooms and galleries)			
(a)	With equipment using or processing flammable gas; or	$<$ 12 air changes per hour, or $<$ 74 ft/min (22.2 m/min) velocity for galleries	$\geq$ 12 air changes per hour, or $\geq$ 74 ft/min (22.2 m/min) velocity in galleries	
(b)	With gas piping; or		$<$ 6 air changes per hour, $<$ 37 ft/min (11 m/min) velocity in galleries	$>$ 6 air changes per hour, or $>$ 37 ft/min (11 m/min) velocity in galleries
(c)	Without gas piping.		NR for galleries	

7-3.2

Dual ventilation rates for Class I, Division 1 and Division 2 areas shall be permitted under the provisions of this document, provided (a) the low ventilation rate is not less than 50 percent of that specified in Table 7-3, (b) the low ventilation rate is in operation only if the supply air temperature is 50°F (10°C) or less, (c) the high ventilation rate is not less than that specified in Table 7-3, and (d) the high ventilation rate is in operation whenever the supply air temperature is above 50°F (10°C), whenever the ventilated space is occupied, or whenever activated by approved combustible gas detectors set to function at 10 percent of the lower explosive limit.

7-3.3*

Recirculation of up to 75 percent of the exhaust air flow rate for unclassified areas shall be permitted provided

(a) The recirculated air and outside air flow rate total is not less than 6 air changes per hour,

(b) Recirculation does not occur during occupancy, and

(c) Recirculation does not occur whenever a combustible gas detector senses a lower explosive limit of 10 percent or greater.

7-3.4

Ventilation system designs shall consider the effects of cold weather operation and the probable presence of corrosive agents.

Chapter 8 Administrative Controls

8-1 General.

This chapter establishes procedures and controls necessary for the execution of the fire prevention and fire protection activities and practices for wastewater interceptor systems, pumping stations, and treatment plants.

8-2 Management Policy and Direction.

8-2.1*

Management shall establish a policy and institute a fire prevention and protection program at each facility.

8-2.2

Combustible materials shall not be stored in areas used for the storage of toxic or reactive chemicals.

8-3* Fire Risk Evaluation.

A complete fire risk evaluation shall be performed during the initial design process.

8-4 Fire Prevention Program.

Each plant shall establish a fire prevention program. This program shall include all of the following:

(a) Fire safety information for all employees and contractors. This information shall include, as a minimum, familiarization with fire protection equipment and procedures, plant emergency alarms and procedures, and how to report a fire;

(b) Documented plant inspections including provisions for handling remedial actions to correct conditions that increase fire hazards;

(c) A description of the general housekeeping practices and the control of transient combustibles, including control of such materials stored in areas containing toxic or reactive chemicals;

(d) Control of flammable and combustible liquids and gases in accordance with NFPA 30, *Flammable and Combustible Liquids Code*, and NFPA 54, *National Fuel Gas Code*;

(e) Control of ignition sources to include smoking, grinding, welding, and cutting in accordance with NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*;

(f) Fire prevention surveillance in accordance with NFPA 601, *Standard on Guard Service in Fire Loss Prevention*; and

(g)* Fire report, including an investigation and a statement on the corrective action to be taken.

8-5 Water-Based Fire Protection Systems.

8-5.1

These systems include fire sprinkler systems, standpipe and hose systems, water spray fixed systems, and foam-water sprinkler systems. Included are the water supplies that are part of these systems such as private fire service mains and appurtenances, fire pumps and water storage tanks, and valves controlling system flow.

8-5.2

All water-based fire protection systems shall be installed in accordance with the manufacturer's specifications and the NFPA standards referenced throughout this document, as summarized in Chapter 9.

8-5.3

All water-based fire protection systems shall be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

8-6 Other Fire Protection and Detection Systems.

8-6.1

All other fire protection and detection systems shall be installed in accordance with the manufacturer's specifications and the NFPA standards referenced throughout this document, as summarized in Chapter 9.

8-6.2*

All other fire protection and detection systems shall be periodically inspected, tested, and maintained in accordance with the NFPA standards referenced throughout this document, as summarized in Chapter 9.

8-6.3

Other fire protection system equipment not addressed by an NFPA standard as referenced in Chapter 9 (e.g., combustible gas detectors, radio communications equipment, and flame arrestors or flame checks) shall be inspected, tested, and maintained in accordance with the manufacturer's specifications.

8-7* Impairments.

8-7.1

A written procedure in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, shall be established to address impairments of all water-based fire protection systems.

8-7.2

A written procedure shall be established to address impairments to other fire protection systems and plant systems that have an impact on the level of fire hazard (dust collection systems, HVAC systems, etc.). These procedures shall include the following:

(a) Identify equipment not available for service,

(b) Identify personnel to be notified (plant fire brigade chief, public fire department, etc.), and

(c) Increase fire surveillance as needed. [*See 8-4(g)*.]

8-7.3

Following repairs, tests shall be conducted on all affected systems to ensure proper operation.

8-7.4

Following restoration, all parties previously notified of the impairment shall be notified of the completion of repairs.

8-8 Fire Emergency Plan.

A written fire emergency plan shall be developed. This plan shall include the following:

(a) Response to fire alarms and fire system supervisory alarms,

(b) Notification of personnel identified in the plan,

(c) Evacuation of employees not directly involved in fire-fighting activities from the fire area,

(d) Coordination with security forces or other designated personnel to admit the public fire department and control traffic and personnel,

(e) Fire extinguishment activities, and

(f) In critical areas, operators' activities during fire emergencies. Approved breathing apparatus shall be readily available in critical areas.

8-9* Fire Brigades.

8-9.1*

If a fire brigade is provided, its organization and training shall be identified in written procedures.

8-9.2

Arrangements shall be made to permit rapid entry into the plant by the municipal fire department, police department, or other authorized personnel in the case of fire or other emergency. The Plant Emergency Organizations, where provided, shall be instructed and trained in accordance with NFPA 600, *Standard on Industrial Fire Brigades*.

8-10* Polychlorinated Biphenyls.

If polychlorinated biphenyls (PCBs) are contained within the wastewater treatment plant, the owner and the local fire officials shall prepare a contingency plan to protect the plant and the collection system from possible contamination in the event that the PCBs or combustion products are leaked or washed into the drains during a fire.

8-11 Fire and Explosion Prevention.

The principal control procedures used to minimize potential fire and explosion incidents at wastewater treatment plants shall include:

(a) Ventilation (*see Chapter 7*),

(b) Education (*see NFPA 1, Fire Prevention Code*),

(c) Risk management and property conservation programs,

(d) Procedures for permitting hot work,

(e) Selection of appropriate materials of construction (*see Chapter 6*), and

(f) Selection of appropriate equipment.

8-11.1 Control of Hazardous Source.

In-house training programs [Plant Emergency Organizations (PEO) and housekeeping or maintenance] that will provide information to understand, identify, prevent, and handle hazardous sources and situations related to potential fire, explosion, and toxicity problems shall be established for all personnel. Close liaison shall be implemented between the local fire department (including other authorized emergency personnel) and wastewater treatment plant safety personnel so that mutually approved emergency procedures (including familiarity with the plant) can be established.

8-11.2 Control of Ignition Sources.

8-11.2.1 Personnel involved shall be made familiar with the conditions for and sources of ignition of special hazards and shall be trained for the safe operation of processes. [*See 8-4(e).*]

8-11.2.2 All personnel shall be trained to report faulty equipment, worn static bonding lines, improperly stored chemicals, and other items needing correction.

8-11.3 Hot Work Permits.

Welding, cutting, and similar spark-producing operations shall not be permitted until a written permit authorizing such work has been issued. The permit shall be issued by a person in authority following his or her inspection of the area to ensure that the proper precautions have been taken and will be followed until the job is completed. (*See NFPA 51B, Standard for Fire Prevention in Use of Cutting and Welding Processes.*)

Chapter 9 Referenced Publications

9-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, 1988 (Rev. B-94).

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.1.1 Consult other NFPA standards for additional requirements relating to wastewater treatment and collection facilities.

A-1-3.1

In existing facilities, it is not always practical to strictly apply the provisions of this standard. Physical limitations might necessitate disproportionate effort or expense with little increase in fire protection. In such cases, the authority having jurisdiction should be satisfied that reasonable fire protection is ensured.

In existing facilities, it is intended that any condition that represents a serious threat to fire protection be mitigated by application of appropriate safeguards. It is not intended to require modification for conditions that do not represent a significant threat to fire protection, even though such conditions are not literally in conformance with these fire protection requirements.

A-1-3.3

For additional information see NFPA 497A, *Recommended Practice for Classification of Class I Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*, and NFPA 497B, *Recommended Practice for the Classification of Class II Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*. While some of this information is not applicable to wastewater treatment facilities, both documents provide useful information.

A-1-5 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-5 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-5 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1

Additional information on sources of hazards, sources of ignition, and mitigation measures associated with collection and transmission of municipal wastewater is contained in Appendix D.

A-2-2

See Figures A-2-2(a) through (g), which provide examples for Table 2.

A-5-1

Additional information is contained in Appendix D.

A-5-4.1

For further information, refer to NFPA 328, *Recommended Practice for the Control of Flammable and Combustible Liquids and Gases in Manholes, Sewers, and Similar Underground Structures*.

A-5-4.2

Other types of detectors, such as heat and smoke detectors, have standards recommending spacing usually based on a certain area per detector. There are no known recognized standards or guidelines for the locating or spacing of combustible gas detectors.

Whether natural or mechanical, air movement is a very important consideration in installing combustible gas detectors. This aspect should be carefully investigated, including the effect of doors, windows, vents, and other openings. It might be necessary to conduct a ventilation study that could involve a nontoxic smoke movement analysis.

Dispersion characteristics can also affect detector placement. Vapors and gases will disperse inversely proportional to their specific density in a quiescent environment. Vapors and gases with densities less than that of air will diffuse quickly at first until the vapor or gas becomes diluted. Heavier-than-air vapors and gases will tend to settle at a low area and not diffuse into the atmosphere unless dispersed by ventilation or temperature currents. Vapors with densities close to that of air will exhibit little mixing effect and will be transported largely by air currents.

There are various types of sensing devices. It is important to select the proper sensing device for each application and for the environment in which it will be placed. Most organic and inorganic compounds can be safely monitored with a catalytic-combustion-type sensor. However, organic and metallic solvents containing lead, silicones, plasticizers, or halogens can poison the catalytic element.

A-5-5.3

In all cases, standard "Danger" signs identifying the purpose of the lights and audible alarms and warning against entry when there is an alarm condition should be posted as near as practical to the warning devices.

A-6-3.1

See Appendix C of this document and NFPA 328, *Recommended Practice for the Control of Flammable and Combustible Liquids and Gases in Manholes, Sewers, and Similar Underground Structures.*

A-6-3.3.3.3 Plastic or fiberglass-reinforced plastic products are often used as materials of construction in unit processes such as rotating biological contactors (RBC), bio-towers, trickling filters, inclined plate (tube) settlers, ventilation ducts, and other equipment that might be subject to corrosion. Under normal operating conditions, these plastic or fiberglass-reinforced plastic materials might be submerged; however, during maintenance or repair they can become exposed. During maintenance and repair operation, extreme care should be taken with open flame such as cutting torches, as these exposed plastic or fiberglass-reinforced plastic materials might present a considerable fuel load if ignited.

A-7-3.3

Ventilation rates and procedures established by this standard might not be sufficient to protect personnel from exposure to toxic gases that might be present in enclosed spaces.

A-8-2.1

Proper preventive maintenance of operating and fire protection equipment, as well as operator training, are important aspects of a viable fire prevention program.

A-8-3

A fire risk evaluation should result in recommendations to integrate the fire prevention and fire protection required in this document into the plant- specific considerations regarding design, layout, and anticipated operating requirements. The evaluation should result in a list of recommended fire prevention features to be provided based on acceptable means for separation or control of common and special hazards, the control or elimination of ignition sources, and the suppression of fires.

This evaluation should focus on materials of construction in ventilation systems and in processes that normally operate in a wet condition (examples: plastic media trickling filters, bio-towers, and rotating biological contactors). These systems and process units can represent a considerable fuel load if ignition occurs during operation. Maintenance, fire spread, and smoke production should be considered in the selection of materials.

Consideration should also be given to locating process areas (examples: screen room, areas containing gas management equipment, etc.) that represent a significant explosion hazard remote from other process areas to reduce the risk of consequent damage should an explosion occur.

A-8-4(g) (*See Sample Fire Report*.)

Sample Fire Report

Name of company: ____________________

Date of fire: ________ Time of fire: ________ Operating facility: ________

Under construction: ____________________

Plant or location where fire occurred: ____________________

Description of facility, fire area, or equipment (include nameplate rating) involved: ________

Cause of fire, such as probable ignition source, initial contributing fuel, equipment failure causing ignition, etc.: ________

Description of fire and events and conditions preceding, during, and after the fire: ________

Types and approximate quantities of portable extinguishing equipment used: ________

Was fire extinguished with portable equipment only? ________ Public fire department called? ________

Employee fire brigade at this location? ________ Qualified for incipient fires? ________

For interior structural fires? ________

Was fixed fire extinguishing equipment installed? ________

Type of fixed extinguishing system: ________

Automatic operation: ________ , manually actuated: ________ , or both: ________

Specific type of detection devices: ________

Did fixed extinguishing system control fire? ________ , extinguish fire ________ , both control and extinguish fire? ________

Did detection devices and extinguishing system function properly? ________

If not, why not? ________

Estimated direct damage due to fire: $ ________, or between $ ________ and $ ________

Estimated additional (consequential) loss: $ ________. Nature of additional loss: ________

Estimated time to complete repairs/replacement of damaged equipment/structure: ________

Number of persons injured: ________ Number of fatalities: ________

What corrective or preventive suggestions would you offer to other utilities who might have similar equipment, structures, or extinguishing systems? ________

A-8-6.2 Maintenance.

Once a detection system is installed, a preventive maintenance program is essential. A detection system is only as good as the care and maintenance it receives. This is especially true in harsh environments. When installing instruments, ease of calibration and maintenance should be considered. Periodic calibration, checks, and adjustments are necessary for detection to remain accurate. If instruments are inaccessible, it is more likely that maintenance procedures will not be followed. Detectors should be located so as not to be exposed to physical damage from normal activities in the area.

Consideration should be given to the scope and limitations of the listing for combustible gas detectors. For example, Underwriters Laboratories Inc., in its *Hazardous Location Equipment Directory*, offers some guidance in maintaining and using combustible gas detectors. The following is extracted from that directory's product category guide for listed gas detectors (JTPX):

Gas or vapor detectors should be calibrated and inspected by the operator in compliance with the manufacturer's instructions, as performance of the instruments will depend on proper maintenance. The instruments should be calibrated with known gas- or vapor-air mixtures at intervals and particularly after replaceable sensors incorporated in the detecting unit are replaced. Certain gases or vapors can adversely affect (poison) the sensors and limit the use of the instruments. Sampling atmospheres containing gases or vapors for which they have not been previously calibrated should, therefore, be avoided.

A-8-7

Impairments to fire protection systems should be as short in duration as practical. If the impairment is planned, all necessary parts and manpower should be assembled prior to removing the protection system from service. When an impairment is not planned, the repair work should be expedited until the repairs are completed.

A-8-9 Fire Brigades.

The size of the plant and its staff, the complexity of fire-fighting problems, and the availability of a public fire department should determine the requirements for a fire brigade. The organization of a fire brigade is encouraged for wastewater treatment facilities located in remote areas.

If a fire brigade is provided, its organization and training should be identified in written procedures. Recommendations contained in NFPA 600, *Standard on Industrial Fire Brigades*, and OSHA 29 CFR, 1910.156, should be consulted for additional information.

The following items discuss special fire-fighting conditions unique to wastewater facilities. This information might be useful in fire brigade training and fire preplanning.

(a) Cable tray fires should be handled like any fire involving energized electrical equipment. It might not be practical or desirable to de-energize the cables involved in the fire. Water is the most effective extinguishing agent for cable insulation fires, but it should be applied with an electrically safe nozzle. Some cable insulations [polyvinyl chloride (PVC), neoprene, or Hypalon™] can produce dense smoke in a very short time. In addition, PVC liberates hydrogen chloride (HCl) gas. Self-contained breathing apparatus should be used by personnel attempting to extinguish cable tray fires.

(b) Some sludge drying and composting processes (especially solvent extraction drying, sludge drying kilns, and in-vessel composting systems) might produce a product that might be subject to spontaneous combustion. Generally, water will be the most effective fire-fighting agent in these areas. However, fires might be deep-seated in stockpiled products, which might have to be dispersed with front-end loaders or similar equipment to fully extinguish smoldering and burning material.

(c) Some chlorinated hydrocarbon products commonly used as foam suppressants or flocculation agents in wastewater treatment might cause spontaneous combustion when in contact with powdered disinfectants. These chemicals should be stored separately, and care should be exercised in their use.

(d) Plastic or fiberglass-reinforced plastic materials used in process units or ventilation systems might represent a considerable fuel load if ignited during operation or maintenance and might necessitate special response techniques.

A-8-9.1

NFPA 600, *Standard on Industrial Fire Brigades*, and OSHA 29 CFR 1910.156 should be consulted.

A-8-10

Federal regulations (40 CFR, 761.30) specify that the local fire department should be notified of the location of all PCB-filled transformers and other electrical equipment.

Appendix B Wastewater Treatment Processes

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

B-1 General.

B-1.1 Wastewater.

Wastewater is principally the spent water supply of the community. It is used to flush and transport human wastes and the liquid wastes of commerce, industry, and institutions. Ground water, surface water, and storm water might also be present. The primary purposes of wastewater treatment are to protect the health and well-being of the community and the quality of the receiving waterway. The extent or completeness of wastewater treatment to accomplish these purposes is governed by legislation and regulations and will vary from jurisdiction to jurisdiction.

B-1.2 Elements of Wastewater Treatment.

The principal elements of wastewater treatment are:

(a) Preliminary treatment,

(b) Primary treatment,

(c) Secondary treatment,

(d) Tertiary treatment,

(e) Disinfection, and

(f) Sludge treatment.

A typical schematic flow and process diagram for a wastewater treatment plant is shown in Figure B-1.

B-2 Preliminary Treatment.

Preliminary treatment comprises the conditioning of wastewater as it enters the wastewater treatment plant. Preliminary treatment removes materials that might be harmful to or might adversely affect the operation of the treatment plant. Such material might include lumber, cardboard, rags, stones, sand, plastic, grease, and scum. Methods and equipment used to remove these materials include bar racks, bar screens, and gravity or aerated grit chambers.

B-3 Primary Treatment.

Primary treatment is first-stage sedimentation, in which settleable, suspended, and floating material is removed from the wastewater following preliminary treatment. Well-operated primary treatment facilities can remove as much as 60 percent of the influent suspended solids and 30 percent of the influent biochemical oxygen demand. However, primary treatment does not remove colloidal or dissolved solids.

B-4 Secondary Treatment.

Secondary treatment is intended to reduce the concentrations of the remaining suspended solids and the dissolved and colloidal organic matter in the wastewater. Such material is not removed to any significant degree in primary treatment. A wastewater treatment plant having secondary treatment following primary treatment commonly can achieve removal of a total of 90 percent of the influent suspended solids and biochemical oxygen demand of the raw wastewater. Secondary treatment processes can be either biological or physical-chemical.

B-4.1 Biological Treatment.

Most municipal secondary treatment processes are biological. These processes can be classified as fixed film or suspended growth. In each process, a mixed population of microorganisms is established in the presence of oxygen. These microorganisms metabolize the dissolved organic matter in the wastewater and form a biological mass. The effluent from fixed film or suspended growth processes contains suspensions of biological solids. These solids are removed from the treated wastewater in a secondary sedimentation tank.

B-4.2 Physical-Chemical Treatment.

Physical-chemical treatment includes one or more physical-chemical unit processes to treat primary effluent. Such processes might include chemical coagulation, precipitation, and filtration to remove suspended matter and activated carbon adsorption to remove soluble organics.

B-5 Tertiary Treatment.

Tertiary treatment is used as necessary to reduce the concentration of inorganic and organic constituents below the concentrations achievable through secondary treatment. Tertiary treatment also includes the removal of nitrogen and phosphorus by additional process unit operations. Tertiary treatment processes can be physical, chemical, biological, or a combination.

B-6 Disinfection.

Disinfection is necessary to destroy pathogenic bacteria, viruses, and amoebic cysts commonly found in wastewater. Disinfection processes can be chemical (ozonation or chlorination) or physical (ultraviolet irradiation). Chemical disinfection using chlorine and, infrequently, ozone are the most widely used means of wastewater disinfection.

B-7 Sludge Treatment.

B-7.1 Sludge Stabilization.

Sludge is the settled solids accumulated and subsequently separated from the liquid during various wastewater treatment processes. Sludge handling and disposal is the most difficult, important, and costly part of the wastewater treatment process. Sludge treatment typically comprises stabilization followed by dewatering prior to disposal. Sludge can be stabilized under either anaerobic or aerobic conditions. Anaerobic sludge digestion takes place in the absence of free oxygen. The solid end product of anaerobic digestion is relatively nonputrescible and inoffensive. The off-gas produced in anaerobic sludge digestion contains about 65 percent methane and can be collected and burned as a fuel.

B-7.2 Sludge Dewatering.

Both anaerobic and aerobic digestion results in a reduction in the total volume and weight of the excess organic matter. It is often desirable, before final disposal, to reduce further the volume and weight of sludge and to change it from a liquid that is more than 95 percent water to a semisolid form. Dewatering can be accomplished by using drying beds, vacuum filters, centrifuges, filter presses, or mechanical gravity units. The dewatering operation often is enhanced by chemically conditioning the sludge before dewatering. The conditioning can include a thickening step that could be gravity or air flotation. Thermal conditioning can also be used to prepare sludge for dewatering.

B-7.3 Sludge Cake Disposal.

After sludge has been dewatered, it is identified as sludge cake. This material is disposed of by several different methods. It can be incinerated to reduce the volume to ash (approximately 10 percent of the original cake). The heat of this combustion can be utilized to produce steam for process and building heat. The cake can be composted to produce a soil conditioner. Cake can be spread directly on land for agricultural use, or it can be landfilled as a waste material.

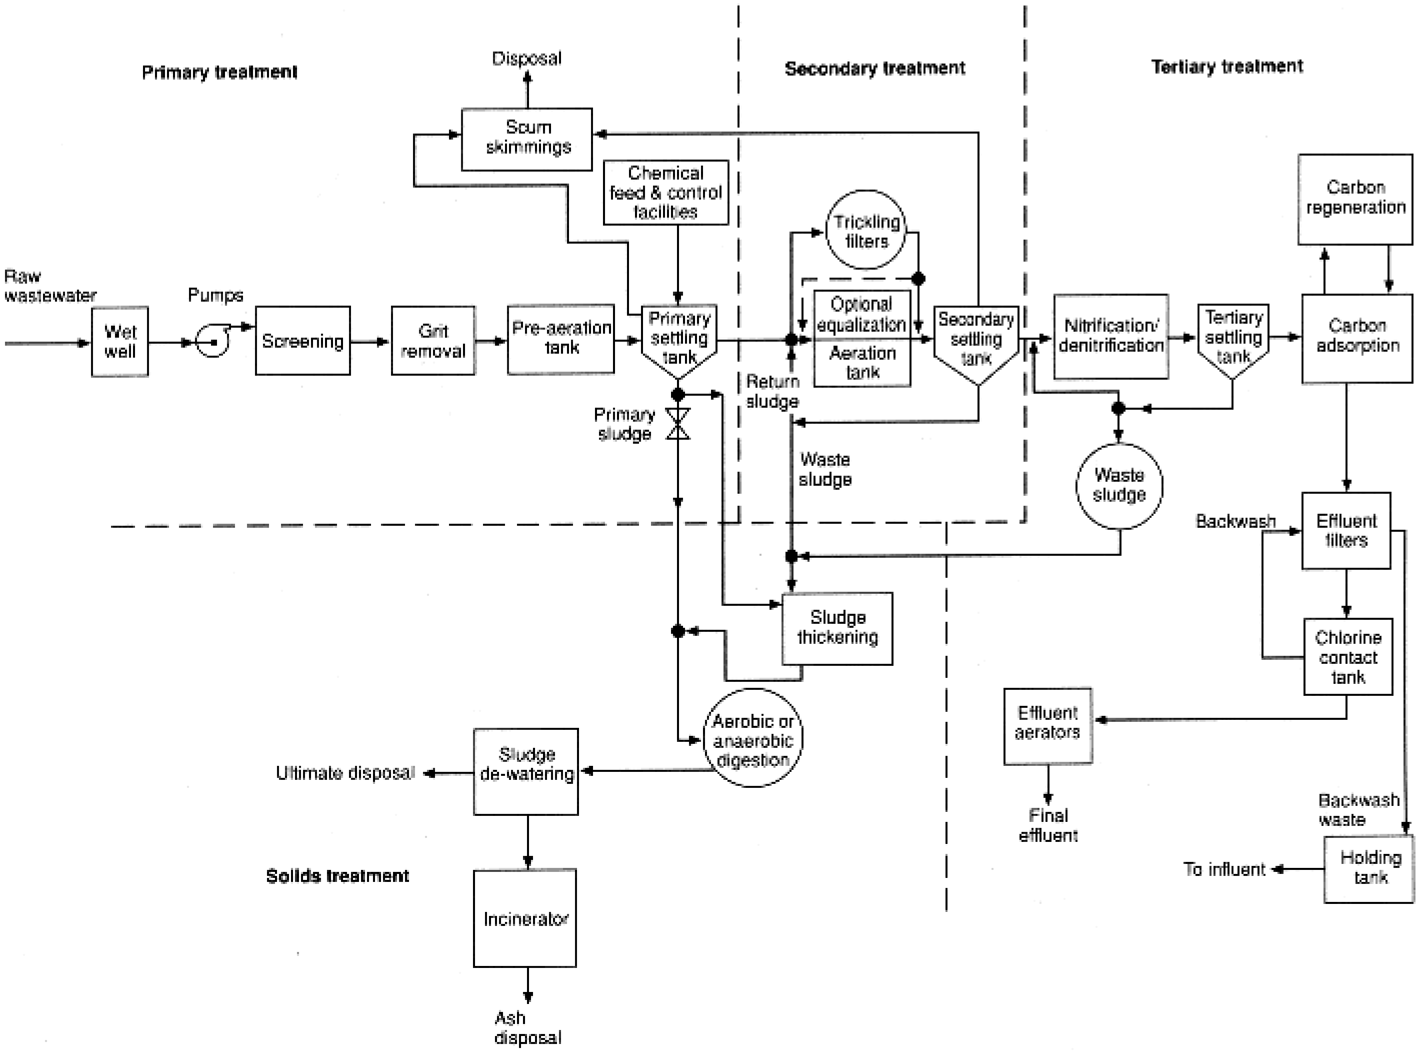

Figure B-1 Typical schematic flow and process diagram.

Appendix C Selection of Collection System Materials

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

C-1 General.

Wastewater collection systems might or might not be vulnerable to the introduction of flammable liquids into the wastewater. These liquids, if lighter than water, will float and collect on the surface. The presence of these materials can present a threat to the integrity of the collection system should ignition occur.

C-2 Materials of Construction.

C-2.1

Some materials commonly used in sewer construction are vulnerable to attack from environmental conditions commonly found in collection systems, but might provide resistance to damage from fire. Other materials might be vulnerable to structural damage from fire but provide protection against long-term structural failure from corrosion.

C-2.2

For additional information on corrosion control, refer to National Association of Corrosion Engineers Recommended Practices RP01 series and the appropriate Water Environment Federation publications.

C-3 Materials Risk Assessment.

C-3.1

The materials risk assessment should include an evaluation of all factors that could potentially affect the safety and long-term functioning of the collection system. Factors to be considered should include both of the following:

(a) The potential that flammable liquids can enter the system from identifiable sources. As an example, a system serving a combined system or a system serving commercial and industrial dischargers might be more vulnerable to exposure to floating flammable materials than separate systems serving residential communities.

(b) The potential for development of conditions that might promote corrosive attack to materials vulnerable to these agents. Experience with existing conditions within the community and with existing systems with similar characteristics should be taken into full account.

C-3.2

The materials risk assessment should consider the long-term threat that these agents present to the community and to the system's ability to serve the community before a final selection is made. It is recommended that the materials risk assessment be presented to local authorities for review and comment before final selection of materials of construction is completed.

C-4 Examples.

C-4.1

Storm sewers serving locations such as residential areas and areas where significant quantities of flammable or combustible materials are not expected to enter the sewer system, sewers, and appurtenant structures could be constructed of any appropriate material.

C-4.2

Storm sewers serving locations such as commercial and industrial areas or areas where there is a possibility that significant quantities of flammable or combustible materials could enter the sewer system through illicit discharges, curb inlets, leaking underground storage tanks, or broken pipes, sewers, and associated structures might be exposed to considerable risk of fire. Materials meeting the definitions of noncombustible, limited-combustible, or low flame spread might be appropriate.

C-4.3

Where conditions or applications warrant selection of other materials for storm sewer piping and appurtenant structures, consideration to flame spread, smoke generation, and the impact that fire or explosion will have on the structural integrity and operability of the sewer system and the economic and environmental consequences of having the sewer system out of service should be included in the materials risk assessment.

C-4.4

Separate sanitary sewers serving locations such as residential areas and areas where significant quantities of flammable or combustible materials are not expected to enter the sewer system, sewers, and appurtenant structures can be constructed of any appropriate material.

C-4.5

Separate sanitary sewers serving locations such as commercial and industrial areas or areas where there is some possibility that significant quantities of flammable or combustible materials could enter the sewer system from illicit discharges, leaking underground storage tanks, or broken pipes, sewers, and appurtenant structures might be exposed to some risk of fire. Materials meeting the definitions of noncombustible, limited combustible, or low flame spread might be appropriate.

C-4.6

Where applications warrant selection of other materials for separate sanitary sewer piping and appurtenant structures, consideration to flame spread, smoke generation, and the impact that a fire or explosion will have on the structural integrity and operability of the sewer system and the economic and environmental consequences of having the sewer system out of service should be included in the materials risk assessment.

C-4.7

Where combined sewers are designed to collect both wastewater and storm water or where there is a possibility that significant quantities of flammable or combustible materials could enter the sewer system by means of curb inlets, illicit discharges, leaking underground storage tanks, or broken pipes, all sewers and other appurtenant structures can be exposed to considerable risk of fire. Materials meeting the definitions of noncombustible, limited combustible, or low flame spread might be appropriate.

C-4.8

Where conditions or applications warrant selection of other materials for combined sewer piping and appurtenant structures, consideration to flame spread, smoke generation, and the impact that a fire or explosion will have on the structural integrity and operability of the sewer system and the economic and environmental consequences of having the sewer system out of service should be included in the materials risk assessment.

Appendix D Chemical and Fuel Fire/Explosion Hazards

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

D-1 General Information.

D-1.1

This appendix provides guidelines for protection against fire and explosion in the chemical and fuel storage and handling facilities. This appendix does not include gas utilization equipment, vehicle maintenance areas, or laboratories. Table D-1 summarizes the various hazards associated with chemical and fuel storage and handling facilities.

Table D-1 Chemical and Fuel Fire/Explosion Hazards

	A	B	C	D	E	F	G
	Materials and Function	**Fire and Explosion Hazard**	**Ventilation**	**Extent of Classified Area**	**NEC-Area Electrical Classification (All Class I, Group D)**	**Material of Construction for Buildings or Structures**	**Fire Protectior Measures**
1	ALCOHOL Used in some teritary treatment.	Flammable vapors	See NFPA 30.				
2	CHLORINE (Gas) Chlorination of water.	Aids combustion; oxidizer, toxic	NR	NR	Refer to Chlorine Institute.	NR (This equipment handles a corrosive chemical that necessitates the use of specific materials of construction. Special consideration should be given to these materials of construction.)	NR
3	OXYGEN (Used in aeration basins; see Chapter 3)	Aids combustion; oxidizer	See NFPA 50 and NFPA 53.			NR	NR
4	DIESEL FUEL, GASOLINE, AND MOTOR OILS Fuels for equipment.	Various	See NFPA 30 and NFPA 513.			NR	Indoor FSS and FE; Outdoor FE
5	LP-GAS	Flammable gas	NR (stored outdoors)		See NFPA 58.	NR	FE
6	OXYGEN GENERATION AND STORAGE	Aids combustion; oxidizer, oxygen-enriched areas	See NFPA 50 and NFPA 53.			NR	FSS (if indoors), H, and FE
7	OZONE GENERATION	Aids combustion; oxidizer, toxic	See NFPA 50 and NFPA 53.			NR	FSS (if indoors), H, and FE
8	ACTIVATED CARBON (Powdered or pulverized)	Combustible	NR	NR	NR	NR	NR

FE — Portable fire extinguisher FSS — Fire suppression system (automatic sprinkler, water spray, foam, gaseous, or dry chemical)
H — Hydrant protection (*see 5-2.4*) NEC — (*See NFPA 70, National Electrical Code*)
NR — No requirement

D-1.2

This appendix also contains additional information on specific areas or unit operations associated with storage and handling of chemicals and fuels commonly used in municipal wastewater treatment plants.

D-2 Sources of Hazards.

(*See Table D-2.*)

D-2.1 Fuel Gases.

Fuel gases include natural gas, manufactured gas, sewer gas, liquefied petroleum gas—air mixtures, liquefied petroleum gas in the vapor phase, mixtures of these gases, and floating flammable liquids. Some of these gases have specific gravities lower than that of air so that, when released, they will rapidly rise and diffuse above the point of leakage. Flammable mixtures are produced when these gases are mixed with air within certain limits. They can be considered as suffocating gases.

D-2.2 Sludge Gases.

These flammable gases result from the fermentation or anaerobic decomposition of organic matter. Explosive conditions (especially concerning compression and storage) can result when these gases are mixed with air.

D-2.3 Sewer Gases.

These flammable gases result from the fermentation or decomposition of organic matter. Explosive conditions (especially concerning the screening, degritting, and primary clarification processes) might result when these gases are mixed with air.

D-2.4 Unit Processes.

Special consideration should be given to the following unit processes associated with solids treatment:

(a) Scum pits collect scum, grease, and other floating flammable liquids from the surface of sedimentation tanks. Special consideration should be given to equipment located in these areas because of potential explosion and fire hazards.

(b) Sumps and tanks that collect drainage from anaerobic sludge treatment processes or that store, mix, and blend sludge might also collect significant volumes of sludge gas. Special consideration should be given to equipment located in these areas because of the potential for explosion.

(c) Anaerobic digesters are unit processes specifically designed to produce sludge gas from the fermentation or anaerobic decomposition of organic matter. The sludge gas normally contains significant volumes of methane as a by-product of the anaerobic digestion process. Special consideration should be given to equipment located in and around anaerobic digesters because of the potential for explosion.

(d) Solvent extraction and dehydration processes can produce a very dry organic dust as a by-product. Special consideration should be given to equipment located in dust-handling areas because of the potential for explosion.

(e) Incinerators used to burn scum or sludge cake are ignition sources when in operation. Special consideration should be given in construction of incineration buildings and in storage of combustible materials in incineration areas.

(f) Sludge dewatering and sludge cake conveyance equipment generate sludge cake and convey it to its final destination (incineration, landfill, etc.). Dried cake can be a combustible material. Special consideration should be given in construction, operation, maintenance, and housekeeping of the equipment and surrounding areas.

(g) Pumping stations that handle raw wastewater should be classified in the same manner as wastewater pumping stations (*see Chapter 2*). In-plant pumping stations should be classified depending upon their location in the process train and the type of material handled. Restrictive classifications are generally not necessary for pumping stations that handle fully treated wastewater.

(h) Grit chambers or screening equipment that is housed in a building or in below-grade pits might be subject to the same fire and explosion hazards as pumping station wet wells.

(i) Imhoff tanks and other similar processes can combine the wastewater liquids and solids treatment streams in a single vessel. Special consideration should be given to equipment located in or around Imhoff tanks or similar processes because of the generation of methane gas from anaerobic solids digestion processes within the vessel and the possibility of volatile substances being released from the wastewater.

(j) The primary sedimentation tank might collect and concentrate floating flammable liquids.

(k) Secondary and tertiary sedimentation tanks and aeration tanks not preceded by primary sedimentation can be subject to the same fire and explosion hazards as primary sedimentation tanks because of the potential of floating flammable liquids collecting on the surface. Where bypassing of primary sedimentation is possible, although not normally utilized, secondary and tertiary sedimentation tanks and aeration tanks might not be subject to the same fire and explosion potential as primary sedimentation.

(l) Unit processes employing oxygen-enriched atmospheres necessitate special consideration. Covered facilities might be unclassified above the covering deck; however, any equipment or instrumentation housed under the cover within the reactor space should be suitable for exposure to volatile hydrocarbons in an oxygen-enriched atmosphere. Oxygen is not itself flammable; however, increased concentrations of oxygen greatly increase the fire hazard. Oxygen aeration tanks and other similar processes should be equipped with continuously operating hydrocarbon LEL monitoring devices that will automatically cut off oxygen supply and purge reactor gases with atmospheric air when 10 percent LEL conditions are registered.

(m) Galleries and other connecting structures that contain pipes transporting flammable gases or liquids necessitate special consideration in design and fire protection.

(n) Plastic media or wood for trickling filters, rotating biological contactors, bio-towers, and other fixed film systems are not a significant hazard in normal operations; however, these materials are normally classified as combustible and can contribute a considerable fuel load if ignited under certain conditions, such as during maintenance and construction. Some fixed film treatment systems are anaerobic and produce a combustible gas by-product, which aggravates the hazard for such enclosures containing these materials.

D-2.5 Chemicals.

Wastewater treatment plants use a variety of gaseous, solid, and liquid chemicals that by themselves or when mixed with oxygen or other chemicals can be a potential source of fire or explosion, or both. Additional information can be found in NFPA 49, *Hazardous Chemicals Data*; NFPA 497A, *Recommended Practice for Classification of Class I Hazardous (Classified) Locations for Electrical Installations in Chemical Process Areas*; and NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*. Chemicals should be handled, processed, and stored in a manner that eliminates or significantly reduces the hazard to the wastewater treatment facility and personnel and is acceptable to the authority having jurisdiction. Chemicals should be properly labeled to identify the materials and hazards, and material safety data sheets should be made available to all personnel.

D-2.6 Hazardous Gases.

