NFPA 402

1996 Edition

Guide for Aircraft Rescue and Fire Fighting Operations

1996 Edition

This edition of NFPA 402, *Guide for Aircraft Rescue and Fire Fighting Operations*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc. at its Annual Meeting held May 20–23, 1996 in Boston, MA. It was issued by the Standards Council on July 18, 1996, with an effective date of August 9, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 402 was approved as an American National Standard on July 26, 1996.

Origin and Development of NFPA 402

These standard operating procedures were first developed by the sponsoring NFPA committee in 1947 and were first adopted by the Association in 1951. They were amended in 1969 and 1973. In 1984, the Committee combined the text of NFPA 406M, *Manual on Aircraft Rescue and Fire Fighting Techniques for Fire Departments Using Structural Fire Apparatus and Equipment*, with the text of NFPA 402, *Recommended Practice for Aircraft Rescue and Fire Fighting Operational Procedures for Airport Fire Departments*, and reidentified the document as NFPA 402M. The entire texts of both NFPA 402 and NFPA 406M were revised to create NFPA 402M. The 1989 edition of NFPA 402M was a complete revision of the manual. This guide was revised again in 1991.

The aircraft figures were deleted for the 1996 edition. A comprehensive collection of figures is now available in a publication titled *NFPA Aircraft Familiarization Charts Manual*.

Task Group on Aircraft Rescue and Fire Fighting Operational Procedures

Edward B. (Ned) Aksim, Consultant, PA; John Cedric Black, BAA plc, England; Brian Boucher, Canadian Air Line Pilots Assn., ON, Canada; Derek K. G. Dodwell, Civil Aviation Authority, England; Robert J. Donahue, Massport, MA; Vic Hewes, Airport Safety Services, GA; Noreene Koan, Assn. of Flight Attendants, CA; Jack McComb, Quality Fire Mgmt., NV;

John J. O'Sullivan, British Airways, England; Davis R. Parsons, Los Angeles City Fire Dept., CA; Richard M. Radford, The Fire Service College, England; Robert G. Relyea, ARFF Working Group, TX; Robert E. Reyff, Dallas, TX; Robert W. Rice, Air Force Flight Test Center, CA; John M. Schuster, 3M Co., MN; Bernard Valois, Safety & Technical Services Directorate, Canada; A. R. Villegas, U.S. Navy, CA; Pam Walden, The Port Authority of NY & NJ, NY; Ronald O. Wikander, Lockheed Aeronautical Systems Co., GA; Larry E. Williams, Emergency Response Training Academy, Inc., AR; Richard G. Winnie, Westinghouse Electro-Optical Systems, FL; Joseph A. Wright, FAA Technical Center, NJ; Joe Ybarra, U.S. Air Force, FL.

Technical Committee on Aircraft Rescue and Fire Fighting

Brian Boucher, *Chair*
Canadian Air Line Pilots Assn., Canada
Rep. Canadian Air Line Pilots Assn.

Robert J. Donahue, *Secretary*
Massport Fire Dept., Logan Int'l Airport, MA

John Cedric Black, BAA plc, Heathrow Airport Ltd, England

Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA

Ralph Colet, John Russo Industrial Inc., CA

Robert L. Darwin, U.S. Dept. of the Navy, DC

Derek K. G. Dodwell, Civil Aviation Authority, England

Fred B. Goodnight, Amerex Corp., AL
Rep. Fire Equipment Mfrs. Assn. Inc.

B. V. Hewes, Airport Safety Services, GA

Paul O. Huston, Paul O. Huston, PE & Assoc., AL

D. Steve Kiernan, Nat'l Foam, Inc., PA

L. M. Krasner, Factory Mutual Research Corp., MA

Dave Lenz, Oshkosh Truck Corp., WI

John J. O'Sullivan, British Airways, England

Davis R. Parsons, Los Angeles City Fire Dept., CA

Nonvoting

Gary Hammack, U.S. Nat'l Transportation Safety Board, DC
(Alt. to L. D. Roman)