Sewer and sludge gas are flammable gases generated by the fermentation or decomposition of organic matter. Explosive conditions (especially concerning screening, degritting, primary clarification, and the anaerobic digestion process) can result when these gases are mixed with air. Specialty gases utilized for (a) laboratory analysis and instrumentation calibration (hydrogen, methane, etc.), (b) wastewater treatment plant unit processes (chlorine, ozone, etc.), and (c) welding operations (acetylene, oxygen, etc.) can form flammable/explosive conditions when either acting alone or mixed with other gaseous organic substances. Fuel gases including natural gas, manufactured gas, and liquefied petroleum gas used as fuels for wastewater treatment plant equipment can cause flammable/explosive conditions when improperly used, handled, or stored. Appropriate measures should be taken to prevent the accumulation of hazardous gases, including ventilation, proper storage, and safe handling/distribution systems. For additional guidance, see NFPA 55, *Standard for the Storage, Use, and Handling of Compressed and Liquefied Gases in Portable Cylinders*, and NFPA 59A, *Standard for the Production, Storage, and Handling of Liquefied Natural Gas (LNG)*. In processes where explosive mixtures cannot be prevented, explosion venting or protection systems should be provided. See NFPA 68, *Guide for Venting of Deflagrations*, and NFPA 69, *Standard on Explosion Prevention Systems,* for additional guidance.

D-2.7 Liquids.

Disposal of waste chemical products through sewers and into wastewater treatment plants and disposal of waste chemical products and scum skimmed from sedimentation tanks can be potential sources or contributing causes of fire and explosive conditions. Hydrocarbon liquids such as gasoline, kerosene, oils, and various chemicals either sent to sewers and drains or used for various applications at wastewater treatment plants can also provide flammable vapor concentrations at certain locations. For additional information, see NFPA 321, *Standard on Basic Classification of Flammable and Combustible Liquids*, and NFPA 329, *Recommended Practice for Handling Underground Releases of Flammable and Combustible Liquids*. Areas of wastewater treatment plants as identified and classified in Tables 2 through 4 (especially areas of primary treatment) should be protected as flammable liquid hazards.

D-2.8 Finely Divided Solids and Dusts.

Finely divided solids used in various wastewater treatment processes (especially sludge dehydration processing) or dust by-products produced by such processes can be combustible or cause potential flammable and explosive conditions. Process areas should be cleaned on a regular schedule to prevent the accumulation of hazardous concentrations of dust. Equipment handling finely divided solids should be designed and installed in a manner that protects against the hazards of fire and explosion. Additional information can be found in NFPA 61, *Standard for the Prevention of Fire and Dust Explosions in Agricultural and Food Products Facilities;* NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials;* and NFPA 8503, *Standard for Pulverized Fuel Systems*.

D-2.9 Materials.

Materials used in wastewater treatment plants due to humid or corrosive atmospheres, including wood, plastic, fiberglass-reinforced plastics (FRPs), paints and coatings, insulating material, and furnishings, can be combustible, limited combustible, or low flame spread under certain conditions. Some of these materials can present a considerable fuel load if ignited. Buildings and structures should be provided with fire protection in accordance with Chapter 6 of this document. Areas where materials are stored should be provided with appropriate fire protection approved by the authority having jurisdiction. For additional guidance, see NFPA 13, *Standard for the Installation of Sprinkler Systems;* NFPA 231, *Standard for General Storage;* and NFPA 231C, *Standard for Rack Storage of Materials*.

Table D-2 Gases Commonly Found in Wastewater Treatment

Name (chemical formula)	Explosive Limits (% vol.) LEL	UEL	Density[1] Heavier/Lighter than Air	Sources
Ammonia[3] (NH_3)	16	25	L	— Storage tank leaks
Chlorine[2] (Cl_2)	nonflammable		H	— Disinfection processes — Storage tanks
Gasoline[3] (C_5H_{12} - C_9H_{20})	1.3	7.1	H	— Storage tanks — Tank truck spills
Hydrogen Chloride (HCl)	nonflammable		H	— Storage tank leaks — Ceramic diffuser cleaning
Hydrogen Sulfide[5, 6] (H_2S)	4.0	44	H	— Sewer gas — Sludge gas
Natural Gas[5]	3.8–6.5	13–17	L	— Gas piping leaks
Nitrogen (N_2)	nonflammable		L	— Storage tanks — Oxygen generation processes — Denitrification processes
Oxygen[2] (O_2)	nonflammable		H	— Generation of oxygen on-site — Activated sludge processes — Storage tanks — Sludge processes
Ozone[2] (O_3)	nonflammable		H	— Disinfection processes — On-site generation processes
Sewer Gas[3]	5.3	19.3	H	— Sewer systems
Sludge Gas[4]	5	15	L	— Sludge digestion processes
Sulfur Dioxide (SO_2)	nonflammable		H	— Dechlorination processes — Storage tanks

NOTE 1: The table lists the physical properties at standard temperature and pressure. Due to actual field conditions, these gases might disperse and might be present throughout the structure.
NOTE 2: These gases accelerate combustion.
NOTE 3: Contains approximately 70 percent carbon dioxide, 5 percent methane, and 25 percent other gases (source: US EPA).
NOTE 4: Contains approximately 65 percent methane, 30 percent carbon dioxide, and 5 percent other gases (source: US EPA).
NOTE 5: Source: NFPA 325, *Guide to Fire Hazard Properties of Flammable Liquids, Gases, and Volatile Solids*.
NOTE 6: Rarely reaches explosive concentration in wastewater treatment plants.

D-3 Conditions for and Sources of Ignition.

The potential ignition of flammable gases, liquids, and solids (including dusts) that can be found at a wastewater treatment plant is limited by certain fundamental conditions. Gases and generated vapors need to be mixed with air or an oxidizer to form a flammable mixture that needs heat of sufficient intensity for ignition. The ignition temperature of a combustible solid is influenced by the rates of airflow and heating as well as the geometry of the rates of airflow and heating and the geometry of the solid. Ignition can result from one or more of the following causes: (a) open flames or hot surfaces, (b) electrical arc, (c) sparks, or (d) chemical reaction.

D-3.1 Open Flames and Hot Surfaces.

Open flames and hot surfaces might be encountered during normal operation, repair and maintenance operations, or with malfunctioning equipment and appliances within a wastewater treatment plant. Sources of ignition might include welding tasks, boilers, incinerators, kerosene-type lanterns, internal combustion engines, and smoking by personnel. Equipment producing open flames or hot surfaces capable of producing ignition should be properly installed, maintained, and isolated from potential hazards. For additional guidance, see NFPA 31, *Standard for the Installation of Oil-Burning Equipment;* NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines;* NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment;* NFPA 8501, *Standard for Single Burner Boiler Operation;* and NFPA 8502, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boiler-Furnaces*. Smoking should be prohibited in all hazardous areas.

D-3.2 Electrical Arc.

Sustained arcing faults can cause extensive damage to electrical switchgear and motor control centers. This might provide sufficient heat to ignite flammable gases or vapors present or generated as a result of the arc (pyrolysis of insulating material). Electrical equipment should be properly maintained in good operating condition. Faulty equipment should be removed from service. See NFPA 70B, *Recommended Practice for Electrical Equipment Maintenance*, for additional guidance.

D-3.3 Sparks.

Sparks generated by (a) defective or worn electrical and mechanical equipment, (b) activities performed by personnel, and (c) static electricity can be a source of ignition for gases of flammable vapors. Fire prevention practices to eliminate or control this hazard should include a prevention maintenance program, the use of nonsparking tools, and the provision of bonding and grounding conductors in hazardous areas. See NFPA 77, *Recommended Practice on Static Electricity*, for additional guidance.

D-3.4 Chemical Reaction.

Fire and explosion can be the result of the chemical reaction of substances that are (a) introduced in the wastewater treatment plant influent, (b) used for laboratory analysis, (c) necessary to various unit processes, and (d) produced as by-products. Potential chemical reactions can cause hazardous conditions that range in severity from the generation of flames (spontaneous combustion) to explosion. Chemicals should be identified and stored in a proper manner. Noncompatible chemical combinations should be identified, and segregated storage should be provided. See NFPA 491M, *Manual of Hazardous Chemical Reactions*, for additional information.

D-4 Mitigation Measures.

Mitigation of either hazards or potential ignition sources is achieved with a commonly preferred method of copious flushing with air (ventilation). In the event that a foreign combustible material enters the sewer system, removal by vacuum or coverage with foam might become necessary. Whenever possible, such entry is to be avoided by containment and adsorption. Appropriate use of a combustible gas detector is warranted as a minimal precaution preceding personnel entry into a collection system. The presence of toxic gases should be considered when entering any confined space.

D-5 Storage and Production Facilities.

Special consideration should be given to the following facilities associated with the storage and production of chemicals and fuels used in the treatment of municipal wastewater.

D-5.1

Oxygen generation, storage, and handling facilities necessitate special consideration. Although oxygen is not itself flammable, it does support combustion, and increased concentration of oxygen greatly increases the fire hazard. See NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites*.

D-5.2

Ozone is generated by passing oxygen through an electric field. As with oxygen-generating facilities, there is an increased fire hazard. Ozonation facilities necessitate special consideration because of the extreme heat and electric field generated and the additional concern for the extreme corrosivity and toxicity of ozone. See NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites*.

D-5.3

Chlorine is a very reactive chemical and necessitates special consideration in storing and handling. Chlorine in combination with other chemicals can produce sufficient heat to cause combustion of flammable materials. Chlorine and other reactive chemicals should always be stored separately. (*See information from the Chlorine Institute*.)

D-5.4

Activated carbon stored in bulk or in bags can provide a source of combustible material that can add a considerable fuel load if ignited. Special consideration should be given to equipment located in activated carbon-handling areas or activated carbon storage facilities because of the potential for fire.

Appendix E List of Associations and Abbreviations

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

Formal Interpretation

NFPA 820

Fire Protection in Wastewater Treatment and Collection Facilities

1995 Edition

Reference : Tables 2, 3, and 4
F.I. 92-1

Background: In Tables 2, 3, and 4, footnote code A is defined as "Ventilated at less than 12 air changes per hour."

Question 1: Does this definition include mechanically ventilated at any rate less than 12 air changes per hour (including 1 air change per hour or less)?

Answer: Yes.

Question 2: Does this definition include ventilated with a static vent (without mechanical ventilation)?

Answer: Yes.

Issue Edition: 1992
Reference: Tables 2, 3, 4, and 5
Issue Date: May 11, 1992
Effective Date: June 1, 1992

NFPA 850

1996 Edition

Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations

1996 Edition

This edition of NFPA 850, *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations*, was prepared by the Technical Committee on Electric Generating Plants and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 850 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 850

The Committee on Non-Nuclear Power Generating Plants was organized in 1979 to have primary responsibility for documents on fire protection for non-nuclear electric generating plants. Begun early in 1980, the first edition of NFPA 850 was officially released in 1986 as the *Recommended Practice for Fire Protection for Fossil Fueled Steam Electric Generating Plants*.

The second edition of NFPA 850 was issued in 1990 under the revised title of *Recommended Practice for Fire Protection for Fossil Fueled Steam and Combustion Turbine Electric Generating Plants*. This second edition incorporated a new Chapter 6 on the identification and protection of hazards for combustion turbines.

In 1991 the Committee changed its name to the Technical Committee on Electric Generating Plants. This simplified name was made to reflect the Committee's scope to cover all types of electric generating plants except nuclear.

The 1992 edition of NFPA 850 incorporated a new Chapter 7 on alternative fuel electric generating plants. As part of these changes, the document title was revised to the *Recommended Practice for Fire Protection for Electric Generating Plants*. Various other technical and editorial changes were also made.

This 1996 edition of the standard added a new Chapter 8 on Fire Protection for High Voltage Direct Current (HVDC) converter stations. In addition, the title was changed to *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations* to incorporate the new chapter.

Committee Scope: This Committee shall have primary responsibility for documents on fire protection for electric generating plants and high voltage direct current (HVDC) converter stations, except for electric generating plants using nuclear fuel.

NFPA 850

Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 10 and Appendix E.

Chapter 1 Introduction

1-1 Scope.

This document provides recommendations (not requirements) for fire prevention and fire protection for electric generating plants and high voltage direct current converter stations, except as follows: nuclear power plants are addressed in NFPA 803, *Standard for Fire Protection for Light Water Nuclear Power Plants*; hydroelectric plants are addressed in NFPA 851, *Recommended Practice for Fire Protection for Hydroelectric Generating Plants*; and combustion turbine and internal combustion engine units of 7500 hp or less are addressed in NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*.

1-2 Purpose.

This document is prepared for the guidance of those charged with the design, construction, operation, and protection of gas, oil, alternative fuels (i.e., municipal solid waste, refuse derived fuel, biomass, rubber tires, and other combustibles) or coal-fired steam electric generating plants, combustion turbine and internal combustion engine electric generating plants, and high voltage direct current converter stations. This document provides fire prevention and fire protection recommendations for the safety of construction and operating personnel, the physical integrity of plant components, and the continuity of plant operations. Nothing in this document is intended to restrict new technologies or alternative arrangements.

1-3 Application.

1-3.1

This document is intended for use by persons knowledgeable in the application of fire protection for electric generating plants and high voltage direct current converter stations.

1-3.2

The recommendations contained in this document are intended for new installations only, as the application to existing installations may not be practicable.

1-3.3

It should be recognized that rigid uniformity of generating station design and operating procedures does not exist and that each facility will have its own special conditions that impact on the nature of the installation. Many of the specific recommendations herein may require modification after due consideration of all local factors involved.

1-4 Definitions.

Alternative Fuels. Solid fuels such as municipal solid waste (MSW), refuse derived fuel (RDF), biomass, rubber tires, and other combustibles that are used instead of gas, oil, or coal in a boiler to produce steam for the generation of electrical energy.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Biomass. A boiler fuel manufactured by means of a process that includes storing, shredding, classifying, and conveying of forest and agricultural byproducts (e.g., woodchips, rice hulls, sugar cane, etc.).

Combustible. Any material that does not comply with the definition of either noncombustible or limited combustible.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code.*)

Fire Barrier. A fire barrier is a continuous membrane, either vertical or horizontal, such as a wall or floor assembly, that is designed and constructed with a specified fire resistance rating to limit the spread of fire and that will also restrict the movement of smoke. Such barriers may have protected openings.

Fire Loading. The amount of combustibles present in a given area, expressed in Btu/ft^2 (kJ/m^2).

Fire Point. The lowest temperature at which a liquid in an open container will give off sufficient vapors to burn once ignited. It generally is slightly above the flash point.

Fire Prevention. Measures directed toward avoiding the inception of fire.

Fire Protection. Methods of providing for fire control or fire extinguishment.

Fire Protection Rating. The time, in minutes or hours, that materials and assemblies used as opening protection have withstood a fire exposure as established in accordance with test procedures of NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, and NFPA 257, *Standard on Fire Test of Window and Glass Block Assemblies*, as applicable.

Fire Rated Penetration Seal. An opening in a fire barrier for the passage of pipe, cable, duct, etc., that has been sealed so as to maintain a barrier rating.

Fire-Resistant Fluid. A listed hydraulic fluid or lubricant that is difficult to ignite due to its high fire point and autoignition temperature and that does not sustain combustion due to its low heat of combustion.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with the test procedures of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psia (276 kPa) absolute pressure at 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code.*)

High Fire Point Liquid. A combustible dielectric liquid listed as having a fire point of not less than 572°F (300°C).

High Voltage Direct Current (HVDC) Converter Station. A facility that functions as an electrical rectifier (ac-dc) or an inventor (dc-ac) to control and transmit power in a high voltage network. There are two types of HVDC valves: the mercury arc valve and the present day technology solid state thyristor valve. Both types of valves present a fire risk due to high voltage equipment that consists of oil-filled converter transformers, wall bushings, and capacitors in addition to various polymeric components.

Interior Finish. The exposed interior surfaces of buildings including, but not limited to, fixed or movable walls and partitions, columns, and ceilings. Interior finish materials are grouped in the following classes:

Class A Interior Finish. Materials having flame spread 0-25, smoke developed 0-450 when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. Includes any material classified at 25 or less on the flame spread test scale and 450 or less on the smoke test scale when any element thereof, when tested, does not continue to propagate fire.

Class B Interior Finish. Materials having flame spread 26-75, smoke developed 0-450 when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. Includes any material classified at more than 25, but not more than 75, on the flame spread test scale and 450 or less on the smoke test scale.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Less Flammable Liquid. A combustible dielectric liquid listed as having a fire point of not less than 572°F (300°C).

Limited Combustible. As applied to a building construction material, a material, not complying with the definition of noncombustible material, that in the form in which it is used has a potential heat value not exceeding 3500 Btu/lb (8.14×10^6 J/kg) (*see NFPA 259, Standard Test Method for Potential Heat of Building Materials*), and complies with one of the following paragraphs (a) or (b):

(a) Materials having a structural base of noncombustible material with a surfacing not exceeding a thickness of $^1/_8$ in. (3.175 mm) that has a flame spread rating not greater than 50.

(b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion, and of such composition that the surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread rating greater than 25 nor evidence of continued progressive combustion as tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Materials subject to increase in combustibility or flame spread rating beyond the limits herein established through the effects of age, moisture, or other atmospheric condition are considered combustible.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Mass Burn. A process in which municipal solid waste is hauled directly to a tipping floor or storage pit and then is used as a boiler fuel without any special processing.

Municipal Solid Waste (MSW). Solid waste materials consisting of commonly occurring residential and light commercial waste.

Noncombustible. A material that in the form in which it is used and under the conditions anticipated will not aid combustion or add appreciable heat to an ambient fire. Materials when tested in accordance with ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, and conforming to the criteria contained in Section 7 of the referenced standard are considered as noncombustible.

Nonflammable Fluid. A nonflammable dielectric fluid that does not have a flash point and is not flammable in air.

Refuse Derived Fuel (RDF). A boiler fuel manufactured by means of a process that includes storing, shredding, classifying, and conveying of municipal solid waste.

Should. Indicates a recommendation or that which is advised but not required.

1-5 Units.

Metric units in this document are in accordance with the International System of Units, which is officially abbreviated SI in all languages. For a full explanation, see ASTM E 380/ANSI Z210.1, *Metric Practice Guide*.

Chapter 2 Administrative Controls

2-1 General.

2-1.1

This chapter provides recommended criteria for the development of administrative procedures and controls necessary for the execution of the fire prevention and fire protection activities and practices for electric generating plants and high voltage direct current converter stations.

2-1.2

The administrative controls recommended in this chapter should be reviewed and updated periodically.

2-1.3

The intent of this chapter can be met by incorporating the features of this chapter in the plant's operating procedures or otherwise as determined by plant management.

2-2 Management Policy and Direction.

2-2.1

Corporate management should establish a policy and institute a program to promote the conservation of property and continuity of operations as well as protection of safety to life by adequate fire prevention and fire protection measures at each facility.

2-2.2

Proper preventative maintenance of operating equipment as well as adequate operator training are important aspects of a viable fire prevention program.

2-3 Fire Risk Evaluation.

A Fire Risk Evaluation should be initiated as early in the design process as practical to ensure that the fire prevention and fire protection recommendations as described in this document have been evaluated in view of the plant-specific considerations regarding design, layout, and anticipated operating requirements. The evaluation should result in a list of recommended fire prevention features to be provided based on acceptable means for separation or control of common and special hazards, the control or elimination of ignition sources, and the suppression of fires.

2-4 Fire Prevention Program.

A written plant fire prevention program should be established and as a minimum should include the following:

(a) Fire safety information for all employees and contractors. This information should include, as a minimum, familiarization with fire prevention procedures, plant emergency alarms and procedures, and how to report a fire.

(b) Documented plant inspections including provisions for handling of remedial actions to correct conditions that increase fire hazards.

(c) A description of the general housekeeping practices and the control of transient combustibles. Fire experience has shown that transient combustibles can be a significant factor during a fire situation, especially during outages.

(d) Control of flammable and combustible liquids and gases in accordance with appropriate NFPA standards.

(e) Control of ignition sources to include smoking, grinding, welding, and cutting. (*See NFPA 51B, Standard for Fire Prevention in Use of Cutting and Welding Processes*.)

(f) Fire prevention surveillance. (*See NFPA 601, Standard for Security Services in Fire Loss Prevention.*)

(g) Fire report, including an investigation and a statement on the corrective action to be taken. (*See Appendix B.*)

2-5 Testing, Inspection, and Maintenance.

2-5.1

Upon installation, all fire protection systems should be preoperationally inspected and tested in accordance with applicable NFPA standards. Where appropriate standards do not exist, inspection and test procedures outlined in the purchase and design specifications should be followed.

2-5.2

All fire protection systems and equipment should be periodically inspected, tested, and maintained in accordance with applicable *National Fire Codes*®. (*See Table 2-5.2 for guidance.*)

NOTE: Inspection intervals for unattended plants may be permitted to be extended to normal plant inspections.

Table 2-5.2 Reference Guide for Fire Equipment Inspection, Testing, and Maintenance

Item	NFPA No.
Supervisory and Fire Alarm Circuits	72

Fire Detectors	72
Manual Fire Alarms	72
Sprinkler Water Flow Alarms	25/72
Sprinkler and Water Spray Systems	15/25
Foam Systems	11A/11C/16
Halogenated Agent, Chemical & Co. Systems	12/12A/17
Fire Pumps & Booster Pumps	20
Water Tanks & Alarms	25/22/72
P.I.V.s and O.S. & Y. Valves	25/72
Fire Hydrants and Associated Valves	25/24
Fire Hose and Standpipes	14/1962
Portable Fire Extinguishers & Hose Nozzles	10/1962
Fire Brigade Equipment	1971/1972/1973/1974
Fire Doors	80
Smoke Vents	204M
Emergency Lighting	70
Radio Communication Equipment	1221
Audible and Visual Signals	72

2-5.3

Testing, inspection, and maintenance should be documented with written procedures, results, and follow-up actions recorded.

2-6 Impairments.

2-6.1

A written procedure should be established to address impairments to fire protection systems and other plant systems that impact the level of fire hazard (e.g., dust collection systems, HVAC systems, etc.). As a minimum this procedure should:

(a) identify equipment not available for service;

(b) identify personnel to be notified (e.g., plant fire brigade chief, public fire department, etc.); and

(c) increase fire surveillance as needed. [*See 2-4(f).*]

2-6.2

Impairment to fire protection systems should be as short in duration as practical. If the impairment is planned, all necessary parts and manpower should be assembled prior to removing the protection system(s) from service. When an impairment is not planned, or when a system has discharged, the repair work or system restoration should be expedited.

2-6.3

Proper reinstallation after maintenance or repair should be performed to ensure proper systems operation. Once repairs are complete, tests that will ensure proper operation and restoration of full fire protection equipment capabilities should be made. Following restoration to service, the parties previously notified of the impairment should be advised. The latest revision of the design documents reflecting as-built conditions should be available to ensure that the system is properly reinstalled (e.g., drawings showing angles of nozzles).

2-7 Fire Emergency Plan.

2-7.1

A written fire emergency plan should be developed, and, as a minimum, this plan should include the following:

(a) response to fire alarms and fire systems supervisory alarms;

(b) notification of personnel identified in the plan;

(c) evacuation of employees not directly involved in fire-fighting activities from the fire area;

(d) coordination with security forces or other designated personnel to admit public fire department and control traffic and personnel;

(e) fire extinguishment activities;

(f) periodic drills to verify viability of the plan; and

(g) control room operator(s) activities during fire emergencies.

NOTE: Emergency conditions may warrant that breathing apparatus be readily available in the control room. Self-contained breathing apparatus should be considered for activities outside the control room.

2-7.2 Turbine Lubricating Oil Fires.

A critical aspect of responding to turbine lubricating oil fires is minimizing the size and duration of the oil spill. The need for lubrication to protect the turbine-generator bearings and shaft should be balanced against the fire damage from allowing the oil leak to continue. The following steps may be useful in minimizing fire damage and should be considered during preplanning and training for emergency conditions:

(a) tripping the turbine;

(b) breaking condenser vacuum;

(c) emergency purging of the generator; and

(d) shut down oil pumps.

These actions may cause significant mechanical damage to the turbine. The manufacturer should be consulted for additional guidance. (*See Appendix D.*)

2-8 Fire Brigade.

2-8.1

The size of the plant and its staff, the complexity of fire fighting problems, and the availability of a public fire department should determine the requirements for a fire brigade.

2-8.2*

If a fire brigade is provided, its organization and training should be identified in written procedures.

2-8.3

This section discusses special fire fighting conditions unique to fossil fueled steam electric generating plants. This information might be useful in fire brigade training and fire preplanning.

2-8.3.1 Regenerative Air Heaters. Since laboratory tests and reported incidents indicated a rapid increase in temperature to the 2800°F–3000°F (1537°C–1648°C) range in an air preheater fire, great care should be given to manual fire fighting. Large amounts of water will be needed to cool and extinguish a preheater fire. Fire preplanning should be accomplished to ensure use of an adequate number of access doors and safe access to the doors.

2-8.3.2 Electrostatic Precipitators. Once a fire is detected, the unit should go into emergency shutdown immediately. It should be recognized that during operation the atmosphere in the precipitator is oxygen-deficient and opening doors or running system fans following a fuel trip could cause conditions to worsen (increased potential for backdraft explosion). Once the flow of air and fuel to the fire has been stopped and the electrostatic precipitator has been shut down and deenergized, the precipitator doors may be permitted to be opened and water hoses employed if necessary.

2-8.3.3 Cable Trays. Cable tray fires should be handled like any fire involving energized electrical equipment. It may not be practical or desirable to deenergize the cables involved in the fire. Water is the most effective extinguishing agent for cable insulation fires but should be applied with an electrically safe nozzle. Some cables [polyvinyl chloride (PVC), Neoprene, or Hypalon] can produce dense smoke in a very short time. In addition, PVC liberates hydrogen chloride (HCl) gas. Self-contained breathing apparatus should be used by personnel attempting to extinguish cable tray fires.

2-8.3.4 Hydrogen System. Due to the wide explosive limits of hydrogen (4 percent to 75 percent volume of gas in air), under most conditions it is safer to allow a hydrogen fire to burn in a controlled manner until the gas can be shut off rather than to risk an explosion. It may be necessary to extinguish the fire in order to gain access to the shutoff valves.

2-8.3.5 Coal Storage and Handling.

2-8.3.5.1 Once the location and extent of a fire in a coal storage pile has been determined, the coal should be dug out and the heated coal removed. Since moisture accelerates oxidation, water used for fire fighting can aggravate the situation if the seat of the fire is not reached.

2-8.3.5.2 Clearly marked access panels in equipment should be provided for manual fire fighting. Coal dust presents both a fire and explosion hazard. Combustible, finely divided material is easily ignited. However, there is a possibility that a deep seated hard-to-extinguish fire can occur.

CAUTION: Application of an extinguishing agent that disturbs coal dust deposits could result in a dust explosion.

2-8.3.6 Coal Pulverizers. (*See NFPA 8502, Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boilers, and NFPA 8503, Standard for Pulverized Fuel Systems.*)

2-9 Identification of Fire Hazards of Materials.

Materials located in the plant or storage areas should be identified in accordance with NFPA 704, *Standard System for the Identification of the Fire Hazards of Materials*.

Chapter 3 General Plant Design

3-1 Plant Arrangement.

3-1.1 Fire Area Determination.

3-1.1.1 The electric generating plant and high voltage direct current converter station should be subdivided into separate fire areas as determined by the Fire Risk Evaluation for the purpose of limiting the spread of fire, protecting personnel, and limiting the resultant consequential damage to the plant. Fire areas should be separated from each other by fire barriers, spatial separation, or other approved means.

3-1.1.2 Determination of fire area boundaries should be based on consideration of the following:

(a) types, quantity, density, and locations of combustible material;

(b) location and configuration of plant equipment;

(c) consequence of losing plant equipment; and

(d) location of fire detection and suppression systems.

3-1.1.3 Unless consideration of the factors of 3-1.1.2 indicates otherwise, it is recommended that fire area boundaries be provided to separate the following:

(a) cable spreading room(s) and cable tunnel(s) from adjacent areas;

(b) control room, computer room, or combined control/computer room from adjacent areas;

NOTE: Where the control room and computer room are separated by a common wall, the wall need not have a fire resistance rating.

(c) rooms with major concentrations of electrical equipment, such as switchgear room and relay room, from adjacent areas;

(d) battery rooms from adjacent areas;

(e) maintenance shop(s) from adjacent areas;

(f) main fire pump(s) from reserve fire pump(s) where these pumps provide the only source of fire protection water;

(g) fire pumps from adjacent areas;

(h) warehouses from adjacent areas;

(i) emergency diesel generators from each other and from adjacent areas;

(j) fossil fuel-fired auxiliary boiler(s) from adjacent areas;

(k) fuel oil pumping, fuel oil heating facilities, or both, used for continuous firing of the boiler from adjacent areas;

(l) storage areas for flammable and combustible liquid tanks and containers from adjacent areas;

(m) office buildings from adjacent areas;

(n) telecommunication rooms from adjacent areas; and

(o) adjacent turbine generators beneath the underside of the operating floor.

3-1.1.4 Fire barriers separating fire areas should be a minimum of 2-hr fire resistance rating.

3-1.1.5 If a fire area is defined as a detached structure, it should be separated from other structures by an appropriate distance [e.g., 30 ft (9.1 m) minimum for a structure with moderate combustible loading and with a non-fire rated enclosure].

3-1.2 Openings in Fire Barriers.

3-1.2.1 All openings in fire barriers should be provided with fire door assemblies, fire dampers, penetration seals (fire stops), or other approved means having a fire protection rating consistent with the designated fire resistance rating of the barrier. Windows in fire barriers (e.g., control rooms or computer rooms) should be provided with a fire shutter or automatic water curtain. Penetration seals provided for electrical and piping openings should be listed or should meet the requirements for an "F" rating when tested in accordance with ASTM E 814, *Fire Tests of Through-Penetration Fire Stops*. Other test methods for qualifications of penetration seals, such as IEEE 634, *Testing of Fire Rated Penetration Seals*, may be permitted to be considered for this application.

NOTE 1: Listed penetration seals for large diameter piping may not be commercially available. In such instances the design should be similar to listed configurations.

NOTE 2: Listed penetration seals for the internals of non-segregated phase bus ducts and isolated phase bus ducts can be excluded.

3-1.2.2 Fire door assemblies, fire dampers, and fire shutters used in 2-hr rated fire barriers should be rated not less than $1^1/_2$ hr. (*See NFPA 80, Standard for Fire Doors and Fire Windows*.)

3-1.3 Hydrogen Storage.

Hydrogen storage facilities should be separated from adjacent areas. (*See NFPA 50A, Standard for Gaseous Hydrogen Systems at Consumer Sites, and NFPA 50B, Standard for Liquefied Hydrogen Systems at Consumer Sites*.)

3-1.4 Outdoor Oil-Insulated Transformers.

3-1.4.1 Outdoor oil-insulated transformers should be separated from adjacent structures and from each other by firewalls, spatial separation, or other approved means for the purpose of limiting the damage and potential spread of fire from a transformer failure.

3-1.4.2 Determination of the type of physical separation to be used should be based on consideration of the following:

(a) type and quantity of oil in the transformer;

(b) size of a postulated oil spill (surface area and depth);

(c) type of construction of adjacent structures;

(d) power rating of the transformer;

(e) fire suppression systems provided; and

(f) type of electrical protective relaying provided.

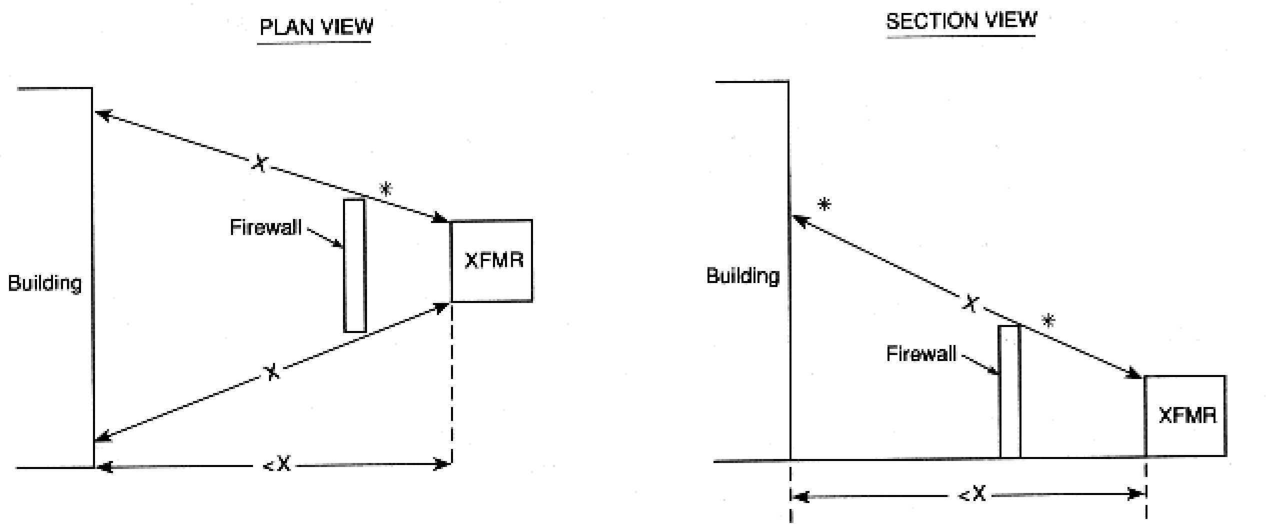
3-1.4.3 Unless consideration of the factors in 3-1.4.2 indicates otherwise, it is recommended that any oil-insulated transformer containing 500 gal (1893 L) or more of oil be separated from adjacent noncombustible or limited combustible structures by a 2-hr rated firewall or by spatial separation in accordance with Table 3-1.4.3. Where a firewall is provided between structures and a transformer, it should extend vertically and horizontally as indicated in Figure 3-1.4.3.

NOTE 1: As a minimum, the firewall should extend at least 1 ft (0.31 m) above the top of the transformer casing and oil conservator tank and at least 2 ft (0.61 m) beyond the width of the transformer and cooling radiators.

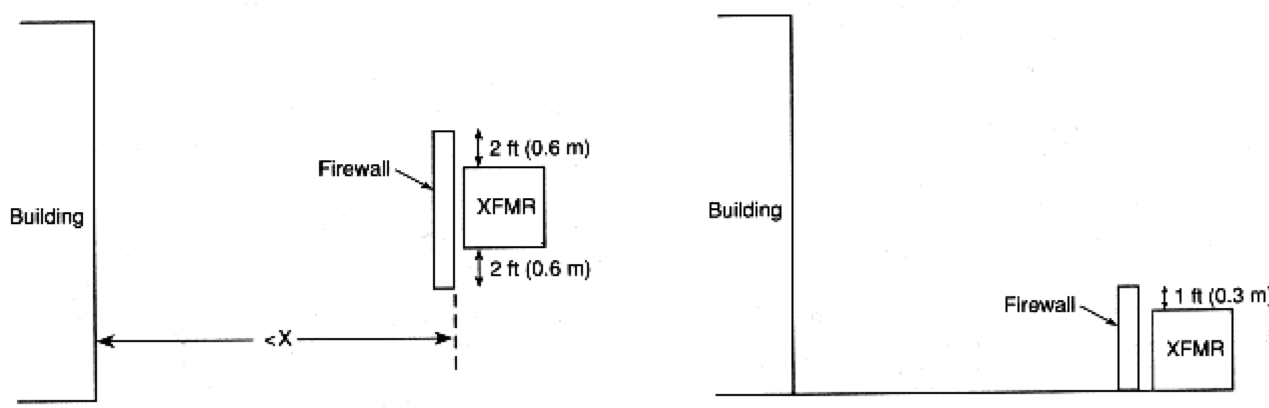
NOTE 2: If columns supporting the turbine building roof at the exterior wall have a 2-hr fire resistive rating above the operating floor, the firewall need not be higher than required to obtain line-of-sight protection to the height of the operating floor.

Table 3-1.4.3 Outdoor Oil Insulated Transformer Separation Criteria

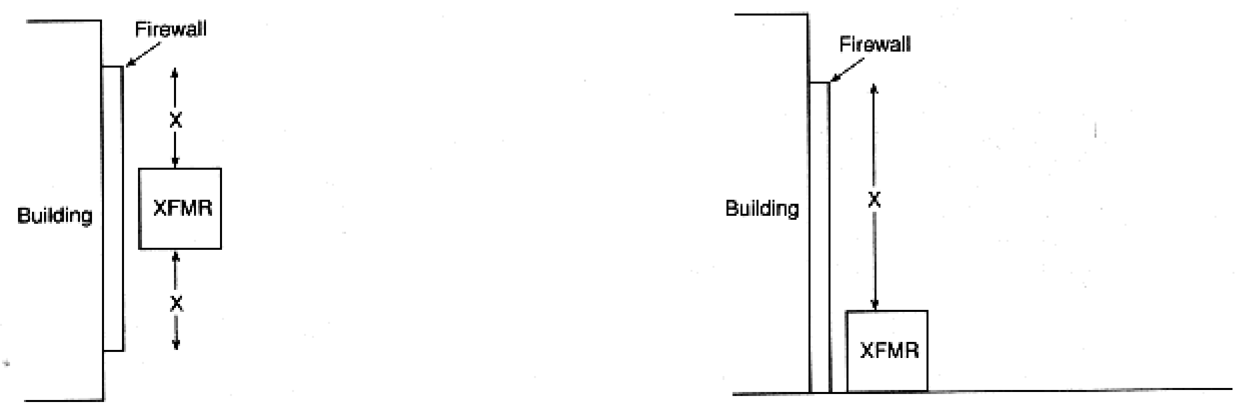
Transformer Oil Capacity	Minimum (Line-of-Sight) Separation without Firewall
Less than 500 gal (1893 L)	See 3-1.4.2
500 gal to 5000 gal (1893 L to 18,925 L)	25 ft (7.6 m)
Over 5000 gal (18,925 L)	50 ft (15 m)



Generic case



Example 1



Example 2

Figure 3-1.4.3 Outdoor oil-insulated transformer separation criteria.

3-1.4.4 Unless consideration of the factors in 3-1.4.2 indicates otherwise, it is recommended that adjacent oil-insulated transformers containing 500 gal (1893 L) or more of oil be separated from each other by a 2-hr rated firewall or by spatial separation in accordance with Table 3-1.4.3. Where a firewall is provided between transformers, it should extend at least 1 ft (0.31 m) above the top of the transformer casing and oil conservator tank and at least 2 ft (0.61 m) beyond the width of the transformer and cooling radiators.