Thomas J. Lett, Albuquerque Fire & Safety Assoc. Inc., NM
(Member Emeritus)

Paul J. Lindsay, Transport Canada, Ottawa, Canada
(Alt. to B. Valois)

John E. Lodge, Lodge Fire Protection Consultancy Ltd, England
(Member Emeritus)

James F. O'Regan, Westboro, MA
(Member Emeritus)

Lawrence D. Roman, U.S. Nat'l Transportation Safety Board, DC

David F. Short, Carmichael Int'l Ltd, England

Bernard Valois, Transport Canada, Ottawa, Canada

Mark T. Conroy, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on aircraft rescue and fire fighting services and equipment, for procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports, with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. This Committee also shall have responsibility for documents on aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 402
Guide for
Aircraft Rescue and
Fire Fighting Operations

1996 Edition

NOTICE: Information on referenced publications can be found in Chapter 13 and Appendix F.

Chapter 1 Administration

1-1 Scope.

1-1.1

This guide provides information relative to aircraft rescue and fire fighting operations and procedures for airport and structural fire departments. These procedures deal with aircraft not involved in military operations. They can, however, be generally applicable to military aircraft not operating in an armament mode. For specific guidance in these matters, consult the commander or fire chief of the nearest military air installation.

1-1.2

Statistics indicate that approximately 80 percent of all major commercial aircraft accidents occur in the critical rescue and fire fighting access area. This is the primary response area for airport-based ARFF services. Approximately 15 percent of the accidents occur in the approach areas. In such instances the community/mutual services could be the prime responders.

1-1.3

Some airport fire departments have the total fire prevention and fire protection responsibility for the entire airport, including structural fire fighting responsibilities in terminal buildings, aircraft hangars, airport hotels, cargo buildings, and other facilities. Procedures for these fire prevention and protection operations are not covered in this guide.

1-2 Purpose.

1-2.1

This guide has been prepared for the use and guidance of those charged with the responsibility of providing and maintaining aircraft rescue and fire fighting (ARFF) services on airports.

1-2.2

The guide's content is also intended for the use of structural fire departments to assist them in developing methods to effectively handle aircraft incidents that might occur within their jurisdiction. It also provides for a basis of understanding, relative to emergencies on airports, that would enhance structural fire departments’ effectiveness when called to assist airport fire departments.

1-3 General.

1-3.1

Providing protection for the occupants of an aircraft takes precedence over all other operations. Fire control is frequently an essential condition to ensure such survival. The objectives of the airport fire department should be to respond to any aircraft emergency in the minimum possible time and employ rescue and fire fighting techniques effectively. These objectives can be accomplished when properly trained personnel work together as a team and apply the operational procedures presented in this guide.

1-3.2

Governmental and organizational publications frequently referenced in this guide can be found in Chapter 14.

1-3.3

If a value for measurement as given in this guide is followed by an equivalent value in other units, the first stated is to be regarded as the requirement. A given equivalent value might be approximate.

1-3.4

Metric units of measurement in this guide are in accordance with the modernized metric systems known as the International System of Units (SI). One unit (liter), outside of, but recognized by SI, is commonly used in international fire protection.

1-4 Definitions.

Air Accident Investigations Branch (AAIB). A UK agency that is responsible for investigating and determining the probable cause of all British aircraft accidents.

Air-Cushioned Vehicle (ACV). A vehicle that can travel on land and water.

Aircraft Accident. An occurrence during the operation of an aircraft in which any person involved suffers death or serious injury or in which the aircraft receives substantial damage.

Aircraft Accident Pre-Incident Planning. This term is used to describe the process of forecasting all factors that could possibly exist involving an aircraft accident that could bear upon the existing emergency resources. A pre-incident plan should define the emergency organizational authority and the responsibilities of all those involved.

Aircraft Defueling. See Fuel Servicing.

Aircraft Familiarization. Refers to the knowledge of vital information that rescue and fire fighting personnel should learn and retain with regard to the specific types of aircraft that normally use the airport and other aircraft that might use the airport due to weather conditions at scheduled destinations.