3-1.4.5 Where a firewall is provided, it should be designed to withstand the effects of exploding transformer bushings or lightning arrestors.

NOTE: A higher noncombustible shield may be permitted to be provided to protect against the effects of an exploding transformer bushing.

3-1.4.6 Where a firewall is not provided, the edge of the postulated oil spill (i.e., containment basin, if provided) should be separated by a minimum of 5 ft (1.5 m) from the exposed structure to prevent direct flame impingement on the structure.

3-1.4.7 Outdoor transformers insulated with a less flammable liquid should be separated from each other and from adjacent structures that are critical to power generation by firewalls or spatial separation based on consideration of the factors in 3-1.4.2 and 3-1.4.5.

3-1.5 Indoor Transformers.

3-1.5.1 Dry-type transformers are preferred for indoor installations.

3-1.5.2 Oil-insulated transformers of greater than 100 gal (379 L) oil capacity installed indoors should be separated from adjacent areas by fire barriers of 3-hr fire resistance rating.

NOTE: Where multiple transformers of less than 100 gal (379 L) capacity each are located within close proximity, additional fire protection may be required based on the Fire Risk Evaluation.

3-1.5.3 Transformers having a rating greater than 35 kV, insulated with a less flammable liquid or nonflammable fluid and installed indoors should be separated from adjacent areas by fire barriers of 3-hr fire resistance rating.

3-1.5.4 Where transformers are protected by an automatic fire suppression system, the fire barrier fire resistance rating may be permitted to be reduced to 1 hr.

3-2 Life Safety.

3-2.1

For life safety for electric generating plants included in the scope of this document, see NFPA *101*®, *Life Safety Code*®.

3-2.2

Structures should be classified as follows, as defined in NFPA *101*, *Life Safety Code*:

(a) General areas should be considered as special purpose industrial occupancies.

NOTE 1: It generally is recognized that boiler and turbine buildings, protected in accordance with this document, meet the intent of NFPA *101*, *Life Safety Code*, for additional travel distances for fully sprinklered facilities.

NOTE 2: NFPA *101* allows additional means of egress components for special purpose industrial occupancies.

These areas may be permitted to be provided with fixed industrial stairs, fixed ladders (*see ANSI A1264.1, Safety Requirements for Workplace Floor and Well Openings, Stairs, and Railing Systems and* ANSI A14.3, *Standard for Safety Requirements for Fixed Ladders*), or alternating tread devices (*see NFPA 101*). Examples of these spaces include catwalks, floor areas, or elevated platforms that are provided for maintenance and inspection of in-place equipment.

NOTE 3: Spaces internal to equipment and machinery are excluded from the requirements of NFPA *101*. Examples of these spaces include, but are not limited to, the internals of the following:

1. boilers;
2. scrubbers;
3. pulverizers;
4. combustion turbine enclosures;
5. cooling towers;
6. bunkers, silos, and hoppers;
7. conveyor pulley take-up areas; or
8. electrostatic precipitators.

(b) Open structures and underground structures (e.g., tunnels) should be considered as occupancies in special structures.

(c) General office structures should be considered as business occupancies.

(d) Warehouses should be considered as storage occupancies.

(e) Coal preparation and handling facilities (e.g., enclosed crusher houses, transfer houses, and conveyors) should be considered special purpose industrial occupancies.

(f) Scrubber buildings should be considered as special purpose industrial occupancies.

3-2.3

In the event of a plant fire, egress of occupants in control facilities may be delayed due to emergency shutdown procedures. Control facilities should have a means of egress that is separated from other plant areas to facilitate a delayed egress.

3-3 Building Construction Materials.

3-3.1

Construction materials being considered for electric generating plants and high voltage direct current converter stations should be selected based on the Fire Risk Evaluation and on consideration of the following NFPA standards:

(a) NFPA 220, *Standard on Types of Building Construction*;

(b) NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*;

(c) NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*;

(d) NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*;

(e) NFPA 259, *Standard Test Method for Potential Heat of Building Materials*.

3-3.2

Construction materials used in the boiler, engine, or turbine-generator buildings or other buildings critical to power generation or conversion should meet the definition of noncombustible or limited combustible, except roof coverings, which should be as outlined in 3-3.3, and except for limited use of translucent reinforced plastic panels as allowed by the Fire Risk Evaluation.

3-3.3

Roof covering should be Class A in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*. Metal roof deck construction, where used, should be “Class I” or “fire classified.”

3-3.4 Interior Finish.

3-3.4.1 Cellular or foamed plastic materials (as defined in Appendix A of NFPA *101*, *Life Safety Code*) should not be used as interior finish.

3-3.4.2 Interior finish in buildings critical to power generation or conversion should be Class A.

3-3.4.3 Interior finish in buildings not critical to power generation or conversion should be Class A or Class B.

3-4 Smoke and Heat Venting, Heating, Ventilating, and Air Conditioning.

3-4.1 Smoke and Heat Venting.

3-4.1.1 General. Smoke and heat vents are not substitutes for normal ventilation systems unless designed for dual usage, and should not be used to assist such systems for comfort ventilation. Smoke and heat vents should not be left open where they can sustain damage from high wind conditions. They should be included in surveillance programs to ensure availability in emergency situations.

3-4.1.2 Heat Vents.

3-4.1.2.1 Heat vents should be provided for areas identified by the Fire Risk Evaluation. Where heat vents are provided, heat generated under fire conditions should be vented from its place of origin directly to the outdoors.

3-4.1.2.2 Heat vents in the boiler and turbine building may be permitted to be provided through the use of automatic heat vents or windows at the roof eave line. Heat venting in areas of high combustible loading can reduce damage to structural components. (*See NFPA 204M, Guide for Smoke and Heat Venting.*)

3-4.1.3 Smoke Vents.

3-4.1.3.1 Smoke venting should be provided for areas identified by the Fire Risk Evaluation. Where smoke venting is provided, smoke should be vented from its place of origin in a manner that does not interfere with the operation of the plant.

3-4.1.3.2 Separate smoke ventilation systems are preferred; however, smoke venting can be integrated into normal ventilation systems using automatic or manually positioned dampers and motor speed control. (*See NFPA 90A, Standard for the Installation of Air Conditioning and Ventilating Systems; NFPA 92A, Recommended Practice for Smoke-Control Systems; and NFPA 204M, Guide for Smoke and Heat Venting.*) Smoke venting also may be permitted to be accomplished through the use of portable smoke ejectors.

3-4.1.3.3 Consideration should be given to smoke venting for the following areas: control room, cable spreading room(s), and switchgear room.

3-4.1.3.4 In the areas with gaseous fire extinguishing systems, the smoke ventilation system should be properly interlocked to ensure the effective operation of the gaseous fire extinguishing system.

3-4.1.3.5 Smoke removal system dampers, where installed, normally are operable only from an area immediately outside of, or immediately within, the fire area served since it is desired to have entry into, and inspection of, the fire area by fire-fighting personnel prior to restoring mechanical ventilation to the fire area. Smoke removal system dampers may be permitted to be operable from the control room if provisions are made to prevent premature operation. This can be accomplished using thermal interlocks or administrative controls.

3-4.1.3.6 The fan power supply wiring and controls for smoke exhaust should be located external to the fire area served by the fan or be installed in accordance with the Fire Risk Evaluation.

3-4.2 Normal Heating, Ventilating, and Air Conditioning Systems.

3-4.2.1 For normal heating, ventilating, and air conditioning systems, see NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, or NFPA 90B, *Standard for the Installation of Warm Air Heating and Air Conditioning Systems*, as appropriate.

3-4.2.2 Air conditioning for the control room should provide a pressurized environment to preclude the entry of smoke in the event of a fire outside the control room.

3-4.2.3 Plastic ducts, including listed fire-retardant types, should not be used for ventilating systems. Listed plastic fire-retardant ducts with appropriate fire protection may be permitted to be used in areas with corrosive atmospheres.

3-4.2.4 Fire dampers (doors) compatible with the rating of the barrier should be provided at the duct penetrations to the fire area (*see Section 3-1*) unless the duct is protected throughout its length by a fire barrier equal to the rating required of fire barrier(s) penetrated.

3-4.2.5 Smoke dampers, where installed, should be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*.

3-4.2.6 The fresh air supply intakes to all areas should either be located so as to minimize the possibility of drawing products of combustion into the plant, or be provided with automatic closure on detection of smoke. Separation from exhaust air outlets, smoke vents from other areas, and outdoor fire hazards should all be considered.

3-5 Drainage.

3-5.1

Provisions should be made in all fire areas of the plant for removal of all liquids directly to safe areas or for containment in the fire area without flooding of equipment and without endangering other areas. (*See Appendix A of NFPA 15, Standard for Water Spray Fixed Systems for Fire Protection.*) Drainage and prevention of equipment flooding should be accomplished by one or more of the following:

(a) floor drains;

(b) floor trenches;

(c) open doorways or other wall openings;

(d) curbs for containing or directing drainage;

(e) equipment pedestals;

(f) pits, sumps, and sump pumps.

3-5.2

The provisions for drainage and any associated drainage facilities should be sized to accommodate all of the following:

(a) The spill of the largest single container of any flammable or combustible liquids in the area.

(b) The maximum expected number of fire hose lines [500 gpm (31.5 L/sec) minimum] operating for a minimum of 10 minutes.

(c) The maximum design discharge of fixed fire suppression systems operating for a minimum of 10 minutes.

NOTE: Design discharge for the turbine building should be based on the expected time necessary to take the turbine off line and put it on turning gear, but not less than 10 minutes.

3-5.3

The drainage system for continuous fuel oil-fired boilers should consist of curbs and gutters arranged to confine the area of potential fuel oil discharge. Consideration also should be given to providing the same measures for coal-fired boilers using oil for ignition. Walking surfaces in the vicinity of burners should be made impervious to oil leakage by the use of checkered steel plate, sheet metal drip pans, or other means. Curbs in passageways should have ramps or steps or be otherwise constructed to present no obstacle to foot traffic. Gutter outlet pipes and all other drains should be trapped to prevent the passage of flames and permit the flow of oil. A clearance between the boiler front and the walk structure is required for the differential movement where the heated boiler elongates. This clearance space in the vicinity of the burners should be flashed and counter-flashed with sheet metal or otherwise arranged to allow movement and to redirect dripping oil, which may impinge on the boiler face.

3-5.4

Floor drainage from areas containing flammable or combustible liquids should be trapped to prevent the spread of burning liquids beyond the fire area.

3-5.5

Where gaseous fire suppression systems are installed, floor drains should be provided with adequate seals or the fire suppression system should be sized to compensate for the loss of fire suppression agent through the drains.

3-5.6

Drainage facilities should be provided for outdoor oil-insulated transformers, or the ground should be sloped such that oil spills will flow away from buildings, structures, and adjacent transformers. Unless drainage from oil spills is accommodated by sloping the ground around transformers away from structures or adjacent equipment, consideration should be given to providing curbed areas or pits around transformers. The pit or drain system or both should be sized in accordance with 3-5.2. If a layer of uniformly graded stone is provided in the bottom of the curbed area or pit as a means of minimizing ground fires, the following should be addressed:

(a) Sizing of the pit should allow for the volume of the stone.

(b) The design should address the possible accumulation of sediment or fines in the stone.

3-5.7

For facilities consisting of more than one generating unit that are not separated by a fire barrier [*see 3-1.1.3(o)*], provisions such as a sloped floor, curb, or trench drain should be provided on solid floors where the potential exists for an oil spill, such that oil released from an incident in one unit will not expose an adjacent unit.

3-5.8

For environmental reasons, liquid discharges resulting from oil spills or operation of a fire suppression system may have to be treated (e.g., oil separation).

3-6 Emergency Lighting.

3-6.1

Emergency lighting should be provided for means of egress. (*See NFPA 101*, *Life Safety Code*.)

3-6.2

Emergency lighting should be provided for critical plant operations areas.

3-7 Lightning Protection.

Lightning protection should be provided for those structures having a risk index (R) of four or greater when evaluated in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

Chapter 4 General Fire Protection Systems and Equipment

4-1 General.

All fire protection systems, equipment, and installations should be dedicated to fire protection purposes.

4-2 Water Supply.

4-2.1

The water supply for the permanent fire protection installation should be based on providing a

2-hr supply for both items (a) and (b) as follows:

(a) Either of items 1 or 2 below, whichever is larger:

1. The largest fixed fire suppression system demand,

2. Any fixed fire suppression system demands that could reasonably be expected to operate simultaneously during a single event [e.g., turbine under floor protection in conjunction with other fire protection system(s) in the turbine area; coal conveyor protection in conjunction with protection for related coal handling structures during a conveyor fire; adjacent transformers not adequately separated according to 3-1.3].

(b) The hose stream demand of not less than 500 gpm (31.5 L/sec).

4-2.2

Where an adequate and reliable water supply, such as a lake, cooling pond, river, or municipal water system, is unavailable, at least two separate water supplies should be provided for fire protection purposes with each supply capable of meeting the fire water flow requirements determined by 4-2.1.

4-2.3

Each water supply should be connected to the yard main by separate connections arranged and valve controlled to minimize the possibility of multiple supplies being impaired simultaneously.

4-2.4

In some rivers and tributaries the existence of microorganisms limits the use of raw water for fire protection without treatment. Consideration of water quality may prevent long-term problems relating to fire protection water supply.

4-2.5 Fire Pumps.

4-2.5.1 Where multiple fire pumps are required, the pumps should not be subject to a common failure, electrical or mechanical, and should be of sufficient capacity to meet the fire flow requirements determined by 4-2.1 with the largest pump out of service.

4-2.5.2 Fire pumps should be automatic starting with manual shutdown. The manual shutdown should be at the pump controllers only. (*See NFPA 20, Standard for the Installation of Centrifugal Fire Pumps.*)

4-2.6 Water Supply Tanks.

4-2.6.1 If tanks are of dual-purpose use, a standpipe or similar arrangement should be provided to dedicate the amount determined by 4-2.1 for fire protection use only. (*See NFPA 22, Standard for Water Tanks for Private Fire Protection.*)

4-2.6.2 Where tanks are used, they should be filled from a source capable of replenishing the two-hour supply for the fire protection requirement in an eight-hour period. The eight-hour (time) requirement for refilling may be permitted to be extended if the initial supply exceeds the minimum storage requirement on a volume per time ratio basis. It normally is preferred for the refilling operation to be accomplished on an automatic basis.

4-3 Valve Supervision.

All fire protection water supply and system control valves should be under a periodic inspection program (*see Chapter 2*) and should be supervised by one of the following methods:

(a) Electrical supervision with audible and visual signals in the main control room or another constantly attended location.

(b) Locking valves open. Keys should be made available only to authorized personnel.

(c) Sealing of valves. This option should be followed only where valves are within fenced enclosures under the control of the property owner.

4-4 Yard Mains, Hydrants, and Building Standpipes.

4-4.1 Yard Mains and Hydrants.

4-4.1.1 Yard mains and outdoor fire hydrants should be installed on the plant site. (*See NFPA 24, Standard for the Installation of Private Fire Service Mains and Their Appurtenances.*)

4-4.1.2 Remotely located plant-related facilities should be reviewed on an individual basis to determine the need for fire protection. If excessively long extensions of underground fire mains are necessary for fire protection at these locations, it may be permitted to supply this need from an available service main in the immediate area. Where common supply piping is provided for service water and fire protection water supply, it should be sized to accommodate both service water and fire protection demands.

4-4.1.3 The supply mains should be looped around the main power block and should be of sufficient size to supply the flow requirements determined by 4-2.1 to any point in the yard loop considering the most direct path to be out of service. Pipe sizes should be designed to encompass any anticipated expansion and future water demands.

4-4.1.4 Indicator control valves should be installed to provide adequate sectional control of the fire main loop to minimize plant protection impairments.

4-4.1.5 Each hydrant should be equipped with a separate shutoff valve located on the branch connection to the supply main.

4-4.1.6 Interior fire protection loops are considered an extension of the yard main and should be provided with at least two valved connections to the yard main with appropriate sectional control valves on the interior loop.

4-4.2 Standpipe and Hose Systems.

4-4.2.1 Standpipe and hose systems should be installed. (*See NFPA 14, Standard for the Installation of Standpipe and Hose Systems.*) The standpipe and hose system is an extension of the yard fire main and hydrant system. The hose stations should be capable of delivering the hose stream demand for the various hazards in buildings.

4-4.2.2 Fire main connections for standpipes should be arranged so that a fire main break can be isolated without interrupting service simultaneously to both fixed protection and hose connections protecting the same hazard or area. Choice of Class I, Class II, or Class III systems should be made by a Fire Risk Evaluation. (*See NFPA 14, Standard for the Installation of Standpipe and Hose Systems.*)

4-4.2.3 The standpipe piping should be capable of providing minimum volume and pressure for the highest hose stations.

4-4.2.4 Due to the open arrangement of these plants, the locations of hose stations should take into account safe egress for personnel operating hose lines.

4-4.3 Hose Nozzles.

Spray nozzles having shutoff capability and listed for use on electrical equipment should be provided on hoses located in areas near energized electrical equipment.

4-4.4 Hose Threads.

Hose threads on hydrants and standpipe systems should be compatible with fire hose used by the responding fire departments.

4-5 Portable Fire Extinguishers.

Portable fire extinguishers should be provided. (*See NFPA 10, Standard for Portable Fire Extinguishers.*)

4-6 Fire Suppression Systems and Equipment — General Requirements.

4-6.1

Fire suppression systems and equipment should be provided in all areas of the plant as identified in Chapters 5, 6, 7, and 8 or as determined by the Fire Risk Evaluation. Fixed suppression systems should be designed in accordance with the following codes and standards unless specifically noted otherwise:

NFPA 11, *Standard for Low-Expansion Foam*

NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

NFPA 13, *Standard for the Installation of Sprinkler Systems*

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*

NFPA 17, *Standard for Dry Chemical Extinguishing Systems*

NFPA 231, *Standard for General Storage*

NFPA 231C, *Standard for Rack Storage of Materials.*

4-6.2

The selection of an extinguishing agent or a combination of extinguishing agents should be based on:

(a) The type of hazard;

(b) The effect of agent discharge on equipment;

(c) The health hazards.

4-6.3 Fire Suppression System Safety Considerations.

4-6.3.1 It is imperative that safety in the use of any fire suppression system be given proper consideration and that adequate planning be done to ensure safety of personnel.

4-6.3.2 Potential safety hazards could include impingement of high velocity discharge on personnel, loss of visibility, hearing impairment, reduced oxygen levels that will not support breathing, toxic effects of the extinguishing agent, breakdown products of the extinguishing agent, and electric conductivity of water-based agents.

4-6.3.3 When working in areas (e.g., combustion turbine compartments) where egress is difficult, the fire extinguishing system should be provided with an isolation (inhibit) switch to prevent discharge of the system. A trouble indication should be provided when the system is in the "inhibit" mode.

4-6.3.4 NFPA standards for the extinguishing systems used should be carefully studied and the personnel safety provisions followed. Evacuation of a protected area is recommended before any special extinguishing system discharges. Alarm systems that are audible above machinery background noise, or that are visual or olfactory or a combination, should be used where appropriate. Personnel warning signs are necessary.

4-7 Fire-Signaling Systems.

4-7.1

The type of protective signaling system for each installation and area should be determined by the Fire Risk Evaluation in consideration of hazards, arrangement, and fire suppression systems. Fire detection and automatic fixed fire suppression systems should be equipped with local audible and visual signals with annunciation in a constantly attended location, such as the main control room. Audible fire alarms should be distinctive from other plant system alarms. See NFPA 72, *National Fire Alarm Code*.

4-7.2

Automatic fire detectors should be installed in accordance with NFPA 72, *National Fire Alarm Code*.

4-7.3

The fire-signaling system or plant communication system should provide the following:

(a) Manual fire alarm devices (e.g., pull boxes or page party stations) installed in all occupied buildings. Manual fire alarm devices should be installed for remote yard hazards as identified by the Fire Risk Evaluation.

(b) Plant-wide audible fire alarm or voice communication systems, or both, for purposes of personnel evacuation and alerting of plant emergency organization. The plant public address system, if provided, should be available on a priority basis.

(c) Two-way communications for the plant emergency organization during emergency operations.

(d) Means to notify the public fire department.

Chapter 5 Identification of and Protection against Hazards

5-1 General.

The identification and selection of fire protection systems should be based on the Fire Risk

Evaluation. This chapter identifies fire and explosion hazards in fossil fueled electric generating stations and specifies the recommended protection criteria unless the Fire Risk Evaluation indicates otherwise.

5-2 Fuel Handling — Gas.

5-2.1

The storage and associated piping systems for gases in the gaseous or liquefied states should comply with NFPA 54, *National Fuel Gas Code*; NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*; and ANSI B31.1, *Code for Power Piping*.

5-2.2

The plant's main and ignitor natural gas shut-off valve should be located near an exterior wall. The valve should be provided with both manual and automatic closing capabilities locally, and remote closing capability from the control room. The valve should be arranged to fail closed on the loss of power or pneumatic control.

5-2.3

Electrical equipment in areas with potentially hazardous atmospheres should be designed and installed in compliance with Articles 500 and 501 of NFPA 70, *National Electrical Code®*, and ANSI C2, *National Electrical Safety Code*.

5-3 Fuel Handling — Oil.

5-3.1

Fuel oil storage, pumping facilities, and associated piping should comply with NFPA 30, *Flammable and Combustible Liquids Code*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; and ANSI B31.1, *Code for Power Piping*.

5-3.2

Internal tank heaters needed to maintain oil pumpability should be equipped with temperature sensing devices that alarm in a constantly attended area prior to the overheating of the oil.

5-3.3

External tank heaters should be interlocked with a flow switch to shut off the heater if oil flow is interrupted.

5-3.4

Tank filling operations should be monitored to prevent overfilling.

5-3.5

While oil unloading operations are in progress, the unloading area should be manned by personnel properly trained in the operation of pumping equipment, valving, and fire safety.

5-3.6

Pump installations should not be located within tank dikes.

5-3.7

Electrical equipment in areas with potentially hazardous atmospheres should be designed and installed in compliance with NFPA 30, *Flammable and Combustible Liquids Code*; Articles 500 and 501 of NFPA 70, *National Electrical Code*; and ANSI C2, *National Electrical Safety Code*.

5-3.8

To prevent hazardous accumulations of flammable vapors, ventilation for indoor pumping facilities for flammable liquids should provide at least 1 ft^3 of exhaust air per ft^2 of floor area (0.30 m^3/m^2), but not less than 150 ft^3/min (0.071 m^3/sec).

5-3.9 Fire Protection.

5-3.9.1 Indoor fuel oil pumping or heating facilities or both should be protected with automatic sprinklers, water spray, foam-water sprinklers, or gaseous total flooding system(s). Local application dry chemical systems may be permitted to be used in areas that normally do not have re-ignition sources, such as steam lines or hot boiler surfaces.

5-3.9.2 The provision of foam systems for tank protection should be considered in the Fire Risk Evaluation with consideration of exposure to other important structures, product value, and resupply capability.

5-3.9.3 Fuel oil handling and storage areas should be provided with hydrant protection in accordance with Section 4-4.

5-4 Fuel Handling — Coal.

5-4.1 Storage.

5-4.1.1 Coal storage piles are subject to fires caused by spontaneous heating of the coal. The coals most susceptible to self-heating are those with high pyritic content and high intrinsic moisture and oxygen content, such as low-rank coals. The mixing of high pyritic coals with high moisture and oxygen coals increases self-heating.

5-4.1.2 There are measures that can be taken to lessen the likelihood of coal pile fires. These measures are dependent on the type and rank of coal. Among the more important are:

(a) Short duration, active, or "live" storage piles should be worked to prevent dead pockets of coal, a potential source of spontaneous heating.

(b) Coal piles should not be located above sources of heat, such as steam lines, or sources of air, such as manholes.

(c) Coal placed in long-term storage should be piled in layers, appropriately spread, and compacted prior to the addition of subsequent layers to reduce air movement and to minimize water infiltration into the pile.

(d) Different types of coal that are not chemically compatible should not be stored in long-term storage piles.

(e) Access to coal storage piles should be provided for fire fighting operations and for pulling out hot pockets of coal.

5-4.2 Bins, Bunkers, and Silos.

The recommendations of this section should be considered to reduce the probability of serious fire. (*See NFPA 8503, Standard for Pulverized Fuel Systems.*)

5-4.2.1* Storage structures should be of noncombustible construction and designed to minimize corners or pockets that cause coal to remain trapped and present a potential for spontaneous combustion.

5-4.2.2* During planned outages, coal bins, bunkers, or silos should be emptied to the extent practical.

5-4.2.3* The period of shutdown requiring emptying of the bins depends on the spontaneous heating characteristics of the coal. However, spontaneous heating can be slowed by minimizing air flow through the bins by such means as inerting or filling the bins with high-expansion foam.

5-4.2.4 During idle periods, flammable gas monitors can be installed at the top of the silo to monitor methane gas and carbon monoxide concentrations. Flammable gas monitors should be arranged to alert plant operators if methane concentrations are detected or carbon monoxide concentration exceeds 1.25 percent concentration by volume. Heat detectors can also be inserted to detect temperature increase due to spontaneous combustion.

5-4.2.5 Once spontaneous heating develops to the fire stage, it becomes very difficult to extinguish the fire short of emptying the bin, bunker, or silo. Therefore, provisions for emptying the bunker should be provided. This might take the form of conveyors discharging to a stacking out pile. Another method would use flanged openings for removing the coal if adequate planning and necessary equipment have been provided. Removing hot or burning coal can lead to a dust explosion if a dust cloud develops. Therefore, means should be provided to prevent a dust cloud, such as covering the coal with a blanket of high-expansion foam.

5-4.2.6* If fire occurs in a silo it is necessary to initiate manual actions for suppression and extinguishment. The following fire fighting strategies have been successfully employed (depending on the specific circumstances and type of coal used):

(a) Use of Class A foams and penetrants;

(b) Injection of inert gas (i.e., carbon dioxide or nitrogen);

(c) Emptying the silo through the feeder pipe to a safe location (inside or outside the powerhouse), and trucking away the debris.

NOTE: All signs of spontaneous combustion and fire must be eliminated prior to the movement of coal.

CAUTION:

1. Water has been successfully used to control bunker and silo fires. However, the possibility of an explosion exists under certain circumstances if the water reaches the coal in a hot spot. Therefore, water is not a recommended fire fighting strategy for these types of fire events. The amount of water delivered to a silo in a stream can create structural support problems.

2. Steam-smothering has also been used to control bunker and silo fires on marine vessels. All openings need to be sealed prior to the introduction of steam. This is rarely possible at electric generating plants due to the relatively porous nature of the equipment.

The use of steam introduces high temperature and moisture that could increase the possibility of spontaneous combustion; therefore, this strategy is not recommended.

3. Locating silo hot spots and extinguishing them before the coal leaves the silo is an accepted practice. The coal hot spots are detected and extinguished. If, as the coal drops down through the silo, additional hot spots are detected, coal flow should be stopped and the hot spots extinguished. If the hot spots are exposed during the lowering of the coal, potential for dust

explosions is increased.

5-4.2.7 Care should be taken where working in enclosed areas near coal bins, bunkers, or silos in confined areas since spontaneous heating of coal can generate gases that are both toxic and explosive. Fixed or portable carbon monoxide monitoring should be provided to detect spontaneous heating and hazardous conditions.

5-4.2.8 Dusttight barriers should be provided between the boiler house and the areas of the coal handling system above the bin, bunker, or silo.

5-4.3* Dust Suppression and Control.

5-4.3.1 Coal dust generated due to coal handling constitutes a fire and explosion hazard that should be controlled by one or more of the following methods:

(a) a dust collection system;

(b) a dust suppression system;

(c) an open-air construction.

5-4.3.2 Where dust collection or suppression systems are installed to prevent hazardous dust concentration, appropriate electrical and mechanical interlocks should be provided to prevent the operation of coal handling systems prior to the starting and sustained operation of the dust control equipment.

NOTE: Constructing enclosure hoods at transfer points can minimize the amount of dust released to surrounding areas, which can reduce the need for dust collection.

5-4.3.3 Dust suppression systems usually consist of spray systems using water or surfactants, or both, to reduce the dust generation of coal handling operations. The sprays are normally applied at or near those locations where the coal is transferred from one conveyor to another.

5-4.3.4 For dust collection systems provided for handling combustible dusts, see NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*. Other recommendations for reducing the probability of explosion and fire from coal dust are:

(a) Fans for dust collectors should be installed downstream of the collectors so that they handle only clean air.

(b) For dust collectors vented to the outside, see NFPA 68, *Guide for Venting of Deflagrations*. Explosion suppression systems may be permitted to be provided for dust collection systems that cannot be safely vented to the outside. (*See NFPA 69, Standard on Explosion Prevention Systems.*)

(c) Dust collection hoppers should be emptied prior to shutting down dust removal systems to reduce the likelihood of collector fires originating from spontaneous heating in the dust hopper.

(d) High level detection with an annunciator alarm should be provided for the dust hoppers.

5-4.3.5 Cleaning methods such as vigorous sweeping of dust or blowing down with steam or compressed air should not be used since these methods can produce an explosive atmosphere. Preferred cleaning methods would use appropriate portable or fixed pipe vacuum cleaners of a type approved for dust hazardous locations or low velocity water spray nozzles and hose.

5-4.4 Coal Conveyors.

5-4.4.1 Coal conveyor belts should be of material designed to resist ignition. U.S. Mine Safety and Health Administration and Canadian Bureau of Mines Standards for fire retardant conveyor belt materials should be used as a guide. However, “fire retardant” belt materials will burn and therefore may require additional fire protection.

5-4.4.2 Each conveyor system should be arranged to automatically shut off driving power in the event of belt slowdown of greater than 20 percent or misalignment of belts. In addition, a complete belt interlock shutdown system should be provided so that, if any conveyor stops, the power to all conveyor systems feeding that belt would be shut down automatically.

5-4.4.3 Hydraulic systems should use only listed fire retardant hydraulic fluids. Where unlisted hydraulic fluids must be used, consideration should be given to protection by a fire suppression system.

5-4.4.4 Foreign materials pose a threat to crushers, pulverizers, and feeders by interrupting the flow of coal or by causing sparks capable of igniting coal dust/air mixtures. Methods of removing tramp metals and other foreign materials include magnetic separators, pneumatic separators, and screens. Means for removing such foreign material should be provided as early in the coal handling process as possible.

5-4.5 Coal Conveying and Handling Structures.

5-4.5.1 Coal conveying and handling structures and supports should be of noncombustible construction.

5-4.5.2 The accumulation of coal dust in enclosed buildings can be reduced by designing structural members such that their shape or method of installation minimizes the surface area where dust can settle. Consideration should be given to installing structural members exterior to the enclosure. Access should be provided to facilitate cleaning of all areas.

5-4.5.3 For explosion venting for enclosed structures, see NFPA 68, *Guide for Venting of Deflagrations*.

5-4.5.4 Provisions should be made for deenergizing both lighting and electrical power circuits without requiring personnel to enter dust-producing sections of the plant during emergencies.

5-4.5.5 Areas of the coal handling system requiring heat should use approved heaters suitable for hazardous areas. The heating equipment should be kept free of dusts and should be designed to limit surface temperature to 329°F (165°C).

5-4.5.6 Electrical equipment within coal handling areas should be approved for use in hazardous locations Class II, Division 1 or Division 2, Group F. Electrical equipment subject to accumulations of methane gas or carbon monoxide should also be listed and installed, as appropriate, for use in hazardous locations Class I, Division 2, Group D. (*See Articles 500 and 501 of NFPA 70, National Electrical Code, and Section 127 of ANSI C2, National Electrical Safety Code*.)

5-4.5.7 Static electricity hazards should be minimized by the permanent bonding and grounding of all equipment, including duct work, conveyor drive belts, pulleys, idlers, take-up reels, motor drives, dust collection equipment, and vacuum cleaning equipment. (*See NFPA 77, Recommended Practice on Static Electricity*.)

5-4.6 Fire Protection.

5-4.6.1 Automatic sprinkler or water spray systems should be provided for coal handling structures that are critical to power generation and subject to accumulations of coal or coal dust. Sprinkler systems should be designed for a minimum of 0.25 gpm/ft^2 (0.17 $L/sec\text{-}m^2$) density over a 2500 ft^2 (232 m^2) area. If water spray systems are used to protect structures, the same densities should be used.

5-4.6.2 Automatic water spray or sprinkler systems should be provided for enclosed coal conveyors that are critical to continuous power generation. Sprinklers should be designed for a minimum of 0.25 gpm/ft^2 (0.17 $L/sec\text{-}m^2$) density over 2000 ft^2 (186 m^2) of enclosed area or the most remote 100 linear ft (30 m) of conveyor structure up to 2000 ft^2 (186 m^2). For water spray design criteria, see NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*.

5-4.6.2.1 If a sprinkler system is used to protect the coal conveyor, particular care should be exercised in locating closed sprinkler heads so that they will be in the path of the heat produced by the fire and still be in a position to provide good coverage of all belt surfaces along the conveyor.

5-4.6.2.2 Conveyors that are below grade or enclosed are extremely hazardous to maintenance or fire fighting personnel in the event of a fire. Automatic water spray or sprinkler systems should be provided for these conveyors even though they may not be critical to plant operations.

5-4.6.2.3 Actuation of water spray or sprinkler systems should shut down the conveyor belt involved and all conveyor belts feeding the involved belt.

5-4.6.2.4 Dust collectors and fans should automatically shut down along with other related equipment upon detection of fire.

5-4.6.2.5 Draft barriers installed at the end and mid-points of enclosed conveyors should be considered in the Fire Risk Evaluation. Draft barriers will reduce the response time of installed automatic sprinkler or detection systems and minimize the chimney effects in the event of fire.

5-4.6.3 Stacker-reclaimer and barge/ship unloader conveyors present unique fire protection concerns. Protection of the equipment and safety of the personnel is made more difficult due to the movement-in-place capabilities of the equipment and its mobility and movement along a fixed rail system. Provision of hydrants in the area may not be sufficient protection primarily due to the extreme delay in response in the event of fire emergency and the difficulty in reaching all areas involved in a fire with hand-held hose equipment.

5-4.6.4 Consideration should be given to the installation of an automatic water spray or sprinkler system over the conveyor belt and striker plate areas within the stacker-reclaimer. The water supply could be from a 3000 gal to 5000 gal (11,355 L to 18,925 L) capacity pressure tank located on-board. A fire department pumper connection should be provided so connection can be made to the fire hydrants in the area during down or repair periods to provide a more adequate water supply. Consideration should be given to protecting enclosed electrical control cabinets by a preengineered fixed automatic gaseous-type suppression system activated by a fixed temperature detection system.

5-4.6.5 Bag-type coal dust collectors that are located inside buildings or structures should be protected with automatic sprinkler or water spray systems inside of the collectors.

5-4.6.5.1 Sprinklers for bag-type dust collectors should be designed for ordinary hazard systems. Sprinkler and water spray systems should be designed for a density of 0.20 gpm (0.013 L/sec) over the projected plan area of the dust collector.

5-4.6.5.2 Protection inside dust collectors should include the clean air plenum and the bag section. If the hopper is shielded from water discharge, sprinklers also should be provided in the hopper section.

5-4.6.5.3 Consideration should be given to providing automatic sprinkler systems for bag-type dust collectors located outdoors that:

(a) are in continuous operation;

(b) process large amounts of coal dust;

(c) have limited access for manual fire fighting. An example of limited access would be collectors that have catwalks for access.

5-5 Steam Generator.

For boiler-furnaces, see NFPA 8501, *Standard for Single Burner Boiler Operation*, and NFPA 8502, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boilers*.

5-5.1 Fire Protection.

5-5.1.1 Boiler-furnaces with multiple oil-fired burners or using oil for ignition should be protected with automatic sprinkler, water spray, foam, or foam-water sprinkler systems covering the burner front oil hazard.

5-5.1.2 Boiler front fire protection systems should be designed to cover the fuel oil burners and ignitors, adjacent fuel oil piping and cable, a 20 ft (6.1 m) distance from the burner and ignitor including structural members and walkways at these levels. Additional coverage should include areas where oil may collect. Sprinkler and water spray systems should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the protected area.

5-5.2 Pulverizers.

5-5.2.1 For pulverized fuel systems, see NFPA 8503, *Standard for Pulverized Fuel Systems*.

5-5.2.2 Carbon monoxide gas detection systems should be considered for pulverizers as an early warning for conditions leading to fires and explosions.

5-5.3 Boiler Feed Pumps.

5-5.3.1 Coverage of steam-driven boiler feed pumps should include oil lubrication lines, bearings, and oil reservoirs. Accidental water discharge on bearing points and hot turbine parts should be considered. If necessary, these areas may be permitted to be protected by shields and casing insulation with metal covers. Boiler feed pumps that are electric motor-driven, with lubricating or hydraulic oil hazards, may require protection depending on the quantity of oil, oil pressure, or exposure to other equipment.

5-5.3.2 Hydraulic and lubricating oil hazards associated with boiler feed pumps that are driven with steam turbines should be protected in accordance with 5-7.4.1. The use of a listed fire-resistant lubricant and hydraulic fluid can eliminate the need for fire protection systems.

5-5.3.3 Curbing or drainage or both should be provided for the steam-driven boiler feed pump oil reservoirs in accordance with Section 3-5.

5-6 Flue Gas.

5-6.1 Forced Draft, Induced Draft, and Flue Gas Recirculation Fans.

5-6.1.1 Coverage of steam-driven fans should include oil lubrication lines, bearings, and oil reservoirs. Accidental water discharge on bearings points and hot turbine parts should be considered. If necessary, these areas may be permitted to be protected by shields and casing insulation with metal covers. Water spray systems for steam turbine-driven forced draft and induced draft fans should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the oil containment equipment surface. Water spray systems should be designed for 0.25 gpm/ft^2 (0.17 L/sec-m^2) for a minimum 20 ft (6.1 m) from the hazard. Combustible oil hazards associated with forced and induced draft fans driven with steam turbines should be protected with automatic sprinkler, water spray, or foam-water sprinkler systems.

5-6.1.2 Forced draft fans, induced draft fans, and flue gas recirculation fans should use a listed fire-resistant fluid for hydraulic drives. Where nonapproved hydraulic fluids are used, protection should be provided as described in 5-6.1.1.