Aircraft Fire Fighting. The control or extinguishment of fire adjacent to or involving an aircraft following ground accidents/incidents. Aircraft fire fighting does not include the control or extinguishment of airborne fires in aircraft.

Aircraft Incident. An occurrence, other than an accident associated with the operation of an aircraft, that affects or could affect continued safe operation if not corrected. An incident does not result in serious injury to persons or substantial damage to aircraft.

Aircraft Rescue and Fire Fighting (ARFF). The fire fighting action taken to prevent, control, or extinguish fire involved or adjacent to an aircraft for the purpose of maintaining maximum escape routes for occupants using normal and emergency routes for egress. Additionally, ARFF personnel will enter the aircraft to provide assistance to the extent possible in the evacuation of the occupants. Although life safety is primary to ARFF personnel, responsibilities such as fuselage integrity and salvage should be maintained to the extent possible.

Airport (Aerodrome). An area on land or water that is used or intended to be used for the landing and takeoff of aircraft and includes buildings and facilities.

Airport Air Traffic Control (ATC). A service established to provide air and ground traffic control for airports.

Airport Familiarization. Refers to the knowledge that rescue and fire fighting personnel must maintain relative to locations, routes, and conditions that will enable them to respond quickly and efficiently to emergencies on the airport and those areas surrounding the airport.

Aluminum. A lightweight metal used extensively in the construction of aircraft airframes and skin sections.

Approved. Acceptable to the authority having jurisdiction.

NOTE: The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Auxiliary Power Unit (APU). A self-contained power source, provided as a component of an aircraft, that is used to energize aircraft systems when power plants are not operating or when external power is not available.

Backdraft. A phenomenon that occurs when a fire takes place in a confined area such as a sealed aircraft fuselage and burns undetected until most of the oxygen within is consumed. The heat continues to produce flammable gases, mostly in the form of carbon monoxide. These gases are heated above their ignition temperature and when a supply of oxygen is introduced, as when normal entry points are opened, the gases could ignite with explosive force.

Bogie. A tandem arrangement of aircraft landing gear wheels. The bogie can swivel up and down so that all wheels follow the ground as the attitude of the aircraft changes or the ground surface changes.

Cockpit Voice Recorder (CVR). A device that monitors flight deck crew communications through a pickup on the flight deck connected to a recorder that is usually mounted in the tail area of the aircraft and that is designed to withstand certain impact forces and a degree of fire.

COMBI. An aircraft designed to transport both passengers and cargo on the same level within the fuselage.

Command Post (CP). The location at the scene of an emergency where the Incident Commander is located and where command, coordination, control, and communications are centralized.

Composite Materials. Lightweight materials having great structural strength. They are made of fine fibers embedded in carbon/epoxy materials. The fibers are usually boron, fiberglass, aramid, or carbon in the form of graphite. Composite materials do not present unusual fire fighting problems, but products of their combustion should be considered a respiratory hazard to fire fighters.

Critical Rescue and Fire Fighting Access Area. The rectangular area surrounding any runway within which most aircraft accidents can be expected to occur on airports. Its width extends 500 ft (150 m) from each side of the runway centerline, and its length is 3300 ft (1000 m) beyond each runway end.

Dangerous Goods. This term is synonymous with the terms “hazardous materials” and “restricted articles.” The term is used internationally in the transportation industry and includes: explosives and any other article defined as a combustible liquid, corrosive material, infectious substances, flammable compressed gases, oxidizing materials, poisonous articles, radioactive materials, and other restrictive articles.

Deck Gun (Deluge Set). See Turret.

Departure. An aircraft taking off from an airport.

Dry Chemical. An extinguishing agent essentially consisting of a chemical salt with fire-inhibiting properties.

Dry Powder. An extinguishing agent suitable for use on combustible metal fires.

Empennage. The tail assembly of an aircraft, which includes the horizontal and vertical stabilizers.

Evacuation Time. The elapsed time between an aircraft accident/incident and the removal of all surviving occupants.

Evacuee. An aircraft occupant who has exited the aircraft following an accident/incident.

Exposure. Any person or property that could be endangered by fire, smoke, gases, or runoff.

Extinguishing Agent Compatibility. Related to the requirement that the chemical composition of each agent be such that one will not adversely affect the performance of other agents that might be used on a common fire.

Extinguishing Agent, Complementary. Refers to an extinguishing agent that has the compatibility to perform fire suppression functions in support of a primary extinguishing agent and where extinguishment might not be achievable using only the primary agent.

Extinguishing Agent, Primary. Agents that have the capability of suppressing and preventing the reignition of fires in liquid hydrocarbon fuels.

Extrication. The removal of trapped victims in an aircraft accident.

Federal Aviation Administration (FAA). An agency of the United States federal government charged with the primary responsibility of regulating aviation activities.

Fire Classifications.

Class A. Ordinary combustibles;

Class B. Flammable liquids;

Class C. Electrically charged components;

Class D. Combustible metals.

Fire Wall. A bulkhead designed to stop the lateral spread of fire in a fuselage or engine nacelle.

Flashback. The tendency of flammable liquid fires to re-ignite from any source of ignition after the fire has once been extinguished.

Flashover. All combustibles in a room or confined space have been heated to the point that they are giving off vapors that will support combustion, and all combustibles ignite simultaneously.

Flight Attendants. Those members of the flight deck crew whose responsibility includes the management of activities within the passenger cabin.

Flight Data Recorder (FDR). An instrument that monitors performance characteristics of an aircraft in flight. It is usually mounted in the tail area of an aircraft and is designed to withstand certain impact forces and a degree of fire. Its purpose is to provide investigators with flight performance data that might be relevant in determining the cause of an accident/incident.

Flight Deck Crew. Those members of the crew whose responsibility includes the management of the aircraft’s flight control and ground movements.

Flight Technical Crew (FTC). Includes pilots, flight engineers, and flight attendants who crew on aircraft movement.

Foam, Aqueous Film Forming Concentrate (AFFF). A concentrated aqueous solution of fluorinated surfactants and foam stabilizers that, when mixed with water and air in designated proportions, is capable of producing an aqueous fluorocarbon film on the surface of hydrocarbon fuels to prevent vaporization.

Foam, Film Forming Fluoroprotein (FFFP) Foam Concentrate. A concentrate that uses fluorinated surfactants to produce a fluid aqueous film for suppressing hydrocarbon fuel vapors. This type of foam also utilizes a protein base plus stabilizing additives and inhibitors to protect against freezing, corrosion, and bacterial decomposition, and it also resists fuel pickup.

Foam, Fluoroprotein. A protein-based foam concentrate to which fluorochemical surfactants have been added. This has the effect of giving the foam a measurable degree of compatibility with dry chemical extinguishing agents and an increase in tolerance to contamination by fuel.

Foam, Protein. A foam concentrate that uses protein as the basic foaming agent and is stabilized with metal salts to impart fire resistance to the foam blanket.

Foam Application Rate. The amount of foam solution in liters or gallons per minute expressed as a relationship with a unit of area, usually square meter or square foot.

Foam Blanket. A covering of foam over the surface of flammable liquids to provide extinguishment and prevent ignition.

Foam Burnback Resistance. The ability of a foam blanket to retain aerated moisture and resist destruction by heat and flame.

Foam Drain Time. The foam drain time — commonly the 25 percent drainage time (or $^1/_4$ drainage time) is the time required for 25 percent of the original foam solution (foam concentrate plus water) to drain out of the foam.

Forcible Entry. The act of making entry into an aircraft or other structure when normal entry points are not accessible.

Forward Looking Infrared (FLIR). A thermal imaging system (camera) which can be vehicle-mounted designed to detect thermal energy.

Frangible Gate/Fence. Gates or fence sections designed to open, break away, or collapse when struck with the bumper of an ARFF vehicle responding to an emergency.

Fuel Servicing. Fueling and defueling of aircraft fuel tanks, not including aircraft fuel transfer operations and design of aircraft fuel systems during aircraft maintenance or manufacturing operations.