5-6.2 Regenerative Air Heaters.

5-6.2.1 Fires have occurred in air heaters after the accumulation of appreciable quantities of unburned combustibles on plate surfaces resulting from incomplete combustion of fuel in the boiler. Incomplete combustion is most likely to occur during startup. Incomplete combustion also can occur during load changes, periods of low firing rate, or normal operation due to unstable or over-rich firing.

5-6.2.2 Fire-loss experience does not presently indicate the need for special protection for other than regenerative-type air heaters. Regenerative-type air heater fires have occurred when firing on all types of fuel. Fires have occurred most frequently when firing oil or shortly after changing to pulverized coal from oil.

5-6.2.3 Temperature sensors should be provided in the inlet and outlet ducts for both flue gas and air. An alarm should be provided in the control room to alarm when air or flue gas temperatures exceed 50°F (28°C) above normal operating temperature. Temperature sensors alone may not be adequate to provide early warning of a fire in an air heater. In large air heaters, air flow rates are high enough so that a fire will be well developed before the temperature increases enough to alarm and warn the operator. The length of time the operator has to take action is greatly reduced, and severe damage can occur. The installation of a special detection system may allow operators time to quickly detect a fire, isolate the air heater, open drains, and activate the water spray system.

NOTE: Special detection systems currently used are:

(a) Infrared detection systems to monitor rotor or stator surfaces, and

(b) Line-type detectors between intermediate and cold-end basket layers.

There has been limited fire experience with both systems to date. Low light television cameras mounted outside the air heater have a possible application in air heater fire detection.

5-6.2.4 A minimum of one observation port should be provided in the inlet and/or outlet ducts for both flue gas and air. Large air heaters may require more than one observation port. Observation ports should be placed such that they are accessible for viewing the rotor or stator surface.

5-6.2.5 A manual water spray system should be provided to protect the rotor or stator. The water spray system should be capable of being activated from the control room or from the air heater area or both. When the rotor or stator is horizontal, water spray applied to the upper surface can be expected to flow by gravity down over plate surfaces. A minimum of 0.60 gpm/ft^2 (0.41 L/sec-m^2) density is recommended. Where the rotor or stator is vertical, water spray should be applied to both sides to obtain adequate penetration. A minimum of 0.30 gpm/ft^2 (0.20 L/sec-m^2) density is recommended on both sides. Water wash systems may not be adequate to give full coverage because of rotor drive failure.

5-6.2.6 Access hatches for the use of hose streams should be provided. Hatches should be designed for quick access. A minimum of one hatch should be provided per 10 ft (3.0 m) of rotor or stator diameter. For horizontal shaft air heaters, access should be provided on both sides of the rotor or stator. For vertical shaft units, access hatches should be provided above the rotor or stator with one hatch below for units under 20 ft (6.1 m) diameter and two hatches below for units 20 ft (6.1 m) or more in diameter.

5-6.2.7 Drainage should be provided to remove suppression water to a safe area. Drains from air heaters, ducts, or both should be accessible or controlled by remotely operated valves.

5-6.2.8 A zero speed switch with alarm in the control room should be provided on the rotor shaft or on the output shaft from the fluid coupling or gear reducer. A zero speed alarm warns of stoppage of the rotor or air hoods. This could be due to failure of the drive motor or coupling that will lead to overheating of a section of the rotor or stator, which may result in a fire. Stoppage also may be caused by high temperatures generated by a fire that has caused the rotor to bind against the housing or the air hoods to bind against the stator.

5-6.3 Flue Gas Bag-Type Dust Collectors.

5-6.3.1 Flue gas bag-type dust collectors (also known as fabric filters) can be damaged by overheating or fire. Filter media can be damaged by flue gases entering at a temperature above the operating temperature of the filter media. Fires have been caused by incomplete combustion in the boiler resulting in carryover of burning particulate igniting the filter media and by maintenance operations such as cutting and welding.

5-6.3.2 Collectors equipped with bags that have an operating temperature limit exceeding 400°F (204°C) should be subdivided into compartments by noncombustible partitions. The partitions should extend through the flue gas bag area. The filter bag area provided in each compartment should be such that the fabric filter systems will not limit boiler load with one compartment fully isolated to repair damaged filter bags. The pressure drop across the fabric filter system should not increase significantly when one compartment is isolated.

5-6.3.3 Collectors equipped with other types of bags should be subdivided into compartments by partitions of 30-minute fire resistance if no automatic sprinkler protection is provided or by noncombustible partitions if sprinklers are provided. Partitions should extend from the hopper, through the bag area to the clean air plenum. Protection inside dust collectors should include the bag area. The design density should be 0.20 gpm/ft^2 (0.14 L/sec-m^2) over the plan area of the dust collector.

5-6.3.4 If automatic sprinkler protection is provided, structural design of the collector should take into consideration maximum water loading. A method should be provided for drainage of water from the hoppers.

5-6.3.5 Each compartment should be equipped with a heat detection system, arranged to alarm in a constantly attended area at a temperature 50°F (28°C) above normal operating temperature.

5-6.3.6 One of the following should be provided to prevent high temperature inlet flue gas from damaging the bags:

(a) Where permitted for emergency conditions, an automatic isolation valve and bypass duct to divert inlet gas streams around the flue gas bag collector, or

(b) A flue gas tempering water spray system in the duct between the boiler and the flue gas bag collector.

5-6.3.7 Manual fire fighting equipment should be available to personnel performing maintenance on a collector. A standpipe system should be provided such that each compartment is accessible by at least one hose system.

5-6.3.8 Access doors or hatches for manual fire fighting and viewing ports should be provided for all compartments.

5-6.4 Electrostatic Precipitators.

5-6.4.1 Electrostatic precipitators can be damaged by heat from a fire. High temperatures can warp collecting plates, decreasing collection efficiency. Combustibles may be generated by over-rich boiler-furnace firing. Solid and liquid products of incomplete combustion can be collected on plate surfaces. Ignition can occur by arcing in the electrostatic precipitator.

5-6.4.2 Temperature sensors should be provided in the inlet and outlet ducts. Alarms should be provided in the control room to indicate abnormal operating temperatures.

NOTE: Temperature sensors alone may not be adequate to provide early warning of a fire in an electrostatic precipitator.

5-6.4.3 Transformer-rectifier sets should use high fire point insulating fluids or should be of the dry type. If mineral oil insulating fluids are used, hydrants or standpipes should be located so that each transformer-rectifier set can be reached by at least one hose stream. In addition either of the following should be provided:

(a) Automatic sprinkler or automatic water spray protection. Fire protection water spray systems provided for transformer-rectifier sets should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the exposed surface of the transformer-rectifier set. Automatic sprinkler systems should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over 3500 ft^2 (325 m^2). The drain system should be capable of handling oil spillage plus the largest design water flow from the fire protection system.

(b) Fire barrier(s) or spatial separation in accordance with Chapter 3. (*See 3-1.4 and 3-1.5.*)

5-6.5* Scrubbers and Exhaust Ducts.

5-6.5.1 General. Fires have occurred in scrubbers with combustible lining, combustible packing, or both. The fires occurred during outages and were caused by cutting and welding. Attempts to manually fight the fires were not successful since smoke and heat prevented access to the scrubber. Where scrubbers were located in buildings, there has been extensive smoke and heat damage to the building. A fire also can occur in ducts with plastic or rubber lining.

5-6.5.2 Scrubber Buildings.

5-6.5.2.1 Buildings should be constructed of materials meeting the criteria outlined in Section 3-3.

5-6.5.2.2 Where scrubbers have plastic or rubber linings, one of the following methods of protection for the building should be provided:

(a) Automatic sprinkler protection at ceiling level sized to provide 0.20 gpm/ft^2 (0.14 L/sec-m^2). The area of operation should be the area of the building or 10,000 ft^2 (930 m^2). Where draft curtains are provided the area of operation can be reduced to the largest area subdivided by draft curtains.

(b) The roof deck and supporting steel should be protected with a 1-hr fire proof coating. Building columns should be protected with a 2-hr fire proof coating from the roof to 20 ft (6 m) below the roof. Columns adjacent to scrubber openings should be protected from the roof to below the opening scrubber opening. Automatic or remotely actuated heat venting should be provided with a vent area of 1 ft^2 per 50 ft^2 of floor area.

5-6.5.2.3 If a listed less flammable fluid is not used, hydraulic and lubricating oil equipment should be protected as described in 5-7.4.

5-6.5.3 Scrubbers.

5-6.5.3.1 Materials of Construction. Scrubbers, internal piping, and ducts should be constructed of noncombustible materials, or the recommendations of 5-6.5.3.2 and 5-6.5.3.3 should be incorporated.

5-6.5.3.2 During outages, all of the following should be done:

(a) Cutting, welding, and other hot work is the most likely cause of ignition. Thus, strict controls should be enforced. Packing should be covered with fire-resistant blankets over sheet metal. Blankets should be kept wet. A charged hose and fire watch should be provided at the work area.

(b) All equipment lined with combustible material should be identified with warning signs or placards.

(c) The scrubber reservoir should be maintained full if possible or returned to service as quickly as possible during an outage.

(d) The absorber inlet and outlet damper should be closed during cutting, welding, or other hot work to reduce the induced draft. When the scrubber outlet damper is open no work should be permitted in the downstream duct or stack.

5-6.5.3.3 Fire Protection. A fire protection system should be provided during outages for absorber vessels containing combustible packing or lining and should include the following:

(a) The fire protection system can be the spray system designed for normal scrubber operation or a specially designed fire protection system. Water spray systems should be designed such that spray patterns cover the lining and packing. Where scrubber spray systems are used for fire protection, system components internal to the scrubber should be noncombustible. The water supply should be from a reliable source available during the outage.

(b) Duct systems. A fire protection system should be provided during maintenance operations. A fixed protection system on the scaffolding is recommended. The system should be designed to protect the work platform and twice the area that can be reached by workers on the platform.

(c) Due to the unique design and operating features of scrubbers, fire protection designers should consult with the scrubber manufacturer for guidance as to material selection for internal fire protection systems and specific protection design features.

(d) Standpipes should be provided such that $1^1/_2$-in. (3.8-cm) hose is available at scrubber access hatches that are open during outages.

(e) Combustible materials in the scrubber should be limited and controlled during maintenance and inspection outages.

5-6.5.4 Limestone Conveyors. Limestone conveyors for use with flue gas desulfurization systems should meet the fire protection requirements of 5-4.4.1, 5-4.4.2, 5-4.4.3, and 5-4.5.1. Conveyors critical to continued plant operation should be provided with an automatic sprinkler or water spray system over the drive pulley, and a fire detection system should be provided and interlocked to shut down the conveyor.

5-6.6 Stacks.

5-6.6.1 Noncombustible liners should be used where practical. (*See Appendix C for fire tests.*)

5-6.6.2 Combustibles should not be stored in the space between the concrete shell and the combustible liner unless the liner is adequately protected by a fire barrier. The barrier could be either a 2-hr fire barrier or a 1-hr fire barrier if automatic sprinkler protection is provided over the combustible material.

5-6.6.3 A fire protection system should be provided for maintenance operations inside plastic stack liners. A fixed protection system installed on scaffolding is recommended. It should be capable of both manual and automatic operation and designed to protect the work platform and twice the area that can be reached by workers on the platform.

5-6.6.4 Ignition sources should be eliminated when working inside plastic liners.

5-7 Turbine-Generator.

5-7.1 Hydrogen System.

5-7.1.1 General.

5-7.1.1.1 For hydrogen storage systems, see NFPA 50A, *Standard for Gaseous Hydrogen Systems at Consumer Sites*, or NFPA 50B, *Standard for Liquefied Hydrogen Systems at Consumer Sites*.

5-7.1.1.2 Bulk hydrogen systems supplying one or more generators should have automatic valves located at the supply and operable either by “dead man” type controls at the generator fill point(s) or operable from the control room. This would minimize the potential for a major discharge of hydrogen in the event of a leak from piping inside the plant. Alternatively, vented guard piping may be used in the building to protect runs of hydrogen piping.

5-7.1.1.3 Routing of hydrogen piping should avoid hazardous areas and areas containing critical equipment.

5-7.1.2 Hydrogen Seal Oil Pumps.

5-7.1.2.1 Redundant hydrogen seal oil pumps with separate power supplies should be provided for adequate reliability of seal oil supply.

5-7.1.2.2 Where feasible, electrical circuits to redundant pumps should be run in buried conduit or provided with fire retardant coating if exposed in the area of the turbine generator to minimize possibility of loss of both pumps as a result of a turbine generator fire.

5-7.1.3 Curbing or drainage or both should be provided for the hydrogen seal oil unit in accordance with Section 3-5.

5-7.1.4 A flanged spool piece or equivalent arrangement should be provided to facilitate the separation of hydrogen supply where the generator is opened for maintenance.

5-7.1.5 For electrical equipment in the vicinity of the hydrogen handling equipment, including detraining equipment, seal oil pumps, valves, etc., see Article 500 of NFPA 70, *National Electrical Code*, and Section 127 of ANSI C2, *National Electrical Safety Code*.

5-7.1.6 Control room alarms should be provided to indicate abnormal gas pressure, temperature, and percentage of hydrogen in the generator.

5-7.1.7 Hydrogen lines should not be piped into the control room.

5-7.1.8 The generator hydrogen dump valve and hydrogen detraining equipment should be arranged to vent directly to a safe outside location. The dump valve should be remotely operable from the control room or an area accessible during a machine fire.

5-7.2 Hydraulic Control System.

5-7.2.1 The hydraulic control system should use a listed fire-resistant fluid.

5-7.2.2 If a listed fire-resistant fluid is not used, hydraulic control equipment should be protected as described in 5-7.4.

5-7.2.3 Fire extinguishing systems, where required for hydraulic control equipment, should include reservoirs and stop, intercept, and reheat valves.

5-7.3 Lubricating Oil Systems.

5-7.3.1 Lubricating oil storage, pumping facilities, and associated piping should comply with NFPA 30, *Flammable and Combustible Liquids Code*.

5-7.3.2 Turbine lubricating oil reservoirs should be provided with a vapor extractor, vented to a safe outside location.

5-7.3.3 Curbing or drainage or both should be provided for the turbine lubricating oil reservoir in accordance with Section 3-5.

5-7.3.4 All oil piping serving the turbine-generator should be designed and installed to minimize the possibility of an oil fire in the event of severe turbine vibration. (*See NFPA 30, Flammable and Combustible Liquids Code; Chapter 3, Piping Systems.*)

5-7.3.5 Piping design and installation should consider the following protective measures:

(a) Welded construction.

(b) Guard pipe construction with the pressure feed line located inside the return line or in a separate shield pipe drained to the oil reservoir.

(c) Route oil piping clear of or below steam piping or metal parts.

(d) Insulation with impervious lagging for steam piping or hot metal parts under or near oil piping or turbine bearing points.

NOTE: On some turbine-generators employing the guard pipe principle, the guard piping arrangement terminates under the machine housing where feed and return piping run to pairs of bearings. Such locations are vulnerable to breakage with attendant release of oil in the event of excessive machine vibration and should be protected.

5-7.3.6 It is desirable to provide for remote operation, preferably from the control room, of the condenser vacuum break valve and the lubricating oil pumps. Breaking the condenser vacuum markedly reduces the rundown time for the machine and thus limits oil discharge in the event of a leak. See the discussion in 2-7.2 on fire emergency planning involving turbine lubricating oil fires.

5-7.3.7 Cable for operation of lube oil pumps should be protected from fire exposure. Protection may consist of separation of cable for ac and dc oil pumps or 1-hr fire resistive coating (derating of cable should be considered).

5-7.4 Fire Protection.

5-7.4.1 Turbine-Generator Area.

5-7.4.1.1 All areas beneath the turbine-generator operating floor that are subject to oil flow, oil spray, or oil accumulation should be protected by an automatic sprinkler or foam-water sprinkler system. This coverage normally includes all areas beneath the operating floor in the turbine building. The sprinkler system beneath the turbine-generator should take into consideration obstructions from structural members and piping and should be designed to a density of 0.30 gpm/ft^2 (0.20 L/sec-m^2) over a minimum application of 5000 ft^2 (464 m^2).

NOTE: To avoid water application to hot parts or other water sensitive areas and to provide adequate coverage, designs that incorporate items such as fusible element operated directional spray nozzles may be necessary.

5-7.4.1.2 Lubricating oil lines above the turbine operating floor should be protected with an automatic sprinkler system covering those areas subject to oil accumulation including the area within the turbine lagging (skirt). The automatic sprinkler system should be designed to a density of 0.30 gpm/ft^2 (0.20 L/sec-m^2).

5-7.4.1.3 Lubricating oil reservoirs and handling equipment should be protected in accordance with 5-7.4.1.1. If the lubricating oil equipment is in a separate room enclosure, protection may be provided by a total flooding gaseous extinguishing system.

NOTE 1: If the lubricating oil reservoir is elevated, sprinkler protection should be extended to protect the area beneath the reservoir.

NOTE 2: If the lubricating oil reservoirs and handling equipment are located on the turbine operating floor and not enclosed in a separate fire area, then all areas subject to oil flow or oil accumulation should be protected by an automatic sprinkler or deluge system.

5-7.4.1.4 Above the operating floor, ceiling level sprinkler systems may not be effective to protect floor level equipment and components from oil fires because of the high ceilings [typically in excess of 40 ft (12 m)]. More effective protection can be provided by containing oil spills and providing local automatic protection systems for the containment areas.

5-7.4.1.5 Foam-water sprinkler systems installed in place of automatic sprinklers described above should be designed in accordance with NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems* or NFPA 16A, *Standard for the Installation of Closed-Head Foam-Water Sprinkler Systems*, and the design densities specified above.

5-7.4.1.6 Electrical equipment in the area covered by a water or foam-water system should be of the enclosed type or otherwise protected to minimize water damage in the event of system operation.

5-7.4.2 Turbine-Generator Bearings.

NOTE: Additional information concerning turbine-generator fire protection can be found in EPRI Research Project 1843-2 report, *Turbine Generator Fire Protection by Sprinkler System*, July 1985.

5-7.4.2.1 Turbine-generator bearings should be protected with a manually or automatically operated closed-head sprinkler system utilizing directional nozzles. Fire protection systems for turbine-generator bearings should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the protected area.

5-7.4.2.2 Accidental water discharge on bearing points and hot turbine parts should be considered. If necessary, these areas may be permitted to be protected by shields and encasing insulation with metal covers.

5-7.4.2.3 If a manually operated water system is installed, consideration should be given to a supplemental automatic gaseous fire extinguishing system.

5-7.4.3 Exciter. The area inside a directly connected exciter housing should be protected with a total flooding automatic carbon dioxide system.

5-7.4.4 Hydrogen Seal Oil. Hydrogen seal oil units should be protected in accordance with 5-7.4.1.

5-7.4.5 Oil Storage Areas. Clean or dirty oil storage areas should be protected based on the Fire Risk Evaluation. This area generally represents the largest concentrated oil storage in the plant. The designer should consider, as a minimum, the installation of fixed automatic fire protection systems and the ventilation and drainage requirements in Chapter 3.

5-8 Electrical Equipment.

5-8.1 Control, Computer, and Communication Rooms.

5-8.1.1 Control, computer, or telecommunication rooms should meet the applicable requirements of NFPA 75, *Standard for the Protection of Electronic Computer/Data Processing Equipment*.

5-8.1.2 A smoke detection system should be installed throughout these rooms, including walk-in-type consoles, above suspended ceilings where combustibles are installed, and below raised floors. Where the only combustibles above the false ceiling are cables in conduit and the space is not used as a return air plenum, smoke detectors may be permitted to be omitted from this area.

5-8.1.3 A preaction sprinkler system for the computer or telecommunications rooms should be considered during the Fire Risk Evaluation. In addition, total flooding gaseous fire extinguishing systems should be considered for areas beneath raised floors that contain cables or for areas or enclosures containing equipment that is of high value or is critical to power generation. Individual equipment and cabinet protection could be considered in lieu of total flooding systems.

5-8.1.4 Cable raceways not terminating in the control room should not be routed through the control room.

5-8.2 Cable Spreading Room and Cable Tunnels.

5-8.2.1 Cable spreading rooms and cable tunnels should be protected with automatic sprinkler, water spray, or automatic gaseous extinguishing systems. Automatic sprinkler systems should be designed for a density of 0.30 gpm/ft^2 (0.20 L/sec-m^2) over 2500 ft^2 (232 m^2) or the most remote 100 linear ft (30 m) of cable tunnels up to 2500 ft^2 (232 m^2).

5-8.2.2 Cable spreading rooms and cable tunnels should be provided with an early warning fire detection system.

5-8.3 Grouped Electrical Cables.

5-8.3.1 Consideration should be given to the use of fire retardant cable insulation such as those passing the Flame Propagation Test of the Institute of Electrical and Electronics Engineers (IEEE-383). Grouped electrical cables should be routed away from exposure hazards or protected as required by the Fire Risk Evaluation. In particular, care should be taken to avoid routing cable trays near sources of ignition or flammable and combustible liquids. Where such routing is unavoidable, cable trays should be designed and arranged to prevent the spread of fire.

5-8.3.2 Cable trays subject to accumulation of coal dust and the spread of an oil spill should be covered by sheet metal. Where potential oil leakage is a problem, solid-bottom trays should be avoided. Changes in elevation can prevent oil travel along cables in a tray.

5-8.3.3 The Fire Risk Evaluation should consider the provision of fire suppression systems or fire retardant cable coatings or both for protection of cable concentrations from exposure fires. Care should be exercised in the selection of fire retardant coatings to ensure that derating of the cable is considered. Consideration also should be given to the ability to add or remove cables and to make repairs to cables protected with fire retardant coatings.

5-8.4 Switchgear and Relay Rooms.

Switchgear rooms and relay rooms should be provided with smoke detection systems.

5-8.5 Battery Rooms.

Battery rooms should be provided with ventilation to limit the concentration of hydrogen to 1 percent by volume. For further information refer to ANSI/IEEE 484, *Recommended Practice for*

Installation Design and Installation of Large Lead Storage Batteries for Generating Stations and Substations.

5-8.6 Transformers.

Oil-filled main, station service, and start-up transformers should be protected with automatic water spray or foam-water spray systems.

5-8.7* Substations and Switchyards.

Substations and switchyards located at the generating facility, utilizing combustible oil filled equipment should be protected by the yard fire hydrant system where practical. Spatial separation of transformers and other equipment containing over 500 gal (1893 L) of oil should be in accordance with 3-1.4. Consideration should be given to water spray protection of transformers critical to the transmission of the generated power.

5-9 Auxiliary Equipment and Other Structures.

5-9.1 Emergency Generators.

5-9.1.1 The installation and operation of emergency generators should be in accordance with NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*.

5-9.1.2 Fire Protection.

5-9.1.2.1 Emergency generators located within main plant structures should be protected by automatic sprinkler, water spray, foam-water sprinkler, or gaseous-type extinguishing systems. Sprinkler and water spray protection systems should be designed for a 0.25 gpm/ft^2 (0.17 L/sec-m^2) density over the fire area.

5-9.1.2.2 Where gaseous suppression systems are used on combustion engines that may be required to operate during the system discharges, consideration should be given to the supply of engine combustion air and outside air for equipment cooling.

5-9.2 Storage Rooms, Offices, and Shops.

Automatic sprinklers should be provided for storage rooms, offices, and shops containing combustible materials that present an exposure to surrounding areas that are critical to plant operations. (*For oil storage rooms, see 5-7.4.5.*)

5-9.3 Warehouses.

Automatic sprinklers should be provided for warehouses that contain high-value equipment and combustible materials that are critical to power generation or that constitute a fire exposure to other important buildings.

5-9.4 Fire Pumps.

Rooms housing diesel-driven fire pumps should be protected by automatic sprinkler, water spray, or foam-water sprinkler systems. If sprinkler and water spray protection systems are provided for fire pump houses, they should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the fire area.

5-9.5 Cooling Towers.

Cooling towers of combustible construction that are essential to continued plant operations should be protected by automatic sprinkler or water spray systems in accordance with NFPA 214, *Standard on Water-Cooling Towers*.

5-9.6 Auxiliary Boilers.

5-9.6.1 Auxiliary boiler-furnaces, their fuel burning systems, combustion products removal systems, and related control equipment should be designed, installed, and operated in accordance with Section 5-5.

5-9.6.2 Oil- or coal-fueled auxiliary boilers installed within main plant structures should be protected by automatic sprinkler, water spray, or foam-water sprinkler systems. A sprinkler system is preferred throughout the auxiliary boiler room on a 0.25 gpm/ft^2 (0.17 L/sec-m^2) density. As a minimum, sprinkler or water spray protection should be provided as outlined in 5-5.1.

5-9.7

Vehicle repair facilities should meet the requirements of NFPA 88B, *Standard for Repair Garages*.

Chapter 6 Identification and Protection of Hazards for Combustion Turbines

6-1 General.

6-1.1

This chapter identifies fire and explosion hazards of combustion turbine electric generating units and specifies recommended protection criteria.

6-1.2

It should be recognized that some combustion turbine generating facilities consist of manufactured modules wherein construction consists of siting these modules, providing fuel supply, essential services, and interconnections to the electric system, while other facilities consist of buildings specifically designed and built or modified for the combustion turbine generator and its auxiliaries. Therefore, some recommendations may be more suitable for one type of plant than the other.

6-2 Application of Chapters 2

through 5 and Chapter 9. The recommendations contained in Chapters 2 through 5 and Chapter 9 may apply to combustion turbine electric generating units. It is incumbent on the Fire Risk Evaluation to determine which recommendations apply to any specific combustion turbine unit. This is done by evaluating the specific hazards that exist in the facility and evaluating the level of acceptable risk for the facility. For large combustion turbine units or combined cycle plants, it is expected that most of the recommendations will apply, whereas for individual packaged combustion turbine units, many of the recommendations will not apply since the hazards described may not exist (e.g., small units may have no cable spreading room or warehouse).

6-3 General Design and Equipment Arrangement.

6-3.1

Adequate separation should be provided, as determined by the Fire Risk Evaluation, between:

(a) adjacent combustion turbine units;

(b) adjacent structures or exposures;

(c) adjacent properties (e.g., tank farms or natural gas facilities that could present a severe exposure).

6-3.2

Consideration should be given to equipment layout that is adjacent to combustion turbines and in line with planes of turbine and compressor disks that have a higher potential for damage from flying debris.

6-4 Unattended Facilities.

Facilities that are operated unattended present special fire protection concerns.

6-4.1

Consideration should be given both to the delayed response time of the fire brigade or public fire-fighting personnel (which may be several hours) and to the lack of personnel available to alert others to a fire condition.

6-4.2

The Fire Risk Evaluation should address delayed response and lack of communication. This may establish the need to provide additional fire protection measures to prevent a major fire spread prior to the arrival of fire-fighting personnel. The delayed response by personnel to the site may necessitate automatic shutoff of fire pumps.

6-4.3

If automatic water or foam fire suppression systems are utilized, a cycling deluge valve should be considered. The arrangement will depend on the type of system and the hazard protected. Thermal detection is recommended.

6-4.4

Remote annunciation of the fire-signaling panel to one or more constantly attended locations is critical for emergency response. The fire-signaling panel should be located at the entry to the unattended plant.

6-4.5

It is important that the responding fire brigade or public fire-fighting forces be familiar with access, plant fire protection systems, emergency lighting, specific hazards, and methods of fire control. This should be reflected in the plant fire emergency plan. (*See Section 2-7*.)

6-4.6

If an automatic foam system is provided for the fuel storage tanks, a cycling system could be provided to shut down the system when the foam concentrate supply is exhausted.

6-5 Combustion Turbine and Internal Combustion Engine Generators.

6-5.1 General.

6-5.1.1 NFPA 37, *Standard for Installation and Use of Stationary Combustion Engines and Gas Turbines*, addresses engines and turbines not exceeding 7500 HP. It includes important items of design, siting, protective devices, and fueling that apply regardless of engine size.

6-5.1.2 Site specific design considerations or manufacturers typical design will govern what equipment has enclosures or how many separate enclosures will be provided for the combustion turbines or the diesel engines. The combustion turbine generator is frequently supplied as a complete power plant package with equipment mounted on skids or pads and provided with metal enclosures forming an all-weather housing. In addition to being weather-tight, the enclosures are designed to provide thermal and acoustical insulation. Smaller diesel engine plants might involve enclosures for equipment but more commonly engine generators are installed in a row in an open room or hall.

6-5.1.3 The major hazards associated with combustion turbine or diesel electric generator units are:

(a) Flammable and combustible fuels; and

(b) Hydraulic and lubricating oils.

6-5.1.4 In the event of a pipe failure, large amounts of oil or fuel could be released and ignite on contact with hot metal parts. In addition to external fire hazards, combustion turbines are subject to the hazard of uncontrolled internal fires if flameout occurs and the fuel is not shut off immediately, or if fuel is admitted to a hot engine and ignition does not occur. Crankcase explosions in diesel engines have caused large external fires. Other hazards associated with the combustion turbine or internal combustion engine generator are:

(a) Electrical equipment; and

(b) Large amounts of filter media and enclosure insulation.

NOTE: Diesel electric plants do not normally use large amounts of filter media and enclosure insulation.

6-5.1.5 In the event of a problem with a diesel engine, shutdown may be difficult. Several different methods, operating independently, should be provided. These can include centrifugally tripped (over speed condition) spring operated fuel rack closure, governor fuel rack closure, electro-pneumatic fuel rack closure, or air inlet guillotine type air shutoff.

6-5.2 Prevention of Internal Fires in Combustion Turbines.

6-5.2.1 Combustion turbines should have flame detectors in the combustion section to detect flameout or ignition failure during startup. In the case of flameout the fuel should be rapidly shut off. If ignition is not achieved within a normal startup time, then the control system should abort the startup and close the fuel valves.

NOTE: When a flameout occurs, fuel valves should close as rapidly as possible (preferably less than 1 second) to preclude the accumulation of unburned fuel in the combustion chamber. Loss experience documents that fires or explosions have occurred in systems where the fuel isolation was not achieved within 3 seconds.

6-5.2.2 In order to prevent conditions that could cause a fire while the unit is operating, control packages for combustion turbines should include the following monitors:

(a) Turbine speed sensor, independent of the main governor, for tripping on overspeed;

(b) Vibration monitors at the main turbine bearings, for tripping on excessive vibration; and

(c) Turbine exhaust temperature monitor, for tripping on high temperature.

NOTE: Monitors for conditions (b) and (c) should have a lower alarm point to alert operators of deteriorating operating conditions. See ANSI B133.4, *Gas Turbine Control and Protection Systems*.

6-5.2.3 Two safety shutoff valves in series on the main fuel line should be used to minimize the likelihood of fuel leaking into the engine. On gas systems an automatic vent to the outside atmosphere should be provided between the two valves.

6-5.3 Prevention of External Fires in Combustion Turbines and Diesel Engines.

6-5.3.1 Piping systems supplying flammable and combustible liquids and gases should be designed to minimize oil and fuel piping failures as described below.

(a) If rigid metal piping is used, it should be designed with freedom to deflect with the engine, in any direction, at the interface with the turbine. This recommendation also should apply to hydraulic lines that are connected to accessory gearboxes or actuators mounted directly in the engine. Properly designed metallic hose is an alternative for fuel, hydraulic, and lube oil lines in high vibration areas, between rigid pipe supply lines and manifolds, and the points of entry at the engine interface.

(b) Rigid piping connected directly to the turbine should be supported such that failures will not occur due to the natural frequency of the piping coinciding with the rotational speed of the combustion turbine. Care should be taken in the design of pipe supports to avoid vibrations induced by other equipment that may excite its natural frequency.

(c) Welded pipe joints should be used where practical. Threaded couplings and flange bolts in fuel and oil piping should be assembled using a torque wrench and torqued to the manufacturer's requirements. Couplings should have a positive locking device to prevent unscrewing.

(d) Instrumentation tubing, piping, and gauges should be protected from accidental mechanical damage. Sight glasses should be unbreakable.

(e) Where practical, lubricating oil lines should use pipe guard construction with the pressure feed line located inside the return line.

6-5.3.2 For diesel engines, the following monitors should be provided:

(a) Speed sensors, independent of governors; and

(b) High exhaust gas temperature alarm with shutdown.

6-5.3.3 In many units the lubricating oil is used for both lubrication and hydraulic control. For combined systems, a listed fire-resistive fluid should be considered. If separate systems are used, the hydraulic control system should use a listed fire-resistive hydraulic fluid, and a listed fire-resistant fluid should be considered for the lubricating system.

NOTE: Diesel engines do not normally have any hydraulic systems.

6-5.3.4 Combustible gas detector(s) should be considered for the enclosure where the fuel for the gas turbine or diesel engine is natural gas or other gaseous-type fuels.

6-5.3.5 For recommendations regarding containment and drainage of liquids, see Section 3-5.

6-5.4 Fire Protection for Combustion Turbines and Diesel Electrical Generators.

6-5.4.1 General.

6-5.4.1.1 Determination of the need for fire suppression for the combustion turbine engine should be based on consideration of the value of the unit, consequences of loss of the unit, and vulnerability of adjacent structures and equipment to damage.

6-5.4.1.2 Water suppression systems, where provided, should follow the recommendations in Chapter 5 and the following criteria:

(a) Water spray nozzles provided to protect the combustion turbine power bearing housings behind the exhaust duct should be directed based on unit geometry to avoid possible water damage.

(b) Automatic sprinkler or water spray protection should be provided for exposed oil piping and areas on the floor under the turbine where leaking oil may collect.

(c) Accidental water discharge on bearing points and hot turbine parts should be considered. If necessary, these areas can be protected by shields and encasing insulation with metal covers.

(d) Fuel valves should be arranged to close automatically on water flow.

(e) Turbine chargers on diesel engines constitute a part of the hazard and protection should be provided.

6-5.4.1.3 Lubricating oil reservoirs and handling equipment should be protected in accordance with 5-7.3.2 and 5-7.4.1.3.

6-5.4.2 Total Flooding Gaseous Systems.

6-5.4.2.1 Where total flooding gaseous systems are used, the turbine enclosure should be arranged for minimum leakage by automatic closing of the doors, ventilation dampers, and automatic shutdown of the fans and other openings. Combustion turbine or diesel engine compartments are designed to be capable of nominally air-tight closure. During operation there is, however, a need for substantial amounts of secondary cooling (compartment ventilation) air. This air can be moved through the compartments by fans or venturi action from the turbine combustion or diesel engine air. This air flow will not stop immediately upon shutdown, and, therefore, it should be considered in the extinguishing system design.

6-5.4.2.2 Gas design concentrations should be held as long as the hazards of hot metal surfaces above the auto-ignition temperature and uncontrolled combustible liquid flow exist (consult manufacturer for cool down times). Proper gaseous extinguishing system design dictates that the design concentration be held in the compartment for the cooling time discussed above to take place. This has been shown to be around 20 minutes for many areas, but can be substantially longer. It also has been shown that the initial gas discharge will not hold for a 20-minute time period in most turbine or engine compartments. Therefore, the designer should determine the level of an extended added discharge that is necessary to maintain fire extinguishment. This usually requires discharge testing to determine if design concentrations can be maintained. Where gas concentrations cannot be effectively maintained, an alternative system, such as high-expansion foam or water extinguishing system, may be desirable.

6-5.4.2.3 System operations should be arranged to close the fuel valves.

6-5.4.2.4 Maintenance of total flooding systems is particularly critical. In addition to the extinguishing equipment, the integrity of the enclosure to be flooded and the interlocks between the two should be maintained.

6-5.4.2.5 It should be noted that deep seated fires, such as oil-soaked insulation, may be present and will require manual extinguishment after the gaseous system soak time.

6-5.4.2.6 For combustion turbines or diesel engines located indoors, provisions should be addressed for safely removing the gas and potential toxic combustion by-products from the turbine enclosure following system actuation.

6-5.4.3 Localized Extinguishing Systems.

6-5.4.3.1 Where units are not enclosed and a first level of protection is desired that will operate before sprinklers, or where sprinklers are not installed, a localized extinguishing system might be appropriate. Such a system should be of an approved local application type such as water mist, carbon dioxide, dry chemical, or other approved gaseous extinguishing system.

6-5.4.3.2 Discharge rates and duration of discharge should be such that cooling and shutdown occurs to prevent reignition of the fire. System operation should be arranged to close fuel valves.

6-5.4.3.3 The positioning of local application nozzles should be such that maintenance access to the turbine or engine is maintained.

6-5.4.4 High-Expansion Foam Systems. Where total flooding high-expansion foam systems are used for the enclosure where the turbine is located, system operation should be arranged to close the fuel valves.

6-5.5 Inlet Air Filter.

6-5.5.1 Air filters should be of a type that will not burn freely when exposed to fire. Filters qualifying as Class 1, as tested in accordance with UL 900, *Standard for Safety Test Performance of Air Filters*, meet these requirements.

6-5.5.2 Manual fire-fighting equipment should be available to personnel performing maintenance on air filters.

6-5.5.3 Access doors or hatches should be provided for manual fire fighting on large air filter structures.

6-5.6 Generators.

6-5.6.1 Hydrogen systems should comply with recommendations in 5-7.1 and 5-7.4.6.

6-5.6.2 Fire protection should be provided in accordance with 6-5.4.1, 6-5.4.2, 6-5.4.3, or 6-5.4.4.

6-5.6.3 Air-cooled generators should be tightly sealed against the ingress of moisture in the event of discharge (accidental or otherwise) of a water spray system. Sealing should be positive, such as by a gasket or grouting, all around the generator housing.

NOTE: The type of generator used with diesel engines is normally provided with an open drip proof enclosure. Shielding might be appropriate with water system, i.e., sprinklers or deluge.

6-5.7 Starting Equipment.

Fire protection should be provided for the starting equipment on the combustion turbine and its enclosure, based on consideration of the factors in 6-5.4.1.

NOTE: Large diesels are started with compressed air from an air receiver and do not require starting the engine.

6-6 Electrical Equipment.

6-6.1 Control Enclosures.

The size of the combustion turbine generator and the site design determine whether control enclosures are provided. Control enclosures normally are used in remote locations and are designed to be unattended. Control enclosures contain turbine and generator control panels, switchgear, batteries, relays, and indication gauges.

6-6.2 Auxiliary Electrical Equipment Enclosures.

Auxiliary electrical equipment enclosures, where provided, normally contain static excitation equipment, switchgear, current transformers, potential transformers, grounding transformers, and other electrical equipment.

6-6.3

A smoke detection system should be provided for alarm only and early warning of an electrical fire.