Fuselage. The main body of an aircraft.

Grid Map. A map of an area overlaid with a grid system of rectangular coordinates that are used to identify ground locations where no other landmarks exist.

Halon. A liquefied gas extinguishing agent that extinguishes fire by chemically interrupting the combustion reaction between fuel and oxygen. Halon agents leave no residue.

Halon 1211. A Class ABC rated extinguishing agent that discharges as an 85 percent liquid that permits a long stream reach.

Halon 1301. An agent having ABC capability in total flooding systems and limited Class A capability when dispensed from portable extinguishers. The agent is discharged as a vapor.

Hazardous Materials. See Dangerous Goods.

Horizontal Stabilizer. That portion of an aircraft's structure that contains the elevators.

Hot Brakes. A condition in which the aircraft's brake and wheel components have become overheated, usually due to excessive braking during landing.

Ignition Temperature. The lowest temperature at which a fuel, when heated, will ignite in air and continue to burn.

Incident Commander (IC). The person in overall command at an emergency.

International Air Transport Association (IATA). An international group composed of the major airlines of the world that reviews aviation policy including safety items.

International Civil Aviation Organization (ICAO). An international aviation body, operating under the auspices of the United Nations, that produces technical safety documents for civil air transport.

Jet Blast. The thrust-producing exhaust from a jet engine.

Joint Aviation Authority (JAA). An agency in Europe charged with the responsibility of regulating safety in civil aviation.

Knockdown. A fire fighting term defining the reduction of flame and heat to a point where further extension of a fire has been abated and the overhaul stage can begin.

Magnesium. A silvery-white or grayish lightweight metal, two-thirds the weight of aluminum. Magnesium alloys are used in the construction of aircraft wheels, engine mounts, and various engine parts.

Main Gear. Refers to the two or more larger landing gear structures of an aircraft, as opposed to wing, nose, or tail gear assemblies.

Master Stream. A fire fighting water stream of large gallonage and extended reach delivered from a master stream appliance such as a deck gun.

Mechanical Ventilation. A process of removing heat, smoke, and gases from a fire area by using exhaust fans, blowers, air conditioning systems, or smoke ejectors.

Mutual Aid. Reciprocal assistance by emergency services under a prearranged plan.

National Transportation and Safety Board (NTSB). A federal agency that is responsible for investigating and determining the probable cause of aircraft accidents.

Nose Gear. That mechanical part of a landing gear system mounted under the nose of an aircraft. It can be designed either as a stationary component or one that retracts into the fuselage.

Overhaul. A fire fighting term involving the process of final extinguishment after the main body of a fire has been knocked down. All traces of fire must be extinguished at this time.

Penetrating Nozzle. An appliance designed to penetrate the skin of an aircraft and inject extinguishing agent.

Practical Critical Fire Area (PCA). This area is two-thirds of the Theoretical Critical Fire Area (TCA). (*See also Theoretical Critical Fire Area*.)

Preservation of Evidence. After an aircraft accident/incident it is imperative that investigative evidence be preserved after life safety and rescue operations have been concluded.

Pressurized Aircraft. Sealed, modern-type aircraft within which the internal atmospheric pressure can be regulated.

Protective Clothing. Fire fighters’ clothing including helmets, protective coats, protective trousers, boots, and gloves.

Rescue. Removal or assistance in the evacuation of occupants of an aircraft involved in an accident/incident or those persons exposed to such accident/incident.

Rescue Path. A fire-free path from an aircraft accident site to a safe area. This path, normally selected by evacuees, must be maintained by fire fighters during the evacuation process.

Resources. Personnel, vehicles, and equipment required to overcome the problems incidental to an aircraft accident/incident.

Response Time. The total period of time measured from the time of an alarm until the first

ARFF vehicle arrives at the scene of an aircraft accident and is in position to apply agent to any fire.

Restricted Articles. See Dangerous Goods.

Runoff. Liquids that flow by gravity away from an aircraft accident and might include aviation fuel (ignited or not), water from fire fighting streams, liquid cargo, or a combination of these liquids.

Runway. A defined rectangular area on a land airport prepared for the landing and taking off of aircraft along its length. Runways are normally numbered relative to their magnetic direction.

Salvage. A fire fighting procedure for protecting property from further loss following an aircraft accident or fire.

Self-Contained Breathing Apparatus (SCBA). A respirator worn by the user that supplies a respirable atmosphere that is either carried in or generated by the apparatus and is independent of the ambient environment.

Size-Up (Risk Assessment). A mental process of evaluating the influencing factors at an emergency prior to committing resources to a course of action.

Skin. The outer covering of an aircraft fuselage, wings, and empennage.

Smoke Ejector. A mechanical device, similar to a large fan, that can be used to force heat, smoke, and gases from a post-fire environment and draw in fresh air.

Surface Movement Guidance and Control System (SMGCS). A process or plan used by airports conducting operations in visibility conditions less than 1200 ft runway visual range (RVR).

Tabletop Training. A workshop style of training involving a realistic emergency scenario and requiring problem-solving participation by personnel responsible for management and support at emergencies.

Theoretical Critical Fire Area (TCA). The theoretical critical fire area (TCA) is a rectangle, the longitudinal dimension of which is the overall length of the aircraft, and the width includes the fuselage and extends beyond it by a predetermined set distance that is dependent on the overall width. Therefore, the aircraft length multiplied by the calculated width equals the size of the TCA.

Threshold. The beginning of that portion of the runway usable for landing.

Titanium. A lightweight, strong alloy with a high resistance to heat and fire. It is difficult to extinguish once ignited. Used mostly for engine parts and adjacent engine areas.

Triage. The sorting of casualties at an emergency according to the nature and severity of their injuries.

Triage Tag. A tag used in the classification of casualties according to the nature and severity of their injuries.

Turboprop Aircraft. An aircraft powered by one or more turbine engines each of which drives a propeller.

Turret. A vehicle-mounted master stream appliance.

Undercarriage. All components of an aircraft landing gear assembly.

United Kingdom Civil Aviation Authority (CAA). An agency charged with the responsibility of regulating safety in civil aviation.

Ventilation. The systematic removal of heated air, gases, and smoke from a fire area and replacing it with fresh air.

Vertical Stabilizer. That portion of the aircraft's empennage that contains the rudder.

Chapter 2 Pre-Incident Planning for Aircraft Emergencies

2-1 General.

2-1.1

Many accidents within the critical rescue and fire fighting access area involve undershoots, overshoots, and rejected takeoffs, and are generally survivable.

Accidents occurring outside of the critical rescue and fire fighting access area could involve impact with adverse terrain with resultant rupture of the aircraft structure.

Rapid response to these areas is crucial for the purpose of saving lives.

2-1.2

In addition to routine training programs, airport ARFF services and all structural fire departments and community emergency services with jurisdictions adjacent to an airport or its traffic patterns are encouraged to frequently schedule and participate in multi-agency training sessions based on the material in this guide. The objective of these sessions should be to focus on achieving maximum unity, compatibility, and effectiveness at aircraft emergencies should they be on or off the airport. (*See Section 2-5.*)

2-1.3

All airport and community emergency services should participate in annual exercises involving a simulated aircraft accident. Frequent command-level training for those persons assigned to major roles in the airport/community emergency plan is also essential. Command training can be presented in the form of workshop or tabletop exercises designed to develop effective emergency management techniques. Guidance for emergency plan exercises is provided in NFPA 424, *Guide for Airport/Community Emergency Planning*.

2-1.4

Command authority at any accident site should be predetermined according to the jurisdictional responsibilities of the agencies involved and as designated in their airport/community mutual aid agreement.

2-2 Emergency Response Preplanning.

2-2.1

All ARFF vehicles in use at the airport should be able to meet the provisions of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, upon acceptance from the manufacturer and should be maintained in a manner to ensure such levels of performance. Special training should be provided to enhance the skills of all vehicle operators, as their performance is critical to successful vehicle utilization, particularly under unfavorable conditions.