6-6.4

A total flooding gaseous suppression system should be considered for the enclosures.

6-7 Combined Cycle Units.

6-7.1 Heat Recovery Steam Generators.

Heat recovery steam generators using supplemental firing should be designed and protected in accordance with Section 5-5.

6-7.2 Steam Turbines.

Steam turbines, generators, and their associated hazards should be designed and protected in accordance with Section 5-7.

Chapter 7 Alternative Fuels

7-1 General.

This chapter identifies fire and explosion hazards of alternative fuel (e.g., RDF, MSW, biomass) fired electric generating plants and specifies recommended protection criteria.

7-2 Application of Chapters 2 through 5 and Chapter 9.

The recommendations contained in Chapters 2 through 5 and Chapter 9 may apply to alternative fuel fired electric generating station units. It is incumbent upon the Fire Risk Evaluation to determine which recommendations apply to any specific alternative fuel fired unit. This is done by evaluating the specific hazards that exist in the facility and determining the level of acceptable risk for the facility. It is expected that most of the recommendations will apply to all units, except where:

(a) Size and specific design eliminate certain hazards (e.g., H_2 seal oil units, cable spreading rooms, or warehouses), and

(b) The Fire Risk Evaluation indicates a single source of water (e.g., a single tank) is considered adequate and reliable.

7-3 Mass Burn Fuels.

7-3.1 General.

7-3.1.1 This section (Section 7-3) identifies fire and explosion hazards that are unique to the use of municipal solid waste (MSW) as a boiler fuel by means of a process that includes the hauling of MSW directly to a tipping floor or storage pit and burning without any special processing. MSW is municipal solid waste consisting of commonly occurring residential and light commercial waste.

7-3.1.2 The major fire and explosion hazards associated with mass burn units are:

(a) Sourcing, receipt, handling, and storage of large quantities of MSW.

(b) Unsuitable waste entering the facility. Examples include certain hydrocarbons, flammable liquids, metal dusts, acetylene, explosives, etc.

(c) Hydraulic and lubricating oils associated with the processing equipment.

(d) Improperly maintained electrical equipment.

(e) Large amounts of MSW accumulating in unsuitable areas as a result of spillage or handling.

(f) Inadequate dust control.

7-3.2 Plant Arrangement.

7-3.2.1 A MSW hot-load unloading area should be designated and separated from other areas (preferably outdoors) so that loads containing smoldering or other suspect constituents can be segregated. Such areas should be properly monitored and equipped to promptly extinguish incipient fires before recombining with other MSW.

7-3.2.2 The refuse pit is normally enclosed on three sides, up to the charging level, by reinforced concrete walls. The thickness of the walls vary with facility design, but should provide a minimum of 2-hr fire separation.

7-3.2.3 Exposed steel columns located at the front of the refuse pit should be protected against structural damage caused by heat (fire). This protection could include concrete encasement, water spray, or other suitable alternatives and should extend from the base of the column to the roof of the refuse pit enclosure. Care should be taken to protect fire-proofing from mechanical damage.

7-3.2.4 Smoke or heat vents should be considered in accordance with 3-4.1.

7-3.2.5 Overhead cranes are often used to mix and stock the refuse within the pit. Undesirable waste (large items such as refrigerators) is often separated from the waste stock by the crane operator for offsite disposal or for shredding/processing (*see 7-3.5*) prior to replacement into the waste stock. All other items are loaded directly into boiler feed hoppers without processing. In addition, the acceptable method for extinguishment of small fires is also direct loading of the smoldering refuse into the hoppers by the crane operator. The following considerations should be given with respect to the crane operator's pulpit:

(a) Locating the pulpit such that operator safety is not compromised.

(b) Ability to have a clear and unobstructed view of all storage and charging areas.

(c) Providing self-contained breathing apparatus for operator egress.

(d) Providing direct communication with the boiler control room and floor manager.

(e) Ability to activate fire protection equipment.

7-3.2.6 Boiler feed equipment, such as a chute or metering bin, should be of noncombustible material and designed to minimize pockets or corners that could cause combustible material to build up. Video monitoring should be considered for locations not readily visible to plant staff. For further guidance, see NFPA 8505, *Recommended Practice for Stoker Operation*.

7-3.2.7 Mass burn facilities utilizing hammermills and flailmills should refer to the criteria in 7-4.2.3.

7-3.3 Prevention of Fires and Explosions in Mass Burn Units.

7-3.3.1 A communication system should be provided between the floor manager and the control room to expedite assistance in the event of fire.

7-3.3.2 The floor operators should ensure that MSW is continuously moved to the processing or storage areas. Vehicles loaded with MSW should not be parked in the building during idle periods.

7-3.3.3 A regular program of housekeeping should be established to keep concentrations of combustible material to a minimum.

7-3.3.4 Operational experience has demonstrated that roving operators and other plant personnel have been key factors in detection of fires and unsafe conditions. It is important that they be properly trained to observe and react to incipient fire situations. These should be reported to the control room operator for evaluation to determine what action is to be taken.

NOTE: The traffic pattern should minimize any requirement for storage of the MSW in tightly enclosed containers, such as trailers, to minimize the occurrence of spontaneous combustion of the fuel.

7-3.4 Fire Protection.

7-3.4.1 Hose stations designed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, should be located throughout MSW storage (tipping building), charging floor, firing floor, hydraulic area, and residue building. Due to the high frequency of use, the following points should be considered:

(a) Location and physical protection so as to avoid potential damage due to traffic patterns.

(b) Size and number to be determined for unique plant geometry (e.g., push walls).

(c) Ease of use, maintenance, and storage, such as through the use of continuous-flow, noncollapsible hose reels.

(d) Protection from freezing in unheated areas.

NOTE: Based on plant geometry, combustible loading, and staff size, a 250-gpm (946-L/min) monitor nozzle may be needed in lieu of or in conjunction with hoses.

7-3.4.2 MSW conveyors should be protected in accordance with 5-4.6.2.

NOTE: Conveyors can be considered protected by overhead building protection if not enclosed or hooded.

7-3.4.3 Hydraulic equipment, reservoirs, coolers, and associated oil-filled equipment should be provided with automatic sprinkler or water spray protection. Sprinklers or spray nozzles should be over oil-containing equipment and for 20 ft (6.1 m) beyond in all directions. A density of 0.25 gpm/ft^2 (10.19 L/min-m^2) should be provided.

Exception: Where a listed fire-resistant fluid is used, protection is not needed.

7-3.4.4 The tipping/receiving building should be provided with automatic sprinkler protection throughout. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 130 ft^2 (120 m^2). High temperature sprinklers [250°F to 300°F (121°C to 149°C)] should be used.

NOTE: The above requirements are based on storage heights not exceeding 20 ft (6.1 m).

7-3.4.5 The MSW Storage Pit, Charging Floor, and Grapple Laydown Areas.

7-3.4.5.1 Automatic sprinkler protection should be provided throughout the refuse enclosure to protect the entire roof area against structural damage. Systems should be designed for a minimum of 0.20 gpm/ft^2 (8.15 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of pit/floor area with the protection area per sprinkler not to exceed 100 ft^2 (9.3 m^2). High temperature sprinklers [250°F to 300°F (121°C to 149°C)] should be used. Exposed steel column protection, where provided, should be designed in accordance with NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, and can be connected to the overhead sprinkler system. Due to the distance between the bottom of the refuse pit and the sprinkler system, manual hoses and monitor nozzles should be considered as the primary means of fighting a MSW storage pit fire.

7-3.4.5.2 In addition to sprinkler protection, the storage pit should be provided with monitor nozzle protection designed to furnish a minimum of 250 gpm (946 L/min) at 100 psi (689 kPa) at the tip. Monitors should be located so as to allow for coverage of all pit areas with at least two (2) streams operating simultaneously. Due to frequency of use and potential for operator fire exposure, oscillating monitor nozzles with manual override should be provided.

7-3.4.6 Particular care should be taken in the selection of fire detection devices in consideration of harsh and dusty environments and high air flows.

7-3.5 Explosion Suppression.

Mass burn facilities utilizing hammermills and flailmills for processing of oversize bulky waste should follow the recommendations of 7-4.2.3.

NOTE: Rotary shears utilizing manual or selective feeding demonstrate less of a hazard than hammermills and flailmills due to elimination of hazardous wastes by the operator during the feeding process.

7-4 Refuse Derived Fuels (RDF).

7-4.1 General.

7-4.1.1 This section (Section 7-4) identifies fire and explosion hazards that are unique to the processing of municipal solid waste (MSW) into refuse derived fuels (RDF). RDF is a boiler fuel manufactured by means of a process that includes storing, shredding, classifying, and conveying the waste to a fuel storage area. It is then conveyed to the boiler through a metering device.

7-4.1.2 The major fire and explosion hazards associated with RDF fired units are:

(a) Sourcing, receipt, handling, and storage of large quantities of MSW.

(b) Unsuitable waste entering the processing stream. Examples include certain hydrocarbons, flammable liquids, metal dusts, acetelyne, explosives, etc. In the event of unsuitable material entering the processing stream, severe explosion and fire could result in the shredders or flailmills.

(c) Handling and storage of large quantities of RDF.

(d) Hydraulic and lubricating oils associated with the processing equipment.

(e) Improperly maintained electrical equipment.

(f) Large amounts of MSW and RDF accumulating in unsuitable areas as a result of spillage, handling, or processing.

(g) Inadequate dust control.

7-4.2 Plant Arrangement.

7-4.2.1 Fire areas should be separated from each other by approved means. In addition to the applicable requirements of 3-1.1.2 and 3-1.1.3, it is recommended that, as a minimum, fire area boundaries be provided to separate:

(a) the tipping floor (including the MSW storage);

(b) the processing area;

(c) RDF storage.

7-4.2.2 Specific MSW and RDF hot-load unloading areas should be designated and separated from other areas (preferably outdoors) so that loads containing smoldering or other suspect constituents can be segregated. Such areas should be properly monitored and equipped to promptly extinguish incipient fires before recombining with other MSW and RDF.

7-4.2.3 There is a potential fire and explosion hazard with the use of hammermills and flailmills and associated dust collection equipment. During the size-reduction process flammable or explosive materials in the waste stream may be ignited.

7-4.2.3.1 The primary shredder and associated dust collectors should be located within an enclosure of damage-limiting construction. It is preferable that the enclosure be detached from the main building. Other alternatives included are locations:

(a) outside of, but sharing a common wall with the main building;

(b) inside of the main building, along an outside wall;

(c) within the main building.

CAUTION: In view of the difficulties in preventing and controlling all types of shredder explosions, it is important to isolate the shredder and surrounding enclosure from vulnerable equipment and occupied areas in the plant. Consideration should be given to the protection of operating personnel or visitors from the potential blast zone.

7-4.2.3.2 Secondary shredders do not exhibit as significant a fire and explosion potential as primary shredders. Where specific designs do not eliminate the potential for explosions in the secondary shredder, refer to 7-4.2.3.1.

7-4.2.3.3 Shredders, shredder enclosures, and openings into the enclosure should be designed so that, by a combination of venting and wall strength, they will resist a postulated worst credible case explosion. Consideration should be given to a substantial increase in explosive pressure as a result of venting of shredders into a combustible vapor-air mixture within the enclosure. It is recommended that designers seek guidance from those having specialized experience in the analysis of such hazards, including specifying and constructing of explosion venting and shredder enclosures.

NOTE: An example of the postulated worst credible case explosion might be an acetylene tank. Explosions involving detonable material are beyond the scope of this document.

7-4.2.3.4 Platforms at intermediate elevations should be of open grating to reduce obstructions to the effective vent area.

7-4.2.3.5 Electrical equipment located inside the shredder enclosure should be rated for use in both hazardous vapor and dust atmospheres in accordance with Articles 500 and 501 of NFPA 70, *National Electrical Code*.

7-4.2.3.6 Service panels or controls for the shredder should be located so as not to expose operating personnel to the blast zone.

7-4.2.3.7 Explosion venting should be sized using the hydrogen nomographs as described in NFPA 68, *Guide for Venting of Deflagrations*. Where ducts are used to vent explosions to the outside, consideration should also be given to increased pressure caused by the length of the vent duct. If the vent area available is inadequate for sufficient explosion venting because of the height of the vent stack or other factors, an explosion suppression system in the shredder should be used to augment the venting arrangement. Refer to 7-4.5.

7-4.2.3.8 Where access door assemblies are provided for primary shredder enclosure, they should be kept secured to prevent unauthorized access when the equipment is operating. The access door assemblies should have the same pressure rating as the enclosure.

7-4.2.4 Boiler Feed Equipment.

7-4.2.4.1 Boiler feed equipment, such as a metering bin, should be of noncombustible material and designed to minimize pockets or corners that could cause combustible material to build up. Video monitoring should be considered for locations not readily visible to plant staff. For further guidance, see NFPA 8505, *Recommended Practice for Stoker Operation*.

7-4.2.4.2 Access hatches should be provided to allow operating personnel to break up accumulations of combustible material or plug gauges. In addition, the hatches should be placed so that the stream from a fire hose can be directed onto a fire that may occur inside the equipment.

NOTE: For personnel safety considerations, see NFPA 8505, *Recommended Practice for Stoker Operation*, for further guidance.

7-4.2.5 Smoke or heat vents should be considered in accordance with 3-4.1.

7-4.3 Prevention of Fires and Explosions in RDF Units.

7-4.3.1 A communication system should be provided between the floor manager and the control room to expedite assistance in the event of fire.

7-4.3.2 The floor operators should ensure that MSW is continuously moved to the processing or storage areas. Vehicles loaded with MSW or RDF should not be parked in the building during idle periods.

7-4.3.3 A regular program of housekeeping should be established to keep concentrations of combustible material to a minimum.

7-4.3.4 The process should be designed to minimize the production of dust. Dust collected in a dust collection system, baghouse, or cyclone should be discharged downstream of the collection system, back to the conveying system, or back to the residue or waste stream. For additional guidance, see 5-4.3.4.

7-4.3.5 Operational experience has demonstrated that roving operators and other plant personnel have been key factors in detection of fires and unsafe conditions. It is important that they be properly trained to observe and react to incipient fire situations. These should be reported to the control room operator for evaluation to determine what action is to be taken.

NOTE: The traffic pattern should minimize any requirement for storage of the MSW or RDF in tightly enclosed containers, such as trailers, to minimize the occurrence of spontaneous combustion of the fuel.

7-4.4 Fire Protection.

7-4.4.1 Hose stations designed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, should be located throughout MSW storage (tipping building), processing structures, and RDF storage structures. Due to the high frequency of use, the following points should be considered:

(a) Location and physical protection so as to avoid potential damage due to traffic patterns.

(b) Size and number to be determined for unique plant geometry (e.g., push walls).

(c) Ease of use, maintenance, and storage, such as through the use of continuous-flow, noncollapsible hose reels.

(d) Protection from freezing in unheated areas.

NOTE: Based on plant geometry, combustible loading, and staff size, a 250-gpm (946 L/min) monitor nozzle may be needed in lieu of or in conjunction with hoses.

7-4.4.2 Based on the combustible loading, location, and essential use, an automatic sprinkler system should be considered for dust collectors, baghouses, and cyclone type separators. See 5-4.6.5.

7-4.4.3 MSW and RDF conveyors should be protected in accordance with 5-4.6.2.

NOTE: Experience has shown that shredder discharge conveyors are particularly susceptible to high fire frequencies. Consideration should be given to the use of water spray systems in conjunction with spark detection in these cases. Conveyors other than shredder discharge can be considered protected by overhead building protection, if not enclosed or hooded.

7-4.4.4 Interlocks. The actuation of a fire suppression system should cause equipment it protects to shut down. With the shutdown of the equipment, the upstream feed conveyors should also shut down to stop feeding combustible material to the fire, while downstream conveyors should be stopped to prevent the spread of the fire. A manual override should be provided.

NOTE: Where a facility has a rigidly enforced operating sequence and satisfies itself and the authority having jurisdiction that the operating practices and the judgment of the plant operators provide acceptable protection, this interlock with the fire protection system may be permitted to be provided through operator action in accordance with operating procedures.

7-4.4.5 Classifiers/trommels, such as rotating screens, should be provided with water spray protection to prevent fire from propagating downstream through the screen. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) of the entire screen area with nozzles no more than 10 ft (3.0 m) on center. Consideration should be given to avoiding physical damage from mobile equipment operation in the area and from the material being processed.

7-4.4.6 Hydraulic equipment, reservoirs, coolers, and associated oil-filled equipment should be provided with automatic sprinkler or water spray protection. Sprinklers or spray nozzles should be over oil-containing equipment and for 20 ft (6.1 m) beyond in all directions. A density of 0.25 gpm/ft^2 (10.19 L/min-m^2) should be provided.

Exception: Where a listed fire-resistant fluid is used, protection is not needed.

7-4.4.7 The tipping/receiving building should be provided with automatic sprinkler protection throughout. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 130 ft^2 (12.0 m^2). High temperature sprinklers [250°F to 300°F (121°C to 149°C)] should be used.

NOTE: The above requirements are based on storage heights not exceeding 20 ft (6.1 m).

7-4.4.8 The processing building should be provided with automatic sprinkler protection throughout. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 130 ft^2 (12.0 m^2).

NOTE: Due to the large quantity of platforms, equipment, and walkways, care should be taken to include coverage under all obstructions greater than 4 ft (1.2 m) wide.

7-4.4.9 The RDF storage building should be provided with automatic sprinkler protection throughout. Systems should be designed for a minimum of 0.35 gpm/ft^2 (14.26 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 100 ft^2 (9.3 m^2). High temperature sprinklers [250°F to 300°F (121°C to 149°C)] should be used. Storage heights in excess of 20 ft (6.1 m) will require higher design densities.

7-4.4.10 The RDF boiler feed system area, including bins, hoppers, chutes, conveyors, etc., should be considered for automatic sprinkler protection. Where provided, the systems should be designed for a minimum of 0.20 gpm/ft^2 (8.15 L/min-m^2) over the most remote 2000 ft^2 (185.8 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 130 ft^2 (12.0 m^2). Internal, as well as external, protection also should be considered depending upon specific equipment design, ceiling heights, and accessibility for manual fire fighting.

7-4.4.11 Shredder enclosures should be provided with automatic sprinkler or water spray protection. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 100 ft^2 (9.3 m^2). Water spray protection should also be provided within the shredder housings at intake and discharge chutes and within vent shafts.

7-4.4.12 The environment should be considered in selecting detection devices. Heat detection is most reliable under conditions encountered in process areas. Smoke detection should not be used in process areas. If flame detectors are used, an air sweep of the lens should be provided.

7-4.5 Explosion Suppression.

7-4.5.1 Explosion suppression systems should be considered for protection of shredders. If such systems are selected, they should be designed and installed by qualified individuals using listed components. See NFPA 69, *Standard on Explosion Prevention Systems*, for further guidance.

7-4.5.2 Explosion suppression system detectors and agent distribution should cover the entire shredder volume and all contiguous areas, including inlet and discharge conveyors, reject chutes, and dust collection systems.

7-4.5.3 Mountings for explosion suppression system detectors and extinguishers should be cleaned frequently to ensure successful operation. Mountings, which include provisions for air purges, pneumatic rodding, and manual cleanout, have been found to be effective.

7-5 Biomass Fuels.

7-5.1 General.

7-5.1.1 This section (Section 7-5) identifies fire and explosion hazards that are unique to the processing of forest and agricultural by-products (e.g., woodchips, rice hulls, sugar cane, etc.) into boiler fuel manufactured by means of a process that can include, but is not limited to, storing, shredding, classifying, and conveying the biomass to a fuel storage area and conveying it from the storage area to feed the boiler through a metering device. In general, biomass fuels are such that fires of low to moderate intensity would be expected. There can be cases, however, where fuel type and processing will present a greater fire hazard and so require a higher level of protection.

7-5.1.2 The major fire and explosion hazards associated with biomass fired units are:

(a) Sourcing, receipt, handling, and storage of large quantities of biomass.

(b) Unsuitable biomass (e.g., herbicides, explosives, flammable liquids, tramp metal) entering the processing stream.

(c) Hydraulic and lubricating oils associated with the processing equipment.

(d) Improperly maintained electrical equipment.

(e) Large amounts of biomass accumulating in unsuitable areas as a result of spillage, handling, or processing.

(f) Inadequate dust control.

7-5.2 Plant Arrangement.

7-5.2.1 The initial biomass receiving and storage area, whether indoors or outdoors, should be designed in accordance with:

(a) NFPA 46, *Recommended Safe Practice for Storage of Forest Products*

(b) NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Products Facilities*

(c) NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*

(d) NFPA 231, *Standard for General Storage*, Appendix C

(e) NFPA 299, *Standard for Protection of Life and Property from Wildfire*

(f) NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*.

7-5.2.2 Specific biomass unloading areas should be designated and separated from other areas (preferably outdoors) so that loads containing smoldering or other suspect constituents can be segregated. Such areas should be properly staffed and equipped to promptly extinguish incipient fires before recombining with other biomass.

7-5.2.3 Where process or handling equipment involves biomass materials with particle size less than 80 mesh and with moisture content less than 30 percent by volume, a potential explosion hazard exists. Refer to NFPA 68, *Guide for Venting of Deflagrations*; NFPA 69, *Standard on Explosion Prevention Systems*; and NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*, for further guidance.

7-5.2.4 Fire areas should be separated from each other by approved fire barriers, spatial separation, or other approved means. In addition to the requirements of 3-1.1.3, it is recommended that, as a minimum, fire area boundaries be provided to separate:

(a) the receiving/storage area; and

(b) the processing area.

7-5.2.5 Boiler feed equipment, such as a metering bin, should be of noncombustible material and designed to minimize pockets or corners that could cause combustible material to build up. Video monitoring should be considered for locations not readily visible to plant staff. Refer to NFPA 8501, *Standard for Single Burner Boiler Operation*; NFPA 8502, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burners*; NFPA 8503, *Standard for Pulverized Fuel Systems*; NFPA 8504, *Standard on Atmospheric Fluidized-Bed Boiler Operation*; and NFPA 8505, *Recommended Practice for Stoker Operation*.

7-5.2.6 Where access hatches are provided, they should allow operating personnel to break up accumulations of combustible material or plug gauges. In addition, the hatches should be placed so that the stream from a fire hose can be directed onto a fire that may occur inside the equipment.

NOTE: For personnel safety considerations, see NFPA 8505, *Recommended Practice for Stoker Operation*, for further guidance.

7-5.2.7 Smoke or heat vents should be considered in accordance with 3-4.1.

7-5.2.8 For biomass facilities utilizing processes described in 7-5.2.4, refer to 7-3.2.3.

7-5.3 Prevention of Fires and Explosions in Biomass Units.

7-5.3.1 Outdoor Storage. For the prevention of fires with outdoor storage of biomass, see NFPA 46, *Recommended Safe Practice for Storage of Forest Products*.

7-5.3.2 Indoor Storage.

7-5.3.2.1 A communication system should be provided between facility personnel and the control room to expedite assistance in the event of fire.

7-5.3.2.2 For biomass materials subject to spontaneous ignition, the piles should be rotated on a regular basis.

7-5.3.2.3 Vehicles loaded with biomass should not be parked in the building or storage areas.

7-5.3.2.4 A regular program of housekeeping should be established to keep concentrations of combustible material to a minimum.

7-5.3.2.5 Operational experience has demonstrated that roving operators and other plant personnel have been key factors in detection of fires and unsafe conditions. It is important that they be properly trained to observe and react to incipient fire situations. These should be reported to the control room operator for evaluation to determine what action is to be taken.

7-5.3.2.6 The process should be designed to minimize the production of dust. Dust collected in a dust collection system, baghouse, or cyclone should be discharged downstream of the collection system, back to the conveying system, or back to the residue or waste stream. For additional guidance, see 5-4.3.4.

7-5.4 Fire Protection.

7-5.4.1 For the fire protection of outdoor biomass material, see NFPA 46, *Recommended Safe Practice for Storage of Forest Products*.

7-5.4.2 Hose stations designed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, should be located throughout the biomass storage, handling, and processing buildings. The following points should be considered:

(a) Location and physical protection so as to avoid potential damage due to traffic patterns.

(b) Size and number to be determined for unique plant geometry (e.g., push walls).

(c) Ease of use, maintenance, and storage, such as through the use of continuous-flow, noncollapsible hose reels.

(d) Protection from freezing in unheated areas.

NOTE: Based on plant geometry, combustible loading, and staff size, a 250-gpm (946 L/min) monitor nozzle may be needed in lieu of or in conjunction with hoses.

7-5.4.3 For biomass handling structures and conveyors, refer to 5-4.6.

NOTE: Conveyors can be considered protected by overhead sprinklers if not enclosed or hooded.

7-5.4.4 Biomass storage buildings should be provided with automatic sprinklers throughout. Systems should be designed for a minimum of 0.25 gpm/ft^2 (10.19 L/min-m^2) over the most remote 3000 ft^2 (279 m^2) (increase by 30 percent for dry pipe systems) of floor area with the protection area per sprinkler not to exceed 130 ft^2 (12.0 m^2).

NOTE: Biomass fuels exhibit a wide range of burning characteristics and upon evaluation can require increased levels of protection.

7-5.4.5 Based on the combustible loading, location, and essential use, an automatic sprinkler system should be considered for dust collectors, baghouses, and cyclone type separators. See 5-4.6.5.

7-5.4.6 Hydraulic equipment, reservoirs, coolers, and associated oil-filled equipment should be provided with automatic sprinkler or water spray protection. Sprinklers or spray nozzles should be over oil-containing equipment and for 20 ft (6.1 m) beyond in all directions. A density of 0.25 gpm/ft^2 (10.19 L/min-m^2) should be provided.

Exception: Where a listed fire-resistant fluid is used, protection is not needed.

7-5.5 Explosion Protection.

Biomass units utilizing equipment capable of producing explosive concentrations of gases or dusts as described in 7-5.2.3 should be provided with explosion venting or explosion suppression systems. For further guidance, see NFPA 68, *Guide for Venting of Deflagrations*, NFPA 69, *Standard on Explosion Prevention Systems*, and NFPA 664, *Standard for the Prevention of Fires and Explosions in Wood Processing and Woodworking Facilities*.

7-6 Rubber Tires.

7-6.1 General.

7-6.1.1 This section (Section 7-6) identifies fire and explosion hazards that are unique to the processing of rubber tires as a primary or secondary boiler fuel by means of a process that can include, but is not limited to, storing, shredding, and conveying the rubber tires to a fuel storage area (and conveying it from the storage area to fuel the boiler).

NOTE: In general, rubber tires have a Btu content of 15,000 Btu/lb; roughly two to three times that of wood or RDF.

7-6.1.2 There are several inherent fire hazards associated with scrap tires, whether outside or inside a building. Once tires are ignited, the fire develops rapidly, and it is difficult to extinguish. The tires will generate a large amount of black smoke. In addition, as the tires burn they generate oil that can spread and increase the size of the fire.

7-6.1.3 Hazards Associated with Scrap Rubber Tires. The major fire and explosion hazards associated with scrap rubber tire units are:

(a) Storage of large quantities of tires, whether inside or outside;

(b) Fast developing and rapidly spreading fire that burns for an extended period of time;

(c) Hampering of fire fighting due to the generation of large amounts of black smoke and water pollution from runoff;

(d) Unsuitable material entering the processing stream;

(e) Large amounts of scrap tires accumulating in unsuitable areas as a result of spillage, handling, and processing;

(f) Inadequate dust control.

7-6.2 Plant Arrangement.

7-6.2.1 The initial receiving and storage areas should be located outdoors. The area should be secured and cleared of all vegetation within 100 ft (30.5 m) of tire storage. See Appendix C of NFPA 231D, *Standard for Storage of Rubber Tires*, for further guidance on pile size, separation, and access.

7-6.2.2 The boiler feed equipment, such as a metering bin, should be of noncombustible material and designed to minimize pockets or corners that would cause combustible material to build up. Video monitoring should be considered for locations not readily visible to plant staff. Refer to NFPA 8501, *Standard for Single Burner Boiler Operation*; NFPA 8502, *Standard for the Prevention of Furnace Explosions/Implosions in Multiple Burner Boilers*; NFPA 8503, *Standard for Pulverized Fuel Systems*; NFPA 8504, *Standard on Atmospheric Fluidized-Bed Boiler Operation*; and NFPA 8505, *Recommended Practice for Stoker Operation*.

7-6.2.3* Where overhead cranes are used to load inside feed hoppers from inside the storage pits, the following should be considered:

(a) Locating the pulpit so that operator safety is not compromised.

(b) The ability to have a clear and unobstructed view of all storage and charging areas.

7-6.2.4 For tire plant processes that generate dust explosion potential, refer to NFPA 68, *Guide for Venting of Deflagrations*, NFPA 69, *Standard on Explosion Prevention Systems*, and individuals having specialized experience.

7-6.2.5 Smoke or heat vents should be considered in accordance with 3-4.1.

7-6.3 Prevention of Fires and Explosions in Scrap Rubber Tires.

7-6.3.1 A communication system should be provided between facility personnel and the control room to expedite assistance in the event of fire.

7-6.3.2 The facility personnel should ensure that scrap tires are continuously moved to the processing or storage areas. Vehicles loaded with scrap tires should not be parked in the building during idle periods.

7-6.3.3* A regular program of housekeeping should be established to keep concentrations of combustible material to a minimum.

7-6.3.4 The process should be designed to minimize the production of dust. Dust collected in a dust collection system, baghouse, or cyclone should be discharged downstream of the collection system, back to the conveying system, or back to the residue or waste stream. For additional guidance, see 5-4.3.4.

7-6.4 Fire Protection.

7-6.4.1 For the water supply and fire protection requirements of outdoor storage of scrap rubber tires, see Appendix C of NFPA 231D, *Standard for Storage of Rubber Tires.*

7-6.4.2 Hose stations designed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, should be located throughout the facility. The following points should be considered:

(a) Location and physical protection so as to avoid potential damage due to traffic patterns;

(b) Size and number to be determined for unique plant geometry (e.g., push walls);

(c) Protection from freezing in unheated areas;

NOTE 1: Hose stations are considered essential for final fire control and extinguishment. Addition of foam to hose streams should be considered.

NOTE 2: Plant geometry, combustible loading, and staffing may indicate that the use of 250 gpm monitor nozzles, in lieu of or in conjunction with hoses is acceptable.

7-6.4.3 Based upon the combustible loading, location, and essential use, an automatic sprinkler system should be considered for dust collectors, baghouses, and cyclone type separators. (*See 5-4.6.5*.)

7-6.4.4 For scrap rubber tire handling structures and conveyors, refer to 5-4.6.

NOTE: Experience indicates that sprinkler systems may not be effective and that foam-water spray systems are preferred for fire control. These systems are intended to confine the fire, and manual fire fighting may be required. Guidance should be sought from individuals having specialized experience for the selection of foam and foam application devices.

7-6.4.5 The scrap rubber tire pit should be provided with foam-water spray protection throughout. The system(s) should be designed for a minimum of 0.24 gpm/ft^2 (9.77 L/min-m^2) over the entire pit area with the protection area per nozzle not to exceed 100 ft^2 (9.3 m^2).

CAUTION: Due to the extreme hazard, clearance between the top of storage and foam-water spray systems should be minimized.

7-6.4.6 In addition to the foam-water spray protection, the storage pit should be provided with monitor nozzle protection designed to furnish a minimum of 250 gpm (946 L/min) at 100 psi (689 kPa) at the tip. Monitors should be located so as to allow for coverage of all pit areas with at least two streams operating simultaneously. Due to the potential for operator fire exposure, oscillating monitor nozzles with manual override should be provided.

NOTE: Addition of foam to the monitor nozzles should be considered.

7-6.4.7 For protection and storage of scrap rubber tires indoors, refer to NFPA 231D, *Standard for Storage of Rubber Tires*.

7-6.4.8 The boiler's tire feed system, including bins, hoppers, and chutes, should be considered for automatic foam-water protection. Where provided, the system should be designed for a minimum of 0.30 gpm/ft^2 (12.22 L/min-m^2) over the most remote 2500 ft^2 (232 m^2).

7-6.4.9 All water spray systems should be capable of remote actuation from the control room or other constantly attended areas. Additionally, local actuation stations should be placed adjacent to the fire areas along lines of egress and in consideration of operator safety and protection from damage due to equipment.

7-6.4.10 Hydraulic equipment, reservoirs, coolers, and associated oil-filled equipment should be provided with automatic sprinkler or water spray protection. Sprinklers or spray nozzles should be over oil-containing equipment and for 20 ft (6.1 m) beyond in all directions. A density of 0.25 gpm/ft^2 (10.19 L/min-m^2) should be provided.

Exception: Where a listed fire-resistant fluid is used, protection is not needed.

7-6.4.11 Particular care should be taken in the selection of detection devices in consideration of harsh and dusty environments and high air flows.

7-6.5 Explosion Protection.

Scrap rubber tire units utilizing equipment capable of producing explosive concentrations of gases or dusts should be provided with explosion venting or explosion suppression systems. For further guidance, see NFPA 68, *Guide for Venting of Deflagrations*, and NFPA 69, *Standard on Explosion Prevention Systems*.

7-7 Other Alternative Fuels and Processes.

Other alternative fuels (e.g., culm, peat, gob, etc.) are used as boiler fuels. Also, other technologies exist for the utilization and processing of alternative fuels as boiler fuels. It is recommended that designers seek guidance from those having specialized experience to understand the unique characteristics of any particular fuel or technology in order to properly apply the appropriate portions of this and other applicable documents.

Chapter 8 High Voltage Direct Current (HVDC) Converter Stations

8-1 General.

This chapter identifies the fire hazards of high voltage direct current (HVDC) converter stations and specifies recommended protection criteria.

8-2 Application of

Chapters 2 through 5 and Chapter 9. The recommendations contained in Chapters 2 through 5 and Chapter 9 may apply to high voltage direct current converter stations. It is incumbent upon the Fire Risk Evaluation to determine which recommendations apply to any specific HVDC converter station. This is done by evaluating the specific hazards that exist in the facility and determining the level of acceptable risk for the facility. It is expected that most of the recommendations will apply to all HVDC converter stations.

8-3 HVDC Converter Stations.

8-3.1 General.

8-3.1.1 This section (Section 8-3) identifies fire hazards that are associated with the operation of high voltage direct current converter stations. Conditions that could cause a fire in high voltage converter equipment include:

(a) loose electrical connections;

(b) electrical insulation or resistance breakdowns;

(c) overheated components;

(d) water leakage or intrusion (cooling system malfunction, roof leak, etc.); or

(e) foreign objects (tools, metal scrap, rubbish, vermin, etc.).

8-3.1.2 The hazards that could present a fire risk at a HVDC converter station include:

(a) Converter valve assemblies;

(b) Converter transformers;

(c) Oil-filled wall bushings;

(d) Capacitors containing combustible dielectric fluid or polymers; or

(e) Station services and auxiliary high voltage equipment.

8-3.2 Plant Arrangement.

8-3.2.1 Each thyristor valve hall should be established as a separate fire area. Each valve hall should be separated from adjacent fire areas by fire area boundaries in accordance with 3-1.1.3. Unless consideration of the factors of 3-1.1.2 indicates otherwise, it is recommended that fire area boundaries be provided to separate the following:

(a) service building;

(b) main control room;

(c) valve electronics rooms;

(d) HVAC equipment rooms; and

(e) relay room, SCADA room, and remote terminal unit room (RTU).

NOTE: If the Relay, SCADA, or RTU equipment is located in the main control room, fire partition barriers are not required for this equipment.

8-3.2.2 Converter valves and associated support equipment should use noncombustible or limited combustible materials. Where noncombustible or limited combustible materials are not used, fire-retardant separation barriers should be installed between the following equipment areas:

(a) valve tier levels, by adding to the bottom tray on each level;

(b) valve modules, by adding to the side of each tray section; and

(c) grading capacitors, snubber circuits, and power supplies.

8-3.2.3 Smoke or heat vents should be considered in accordance with 3-4.1.

8-3.2.4 Heating, ventilating, and air-conditioning (HVAC) systems for the valve hall should be provided with fire/smoke dampers arranged to shut down to preclude the entry of smoke from sources outside of the valve hall structure. A separate dedicated HVAC system should serve each valve hall.

8-3.2.5 Outdoor converter transformers and oil-filled smoothing reactor(s) should be arranged in accordance with 3-1.3 and 3-5.6.

8-3.2.6 Drainage provisions should be provided for indoor and outdoor oil-filled wall bushings. Drainage should be arranged in accordance with Section 3-5. Indoor oil-filled wall bushings should be provided with means to prevent the spread of oil to adjacent equipment. Where the converter bushings penetrate the valve hall, provisions should be made to prevent the oil contents of the transformer from entering the valve hall.

8-3.2.7 Mercury arc converters should be arranged to minimize the effects of a hazardous material spill or airborne contamination from mercury that could impede fire fighting efforts and restoration activities.

8-3.3 Fire Prevention.

8-3.3.1 An emergency communication system should be provided throughout the station to expedite assistance in the event of fire.

8-3.3.2 A fire emergency plan should be implemented in accordance with Section 2-7.

8-3.3.3 A regular housekeeping program should be established to maintain combustible and other materials in designated storage areas. Periodic cleaning of the valve and the valve hall structure should be performed in accordance with the manufacturer's instructions for maintaining a clean equipment and building environment.

8-3.3.4 Operational experience has demonstrated that operators and other plant personnel have been key factors in the detection of fires and unsafe conditions. It is important that all personnel be properly trained to observe and react appropriately to any potential fire situation.

NOTE: Control room operator fire emergency training should include, but not be limited to, the following:

(a) station emergency grounding procedures;

(b) valve hall clearance procedures;

(c) electrical equipment isolation; and

(d) timely communication of all fire events to the responding fire brigade and the fire department.

8-3.4 Fire Protection.

8-3.4.1 Hose stations designed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, should be located throughout the converter station.

8-3.4.2 Oil-filled wall bushings should be protected with automatic fire suppression system(s). The fire suppression system design should ensure that the fire suppression agent does not affect the converter valve, the arrestors, or other energized electrical equipment.

8-3.4.3 Auxiliary equipment areas and other structures should be protected with automatic protection systems in accordance with Sections 5-8 and 5-9. Converter transformers should be protected in accordance with 5-8.7.