2-2.2

Operators assigned to each ARFF vehicle should make trial runs to all areas of the airport in all weather conditions during which flight operations take place. Particular emphasis should be placed on the ability to respond to the critical rescue and fire fighting access area since this is where most accidents occur. These runs will demonstrate each vehicle's operational capability and the time required to reach each site. Since many aircraft accidents occur in the overrun areas of the runways, it is important to provide suitable routes for use by the vehicles to enable them to reach these areas. Bridges spanning gullies, streams, ditches, cattle grids, or other ground surface appurtenances should be capable of supporting at least 120 percent of the weight of the heaviest emergency vehicle.

2-2.3

Where construction work of any kind is likely to affect the response capability or operational performance of the ARFF service, prior notification of the work should be provided so that amendments can be made to operational procedures to overcome or minimize their effect. This is particularly important where work on airport water mains is likely to close down one or more fire hydrants.

2-2.4

In order to provide multivehicle access to the accident site, service roads should be so constructed that one vehicle cannot block ingress or egress for other emergency vehicles. This can be accomplished by providing roads of sufficient width or suitable passing and turnaround areas.

2-2.5

Frangible gates or fence sections should be located at strategic locations to allow rapid access by ARFF vehicles to areas outside the airport boundary. Keys to gate locks should be carried on each authorized emergency vehicle, by airport security personnel and designated local emergency services.

2-2.6

Grid maps should be provided for each airport and its environs. They should be ruled with numbered and lettered grids (*see Figure 2-2.6*) to permit rapid identification of any response area. The area covered by a grid map should be a distance of 5 mi (8 km) from the center of the airport. This can vary depending upon the type of terrain or location of the airport in relation to other emergency facilities. Map nomenclature should be compatible with that used by off-airport public safety authorities. Two or more maps might be required where the area exceeds a 5-mi (8-km) radius. One map should display medical facilities, heliports, and other features according to the airport/community emergency plan. Where more than one grid map is used, grid identifications should differ by color and scale to assist in their identification. Prominent local features, access routes, staging areas, and compass headings should be shown to facilitate locating accident and medical facility sites. Copies of grid maps should be prominently displayed at Air Traffic Control, the airport operations office, each airport and community fire station, all mutual aid services, and carried on all appropriate emergency vehicles.