8-3.4.4 The valve hall should be provided with an early warning multi-stage fire detection air sampling system capable of detecting an incipient fire such as an overheated component. Consideration should also be given to providing a second reliable fire detection system such as ionization, photo-electric, projected beam, optical devices, or video cameras. The interlock of a multi-stage smoke sampling system or the redundant fire detection system should be considered to initiate a fast-switch-off or emergency-switch-off of the respective valve group.

8-3.4.5 For the protection of the converter equipment and the building, water-based or gaseous agent suppression systems should be considered. The type and design of the suppression systems should be reviewed in consultation with the valve manufacturer.

8-3.4.6 To mitigate the effects of electrical shock and thermal impact involving the converter equipment, manual fire-fighting equipment utilization and deployment training should be provided for the fire brigade and responding fire department personnel.

Chapter 9 Fire Protection for the Construction Site

9-1 Introduction.

9-1.1

Although many of the activities on electric generating plant and HVDC converter station construction sites are similar to the construction of other large industrial plants, an above average level of fire protection is justified due to life safety consideration of the large number of on-site personnel, high value of materials, and length of the construction period. Consideration of fire protection should include safety to life, potential for delays in construction schedules and plant startup, as well as protection of property.

9-1.2

Major construction projects in existing plants present many of the hazards associated with new construction while presenting additional exposures to the existing facility. The availability of the existing plant fire protection equipment and the reduction of fire exposure by construction activities are particularly important.

9-1.3

For fire protection for plants and areas under construction, see NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations.* This chapter addresses concerns not specifically considered in NFPA 241.

9-2 Administration.

9-2.1

The responsibility for fire prevention and fire protection for the entire site during the construction period should be clearly defined. The administrative responsibilities should be to develop, implement, and periodically update as necessary the measures outlined in this recommended practice.

9-2.2

The responsibility for fire prevention and fire protection programs among various parties on site should be clearly delineated. The fire protection program that is to be followed and the owner's right to administration and enforcement should be established.

9-2.3

The fire prevention and fire protection program should include a Fire Risk Evaluation of the construction site and construction activities at any construction camp. (*See Chapter 2.*)

9-2.4

Written procedures should be established for the new construction site, including major construction projects in existing plants. Such procedures should be in accordance with Sections 2-4, 2-5, 2-6, 2-7, and 2-8.

9-2.5

Security guard service, including recorded rounds, should be provided through all areas of construction during times when construction activity is not in progress. (*See NFPA 601, Standard for Security Services in Fire Loss Prevention.*)

(a) The first round should be conducted one-half hour after the suspension of work for the day. Thereafter, rounds should be made every hour.

(b) Where partial construction activities occur on second and third shifts, the guard service rounds may be permitted to be modified to include only unattended or sparsely attended areas.

(c) In areas where automatic fire detection or extinguishing systems are in service, with alarm annunciation at a constantly attended location, or in areas of limited combustible loading, rounds may be permitted to be omitted after the first round indicated in (a) above.

9-2.6

Construction schedules should be coordinated so that planned permanent fire protection systems are installed and placed in service as soon as possible, at least prior to the introduction of any major fire hazards identified in Chapter 5.

9-2.7

In-service fire detection and fire extinguishing systems provide important protection for construction materials, storage, etc., even before the permanent hazard is present. Temporary fire protection systems may be warranted during certain construction phases. The need and type of protection should be determined by the individual responsible for fire prevention and fire protection.

9-2.8

Construction and installation of fire barriers and fire doors should be given priority in the construction schedule.

9-3 Site Clearing and Construction Equipment.

9-3.1 Site Clearing.

9-3.1.1 Prior to clearing forest and brush covered areas, the owner should ensure that a written fire control plan is prepared and that fire-fighting tools and equipment are made available as recommended by NFPA 295, *Standard for Wildfire Control*. Contact should be made with local fire and forest agencies for current data on restrictions and fire potential, and to arrange for necessary permits.

9-3.1.2 All construction vehicles and engine-driven portable equipment should be equipped with effective spark arrestors. Vehicles equipped with catalytic converters should be prohibited from wooded and heavily vegetated areas.

9-3.1.3 Fire tools and equipment should be used for fire emergencies only and should be distinctly marked.

9-3.1.4 Each site utility vehicle should be equipped with at least one fire-fighting tool, portable fire extinguisher, or backpack pump filled with 4 gal to 5 gal (15 L to 19 L) of water.

9-3.1.5 Cut trees, brush, and other combustible spoil should be disposed of promptly.

9-3.1.6 Where it is necessary to dispose of combustible waste by onsite burning, designated burning areas should be established with approval by the owner and should be in compliance with federal, state, and local regulations and guidelines. The contractor should coordinate burning with the agencies responsible for monitoring fire danger in the area and obtain all appropriate permits prior to the start of work. (*See Section 9-2.*)

9-3.1.7 Local conditions may require the establishment of fire breaks by clearing or use of selective herbicides in areas adjacent to property lines and access roads.

9-3.2 Construction Equipment.

Construction equipment should meet the requirements of NFPA 512, *Standard for Truck Fire Protection*.

9-4 Construction Warehouses, Shops, and Offices.

9-4.1

All structures that are to be retained as part of the completed plant should be constructed of materials as indicated in Chapter 3 and should be in accordance with other recommendations for the completed plant.

9-4.2

Construction warehouses, offices, trailers, sheds, and other facilities for the storage of tools and materials should be located with consideration of their exposure to major plant buildings or other important structures. (*For guidance in separation and protection, see NFPA 80A, Recommended Practice for Protection of Buildings from Exterior Fire Exposures*.)

9-4.3

Large central office facilities may be of substantial value and contain high value computer equipment, irreplaceable construction records, or other valuable contents, the loss of which may result in significant construction delays. An analysis of fire potential should be performed. This analysis may indicate a need for automatic sprinkler systems or other protection or the desirability of subdividing the complex to limit values exposed by one fire.

9-4.4

Warehouses that contain high value equipment (as defined by the individual responsible for fire prevention and fire protection), or where the loss of or damage to contents would cause a delay in startup dates of the completed plant, should be arranged and protected as indicated below. Although some of these structures are considered to be “temporary” and will be removed upon completion of the plant, the fire and loss potential should be thoroughly evaluated and protection provided where warranted.

9-4.4.1 Building construction materials should be noncombustible or limited combustible. (*See Chapter 3.*)

9-4.4.2 Automatic sprinkler systems should be designed and installed in accordance with the applicable NFPA standards. Waterflow alarms should be provided and located so as to be monitored at a constantly attended location as determined by the individual responsible for fire prevention and fire protection.

9-4.4.3 Air-supported structures sometimes are used to provide temporary warehousing space. Although the fabric envelope may be a fire-retardant material, the combustibility of contents and the values should be considered, as with any other type of warehouse. Because it is impractical to provide automatic sprinkler protection for them, air-supported structures should be used only for noncombustible storage. An additional factor to consider is that relatively minor fire damage to the fabric envelope may leave the contents exposed to the elements.

9-4.5

Temporary enclosures, including trailers, inside permanent plant buildings should be prohibited except where permitted by the individual responsible for fire prevention and fire protection. Where the floor area of a combustible enclosure exceeds 100 ft^2 (9.29 m^2) or where the occupancy presents a fire exposure, the enclosure should be protected with an approved automatic fire extinguishing system.

9-4.6

Storage of construction materials, equipment, or supplies that are either combustible or in combustible packaging should be prohibited in main plant buildings unless:

(a) An approved automatic fire extinguishing system is in service in the storage area, or

(b) Where loss of the materials or loss to the surrounding plant area would be minimal, as determined by the individual responsible for fire prevention and fire protection.

9-4.7

Construction camps comprised of mobile buildings arranged with the buildings adjoining each other to form one large fire area should be avoided. If buildings cannot be adequately separated, consideration should be given to installing fire walls between units or installing automatic sprinklers throughout the buildings.

9-4.8

Fire alarms should be connected to a constantly attended central location. All premise fire alarm systems should be installed, tested, and maintained as outlined in NFPA 72, *National Fire Alarm Code.*

9-4.9

The handling, storage, and dispensing of flammable liquids and gases should meet the requirements of NFPA 30, *Flammable and Combustible Liquids Code*; NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*; and NFPA 395, *Standard for the Storage of Flammable and Combustible Liquids at Farms and Isolated Sites*.

9-4.10

Vehicle repair facilities should meet the requirements of NFPA 88B, *Standard for Repair Garages*.

9-5 Construction Site Lay-Down Areas.

9-5.1

Fire hydrant systems with an adequate water supply should be provided in lay-down areas where the need is determined by the individual responsible for fire prevention and fire protection.

9-5.2

Combustible materials should be separated by a clear space to allow access for manual fire-fighting equipment (*see Section 9-8*). Access should be provided and maintained to all fire-fighting equipment including fire hoses, extinguishers, and hydrants.

9-6 Temporary Construction Materials.

9-6.1

Noncombustible or fire-retardant scaffolds, form work, decking, and partitions should be used both inside and outside of permanent buildings where a fire could cause substantial damage or delay construction schedules.

9-6.1.1 The use of noncombustible or fire-retardant concrete form work is especially important for large structures (e.g., turbine-generator pedestal) where large quantities of forms are used.

9-6.1.2 The use of listed pressure-impregnated fire-retardant lumber or listed fire-retardant coatings generally would be acceptable. Pressure-impregnated fire-retardant lumber should be used in accordance with its listing and manufacturer's instructions. Where exposed to the weather or moisture (e.g., concrete forms), the fire retardant used should be suitable for this exposure. Fire-retardant coatings are not acceptable on walking surfaces or surfaces subject to mechanical damage.

9-6.2

Tarpaulins and plastic films should be of listed weather-resistant and fire-retardant materials. (*See NFPA 701*, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*.)

9-7 Underground Mains, Hydrants, and Water Supplies.

9-7.1 General.

9-7.1.1 Where practical, the permanent underground yard system, fire hydrants, and water supply (at least one water source), as indicated in Chapter 4, should be installed during the early stages of construction. Where provision of all or part of the permanent underground system and water supply is not practical, temporary systems should be provided. Temporary water supplies should be hydrostatically tested, flushed, and arranged to maintain a high degree of reliability, including protection from freezing and loss of power.

9-7.1.2 The necessary reliability of construction water supplies, including redundant pumps, arrangement of power supplies, and use of combination service water and construction fire protection water, should be determined by the individual responsible for fire prevention and fire protection.

9-7.2

Hydrants should be installed, as indicated in Chapter 4, in the vicinity of main plant buildings, important warehouses, office or storage trailer complexes, and important outside structures with combustible construction or combustible concrete form work (e.g., cooling towers). Where practical, the underground main should be arranged to minimize the possibility that any one break will remove from service any fixed water extinguishing system or leave any area without accessible hydrant protection.

9-7.3

A fire protection water supply should be provided on the construction site and should be capable of furnishing the largest of the following for a minimum 2-hour duration:

(a) 750 gpm (47.3 L/sec), or

(b) The in-service fixed water extinguishing system with the highest water demand and 500 gpm (31.5 L/sec) for hose streams.

9-7.3.1 The highest water demand should be determined by the hazards present at the stage of construction, which might not correspond with the highest water demand of the completed plant.

9-7.3.2 As fixed water extinguishing systems are completed, they should be placed in service, even when the available construction phase fire protection water supply is not adequate to meet the system design demand. The extinguishing system will at least provide some degree of protection, especially where the full hazard is not yet present. However, when the permanent hazard is introduced, the water supply should be capable of providing the designed system demand. When using construction water in permanent systems, adequate strainers should be provided to prevent clogging of the system by foreign objects and dirt.

9-7.3.3 The water supply should be sufficient to provide adequate pressure for hose connections at the highest elevation.

9-8 Manual Fire Fighting Equipment.

9-8.1

First aid fire-fighting equipment should be provided, in accordance with NFPA 600, *Standard on Industrial Fire Brigades* and NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

NOTE: Mobile fire-fighting equipment can be utilized to provide necessary first aid fire-fighting equipment.

9-8.2

Portable fire extinguishers of suitable capacity should be provided in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*, where:

(a) Flammable liquids are stored or handled,

(b) Combustible materials are stored,

(c) Temporary oil- or gas-fired equipment is used,

(d) A tar or asphalt kettle is used, or

(e) Welding or open flames are in use.

9-8.3

Hoses and nozzles should be available at strategic locations, such as inside hose cabinets or hose houses or on dedicated fire response vehicles.

9-8.4

If fire hose connections are not compatible with local fire-fighting equipment, adapters should be made available.

Chapter 10 Referenced Publications

10-1

The following documents or portions thereof are referenced within this recommended practice and should be considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-4 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-8.2

Recommendations contained in NFPA 600, *Standard on Industrial Fire Brigades,* and 29 CFR 1910, Subparts E and L should be consulted for additional information.

A-5-4.2.1 Spontaneous Heating. The chemical properties of coals that effect spontaneous combustion are oxygen content, moisture, impurities (especially sulfur in the form of pyrites), and volatiles. The physical properties are particle size and friability.

Spontaneous heating occurs due to oxidation of freshly exposed coal surfaces. For spontaneous heating to lead to ignition sufficient air must be present and in contact with fresh (unoxidized) surfaces, yet without sufficient air movement to dissipate heat generated by oxidation. The oxidation rate of coal at ambient temperatures is determined by its rank, its exposed surface area and the percentage of free oxygen in the atmosphere permeating the coal. Coal of low rank (soft coal) will have a higher oxidation rate than harder coal under the same conditions. Likewise, if coal is crushed to a finer particle size, more surface area will be exposed and the oxidation rate will increase. A reduction in free oxygen content in the atmosphere permeating the coal reduces the rate of oxidation (almost proportionately). Oxidation will continue at a reduced rate until the free oxygen is exhausted. Heat produced by spontaneous combustion will be absorbed by the coal resulting in an increase in coal temperature. Due to the chimney effect, air infiltration leakage might be expected around the discharge valve or other bottom leaks of silos and bunkers or in the top 5 ft to 6 ft (1.5 m to 1.8 m) of the coal in the bunker. Therefore “hot spots” will tend to develop in the lower and upper portions of the coal in the silo and near any seams or openings that allow air infiltration. Inerting the coal with carbon dioxide or nitrogen, and covering the top of the bunker to prevent air to cause spontaneous ignition is a common practice for forced and extended outage with coal in the bunker. As the coal temperature increases the rate of oxidation will also increase. Due to the range and number of variables it is difficult to define the time to ignition of coal in storage.

Spontaneous heating can be mitigated by minimizing wetting of the coal, the duration of storage of the coal, and air movement in the silo.

A-5-4.2.2 Silo Construction. If the plant is designed to burn a type of coal that is considered prone to spontaneous combustion or one that has a high percentage of “volatiles,” silos should be cylindrical with conical hoppers. The coal’s angle of repose should be considered when designing the internal slope of the silo and hopper so that coal will flow freely (normally 60 degrees from the horizontal will be sufficient) to avoid arching and voiding. Air cannons located at the throat of the silo can be used to ensure that coal continues to flow, however, caution is necessary to ensure that air cannons are not utilized during a fire or where low coal levels could result in suspended coal dust entering the explosive range.

Experience indicates that coal volatility content above 38 percent might be conducive to spontaneous heating. The designer might consider inerting the silo if the volatiles content of the coal exceeds 38 percent. Where the coal used has known spontaneous heating problems, special conveyors and chutes or pans can be provided to unload silos during forced outages.

A-5-4.2.3 Silo Operations and Maintenance. Where possible, coal silos should be operated at full capacity and coal should flow continuously. When silos are not operated at or near full volume spontaneous combustion may occur at an increased rate. These conditions should be monitored periodically. Daily carbon monoxide samples should be taken at the top of each silo to establish a benchmark carbon monoxide level. Increased carbon monoxide levels can give an early indication of a hot spot or silo fire. Some experience in this area indicates that the carbon monoxide levels may rise days before fires are detected by other means. Silo should be run empty and inspected if the carbon monoxide levels exceed twice the benchmark concentration.

Dependent on bin, bunker, or silo construction, the internal space might allow the build-up of coal on its walls. Removing the coal from the bin, bunker, or silo wall can be employed to minimize the risk of spontaneous combustion of the trapped coal.

During planned maintenance outages, silos should be emptied and thoroughly cleaned of coal deposits. Operating procedures should ensure that magnetic separators are in service when coal is being conveyed into the silo to avoid introducing tramp metals. Movement of tramp metal within the silo can result in an ignition source by striking metal parts causing sparks that might ignite coal dust.

Three fires involving coal silos at one operating electric generating station occurred at or near cracks in the bottom cone of the silo. During maintenance outages the cones should be thoroughly inspected for cracks.

A long thermocouple [i.e., 10 ft (3 m)] connected to a portable instantaneous readout monitor can be employed. Pushing the thermocouple into the coal storage can detect developing hot areas or strata at different depths. Periodic monitoring of temperature change in these areas will help predict spontaneous combustion development and aid in response preplanning. Portable infrared heat detection or thermography has also proven useful in locating hot spots. Typical hot spots are easily detected when they are in the size range of 2 ft (0.6 m) in diameter. Hot spots in the center and higher up may not be found until the hot spot enters the cone area as the coal level drops.

A-5-4.2.6 Manual Fire Suppression. Fire fighting in coal silos is a long and difficult activity. Some fire-fighting operations have taken several days to completely extinguish a fire.

Smoldering coal in a coal bin, bunker, or silo is a potentially dangerous situation that depends on the location of the smoldering coal. There is a risk of a flash fire or explosion if the smoldering coal is disturbed. This risk should be considered in preplanning. Personnel responding to a coal fire should have proper personal protective equipment, including SCBA and turnout gear, and training in this hazard.

The area surrounding the smoldering coal should also be considered. The potential of developing an immediately dangerous to life and health (IDLH) atmosphere is possible. This should also be considered in preplanning.

Depending on the strategy selected, resource demands will be varied but challenging. Prefire planning is an important element in successful silo fire control and should be included in the initial plant Fire Risk Evaluation (*see Section 2-3*) and the Fire Emergency Plan (*see Section 2-7*). Control room operators should be involved with the preplanning.

Use of Class A Foams and Penetrants. Use of Class A foams and penetrants have found some success but it has been difficult to predict the resources required for successful fire control. The agents generally require mixing with water prior to application, usually in the range of 1 percent by volume, mixed in a manner similar to Class B agents. While the typical application of Class A foam is to fight wildland fires at 1 percent, many plants have reported success with using Class A foams at 0.1 percent. This causes the agent to act as a surfactant. Higher proportions have caused excessive bubble accumulation that impedes penetration into the coal.

The application of foams and penetrants can be enhanced by using an infrared camera to search for hot spots, either on the sides or top of the silo, to facilitate injection of the agent as close as possible to the fire area. The infrared imagery can be used to evaluate performance and monitor progress of the attack. The water/agent solution must penetrate to the seat of combustion to be effective. This can be affected by the degree of compaction, voids, rate of application, evaporation rate, etc. Run-off must be drained through feeder pipe and will require collection, clean-up, and disposal.

Use of Inerting Gas. Carbon dioxide and nitrogen have been used successfully as gaseous inerting agents.

Carbon dioxide vapor has proven to be an effective fire suppression agent when forced through the coal by pressure injection in the lower part of the silo. The rate of application should be sufficient to compensate for limited losses at the coal valve and for absorption by the coal.

Inerting can normally be initiated within an eight hour shift if a supply of carbon dioxide is available.

Since carbon dioxide is stored as a liquid, it must be vaporized before injection into the silo. This is accomplished using an external, in-line vaporizer sized such that the anticipated application rate can be increased if the maximum anticipated leakage rate is exceeded.

Normal inerting procedure involves starting the carbon dioxide flow at a pre-set volume from the flow control valve. The system pipe should be grounded to prevent a static spark potentially igniting a flammable vapor concentration. Initially, the carbon dioxide vapor should be injected into the space above the coal at the top of the silo to mitigate the potential of developing an explosive atmosphere. Once this inerting is established, the flow can be reduced and the primary flow directed into the bottom (while continuing trickle injection into the top) of the silo. Silo geometry is conducive to establishing a chimney affect that will prevent the carbon dioxide from settling throughout the silo. Therefore it is necessary to add injection points near the bottom.

Experience indicates that carbon dioxide inerting is considered successful when the carbon dioxide concentration reaches 65 percent. However, the logistics of injecting carbon dioxide might result in almost 100 percent saturation throughout most of the silo in order to achieve at least 65 percent concentration in all portions of the silo. Since leakage in the silo is inevitable, it will be necessary to anticipate using a large quantity of carbon dioxide. Experience at one utility suggests that it is advisable to order a quantity of carbon dioxide equivalent to about 3 times the gross volume of the silo. If liquid carbon dioxide cylinders are used, an additional quantity will be necessary since only about 70 percent of the cylinder's contents can be extracted as a vapor.

The following is an example of calculating the quantity of carbon dioxide. If a silo is 30,000 ft^3 and low pressure carbon dioxide is used:

- 30,000 $ft^3 \times 3$ (times the gross volume) = 90,000 ft^3 of carbon dioxide.
- 90,000 ft^3 of carbon dioxide / 8.3 ft^3/lb of carbon dioxide = 10,843 lb (or about 5.5 tons).

The carbon dioxide storage system should be arranged so that it can be replenished during operation in the event that the fire is embedded, which could cause extinguishment to be delayed for a matter of days.

When carbon dioxide is used, there is a risk of oxygen depletion in the area above, around, or below a silo, bin, or bunker. Areas where gas could collect and deplete oxygen should be identified with appropriate barriers and warning signs. This might include the tripper room and areas below the discharge feeder gate.

Nitrogen has been used successfully to inert silo fires. It is applied in a manner very similar to carbon dioxide. A notable difference is that nitrogen has about the same density as air (whereas carbon dioxide is significantly more dense.) Therefore it must be applied at numerous injection points around the silo to ensure that it displaces available oxygen. This results in the need for more injection equipment and a larger quantity of agent.

Emptying the Silo. The silo can be unloaded through the feeder pipe but it is a dirty, messy operation. It is necessary to bypass the feeder belt and to dump the coal onto the floor of the power house at the feeder elevation. A hose crew should be available to extinguish burning coal as it is discharged from the silo. There is a risk that dust raised during this activity can ignite explosively. High expansion foam can be applied.

Carbon monoxide produced during the combustion process will also tend to settle in the lower elevation and can be a hazard to the hose crew. Once spilled and extinguished, it is usually necessary to shovel the coal into a dump truck for transport back to the coal pile.

Manual Fire Fighting. Regardless of the type of suppression approach selected, prefire planning is an important element of successful fire control and extinguishment. All necessary resources should be identified and in place prior to beginning fire suppression activities. If necessary materials are not stockpiled onsite, suppliers should be contacted in advance to ensure that equipment and supplies are available on relatively short notice.

The personnel requirements for this fire-fighting activity should be identified in advance. Personnel should be trained and qualified for fire fighting in the hot, smoky environment that might accompany a silo fire. This includes the use of self-contained breathing apparatus and personal protective equipment. Personnel engaged in this activity should be minimally trained and equipped to the structural fire brigade level as defined in NFPA 600, *Standard on Industrial Fire Brigades*. If station personnel are not trained in use of self-contained breathing apparatus, it will be necessary for the public fire department to perform fire-fighting in these areas. Station personnel are still needed to assist with operational advice and guidance. The public fire-fighting agency that responds to a fire at the facility should be involved in preplanning fire-fighting activities for silo fires. The public fire service might need specific instruction concerning operation and potential hazards associated with coal silo fires as well as operation in the power plant environment. It is important that the responding fire service be supplied information and guidance at every opportunity.

The resources of the station and the local fire service need to work in concert, including working with control room operators and keeping them apprised of fire control operations. Preplanning should include administrative details such as chain of command, access, etc. Operations should be coordinated by an established incident command system in conformance with NFPA 1561, *Standard on Fire Department Incident Command System*. All personnel should be familiar with and practice this system prior to the event.

A-5-4.3 Coal Dust Hazards.

The hazard of any given coal dust is related to the ease of ignition and the severity of the ensuing explosion. The Bureau of Mines of the U.S. Department of Interior has developed an arbitrary scale, based on small scale tests, that is quite useful for measuring the potential explosion hazard of various coal dusts. The ignition sensitivity is a function of the ignition temperature and the minimum energy of ignition, whereas the explosivity is based on data developed at the Bureau of Mines. The test results are based on a standard Pittsburgh coal dust taken at a concentration of 0.5 ounces per cubic foot. The Explosibility Index is the product of ignition sensitivity and explosion severity. This method permits evaluation of relative hazards of various coal dusts.

When coal silos are operated with low inventory there is potential for suspended coal dust to enter the explosive range. As in spontaneous heating, the explosive range and potential for explosion are based on the above variables.

A-5-6.5 Scrubber Fire Loss Experience.

There have been at least three major fires involving scrubbers with plastic lining or plastic fill. They have the following factors in common:

(a) Fire occurred during an outage;

(b) Fire was detected immediately;

(c) Fire was caused by cutting and welding;

(d) Rapid fire spread prevented access to the interior of the scrubber which made manual fire fighting ineffective.

The following are brief summaries of the losses reported to date:

Fire No. 1. The scrubber was 36 ft (11 m) in diameter and 139 ft (42 m) high. The scrubber contained two sections of polypropylene packing: one section was 4 ft (1.2 m) thick and one section was 3 ft (1 m) thick. The 3 ft (1 m) thick section was removed at the time of the fire. Both layers of packing extended across the full diameter of the tower. An outside contractor was making repairs on a turning vane at the top of the scrubber. A welding blanket had been placed over the top of the fill. Sparks from the welding operation fell through the wood work platform and ignited the polypropylene packing 30 ft (9 m) below. The fire was detected immediately. Plant employees reacted rapidly and followed procedures established in advance. They actuated the demister spray nozzles, then closed access doors and the outlet damper to isolate the scrubber. Plant employees used $1^1/_2$ in. (3.8 cm) hose on the outside of the duct. The public fire department responded. Total fire duration was two minutes. Property damage was estimated at $5,000,000, the outage was 41 days.

Fire No. 2. There were four scrubbers in one building. The scrubbers were 30 ft × 30 ft × 80 ft (9 m × 9 m × 24 m) high. The scrubbers have an extensive amount of plastic packing and are lined. Maintenance was being performed on one of the scrubbers. A crew planned to make repairs to the liner near the top of the scrubber. The repair work involved cutting and welding operations. Hot metal fell down inside the scrubber. A small fire was observed in the lower part of the scrubber which quickly spread and burned out the lining and packing. Fire burned through the expansion joint on the top of the scrubber and spread throughout the penthouse with damage to building structural steel in the area above the scrubber. Property damage was estimated at $7,000,000, the outage was about eight months. This was due to the need for the replacement of the shell.

Fire No. 3. There were three absorber towers in one building. The towers were 40 ft × 65 ft × 185 ft (12.1 m × 19.7 m × 56 m) high. The scrubbers were lined with a rubber coating and had polypropylene mist eliminators. Workers were in the exhaust duct of one of the scrubbers attempting to seal small holes in the duct. Plastic sheeting was used to protect an expansion joint. Sparks from the welding operation ignited the plastic. Fire was detected immediately. Portable extinguishers were used to fight the fire. The fire quickly spread to wood scaffolding. The plant fire brigade responded but could not enter the duct due to dense smoke. Fire spread to the polypropylene mist eliminator and the rubber lining in the scrubber. Heat from the fire vented into the building collapsing the roof. The scrubber was destroyed. Property damage was estimated at $42,000,000. The station was under construction and its completion was delayed two years by the fire.

Appendix B Sample Fire Report

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

Name of company: ____

Date of fire: ____ Time of fire: ____________ Operating facility: ________________

Under construction: ____

Plant or location where fire occurred: ___________________________________

Description of facility, fire area, or equipment (include nameplate rating) involved:

____

Cause of fire, such as probable ignition source, initial contributing fuel, equipment failure causing ignition, etc.:

____

____

____

Story of fire, events, and conditions preceding, during, and after the fire:

____

____

____

Types and approximate quantities of portable extinguishing equipment used:

____

____

Was fire extinguished with portable equipment only? ________________________________

Public fire department called? ________ Employee fire brigade at this location? __________

Qualified for incipient fires? __________ For interior structural fires? __________________

Was fixed fire extinguishing equipment installed?____________________________________

Type of fixed extinguishing system: ____ ____

Automatic operation: ________ , manually actuated:__________ , or both: ____________

Specific type of detection devices: ____

Did fixed extinguishing system control? ____________ and/or extinguish fire? ________

Did detection devices and extinguishing system function properly? ______________________

If "no," why not? ____

____

Estimated direct damage due to fire: $ ______________ , or between $ ________and $ __

Estimated additional (consequential) loss: $ ____________ Nature of additional loss: ____

____

____

Estimated time to complete repairs/replacement of damaged equipment/structure:

____

Number of persons injured: ________________________ Number of fatalities: ________

What corrective or preventive suggestions would you offer to other utilities who may have similar equipment, structures, or extinguishing systems? ______________________________

Appendix C Fire Tests

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

NOTE: Footnotes refer to reference list numbers at end of Appendix C.

This Appendix summarizes the results of fire tests in which automatic sprinklers or water spray systems were used to extinguish or control fires in oil and grouped cables. Also included in this Appendix are results of tests conducted on fiberglass stack liners.

C-1 Combustible Oil Fire Tests.

C-1.1 General.

Oils (except for crude oil) handled in bulk in power stations are limited to combustible liquids that lend themselves to control and extinguishment by water-type protective systems.

In order to ensure satisfactory results on such fires, the system design should take into account the physical nature of the expected fire, which will take one or more of three forms: a pressure jet or spray, a three-dimensional rundown of burning fuel over equipment and structures, or a spill or pool of fuel.

Fire experience with liquid fires in power stations confirms that a fire frequently displays multiple characteristics. A turbine-generator fire frequently originates as a spray fire at a bearing with burning oil running down to lower levels of the station where a spill or pool fire results. Similarly, a leak at an oil-fired boiler produces a spray fire with burning oil running down the boiler wall to a lower floor. A hydraulic oil leak on a fan drive likewise combines spray fire and spill fire characteristics.

A protective system is expected to control or extinguish a liquid fire, as well as provide exposure protection for the structure and equipment in the vicinity of the fire. The oil fire tests summarized in the following section indicate that complete extinguishment of pressure jet or spray fires may be difficult to achieve at any practical application density. The tests also show that spill or pool fires can be controlled, and equipment and structures in the general area protected, with area sprinkler protection operating at moderate densities [0.15 gpm/ft-0.20 gpm/ft^2 (6.11 L/min-m^2 - 8.15 L/min-m^2)]. Where the probable location of spray fires can be identified (e.g., exposed pipe runs without guard pipe or specific items of equipment), high velocity directional spray nozzles of open or fused type operating at applied densities of approximately 0.25 gpm/ft^2 (10.19 L/min-m^2) can radically limit the damage area resulting from a jet or spray fire.

The design specifics for water protective systems should be covered by the Fire Risk Evaluation based on the conditions existing in a particular plant.

C-1.2 Tests.

Limited fire testing has been conducted to develop design criteria for fire suppression systems for lubricating oil fires. The first series of tests were conducted by the Factory Mutual Research Corporation in 1957[1] under the sponsorship of the U.S. Atomic Energy Commission. These tests included large spill fires [up to 2100 ft^2 (195 m^2)], with ceiling heights similar to those found in turbine building lower elevations [33 ft (10 m)]. The tests showed that oil spill fires could be extinguished and structural damage held to a minimum with automatic sprinklers at ceiling level delivering a discharge density as low as 0.13 gpm/ft^2 (5.30 L/min-m^2). Also included in these tests was one oil spray fire test. This test showed that ceiling level sprinklers were unsuccessful at extinguishing the spray fire even with discharge densities up to 0.36 gpm/ft^2 (14.67 L/min-m^2). It further showed that damage caused by direct impingement of an oil spray fire on a structural column may not be prevented by ceiling sprinkler protection at a 0.36 density.

These pool fire tests involved a $^1/_4$ in. (6.35 mm) deep pool of oil but with normal building ventilation.

A later series of tests conducted in Finland in 1979[2] by a committee of insurance companies and utility companies showed similar results. These tests on oil spray and pool fires indicated the difficulty of extinguishing oil spray fires. Densities of up to 0.66 gpm/ft^2 (26.89 L/min-m^2) from automatic sprinklers 10 ft (3.05 m) overhead were unable to extinguish the spray fire. Water spray systems using high velocity and medium velocity spray nozzles were also tested on spray fires using densities up to 1.0 gpm/ft^2 (40.75 L/min-m^2). These tests showed the importance of nozzle placement in covering the entire oil spray to suppress a spray fire. Since the location and direction of an oil leak that could result in a spray fire is not readily predictable, the emphasis of water spray system design must be on area cooling to minimize fire damage rather than extinguishment of the spray fire. Tests showed that a density of 0.3 gpm/ft^2 (12.22 L/min-m^2) provided adequate cooling.

The Finnish tests also included pool fires in a collection pan of approximately 130 ft^2, 1 ft deep (12.08 m^2, 0.30 m). These tests showed that even distribution of 0.18 gpm/ft^2 (7.33 L/min-m^2) could extinguish an oil pool fire.

The difference in densities for oil pool fires between the two test series may be the result of test conditions. The Finnish test series involved a 12 in. (30.48 cm) deep pool of oil with ventilation rates of 75,000 cfm to enable filming of the test.

C-2 Fire-Resistant Fluid.

C-2.1 General.

In the United States, less flammable hydraulic fluids have been used in the control oil systems of larger turbines for a number of years. In the countries that formerly comprised the U.S.S.R.

these fluids are used for both the control and lubrication oil systems of steam turbines. Loss experience where this information is available (U.S.) has been good. Incidents involving less hazardous hydraulic fluids have resulted in relatively minor fires causing little damage. In one instance a utility indicated that a 1 in. (2.5 cm) diameter leak occurred in a control oil system with fluid sprayed onto a 1000°F (538°C) surface. A small fire resulted that was easily extinguished with a light water spray. Operators were able to isolate the line with no property damage and a one hour delay in startup. Plant personnel estimated that if mineral oil was involved under the same conditions a severe fire would have occurred with no possibility of the operators accessing the area to isolate the leak. This would have resulted in major fire damage and an extended outage.

C-2.2 Tests.

One of the listing organizations for less flammable fluids conducts the following two tests to qualify less flammable hydraulic fluids for listing. In both tests, the fluid is heated to 140°F (60°C) and discharged through an oil burner type, 80 degree hollow cone spray nozzle at 1000 psi (6.7 MPa). The tests are as follows:

(a) *Hot Surface Ignition Test:* The fluid is sprayed onto a steel channel heated to 1300°F (704°C). The spray is directed onto the heated surface for 60 seconds from a distance of 6 in. (15.2 cm). If ignition occurs the spray pattern is directed away from the hot surface to an open area. Local burning on the channel is acceptable. It is not acceptable if flame follows the spray pattern to the open area.

(b) *Flame Propagation Test:* A propane torch is used to ignite the spray 6 in. (15.2 cm) and at 18 in. (44.7 cm) from the nozzle. Ten tests are conducted at each location with the torch flame moved through the spray pattern. It is not acceptable if the spray burns longer than five seconds after the torch is removed from the spray pattern in any of the 20 tests.

C-3 Grouped Cable Fire Tests.

C-3.1 General.

The fire hazard presented by grouped cables depends on the number of trays in a given area, arrangement of trays (vertical vs. horizontal), type of cable used, arrangement of cable in the tray, and the type of tray (ladder vs. solid bottom). The tests indicated that water could penetrate densely packed ladder cable trays arranged six trays high, and although fire propagation could be limited in the horizontal direction, it would probably involve the entire array in the vertical direction. A 0.30 gpm/ft^2 (12.22 L/min-m^2) design density from ceiling sprinklers was effective. However, lower densities were not tried on full scale tests.

C-3.2 Tests.

Three fire test programs have been carried out using water to extinguish grouped cable fires. All tests involved polyethylene insulated, PVC jacketed cable in ladder type cable trays. The first series of tests was carried out by a group of insurance companies in Finland in 1975.[3] The tests involved protection of cables in a $6^1/_2$ ft × $6^1/_2$ ft × 65 ft (1.98 m × 1.98 m × 19.82 m) long enclosure similar to a cable tunnel. Six cable trays were located along each side of the tunnel.

Protection consisted of 135°F (57.2°C) rated sprinklers spaced 13 ft^2 (4 m) apart at ceiling level. A 0.40 gpm/ft^2 (16.30 L/min-m^2) density was used for the sprinkler system. The tests showed the ability of a sprinkler system to prevent horizontal fire spread in the group of six trays where the fire started and to protect cables on the opposite wall of the tunnel.

The second series of tests were carried out by the Central Electricity Generating Board of the United Kingdom in 1978.[4] The purpose was to compare the effectiveness of a deluge system activated by heat detection wire with a fusible link actuated automatic sprinkler system.

Cable trays were arranged six trays high and two trays wide (12 trays).

The water spray system was activated by a 160°F (71.1°C) rated heat detector wire. The wire was installed 9 in. (22.86 cm) above each cable tray and along the center of the bottom tray. Spray nozzles were positioned at 10-ft (3.05-m) intervals at ceiling level in the aisle between cable tray arrays. The automatic sprinkler system was located directly above the cable tray array with sprinkler heads spaced 10 ft (3.05 m) apart.

This test series showed that both protection systems could control a fire involving grouped cable. The water spray system responded faster with less fire damage to cable. The water spray system limited damage to cables in one or two trays. The sprinkler system limited damage to six to nine trays.

The third test program was conducted by the Factory Mutual Research Corporation[5] under the sponsorship of the Electric Power Research Institute.

One phase of the tests studied the ability of a ceiling sprinkler system to control a fire in a cable tray array. Cable trays were arranged six trays high and two trays wide with a number of vertical cable trays in the space between. The test was carried out in a room 40 ft × 40 ft × 20 ft high (12.20 m × 12.20 m × 6.10 m high). Protection consisted of 160°F (71.1°C) rated sprinklers on 10 ft × 10 ft (3.05 m × 3.05 m) spacing at ceiling level. A 0.30 gpm/ft^2 (12.22 L/min-m^2) density was used. Ionization detectors were provided at ceiling level.

Where sprinklers actuated, from one to three sprinklers opened to control the fire. Fire propagated the entire height of vertical trays, but could be contained within the 8 ft (2.44 m) length of most of the horizontal trays. Cable was damaged in most of the trays. Ionization detectors responded within 21 to 25 seconds.

C-4 Stack Liner Fire Tests.

C-4.1 General.

Tests were conducted on four fire-retardant fiberglass reinforced plastic liners by Factory Mutual Research Corporation.[6] The liners were 3 ft (0.91 m) in diameter and 30 ft (9.15 m) long. They were suspended vertically above a 10 ft^2 (0.93 m) pan containing 3 in. (7.62 cm) of heptane. The liners were exposed to this ignition source for 2$^1/_2$ minutes, at which time the pan was removed.

C-4.2 Tests.

Results were similar with all four materials tested. There was an initial moderate temperature rise due to the heat input from the heptane fire, a leveling off of temperature prior to involvement of the plastic, then a very rapid temperature increase caused by heat contribution from the burning liner; another leveling off during a period of active liner burning, then a decrease in temperature coincident with removal of the exposure fire. From a review of the test data, it appeared that once burning of the liner started, fire spread over the surface was almost instantaneous. Temperatures at different elevations in the liner interior reached 1000°F (537.8°C) almost simultaneously in each test.

Appendix D Emergency Shutdown

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

The following describes fire experience that has occurred over the last several years where lubricating oil supply was shut down more rapidly than normal, either intentionally or accidentally. Lubricating oil was shut off at 0 rpm for fire No. 1, at 1000 rpm for fire No. 2, from 1000 rpm - 1400 rpm for fire No. 3, and in excess of 3000 rpm for fire No. 4.

No. 1. In August 1989 a 640 MW(e) five casing, double reheat machine with inlet steam pressure at 3675 psig (25,339 kPa) and 1000°F (537.8°C) was operating normally when a fire was discovered near the main lube oil tank. Unsuccessful attempts were made to manually fight the fire when control cable burned through and control and throttle valves started to close. At six minutes the ac lube oil pump started. The operator sent an assistant to vent hydrogen from the generator and purge with carbon dioxide. A valve was then manually operated to break condenser vacuum. This action resulted in reducing the coast-down time to 30 minutes from 45 minutes - 60 minutes. When the shaft stopped rotating, the operator took the unit off turning gear and shut down the ac and emergency dc oil pumps. The fire department and plant fire brigade quickly controlled the fire with one $2^1/_2$ in. (6.4 cm) and one $1^1/_2$ in. (3.8 cm) hose stream.

There was no damage to the bearings as a result of the shutdown. A runout check indicated that measured clearances were well within tolerance. Steel beams supporting the operating floor sagged from 2 in. (5 cm) to 3 in. (7.6 cm) over a 1500 ft^2 (138 m^2) area in front of the front standard. Cable, in trays near the fire area, was damaged. The action taken by the operator resulted in substantially reduced damage to the turbine and the building, and was credited with substantially reducing the length of time the turbine was out of service. The turbine was put back on turning gear about 26 days after the fire. The operating floor could be reinforced, and the unit operated until the next scheduled outage.

No. 2. In July 1987 a 35 MW(e) single flow, double automatic extraction, condensing machine with inlet steam pressure of 1250 psig (8618 kPa) and 900°F (482°C) was operating normally while millwrights attempted to clean the oil cooler tubes on one of the two oil coolers. During the cleaning process one of the tubes dropped out of the tube sheet and oil was ejected vertically at about 40 psi (275.8 kPa) through a $^5/_8$ in. (1.6 cm) opening in the tube sheet. The oil spray ignited off a steam stop valve overhead. Approximately 20 ceiling sprinklers and 16 spray nozzles directly below the operating floor opened. Oil mist and droplets passed up through a 6 in. (15.2 cm) wide opening between the operating floor and the wall and burned above the operating floor. Approximately 15 minutes into the fire, fearing building collapse, the ac driven lubricating oil pumps were shut off. The fire intensity decreased noticeably. Approximately 15 minutes later (30 minutes into the fire) the dc pump was shut down with the turbine turning at approximately 1000 rpm. The oil fire was quickly extinguished.

The main shaft bearings were wiped, and the thrust bearing destroyed. There were indications of minor rubbing at the high pressure end, and hangars for the main steam stop valve were cracked. There was little evidence of high temperatures in the basement area, due to the effect of the automatic sprinkler protection. However, there was a large amount of deformed structural steel above the operating floor, on the wall, and at roof level.

No. 3. In January 1989 a 12.5 MW(e) condensing, double automatic extraction turbine with inlet steam pressure of 475 psig (3275 kPa) and 750°F (400°C) was operating normally when maintenance personnel discovered a drip-sized leak at an elbow on the control oil piping. Control room personnel were notified, and, since they had difficulty reducing load, they tripped the unit by opening the breaker. A fire started in the vicinity of the hydraulic cylinder. There was no fixed protection provided, personnel attempted to fight the fire with hand extinguishers and hose streams without success. Two minutes after the fire started, with the machine turning at between 1100 rpm and 1400 rpm, the operator was ordered to stop the main and emergency oil pumps. Approximately 150 gal (568 L) of oil were lost before pumps were stopped. The fire department responded four minutes after the fire started and using one $2^1/_2$ in. (6.4 cm) and two $1^3/_4$ in. (4.4 cm) hose lines brought the fire under control 23 minutes after it started.

There was damage to turbine bearings, and the shaft ends were scored. In addition all control wiring under the turbine shroud was burned, and there was damage to gauges, indicators, and controls mounted in the turbine shroud. Structural steel was warped at the roof of the building. Repairs to the turbogenerator were estimated at 2 to 3 weeks.

No. 4. In February 1988 two 660 MW(e) units were operating at 550 and 530 MW(e), respectively. The units were end to end. Power and control cable for the lube oil pump motors for both machines were located above a control valve servomotor enclosure for one of the units. Piping to the enclosure was guarded and contained control oil at 250 psig (1724 kPa). A leak occurred in the control oil piping within the guard pipe. The turbine tripped automatically. Oil flooded the guard pipe and backed up into the servomotor enclosure igniting in the vicinity of the main steam stop valves. The fire damaged power and control cable for both machines shutting down ac and dc oil pumps for both units. Both machines were rotating in excess of 3000 rpm at the time lube oil was lost.

Extensive repairs were needed to mill bearing surfaces and to straighten and balance the shafts on both units. One machine was out of service for approximately three months, the other for five months.

Appendix E Referenced Publications

E-1

The following documents or portions thereof are referenced within this recommended practice for informational purposes only and thus are not considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

E-1.1 NFPA Publication.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 1561, *Standard on Fire Department Incident Management System,* 1995 edition.

NFPA 851

1996 Edition

Recommended Practice for Fire Protection for Hydroelectric Generating Plants

1996 Edition

This edition of NFPA 851, *Recommended Practice for Fire Protection for Hydroelectric Generating Plants*, was prepared by the Technical Committee on Electric Generating Plants and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 851 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 851

The Committee on Non-Nuclear Power Generating Plants was organized in 1979 to have primary responsibility for documents on fire protection for non-nuclear electric generating plants. The Hydroelectric Subcommittee was formed in 1982 to write this document. The first edition of NFPA 851 was issued in 1987 and revised in 1992. The 1996 edition contains minor changes to clarify the life safety recommendations and generator windings protection.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire protection for electric generating plants and high voltage direct current (HVDC) converterstations, except for electric generating plants using nuclear fuel.

NFPA 851

Recommended Practice for Fire Protection for Hydroelectric Generating Plants

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7.

Chapter 1 Introduction

1-1 Scope.

This document provides recommendations (not requirements) for fire prevention and fire protection for hydroelectric generating plants. The term “hydroelectric generating plant” also may be referred to as “station,” “project,” “unit(s),” “facility,” or “site.”

1-2 Purpose.

1-2.1

This document provides guidance for those charged with the design, construction, and operation of hydroelectric generating plants.

1-2.2

This document provides fire prevention and fire protection recommendations primarily to safeguard physical property and continuity of power production, but its application can also enhance safety of site personnel. This document is not intended to restrict new technologies or alternate arrangements.

1-3 Application.

1-3.1

This document is intended for use by persons knowledgeable in the application of fire protection to hydroelectric generating plants.

1-3.2

The recommendations contained in this document are intended for new installations only, as the application to existing installations might not be practicable.

1-3.3

It should be recognized that rigid uniformity of generating station design and operating procedures does not exist and that each facility will have its own special conditions that impact on the nature of the installation. Many of the specific recommendations herein may require modification after due consideration of all local factors involved. Individual generating units, particularly those of less than 25 MW, should be given a cost-benefit analysis to determine the extent to which fire protection is justified.

1-4 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Combustible. Any material that does not comply with the definition of either noncombustible or limited combustible.

Combustible Liquid. A liquid having a flash point at or above 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code.*)

Fire Barrier. A fire barrier is a continuous membrane, either vertical or horizontal, such as a wall or floor assembly, that is designed and constructed with a specified fire resistance rating to limit the spread of fire and that will also restrict the movement of smoke. Such barriers may have protected openings.

Fire Loading. The amount of combustibles present in a given area, expressed in Btu/ft^2 (kJ/m^2).

Fire Point. The lowest temperature at which a liquid in an open container will give off sufficient vapors to burn once ignited. It is generally slightly above the flash point.

Fire Prevention. Measures directed towards avoiding the inception of fire.

Fire Protection. Methods of providing for fire control or fire extinguishment.

Fire Protection Rating. The time, in minutes or hours, that materials and assemblies used as opening protection have withstood a fire exposure as established in accordance with test procedures of NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, and NFPA 257, *Standard for Fire Tests of Window Assemblies*, as applicable.

Fire Rated Penetration Seal. An opening in a fire barrier for the passage of pipe, cable, duct, etc., that has been sealed so as to maintain a barrier rating.

Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as established in accordance with the test procedures of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

Flammable Liquid. Any liquid having a flash point below 100°F (37.8°C) and having a vapor pressure not exceeding 40 psia (276 kPa) absolute pressure at 100°F (37.8°C). (*See NFPA 30, Flammable and Combustible Liquids Code.*)

High Fire Point Liquid. A combustible dielectric liquid listed as having a fire point of not less than 572°F (300°C).

Interior Finish. The exposed interior surfaces of buildings including, but not limited to, fixed or movable walls and partitions, columns, and ceilings. Interior finish materials are grouped in the following classes:

Class A Interior Finish. Materials having flame spread 0-25, smoke developed 0—450 when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. Includes any material classified at 25 or less on the flame spread test scale and 450 or less on the smoke test scale when any element thereof, when tested, does not continue to propagate fire.

Class B Interior Finish. Materials having flame spread 26-75, smoke developed 0—450 when tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. Includes any material classified at more than 25, but not more than 75, on the flame spread test scale and 450 or less on the smoke test scale.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Less Flammable Liquid. A combustible dielectric liquid listed as having a fire point of not less than 572°F (300°C).

Limited Combustible. As applied to a building construction material, a material, not complying with the definition of noncombustible material, that in the form in which it is used has a potential heat value not exceeding 3500 Btu/lb (8.14×10^6 J/kg) (see NFPA 259, *Standard Test Method for Potential Heat of Building Materials*), and complies with one of the following paragraphs (a) or (b).

(a) Materials having a structural base of noncombustible material with a surfacing not exceeding a thickness of $^1/_8$ in. (3.175 mm) that has a flame spread rating not greater than 50.

(b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread rating greater than 25 nor evidence of continued progressive combustion, and of such composition that the surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread rating greater than 25 nor evidence of continued progressive combustion as tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Materials subject to increase in combustibility or flame spread rating beyond the limits herein established through the effects of age, moisture, or other atmospheric condition are considered combustible.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Noncombustible. A material that, in the form in which it is used and under the conditions anticipated, will not aid combustion or add appreciable heat to an ambient fire. Materials when tested in accordance with ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, and conforming to the criteria contained in Section 7 of the referenced standard shall be considered noncombustible.

Nonflammable Fluid. A nonflammable dielectric fluid that does not have a flash point and is not flammable in air.

Should. Indicates a recommendation or that which is advised but not required.

1-5 Units.

Metric units in this document are in accordance with the International System of Units, which is officially abbreviated SI in all languages. For a full explanation, see ASTM E380/ANSI Z210.1, *Metric Practice Guide*.

Chapter 2 Administrative Controls

2-1 General.

2-1.1

This chapter provides recommended criteria for the development of administrative procedures and controls necessary for the execution of the fire prevention and fire protection activities and practices for hydroelectric generating plants.

2-1.2

The administrative controls recommended in this chapter should be reviewed and updated periodically.

2-1.3

The intent of this chapter can be met by incorporating the features of this chapter in the plant's operating procedures or otherwise as determined by plant management.

2-2 Management Policy and Direction.

2-2.1

Corporate management should establish a policy and institute a program to promote the conservation of property and continuity of operations as well as protection of safety to life by adequate fire prevention and fire protection measures at each facility.

2-2.2

Proper preventative maintenance of operating equipment as well as adequate operator training are important aspects of a viable fire prevention program.

2-3 Fire Risk Evaluation.

A Fire Risk Evaluation should be initiated early in the design process to ensure that the fire prevention and fire protection recommendations as described in this document have been evaluated in view of the plant's specific considerations regarding design, layout, and anticipated operating requirements. The evaluation should result in a list of recommendations based on acceptable means for separation or control of common and special hazards, the control or elimination of ignition sources, and the suppression of fires.

2-4 Fire Prevention Program.

A written plant fire prevention program should be established and, as a minimum, should include the following:

(a) Fire safety information for all employees and contractors. This information should include, as a minimum, familiarization with fire prevention procedures, plant emergency alarms and procedures, and how to report a fire.

(b) Documented plant inspections including provisions for remedial actions to correct conditions that increase fire hazards.

(c) A description of the general housekeeping practices and the control of transient combustibles.

(d) Control of flammable and combustible liquids and gases in accordance with appropriate NFPA standards.

(e) Control of ignition sources to include smoking, grinding, welding, and cutting. (*See NFPA 51B, Standard for Fire Prevention in Use of Cutting and Welding Processes*.)

(f) Fire prevention surveillance. (*See NFPA 601, Standard for Security Services in Fire Loss Prevention.*)

(g) Fire report, including an investigation and a statement on the corrective action to be taken. (*See Appendix B.*)

2-5 Testing, Inspection, and Maintenance.

2-5.1

Upon installation, all fire protection systems should be preoperationally inspected and tested in accordance with applicable NFPA standards. Where appropriate standards do not exist, inspection and test procedures outlined in the purchase and design specifications should be followed.

2-5.2

All fire protection systems and equipment should be periodically inspected, tested, and maintained in accordance with applicable *National Fire Codes®*. (*See Table 2-5.2 for guidance.*)

Table 2-5.2 Reference Guide for Fire Equipment Inspection, Testing, and Maintenance

Item	NFPA No.
Supervisory and Fire Alarm Circuits	72
Fire Detectors	72
Manual Fire Alarms	72
Sprinkler Water Flow Alarms	13/72
Sprinkler and Water Spray Systems	15/13
Foam Systems	11A/11C/16
Halogenated Agent, Chemical, & CO_2 Systems	12/12A/17
Fire Pumps & Booster Pumps	20
Water Tanks & Alarms	13/22/72
P.I.V.s and O.S. & Y. Valves	13/72
Fire Hydrants and Associated Valves	13/24
Fire Hose and Standpipes	14/1962

Portable Fire Extinguishers & Hose Nozzles	10/1962
Fire Brigade Equipment	1971/1972/1973/1974
Fire Doors	80
Smoke Vents	204M
Emergency Lighting	70
Radio Communication Equipment	1221

NOTE: Inspection intervals for unattended plants may be permitted to be extended to normal plant inspections.

2-5.3

Testing, inspection, and maintenance should be documented with written procedures, results, and follow-up actions recorded.

2-6 Impairments.

2-6.1

A written procedure should be established to address impairments to fire protection systems, and as a minimum this procedure should include the following:

(a) Identification and tracking of impaired equipment.

(b) Identification of personnel to be notified (e.g., plant fire brigade chief, public fire department, etc.).

(c) Determination of needed fire protection and fire prevention measures.

2-6.2

Impairments to fire protection systems should be as short in duration as practical. If the impairment is planned, all necessary parts and personnel should be assembled prior to removing the protection system(s) from service. When an impairment is not planned, or when a system has discharged, the repair work or system restoration should be expedited.

2-6.3

Proper reinstallation after maintenance or repair should be performed to ensure proper systems operation. Once repairs are complete, tests that will ensure proper operation and restoration of full fire protection equipment capabilities should be made. Following restoration to service, the parties previously notified of the impairment should be advised. The latest revision of the design documents reflecting as-built conditions should be available to ensure that the system is properly reinstalled (e.g., drawings showing angles of nozzles).

2-7 Fire Emergency Plan.

A written fire emergency plan should be developed, and, as a minimum, this plan should include the following:

(a) Response to fire alarms and fire systems supervisory alarms.

(b) Notification of personnel identified in the plan.

(c) Evacuation of personnel not directly involved in fire-fighting activities from the fire area.

(d) Coordination with security forces or other designated personnel to admit public fire department and control traffic and personnel.

(e) Fire extinguishment activities.

(f) Periodic drills to verify viability of the plan.

(g) Control room operator(s) activities during fire emergencies. Approved breathing apparatus should be readily available in the control room area.

2-8 Fire Brigade.

2-8.1

The size of the plant and its staff, the complexity of fire-fighting problems, and the availability and response time of a public fire department should determine the requirements for a fire brigade.

2-8.2*

If a fire brigade is provided, its organization and training, including special fire-fighting conditions unique to hydroelectric plants, should be outlined in written procedures.

2-8.3

Cable tray fires, unique to hydroelectric generating plants, should be handled like any fire involving energized electrical equipment. It may not be practical or desirable to deenergize the cables involved in the fire. Water is the most effective extinguishing agent for cable insulation fires but should be applied with an electrically safe nozzle. Some cables [polyvinyl chloride (PVC), Neoprene, or Hypalon] can produce dense smoke in a very short time. In addition, PVC liberates hydrogen chloride (HCl) gas. Self-contained breathing apparatus should be used by personnel attempting to extinguish cable tray fires.

Chapter 3 General Plant Design

3-1 Plant Arrangement.

3-1.1 Fire Area Determination.

3-1.1.1 The hydroelectric generating plant should be subdivided into separate fire areas as determined by the Fire Risk Evaluation for the purposes of limiting the spread of fire, protecting personnel, and limiting the resultant consequential damage to the plant. Fire areas should be separated from each other by approved fire barriers, spatial separation, or other approved means.

3-1.1.2 Determination of fire area boundaries should be based on consideration of the following: types, quantity, density, and locations of combustible material; location and configuration of plant equipment; consequences of losing plant equipment; location of fire detection and suppression systems; and personnel safety/exit requirements. It is recommended that most fire barriers separating fire areas be of two hours fire resistance rating. If a fire area is defined as a detached structure, it should be separated from other structures by an appropriate distance. (*See NFPA 80A, Recommended Practice for Protection of Buildings from Exterior Fire Exposures.*) Unless consideration of the above factors indicates otherwise, it is recommended that fire area boundaries be provided as follows:

(a) To separate cable spreading room(s) and cable tunnel(s) from adjacent areas.

(b) To separate the control room, computer room, or combined control/computer room from adjacent areas. Where the control room and computer room are separated by a common wall, the wall need not have a fire resistance rating.

(c) To separate rooms with major concentrations of electrical equipment, such as switchgear room and relay room, from adjacent areas.

(d) To separate battery rooms from adjacent areas.

(e) To separate maintenance shop(s) from adjacent areas.

(f) To separate main fire pump(s) from reserve fire pump(s), where these pumps provide the only source of water for fire protection.

(g) To separate fire pumps from adjacent areas.

(h) To separate warehouses and combustible storage areas from adjacent areas.

(i) To separate emergency generators from each other and from adjacent areas.

(j) To separate oil storage and purification rooms from adjacent areas.

(k) To separate fan rooms and plenum chambers from adjacent areas (fire dampers may not be advisable in emergency ventilation ducts — see Section 3-4).

(l) To separate office areas from adjacent areas.

(m) To separate telecommunication rooms from adjacent areas.

(n) To separate the intake hoist housing from generator floor area and from adjacent areas.

(o) To separate the tailrace service gallery from turbine/generator floors and governor hydraulic equipment.

3-1.2 Outdoor Oil-Insulated Transformers.

3-1.2.1 Outdoor oil-insulated transformers should be separated from adjacent structures and from each other by firewalls, spatial separation, or other approved means for the purpose of limiting the damage and potential spread of fire from a transformer failure.

3-1.2.2 Determination of the type of physical separation should be based on consideration of the following:

(a) type and quantity of oil in the transformer,

(b) size of a postulated oil spill (surface area and depth),

(c) type of construction of adjacent structures,

(d) power rating of the transformer,

(e) fire suppression systems provided, and

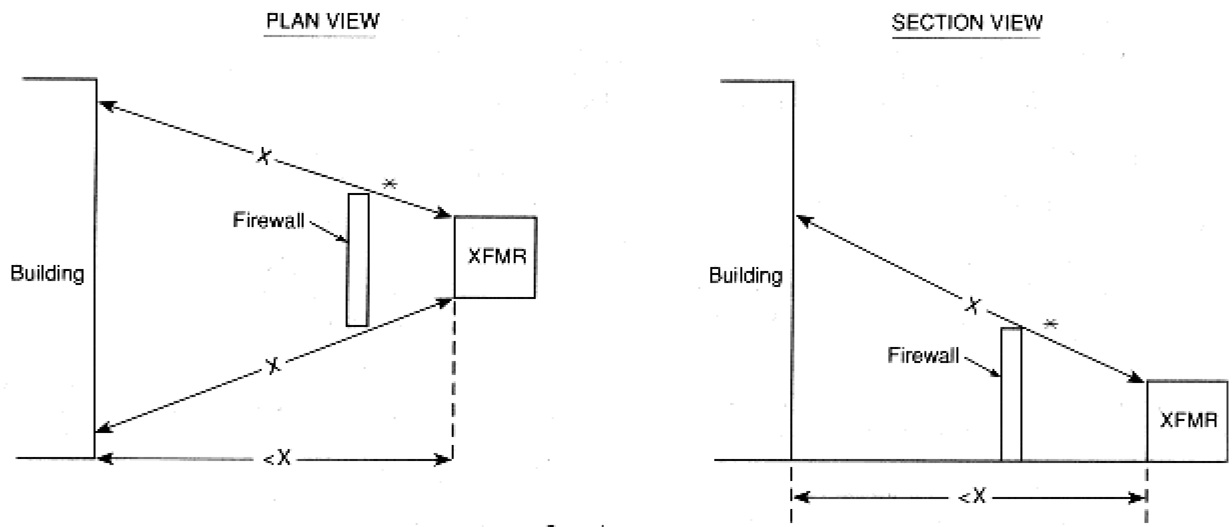
(f) type of electrical protective relaying provided.

3-1.2.3 Unless consideration of the factors in 3-1.2.2 indicates otherwise, it is recommended that any oil-insulated transformer containing 500 gal (1893 L) or more of oil be separated from adjacent noncombustible or limited combustible structures by a 2-hr rated firewall or by spatial separation in accordance with Table 3-1.2.3. Where a firewall is provided between structures and a transformer, it should extend vertically and horizontally as indicated in Figure 3-1.2.3.

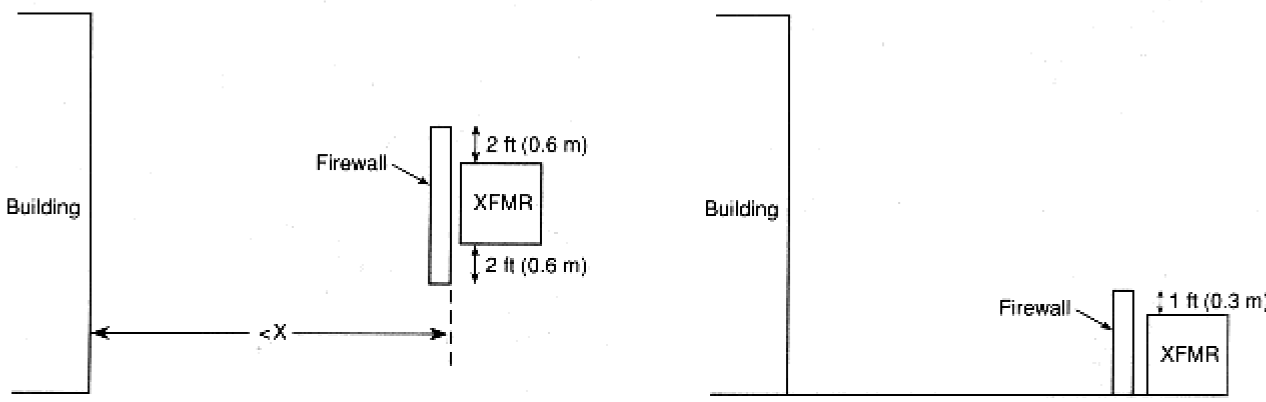
NOTE: As a minimum, the firewall should extend at least 1 ft (0.31 m) above the top of the transformer casing and oil conservator tank and at least 2 ft (0.61 m) beyond the width of the transformer and cooling radiators.

Table 3-1.2.3 Outdoor Oil-Insulated Transformer Separation Criteria

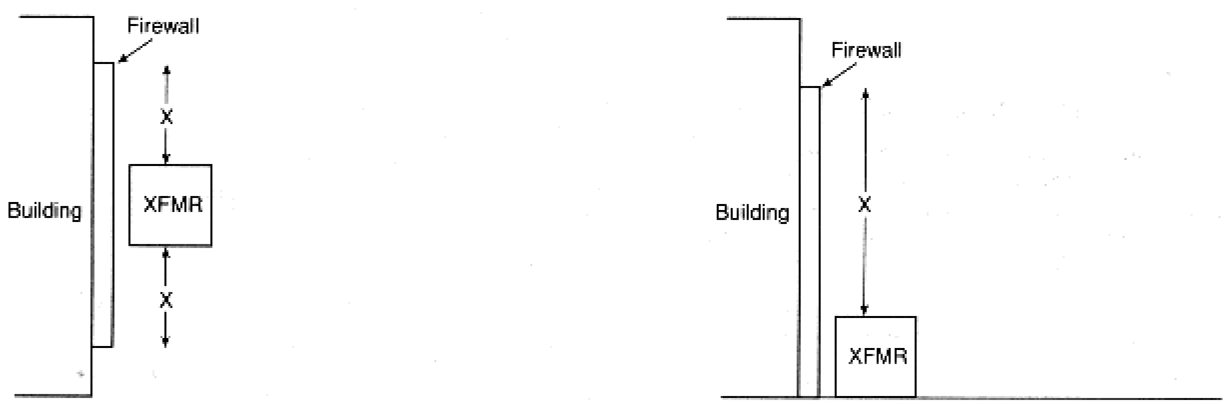
Transformer Oil Capacity	Minimum (Line-of-Sight) Separation without Firewall
Less than 500 gal (1893 L)	See 3-1.2.2
500 gal to 5000 gal (1893-18,925 L)	25 ft (7.6 m)
over 5000 gal (18,925 L)	50 ft (15 m)



Generic case



Example 1



Example 2

Figure 3-1.2.3 Illustration of oil-insulated transformer separation recommendations.

3-1.2.4 Unless consideration of the factors in 3-1.2.2 indicates otherwise, it is recommended that adjacent oil-insulated transformers containing 500 gal (1893 L) or more of oil be separated from each other by a 2-hr rated firewall or by spatial separation in accordance with Table 3-1.2.3. Where a firewall is provided between transformers, it should extend at least 1 ft (0.31 m) above the top of the transformer casing and oil conservator tank and at least 2 ft (0.61 m) beyond the width of the transformer and cooling radiators.

3-1.2.5 Where a firewall is provided, it should be designed to withstand the effects of exploding transformer bushings or lightning arrestors.

NOTE: A higher noncombustible shield may be permitted to be provided to protect against the effects of an exploding transformer bushing.

3-1.2.6 Where a firewall is not provided, the edge of the postulated oil spill (i.e., containment basin, if provided) should be separated by a minimum of 5 ft (1.5 m) from the exposed structure to prevent direct flame impingement on the structure.

3-1.2.7 Outdoor transformers insulated with a less flammable liquid should be separated from each other and from adjacent structures that are critical to power generation by firewalls or spatial separation based on consideration of the factors in 3-1.2.2, 3-1.2.5, and 3-1.2.6.

3-1.3 Indoor Transformers.

3-1.3.1 Dry-type transformers are preferred for indoor installations.

3-1.3.2 Oil-insulated transformers of greater than 100 gal (379 L) oil capacity installed indoors should be separated from adjacent areas by fire barriers of 3-hr fire resistance rating.

NOTE: Where multiple transformers of less than 100 gal (379 L) capacity each are located within close proximity, additional fire protection could be required based on the Fire Risk Evaluation.

3-1.3.3 Transformers insulated with less flammable liquids, having a rating above 35 KV and installed indoors, should be separated from adjacent areas by fire barriers of 3-hr fire resistance rating.

3-1.3.4 Where transformers are protected by an automatic fire suppression system, the fire barrier fire resistance rating may be permitted to be reduced to 1 hr.

3-1.4 Circuit Breakers.

3-1.4.1 The preferred location for oil circuit breakers is outdoors. Consideration should be given to dry or gas-cooled circuit breakers for indoor applications.

3-1.4.2 Oil-cooled circuit breakers should be separated from adjacent areas by fire barriers having a 3-hr fire resistance rating.

3-1.5 Openings in Fire Barriers.

3-1.5.1 All openings in fire barriers should be provided with fire door assemblies, fire dampers, penetration seals (fire stops), or other approved means having a fire protection rating consistent with the designated fire resistance rating of the barrier. Windows in fire barriers (e.g., control rooms or computer rooms) should be provided with a fire shutter or automatic water curtain. Penetration seals provided for electrical and piping openings should be listed or should meet the requirements for an “F” rating when tested in accordance with ASTM E814, *Fire Tests of*

Through-Penetration Fire Stops. Other test methods for qualifications of penetration seals, such as IEEE 634, *Testing Fire Rated Penetration Seals*, may be permitted to be considered for this application.

NOTE: Listed penetration seals for large diameter piping might not be commercially available. In such instances the design should be similar to listed configurations.

3-1.5.2 Fire door assemblies, fire dampers, and fire shutters used in 2-hr rated fire barriers should be rated not less than $1^1/_2$ hr. (*See NFPA 80, Standard for Fire Doors and Fire Windows.*)

3-2 Life Safety.

3-2.1

For life safety for hydroelectric generating plants, see NFPA *101*®, *Life Safety Code*®.

3-2.2

Structures should be classified as follows, as defined in NFPA *101*, *Life Safety Code*:

(a) General areas should be considered as special purpose industrial occupancies.

NOTE 1: Hydroelectric powerhouse structures protected in accordance with this document meet the intent of NFPA *101*, *Life Safety Code*, for additional travel distances for fully sprinklered facilities.

NOTE 2: NFPA *101* allows additional means of egress components for special purpose industrial occupancies. These areas may be permitted to be provided with fixed industrial stairs, fixed ladders (see ANSI A1264.1, *Safety Requirements for Workplace Floor and Well Openings, Stairs, and Railing Systems*, and ANSI A14.3, *Standard for Safety Requirements for Fixed Ladders*), or alternating tread devices (see NFPA *101*). Examples of these spaces include catwalks, floor areas, or elevated platforms that are provided for maintenance and inspection of in-place equipment.

NOTE 3: NFPA *101* allows spaces not subject to human occupancy because of the presence of machinery or equipment to be excluded from egress capacity requirements. Examples of these spaces include:

(1) Turbine scroll cases;

(2) Generators;

(3) Access tunnels for dam inspections;

(4) Entry into draft tubes; or

(5) Penstocks.

(b) Temporary occupancies and means of egress inside the structures and piers of large “bulb” units should be evaluated based on occupancies in special structures.

(c) Open structures and underground structures (e.g., tunnels) should be considered as occupancies in special structures.

(d) General office structures should be considered as business occupancies.

(e) Warehouses should be considered as storage occupancies.

3-3 Building Construction Materials.

3-3.1

Construction materials being considered for hydroelectric generating plants should be selected based on the Fire Risk Evaluation using the following standards:

(a) NFPA 220, *Standard on Types of Building Construction;*

(b) NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials;*

(c) NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source;*

(d) NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials;*

(e) NFPA 259, *Standard Test Method for Potential Heat of Building Materials.*

3-3.2

Building components for all powerhouse and subsurface structures should be of noncombustible or limited combustible materials, except as noted in 3-3.3.

3-3.3

Roof coverings should be Class A in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*. Metal roof deck construction, where used, should be Class I listed or approved.

3-3.4 Interior Finish.

3-3.4.1 Cellular or foam plastic materials should not be used in interior finish in buildings critical to the generation processes or in subsurface structures.

3-3.4.2 Interior finish in buildings critical to power generation should be Class A.

3-3.4.3 Interior finish in buildings not critical to the generation processes should be Class A or Class B.

3-4 Smoke and Heat Venting, Heating, Ventilating, and Air Conditioning.

3-4.1 Smoke and Heat Venting.

3-4.1.1 Smoke and heat vents are not substitutes for normal ventilation systems unless designed for dual usage, and should not be used to assist such systems for comfort ventilation. Smoke and heat vents should not be left open where they can sustain damage from high wind conditions. They should be included in surveillance programs to ensure availability in emergency situations.

3-4.1.2 Heat vents should be provided for areas identified by the Fire Risk Evaluation. Where heat vents are provided, heat generated under fire conditions should be vented from its place of origin directly to the outdoors.

3-4.1.3 Smoke venting should be provided for areas identified by the Fire Risk Evaluation. Where smoke venting is provided, smoke should be vented from its place of origin in a manner that does not interfere with the operation of the plant.

3-4.1.3.1 Separate smoke ventilation systems are preferred; however, smoke venting can be integrated into normal ventilation systems using automatic or manually positioned dampers and motor speed control. (*See NFPA 90A, Standard for the Installation of Air Conditioning and Ventilating Systems, and NFPA 204M, Guide for Smoke and Heat Venting.*) Smoke venting also may be permitted to be accomplished through the use of portable smoke ejectors.

3-4.1.3.2 Consideration should be given to smoke venting for the following areas: control room, cable spreading room(s), and switchgear room.

3-4.1.3.3 In the areas with gaseous fire extinguishing systems, the smoke ventilation system should be properly interlocked to ensure the effective operation of the gaseous fire extinguishing systems.

3-4.1.3.4 Smoke removal system dampers, where installed, are normally operable only from an area immediately outside of, or immediately within, the fire area served since it is desired to have entry into, and inspection of, the fire area by fire-fighting personnel prior to restoring mechanical ventilation to the fire area. Smoke removal system dampers may be permitted to be operable from the control room if provisions are made to prevent premature operation. This can be accomplished using thermal interlocks or administrative controls.

3-4.1.4 The fan power supply wiring and controls for smoke exhaust should be located external to the fire area served by the fan or be installed in accordance with the Fire Risk Evaluation.

3-4.1.5 Ventilation exhaust systems, particularly those for subsurface portions of underground facilities, should have fans able to continuously exhaust smoke and chemical fumes that can result from fires or from extinguishing of fires. The design and selection of the fans and other elements of the system should take into account additional ventilation needs for removing smoke and high temperature gases. Therefore the fan and its associated components, along with any ductwork, should be capable of handling high temperatures without deforming. The specific weight and volume of the heated air during a fire and the climatic conditions should also be considered. Total fan capacity should be provided so that ventilation requirements can be met with the largest fan out of service.

NOTE: When fire heats air and introduces products of combustion into the air in tunnels and in underground hydroelectric plants, the ventilation conditions that existed while the air was cold are altered. Frictional resistance to flow of heated air containing products of combustion is much greater than frictional resistance to flow of cold air that does not contain products of combustion. In the event of mild heating, increased resistance to flow would decrease the rate of ventilation. Then, after the fire is contained and the air is cooled, the air and smoke could be evacuated. Therefore, considerations for the health and safety of people underground should cause the designers to increase the rate of evacuating hot air containing smoke. As the fire underground increases the temperature of the air, ventilation flow can be reversed. The cooler ventilating air may flow in one direction occupying much of the lower spaces of tunnels while plumes of heated air flow rapidly outward from the area of the fire beneath the tunnel ceiling in the opposite direction from, and above, the mass of cooler air. The designer should then consider the stratification of air flow, the numerous nodes or junctures between tunnels and shafts, the likely frictional resistances with and without fire, and the placement and capacities of the fans and fire stops. Some useful information is available in the proceedings of Session XI, *Fires*, of the 2nd International Mine Ventilation Congress. The designer is advised to be thoroughly familiar with Chapter 41, Fire and Smoke Control, in the *ASHRAE Handbook*.

3-4.2 Normal Heating, Ventilating, and Air Conditioning Systems.

3-4.2.1 For normal heating, ventilating, and air conditioning systems, see NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, or NFPA 90B, *Standard for the Installation of Warm Air Heating and Air Conditioning Systems*, as appropriate.

3-4.2.2 Air conditioning for the control room should provide a pressurized environment to preclude the entry of smoke in the event of a fire outside the control room.

3-4.2.3 Plastic ducts, including listed fire-retardant types, should not be used for ventilating systems. Listed plastic fire-retardant ducts with appropriate fire protection may be permitted to be used in areas with corrosive atmospheres.

3-4.2.4 Fire dampers (doors) compatible with the rating of the barrier should be provided at the duct penetrations to the fire area (*see Section 3-1*) unless the duct is protected throughout its length by a fire barrier equal to the rating required of fire barrier(s) penetrated.

3-4.2.5 Smoke dampers, where installed, should be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*.

3-4.2.6 The fresh air supply intakes to all areas should be located remotely from the exhaust air outlets and smoke vents of other fire areas to minimize the possibility of drawing products of combustion into the plant.

3-4.2.7 Fire hazards should not be located in the principal access or air supply (e.g., conduits, shafts, tunnels) in order to avoid loss of fresh air in the event of a fire.

3-5 Drainage.

3-5.1

Provisions should be made in all fire areas of the plant for removal of all liquids directly to safe areas or for containment in the fire area without flooding of equipment and without endangering other areas. (*See Appendix A of NFPA 15, Standard for Water Spray Fixed Systems for Fire Protection.*) Drainage and prevention of equipment flooding should be accomplished by one or more of the following:

(a) Floor drains.

(b) Floor trenches.

(c) Open doorways or other wall openings.

(d) Curbs for containing or directing drainage.

(e) Equipment pedestals.

(f) Pits, sumps, and sump pumps.

NOTE: Draining the space above the turbine head cover by gravity may not be possible. Both ac and dc drainage pumps discharging into piping leading to the station sump are often provided with suctions in the well where the shaft first extends above the gland seal. In addition, gravity drainage may be impossible from some of the enclosed volumes of “bulb” units. In such cases, accumulated liquids from oil spills and from fire suppression should be pumped to sumps or to other containment volumes.

3-5.2

The provisions for drainage and any associated drainage facilities (pits, sumps, and sump pumps) should be sized to accommodate all of the following:

(a) The spill of the largest single container of any flammable liquid or combustible liquid, or both, in the area.

(b) The maximum design volume of discharge from the expected number of fire hose lines operating for a minimum of 20 minutes.

(c) The maximum design volume of discharge from the fixed fire suppression system(s) operating for a minimum of 20 minutes.

NOTE: The provisions for drainage and any associated drainable facilities (pits, sumps, drains to downstream surge chamber and/or tail tunnels or tailrace, and sump pumps) for underground power plants should be sized to accommodate the discharge from the maximum expected discharge of fixed fire suppression system(s) operating for a minimum of two hours.

3-5.3

Floor drainage from areas containing flammable or combustible liquids should be trapped to prevent the spread of burning liquids beyond the fire area.

3-5.4

Where gaseous fire suppression systems are installed, floor drains should be provided with adequate seals or the fire suppression system should be sized to compensate for the loss of fire suppression agent through the drains.

3-5.5

Drainage facilities should be provided for outdoor oil-insulated transformers, or the ground should be sloped such that oil spills will flow away from buildings, structures, and adjacent transformers. Unless drainage from oil spills is accommodated by sloping the ground around transformers away from structures or adjacent equipment, consideration should be given to providing curbed areas or pits around transformers. The pit or drain system or both should be sized in accordance with 3-5.2. The curbed area or pit may be permitted to be filled with uniformly graded, crushed stone as a means of minimizing ground fires.

3-5.6

For facilities consisting of more than one generating unit, a curb or trench drain should be provided on solid floors where the potential exists for an oil spill, such that oil released from an incident on one unit will not expose an adjacent unit.

3-5.7

For environmental reasons, liquid discharges resulting from oil spills or operation of a fire suppression system may have to be treated (e.g., oil separation).

3-5.8

An emergency power supply should be provided for principal drainage pumps in situations where flooding would be dangerous.

3-6 Emergency Lighting.

3-6.1

Emergency lighting should be provided for means of egress in accordance with NFPA *101*, *Life Safety Code*.

3-6.2

Emergency lighting should be provided for critical plant operations areas.

3-7 Lightning Protection.

Lightning protection, where required, should be provided in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

Chapter 4 General Fire Protection Systems and Equipment

4-1 General Considerations.

All fire protection systems, equipment, and installations should be dedicated to fire protection purposes.

4-2 Water Supply.

4-2.1

Hydroelectric plants are commonly located in remote areas adjacent to rivers or at the base of lakes. Fire protection water supplies may be permitted to be limited to the water from the river, lake, reservoir, or private tank(s). Consideration should be given to the special problems for this type of water supply (i.e., freezing, low flow, heavy sediment) associated with requirements for the fire protection systems, equipment, and installation.

4-2.2

The water supply for the permanent fire protection installation should be based on the largest fixed fire suppression system demand plus the maximum hose stream demand of not less than 500 gpm (31.5 L/sec) for a two-hour duration.

4-2.3

If a single water supply is utilized, two independent connections should be provided. If a situation can arise in which the primary water supply can become unavailable (e.g., dewatering of penstocks), an auxiliary supply should be provided. Each supply should be capable of meeting the requirements in 4-2.2.

4-2.3.1 Where multiple fire pumps are required, the pumps should not be subject to a common failure, electrical or mechanical, and should be of sufficient capacity to meet the fire flow requirements determined by 4-2.2 with the largest pump out of service.

4-2.3.2 Fire pumps should be automatic starting with manual shutdown. The manual shutdown should be at the pump controllers only. (*See NFPA 20, Standard for the Installation of Centrifugal Fire Pumps.*)

NOTE: For unattended stations, see Section 4-9.

4-2.3.3 If tanks are of dual-purpose use, a standpipe or similar arrangement should be provided to dedicate the amount determined by 4-2.2 for fire protection use only. (*See NFPA 22, Standard for Water Tanks for Private Fire Protection.*)

4-2.3.4 Where tanks are used, they should be filled from a source capable of replenishing the 2-hour supply for the fire protection requirement in an 8-hour period. The 8-hour (time) requirement for refilling may be permitted to be extended if the initial supply exceeds the minimum storage requirement on a volume per time ratio basis. It is normally preferred for the refilling operation to be accomplished on an automatic basis.

4-2.4

Each water supply should be connected to the station supply main by separate connections, arranged and valve controlled to minimize the possibility of multiple supplies being impaired simultaneously.

4-2.5

In some rivers and tributaries, the existence of microorganisms limits the use of raw water for fire protection without treatment. Consideration of water quality can prevent long-term problems relating to fire protection water supply.

4-2.6

Upstream water is frequently the fire protection water supply. Water for fire suppression should not be taken downstream from any closure device in a penstock, flume, or forebay.

4-3 Valve Supervision.

All fire protection water system control valves should be under a periodic inspection program (*see Chapter 2*) and should be supervised by one of the following methods:

(a) Electrical supervision with audible and visual signals in the main control room or other constantly attended location.

(b) Locking valves open. Keys should be made available only to authorized personnel.

(c) Sealing of valves. This option should be followed only when valves are within fenced enclosures under the control of the property owner.

4-4 Supply Mains and Hydrants.

4-4.1

Supply mains and fire hydrants should be installed on the plant site. (*See NFPA 24, Standard for the Installation of Private Fire Service Mains and Their Appurtenances.*)

4-4.1.1 Remotely located plant-related facilities should be reviewed on an individual basis to determine the need for fire protection. If excessively long extensions of underground fire mains are necessary for fire protection at these locations, it may be permitted to supply this need from an available service main in the immediate area.

4-4.1.2 The supply mains should be looped and of sufficient size to supply the flow requirements determined by 4-2.2 to any point in the loop considering the most direct path to be out of service. Pipe sizes should be designed to encompass any anticipated expansion and future water demands.

4-4.1.3 Indicator control valves should be installed to provide adequate sectional control of the fire main loop to minimize plant protection impairments.

4-4.2

Each hydrant should be equipped with a separate shutoff valve located on the branch connection to the supply main.

4-4.3

It may be necessary for the fire department to draft from the river or lake adjacent to the plant. However, the terrain and elevation above the water supply may make it difficult for drafting. Consideration should be given to installing a dry hydrant with adequate fire apparatus access that will take suction from the river above the hydroelectric plant.

4-5 Standpipe and Hose Systems.

4-5.1

Standpipe and hose systems should be installed. (*See NFPA 14, Standard for the Installation of Standpipe and Hose Systems.*) The standpipe and hose system is an extension of the fire main and hydrant system. The hose stations should be capable of delivering the hose stream demand for the various hazards in buildings.

4-5.2

Fire main connections for standpipes should be arranged so that a fire main break can be isolated without interrupting service simultaneously to both fixed protection and hose connections protecting the same hazard or area. For the important hazards the arrangement should permit operation of at least two hose lines on a fire. For areas of high water demand, the installation should meet the requirements for a Class III system. (*See NFPA 14, Standard for the Installation of Standpipe and Hose Systems.*) For other areas, a Class II system may be permitted to suffice.

4-5.3

The standpipe piping should be capable of providing minimum volume and pressure for the highest hose stations.

4-5.4

Due to the open arrangement of these plants, the locations of hose stations should take into account safe egress for personnel operating hose lines.

4-5.5

Spray nozzles having shutoff capability and listed for use on electrical equipment should be provided on hoses located in areas near energized electrical equipment.

4-5.6 Hose Threads.

Hose threads on hydrants and standpipe systems should be compatible with fire hose used by the responding fire departments.

4-6 Portable Fire Extinguishers.

For first aid fire protection, suitable fire extinguishers should be installed in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

4-7 Fire Suppression Systems and Equipment — General Requirements.

4-7.1

Fire suppression systems and equipment should be provided in all areas of the plant as identified in Chapter 5 or as determined by the Fire Risk Evaluation. Fixed suppression systems should be designed in accordance with the following codes and standards unless specifically noted otherwise:

NFPA 11, *Standard for Low-Expansion Foam*

NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*

NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*

NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*

NFPA 13, *Standard for the Installation of Sprinkler Systems*

NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*

NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*

NFPA 231, *Standard for General Storage*

NFPA 231C, *Standard for Rack Storage of Materials.*

4-7.2

The selection of extinguishing agent should be based on:

(a) Type of hazard.

(b) Effect of agent discharge on equipment.

(c) Health hazards.

NOTE: Personnel hazards created by the discharge of CO_2 should be considered in the design of the system. The design should take into account the immediate release of CO_2 into the protected area and the possibility of CO_2 leakage, migration, and settling into adjacent areas and lower elevations of the plant. See NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*, for hazards to personnel. As a minimum, if CO_2 systems are provided, they should be provided with an odorizer for alerting personnel, and breathing apparatus should be provided for operators in areas that cannot be abandoned.

4-7.3 Fire Suppression System Safety Considerations.

It is imperative that safety in the use of any fire suppression system be given proper consideration and that adequate planning be done to ensure safety of personnel.

Potential safety hazards could include impingement of high velocity discharge on personnel, loss of visibility, hearing impairment, reduced oxygen levels that will not support breathing, toxic effects of the extinguishing agent, and electric conductivity of water-based agents.

NFPA standards for the extinguishing systems used should be carefully studied and the personnel safety provisions followed. Evacuation of a protected area is recommended before any special extinguishing system discharges. Alarm systems that are audible above machinery background noise, or that are visual or olfactory or a combination, should be used where appropriate. Personnel warning signs are necessary. (*See NFPA 12, Standard on Carbon Dioxide Extinguishing Systems, and NFPA 12A, Standard on Halon 1301 Fire Extinguishing Systems.*)

4-8 Fire Signaling Systems.

4-8.1

Fire detection and automatic fixed fire suppression systems should be equipped with local audible and visual signals with annunciation in the main control room or another constantly attended location. (*See NFPA 72, National Fire Alarm Code*.)

4-8.1.1 Audible fire alarms should be distinctive from other plant system alarms.

4-8.1.2 Special consideration should be given to alerting personnel in confined spaces, such as in scroll/spiral cases or draft tubes, that a fire alarm system has been activated.

4-8.2

Automatic fire detectors should be installed in accordance with NFPA 72, *National Fire Alarm Code.*

4-8.3

The fire signaling system or plant communication system should provide the following:

(a) Manual fire alarm devices (e.g., pull boxes or page party stations) installed in all occupied buildings. Manual fire alarm devices should be installed for remote yard hazards as identified by the Fire Risk Evaluation.

(b) Plant-wide audible fire alarm or voice communication systems, or both, for purposes of personnel evacuation and alerting of plant emergency organization. The plant public address system, if provided, should be available on a priority basis.

(c) Two-way communications for the plant emergency organization during emergency operations.

(d) Means to notify the public fire department.

4-9 Unattended Plants.

4-9.1

Hydroelectric plants that are operated unattended, or with minimal staffing, present special fire protection concerns.

4-9.2

Consideration should be given both to the delayed response time of the fire brigade or public fire-fighting personnel (which can be several hours) and to the lack of personnel available to alert others on site to a fire condition.

4-9.3

The Fire Risk Evaluation should address delayed response and lack of communication. This may establish the need to provide additional fire protection measures to prevent a major fire spread prior to the arrival of fire-fighting personnel. The delayed response by personnel to the site may necessitate automatic shutoff of fire pumps.

4-9.4

If automatic water-based fire suppression systems are utilized, a cycling deluge valve should be considered. The arrangement will depend on the type of system and the hazard protected. Thermal detection is recommended. (System design should be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, or NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*.)

4-9.5

Remote annunciation of the fire signaling panel to one or more constantly attended location is critical for emergency response. The fire signaling panel should be located at the entry to the plant.

4-9.6

An emergency lighting system for critical operating areas that depends on batteries or fuel supplies should be manually operated from a switch at the entry to the plant. The emergency lighting may be permitted to consist either of fixed units or of portable lights. (*See 3-6.2.*)

4-9.7

It is important that the responding fire brigade or public fire-fighting forces be familiar with access, plant fire protection systems, emergency lighting, specific hazards, and methods of fire control. This should be reflected in the plant fire emergency plan. (*See Section 2-7.*)

4-9.8

The air supply and exhaust systems for the plant should be automatically shut down in the event of a fire. Manual override should be located at the entry to the plant so that emergency responders can activate these controls upon arrival.

Chapter 5 Identification and Protection of Hazards

5-1 General.

The identification and selection of fire protection systems should be based on the Fire Risk Evaluation. This chapter identifies fire and explosion hazards in hydroelectric generating stations and specifies the recommended protection criteria unless the Fire Risk Evaluation indicates otherwise.

5-2 Turbine-Generator Hydraulic Control and Lubricating Oil Systems.

5-2.1 Hydraulic Control Systems.

5-2.1.1 Hydraulic control systems should use a listed fire-resistant fluid.

5-2.1.2 Determination of the need for fire-resistant fluid should be based on the quantity of fluid involved in the system, whether or not equipment that utilizes this fluid will operate hot or be exposed to external sources of ignition, and whether exposure problems are created for adjacent equipment by the use of nonfire-resistant fluid.

5-2.1.3 If a listed fire-resistant fluid is not used, hydraulic control equipment should be protected. Fire extinguishing systems, where installed for hydraulic control equipment, should include protection for reservoirs, other equipment, valves, and associated piping.

5-2.2

Wherever possible, oil piping should be welded and flanged to minimize the possibility of an oil leak due to severe vibration.

5-2.3

Oil piping should be routed away, or be shielded from, electrical equipment or other sources of ignition.

5-2.4

Fixed fire protection for this equipment, where provided, should be as follows:

(a) Automatic wet pipe sprinkler systems utilizing a design density of 0.25 gpm/ft^2 (0.17 $L/sec\text{-}m^2$) for the entire hazard area (*see 3-5.3*).

(b) Automatic foam-water sprinkler systems providing a density of 0.16 gpm/ft^2 (0.11 L/sec-m^2).

(c) Gaseous extinguishing systems of either the local application or total flooding types. Safety considerations associated with these extinguishing agents should be evaluated prior to the selection of gas-type protection systems.

NOTE: When areas or rooms are located beneath areas protected by CO_2 (or other extinguishing gases), consideration should be given in the design for the possible settling of the gas to lower levels and its effect on personnel who may be in these areas.

5-2.5

Consideration for protection of horizontal and vertical turbine bearings should be made based on the Fire Risk Evaluation.

5-2.6

Curbs [minimum 6 in. (0.15 m) high] or drains or both should be provided for the oil storage and oil purification areas in accordance with Chapter 3.

5-2.7

Fire extinguishing systems, where installed for lube oil systems employing combustible-type oil, should include protection for the reservoirs, pumps, and all oil lines, especially where unions exist on piping and beneath any shielded area where flowing oil can collect. Facilities not provided with curbs or drains should extend coverage for a distance of 20 ft (6 m) from the oil lines, when measured from the outermost oil line.

5-2.8

Clean or dirty oil storage areas should be protected based on the Fire Risk Evaluation. This area generally represents the largest concentrated oil storage in the plant. The designer should consider, as a minimum, the installation of fixed automatic fire protection systems, and the ventilation and drainage requirements in Chapter 3.

5-3 Generator Windings.

5-3.1

Protection of generator windings should be provided by gaseous extinguishing systems, waterspray rings, or both. Consideration for protection should be given to the composition of the winding insulation and the rating of the generator.

5-3.2

Gaseous suppression systems should be actuated by protective relays or fire detection systems or both.

5-3.3

Waterspray rings should be manually actuated or automatically actuated by an interlocked system that requires the unit to be tripped.

5-4 Control, Computer, and Communication Rooms.

5-4.1

Control, computer, and telecommunication rooms should meet applicable requirements of NFPA 75, *Standard for the Protection of Electronic Computer/Data Processing Equipment*.

5-4.2

A smoke detection system should be installed throughout these rooms including walk-in-type consoles, above suspended ceilings where combustibles are installed, and below raised floors. Where the only combustibles above the false ceiling are cables in conduit and the space is not used as a return air plenum, smoke detectors may be permitted to be omitted from this area.

5-4.3

A preaction sprinkler system for the computer or telecommunications rooms should be considered during the Fire Risk Evaluation. In addition, gaseous extinguishing systems should be considered for areas beneath raised floors that contain cables or for areas or enclosures containing equipment that is of high value or is critical to power generation. Individual equipment or cabinet protection could be considered in lieu of total flooding systems.

5-4.4

Cable raceways not terminating in the control room should not be routed through the control room.

5-5 Cable Concentrations.

5-5.1

Consideration should be given to the use of fire-retardant cable insulation such as the types that pass the flame propagation test of the Institute of Electrical and Electronics Engineers (IEEE-383).

5-5.2

Areas with significant concentrations of combustible cable jacketing or oil-filled cable should be protected with automatic sprinkler or water spray systems. However, if water-type systems cannot be used, foam or gaseous extinguishing systems should be provided.

5-5.3

Sprinkler or water spray systems should be designed for a density of 0.30 gpm/ft^2 (0.20 L/sec-m^2) over 2500 ft^2 (232 m^2). This coverage is for area protection. Individual cable tray tier coverage could be required based on the Fire Risk Evaluation.

5-5.4 Cable with Fire-Retardant Coatings.

5-5.4.1 A suitable alternative for combustible jacket cable automatic protection would be cable with fire-retardant coatings. The method of protection should be based on the Fire Risk Evaluation.

5-5.4.2 Care should be exercised in selection of fire-retardant coatings to ensure that derating of the cable is considered. Consideration should also be given to the ability to add or remove cables and to make repairs to cables protected with fire-retardant coatings.

5-5.5

Grouped electrical cables should be routed away from exposure hazards or protected as required by the Fire Risk Evaluation. In particular, care should be taken to avoid routing cable trays near sources of ignition or flammable or combustible liquids. Where such routing is unavoidable, cable trays should be designed and arranged to prevent the spread of fire.

5-6 Cable Tunnels.

5-6.1

Where protection is required by the Fire Risk Evaluation, cable tunnels should be protected by automatic water spray, automatic wet pipe sprinkler, or foam systems. Automatic sprinkler systems should be designed for a density of 0.30 gpm/ft^2 (0.20 L/sec-m^2) over 2500 ft^2 (232 m^2) or the most remote 100 linear ft (30 m) of cable tunnel up to 2500 ft^2 (232 m^2).

5-6.2

Portable high-expansion foam generators may be permitted to be used to supplement fixed fire protection system(s). (*See NFPA 11C, Standard for Mobile Foam Apparatus.*)

5-6.3

Ventilation and drainage should be provided for these areas in accordance with Chapter 3.

5-7 Transformers.

Oil-filled main, station service, and startup transformers should be protected with automatic water spray or foam-water spray systems.

5-8 Indoor Oil-Filled Electrical Equipment.

Automatic sprinkler, foam-water, and water spray systems should be considered for oil-filled electrical equipment. Where the hazard is not great enough to warrant a fixed fire suppression system, automatic fire detection should be considered. (*See 4-8.2.*)

5-9 Battery Rooms.

Battery rooms should be provided with ventilation to limit the concentration of hydrogen to one percent by volume. For further information, refer to ANSI/IEEE 484, *Recommended Practice for Installation Design and Installation of Large Lead Storage Batteries for Generating Stations and Substations*.

5-10 Switchgear and Relay Rooms.

Switchgear rooms and relay rooms should be provided with smoke detection systems.

5-11 Emergency Generators.

5-11.1

The installation and operation of emergency generators should be in accordance with NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*.

5-11.2

Emergency generators located within main plant structures should be protected by automatic sprinkler, water spray, foam-water sprinkler, or gaseous-type extinguishing systems. Sprinkler and water spray protection systems should be designed for a 0.25 gpm/ft^2 (0.17 L/sec-m^2) density over the fire area.

5-11.3

Where gaseous suppression systems are used on combustion engines, which can be required to operate during the system discharges, consideration should be given to the supply of engine combustion air and outside air for equipment cooling.

5-12 Air Compressors.

Automatic sprinkler protection, with a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the postulated oil spill, should be considered for air compressors containing a large quantity of oil. Where the hazard is not great enough to warrant a fixed fire suppression system, automatic fire detection should be considered. (*See 4-8.2.*)

5-13 Hydraulic Systems for Gate and Valve Operators.

Hydraulic control systems should use a listed fire-resistant fluid. Automatic sprinkler protection designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the fire area should be considered for hydraulic systems not using a listed fire-resistant fluid. Where the hazard is not great enough to warrant a fixed fire suppression system, automatic fire detection should be considered. (*See 4-8.2.*)

5-14 Fire Pumps.

Rooms housing diesel-driven fire pumps should be protected by automatic sprinkler, water spray, or foam-water sprinkler systems. If sprinkler and water spray protection systems are provided they should be designed for a density of 0.25 gpm/ft^2 (0.17 L/sec-m^2) over the fire area. For automatic foam-water sprinkler systems, a density of 0.16 gpm/ft^2 (0.11 L/sec-m^2) should be provided.

5-15 Storage Rooms, Offices, and Shops.

Automatic sprinklers should be provided for storage rooms, offices, and shops containing combustible materials that present an exposure to surrounding areas that are critical to plant operations. (*For oil storage rooms, see 5-2.8.*)

5-16 Warehouses.

Automatic sprinklers should be provided for warehouses that contain high-value equipment and combustible materials that are critical to power generation or that constitute a fire exposure to other important buildings.

5-17 Auxiliary Heating.

The storage and piping systems of fuels in the gaseous or liquefied state should comply with NFPA 31, *Standard for the Installation of Oil Burning Equipment*; NFPA 54, *National Fuel Gas Code*; NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*; and NFPA 8501, *Standard for Single Burner Boiler Operation*, as applicable.

5-18 Garages.

Vehicle repair facilities should meet the requirements of NFPA 88B, *Standard for Repair Garages*.

Chapter 6 Fire Protection for the Construction Site

6-1 Introduction.

6-1.1

Although many of the activities in hydroelectric generating plant construction are similar to the construction of other large industrial plants, sites for hydroelectric generating plants are frequently located in remote areas with restricted access and limited construction space. Congested or distant construction facilities may be required, and specialized activities such as deep excavation and tunneling may be encountered. An above average level of construction fire protection is justified due to the life safety consideration of the large number of on-site personnel, high value of materials, and length of construction period.

6-1.2

Major construction projects in existing plants present many of the hazards associated with new construction while presenting additional exposures to the existing facility. The availability of the existing plant fire protection equipment and the reduction of fire exposure by construction activities are particularly important.

6-1.3

For fire protection for plants and areas under construction, see NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations.* This chapter addresses concerns not specifically considered in NFPA 241.

6-2 Administration.

6-2.1

The responsibility for fire prevention and fire protection for the entire site during the construction period should be clearly defined. The administrative responsibilities should be to develop, implement, and periodically update as necessary the measures outlined in this practice.

6-2.2

The responsibility for fire prevention and fire protection programs among various parties on site should be clearly delineated. The fire protection program that is to be followed and the owner’s right to administration and enforcement should be established.

6-2.3

The fire prevention and fire protection program should include a Fire Risk Evaluation of the construction site and construction activities at any construction camp. (*See Chapter 2.*)

6-2.4

Written administrative procedures should be established for the construction site, and such procedures should, as a minimum, be in accordance with Sections 2-4, 2-5, and 2-7.

6-2.5

Security guard service, including recorded rounds, should be provided through all areas of construction during times when construction activity is not in progress. (*See NFPA 601, Standard for Security Services in Fire Loss Prevention.*)

6-2.5.1 The first round should be conducted one-half hour after the suspension of work for the day. Thereafter, rounds should be made every hour.

6-2.5.2 Where partial construction activities occur on second and third shifts, the security service rounds may be permitted to be modified to include only unattended or sparsely attended areas.

6-2.5.3 In areas where automatic fire detection or extinguishing systems are in service, with alarm annunciation at a constantly attended location, or in areas of limited combustible loading, rounds may be permitted to be omitted after the first round indicated in 6-2.5.1.

6-2.6

Construction should be coordinated so that planned permanent fire protection systems are installed and placed in service as soon as possible, at least prior to the introduction of any major fire hazards identified in Chapter 5. In-service fire detection and fire extinguishing systems provide important protection for construction materials, storage, etc., even before the permanent hazard is present. Temporary fire protection systems may be warranted during certain construction phases. The need and type of protection should be determined by the individual responsible for fire prevention and fire protection. Construction and installation of fire barriers and fire doors should be given priority in the construction schedule.

6-3 Site Clearing, Excavation, and Tunneling.

6-3.1 Site Clearing.

6-3.1.1 Prior to clearing forest and brush covered areas, the owner should ensure that a written fire control plan is prepared and that fire-fighting tools and equipment are made available as recommended by NFPA 295, *Standard for Wildfire Control*. Contact should be made with local fire and forest agencies for current data on restrictions and fire potential and to arrange for necessary permits.

6-3.1.2 All construction vehicles and engine-driven portable equipment should be equipped with effective spark arrestors. Vehicles equipped with catalytic converters should be prohibited from wooded and heavily vegetated areas.

6-3.1.3 Fire tools and equipment should be used for fire emergencies only and should be distinctly marked.

6-3.1.4 Each site utility vehicle should be equipped with at least one fire-fighting tool, portable fire extinguisher, or backpack pump filled with 4 gal to 5 gal (15 L to 19 L) of water.

6-3.1.5 Cut trees, brush, and other combustible spoil should be disposed of promptly.

6-3.1.6 Where it is necessary to dispose of combustible waste by onsite burning, designated burning areas should be established with approval by the owner and should be in compliance with federal, state, and local regulations and guidelines. The contractor should coordinate burning with the agencies responsible for monitoring fire danger in the area and obtain all appropriate permits prior to the start of work. (*See Section 6-2.*)

6-3.1.7 Local conditions may require the establishment of fire breaks by clearing or use of selective herbicides in areas adjacent to property lines and access roads.

6-3.2 Excavation and Tunneling.

6-3.2.1 Construction activities related to tunnels, shafts, and other underground excavations are strictly regulated by federal and state agencies. Fire prevention consists of adequate ventilation, good housekeeping, and limiting the types of fuel, explosives, and combustibles underground as well as adjacent to entrances and ventilation intakes. Inspection of site conditions and the testing of air quality should be assigned to qualified personnel specifically trained in the use of those instruments specified by the regulating agency.

6-3.2.2 Pre-excavation geologic surveys should include tests for carbonaceous or oil-bearing strata, peat, and other organic deposits that can be a source of combustible dusts or explosive gases.

6-3.2.3 The use of vehicles and equipment requiring gasoline, liquefied petroleum gas, and other fuels in excavations with limited air circulation should be restricted.

6-3.2.4 A general plan of action for use in times of emergency should be prepared for every underground excavation. (*See Section 6-2.*)

6-3.3 Construction Equipment.

Construction equipment should meet the requirements of NFPA 121, *Standard on Fire Protection for Self-Propelled Mobile Surface Mining Equipment*, and NFPA 512, *Standard for Truck Fire Protection.*

6-4 Construction Warehouses, Shops, Offices, and Construction Camps.

6-4.1

All structures that are to be retained as part of the completed plant should be constructed of materials as required in Chapter 3 and should comply with other requirements of this document for the completed plant.

6-4.2

Construction warehouses, offices, trailers, sheds, and other facilities for the storage of tools and materials should be located with consideration for their exposure to major plant buildings or other important structures. These buildings should be located according to the requirements of NFPA 80A, *Recommended Practice for Protection of Buildings from Exterior Fire Exposures*, and NFPA 299, *Standard for Protection of Life and Property from Wildfire*, as applicable.

6-4.3

Mobile homes should be installed and located according to the requirements of NFPA 501A, *Standard for Fire Safety Criteria for Manufactured Home Installations, Sites, and Communities*. Insulating materials utilized in mobile homes should be noncombustible.

6-4.4

Large central office or storage facilities, where provided, should be located so as not to expose major plant buildings or other important structures. These facilities can be of substantial value, containing high value computer equipment, irreplaceable construction records, or other valuable contents, the loss of which could result in significant construction delays. The Fire Risk Evaluation may indicate a need for automatic sprinklers or other protection, the desirability of subdividing the complex to limit values exposed by one fire, or a combination of the above.

6-4.5

Construction camps comprised of mobile buildings arranged with the buildings adjoining each other to form one large fire area should be avoided. If buildings cannot be adequately separated, consideration should be given to installing fire walls between units or installing automatic sprinklers throughout the buildings.

6-4.6

Construction camp buildings should be designed and installed in accordance with NFPA *101*, *Life Safety Code*.

6-4.7

Area fire alarms should be connected to a constantly attended central location such as a fire station or site manager's office with monitoring and central alarm control. Dormitory buildings and bunkhouses should be provided with smoke detection throughout. The alarm panels for the individual buildings served should be located at the entrance to the building. Detector installation should conform to NFPA 72, *National Fire Alarm Code.*

6-4.8

The location for central alarm control should be provided with the following:

(a) Remote fire pump start button.

(b) Manual siren start/stop button.

(c) Provision for alerting the fire crew by VHF radio, fire alert paging, etc.

(d) Monitors for communication between security guard and fire crew at place of fire.

(e) Radio link between security guards' office and the respective fire department.

6-4.9

Warehouses and shops can contain materials whose loss or damage would cause a delay in startup or severe financial loss. Although some of these structures are considered to be temporary and will be removed upon completion of the plant, the fire and loss potential should be thoroughly evaluated and protection provided where warranted. Where the Fire Risk Evaluation indicates a need for protection for warehouses and shops the following guidelines should apply.

6-4.9.1 Building construction materials should be noncombustible or limited combustible. (*See Chapter 3*.)

6-4.9.2 Automatic sprinkler systems should be designed and installed in accordance with the applicable NFPA standards. Waterflow alarms should be provided and located so as to be monitored at a constantly attended location as determined by the individual responsible for fire prevention and fire protection.

6-4.9.3 Air-supported structures are sometimes used to provide temporary warehousing space. Although the fabric envelope may be a fire-retardant material, the combustibility of contents and their value should be considered, as with any other type of warehouse. Because it is impractical to provide automatic sprinkler protection for them, air-supported structures should only be used for noncombustible storage. An additional consideration is that relatively minor fire damage to the fabric envelope can leave the contents exposed to the elements.

6-4.10

Temporary enclosures, including trailers, inside permanent plant buildings should be prohibited except where permitted by the individual responsible for fire prevention and fire protection. Where the floor area of a combustible enclosure exceeds 100 ft^2 (9.3 m^2) or where the occupancy presents a fire exposure, the enclosure should be protected with an approved automatic fire extinguishing system.

6-4.11

Storage of construction materials, equipment, or supplies that are either combustible or in combustible packaging should be prohibited in main plant buildings unless:

(a) An approved automatic fire extinguishing system is in service in the storage area, or

(b) The loss of the materials or loss to the surrounding plant area would be minimal, as determined by the individual responsible for fire prevention and fire protection.

6-4.12

Construction kitchens should have automatic protection installed over the fryers. Guidance is provided in NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*.

6-4.13

Vehicle repair facilities should meet the requirements of NFPA 88B, *Standard for Repair Garages*.

6-4.14

The handling, storage, and dispensing of flammable liquids and gases should meet the requirements of NFPA 30, *Flammable and Combustible Liquids Code*, NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*, and NFPA 395, *Standard for the Storage of Flammable and Combustible Liquids at Farms and Isolated Sites*.

6-5 Construction Site Laydown Areas.

6-5.1

Fire hydrant systems with an adequate water supply should be provided in laydown areas where the need is determined by the individual responsible for fire prevention and fire protection. (*See Chapter 4*.)

6-5.2

Combustible materials should be separated by a clear space to allow access for manual fire-fighting equipment (*see Section 6-8*). Access should be provided and maintained to all fire-fighting equipment including fire hoses, extinguishers, and hydrants.

6-6 Temporary Construction Materials.

6-6.1

The use of listed pressure-impregnated fire-retardant lumber or listed fire-retardant coatings would be generally acceptable. Pressure-impregnated fire-retardant lumber should be used in accordance with its listing and manufacturer's instructions. Where exposed to the weather or moisture (e.g., draft tubes, semi-spiral cases), the fire retardant used should be suitable for this exposure. Fire-retardant coatings should not be permitted on walking surfaces or surfaces subject to mechanical damage.

6-6.2

Tarpaulins and plastic films should be of listed weather-resistant and fire-retardant materials. (*See NFPA 701*, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*.)

6-6.3

Consideration should be given to providing sprinkler protection for combustible form work where a fire could cause substantial damage or construction delays.

6-7 Underground Mains, Hydrants, and Water Supplies.

6-7.1

Where practical, the permanent underground yard system, fire hydrants, and water supply (at least one totally reliable source of required capacity), as recommended in Chapter 4, should be installed during the early stages of construction. Where provision of all or part of the permanent underground system and water supply is not practical, temporary systems should be provided. Temporary water supplies should be hydrostatically tested, flushed, and arranged to maintain a high degree of reliability, including protection from freezing and loss of power. Where using construction water in permanent systems, adequate strainers should be provided to prevent clogging of the system by foreign objects and dirt.

6-7.2

The necessary reliability of construction water supplies, including redundant pumps, arrangement of primary and backup power supplies, and use of combination service water and construction fire protection water, should be reviewed by the individual responsible for fire prevention and fire protection.

6-7.3

Hydrants should be installed, as recommended by Chapter 4, in the vicinity of main plant buildings, important warehouses, office or storage trailer complexes, important outside structures and laydown areas with combustible construction, construction camp complexes, or combustible concrete form work (e.g., draft tube and turbine-generator blockouts). Where practical, the underground main should be arranged utilizing post indicator valves to minimize the possibility that any one break will remove from service any fixed water extinguishing system or leave any area without accessible hydrant protection.

6-7.4

A fire protection water supply should be provided on the construction site and should be capable of furnishing the largest of the following for at least a 2-hour duration:

(a) 750 gpm (47 L/sec), or

(b) The in-service fixed water extinguishing system with the highest water demand plus 500 gpm (32 L/sec) for hose streams.

NOTE 1: The highest water demand should be determined by the hazards present at the stage of construction, which may not correspond with the highest water demand of the completed plant.

NOTE 2: The water supply should be sufficient to provide adequate flow and pressure for hose connections at the highest elevation.

6-7.5

Vehicles, equipment, materials, and supplies should be placed so that access to fire hydrants and other fire-fighting equipment is not obstructed.

6-7.6

Fixed systems should be provided as soon as construction permits. These systems should be provided in continuous operating condition.

6-7.7

As fixed water extinguishing systems are completed, they should be placed in service, even when the available construction phase fire protection water supply is not adequate to meet the system design demand. The extinguishing system can at least provide some degree of protection, especially where the full hazard is not yet present. However, when the permanent hazard is introduced, the water supply should be capable of providing the designed system demand.

6-7.8

On sites where large differences in elevation exist between construction facilities, satisfying pressure requirements at the highest elevation can result in hazardous pressure conditions at the lower elevations unless some approved method of pressure regulation is included in the system. Attempting to compensate for high-pressure conditions by partially opening dry barrel hydrants can result in erosion at the hydrant thrust block and should be avoided.

6-8 Fire Suppression Systems and Equipment.

6-8.1

In general, fire suppression equipment should be:

(a) Provided where risk of fire exists.

(b) Suitable as to type and size for combating any likely fire.

(c) Protected from mechanical damage.

(d) Located for easy access at well-identified stations.

(e) Maintained in good operating condition.

(f) Protected from freezing.

6-8.2

Portable fire extinguishers of suitable capacity should be provided where:

(a) Flammable liquids are stored or handled.

(b) Temporary oil- or gas-fired equipment is used.

(c) A tar or asphalt kettle is used.

(d) Welding or open flames are in use.

(*See NFPA 10, Standard for Portable Fire Extinguishers.*)

6-8.3

First aid fire-fighting equipment should be provided. (*See NFPA 600, Standard on Industrial Fire Brigades, and NFPA 241, Standard for Safeguarding Construction, Alteration, and*

Demolition Operations.)

6-8.4

Hoses and nozzles should be available at strategic locations inside hose cabinets, hose houses, or on dedicated fire response vehicles.

6-8.5

No fire protection equipment or device should be made inoperable or used for other purposes.

6-8.6

If fire hose connections are not compatible with local fire-fighting equipment, adapters should be made available.

Chapter 7 Referenced Publications

7-1

The following documents or portions thereof are referenced within this recommended practice and should be considered part of the recommendations of the document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

7-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

Appendix A Explanatory Material

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

A-1-4 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-8.2

Recommendations contained in NFPA 600, *Standard on Industrial Fire Brigades*, and 29 CFR 1910, Subparts E and L, should be consulted for additional information.

Appendix B

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

Sample Fire Report

Name of company: ____

Date of fire: __________ Time of fire: __________ Operating facility: ____________

Under construction: ____

Plant or location where fire occurred: ____________________________

Description of facility, fire area, or equipment (include nameplate rating) involved: ________

____

____

Cause of fire, such as probable ignition source, initial contributing fuel, equipment failure causing ignition, etc.: ____

____

____

Story of fire, events, and conditions preceding, during, and after the fire: ______________

____

____

____

Types and approx. quantities of portable extinguishing equipment used: ________________

____

____

____

Was fire extinguished with portable equipment only? ________________________

Public fire department called? ____________ Employee fire brigade at this location? ____

Qualified for incipient fires? ______________ For interior structural fires? ______________

Was fixed fire extinguishing equipment installed? __________________________

Type of fixed extinguishing system: ______________________________________

Automatic operation: __________ , manually actuated: __________ or both: ________

Specific type of detection devices: ______________________________________

Did fixed extinguishing system control? ____________ and/or extinguish fire? ________

Did detection devices and extinguishing system function properly? ________________

If "no," why not? ____

____

Estimated direct damage due to fire: $ _________ , or between $ ____ and $ _________

Estimated additional (consequential) loss: $ ___________ Nature of additional loss: ______

____

Estimated time to complete repairs/replacement of damaged equipment/structure: ___________

Number of persons injured: ________________________ Number of fatalities: ___________

What corrective or preventive suggestions would you offer to other utilities who may have similar equipment, structures, or extinguishing systems? _______________________________

____

____

Submitted by: ______________________________ Title: ______________________________