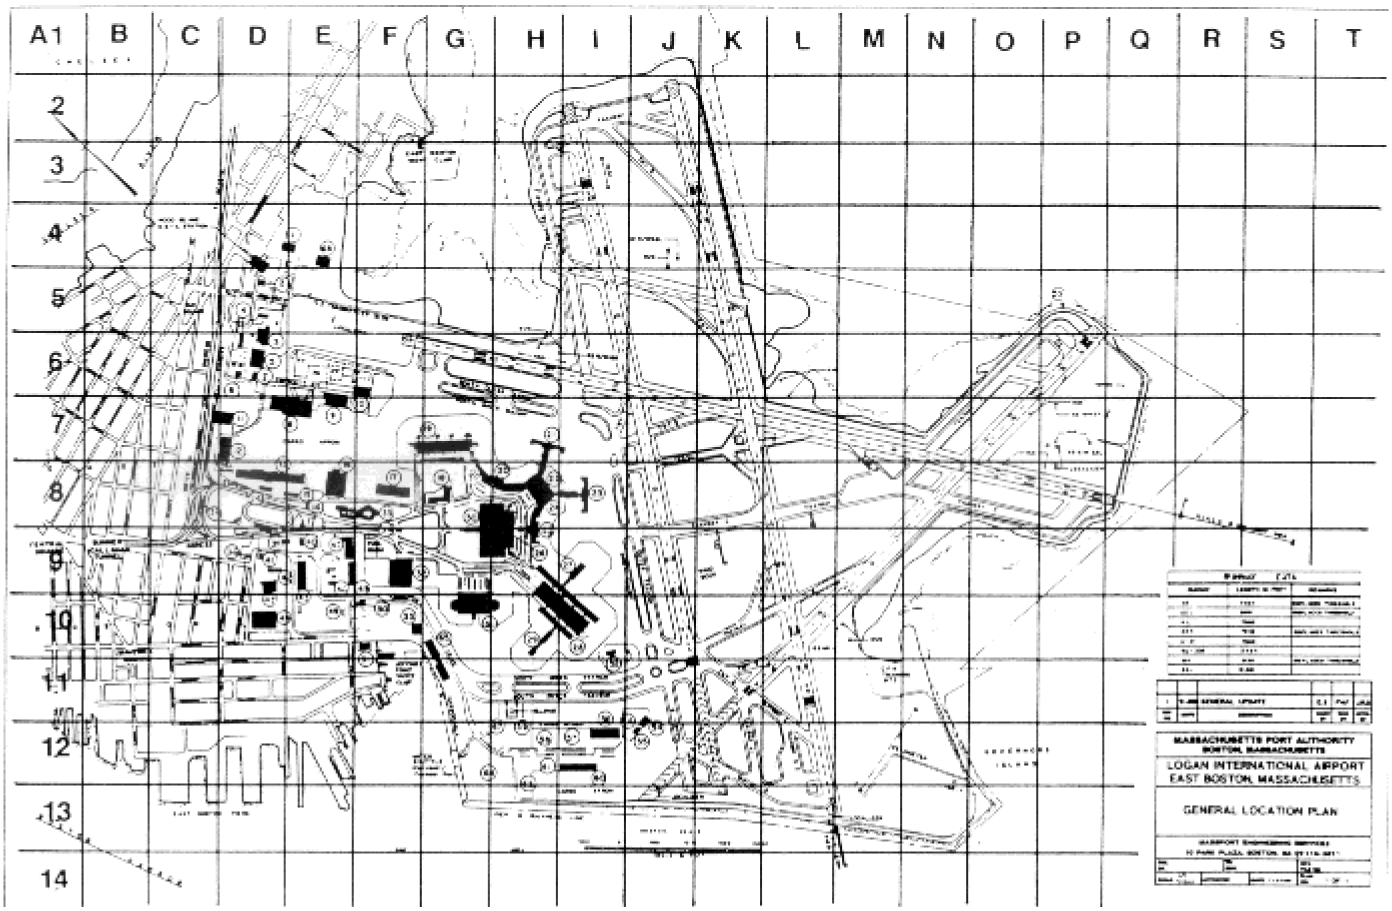

Figure 2-2.6 Typical airport grid map.

2-2.7

Backup systems should be provided in airport fire stations to allow for the rapid operation of vehicle bay doors, for the efficient reception/transmission of vital communications, and for the provision of emergency lighting.

2-2.8

A communication system from the airport to community or regional emergency services should be provided. The reliability of the system should be tested daily.

2-2.9

Any off-airport emergency services authorized to respond to an on-airport incident should pre-incident plan access to the various areas of the airport, particularly the designated staging areas. Personnel should also be trained in the special procedures to be followed once on the airport.

2-2.10

Sufficient ARFF vehicles and equipment should be provided to meet the required level of protection as specified in NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at*

Airports, for the airport during flight operations. When this protection level is reduced for any reason (i.e., off-airport response, mechanical breakdown, lack of qualified personnel, etc.), all incoming and departing aircraft should be notified of the change in ARFF capability.

2-2.11

It is important that pre-incident planning includes response of additional pumping vehicles, ladder trucks, elevated platform vehicles, portable lighting equipment, hoisting and lifting equipment, medical supplies, and any other available specialized equipment or vehicle for which a requirement is anticipated. It is extremely important that the pre-incident plan also ensures the immediate availability of the special vehicles and equipment, provision for qualified driver-operators, and especially the availability of approving authority on an around-the-clock basis.

2-3 Airport Fire Fighter Basic Knowledge.

2-3.1

To assure that airport fire fighters have a suitable degree of skill, basic training should be provided in accordance with NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*.

2-3.2

Comprehensive, continuous in-service training should be provided to maintain each fire fighter's proficiency. For further information on training subjects, see the references listed in Chapter 14 and Appendix F. The following are specific basic training requirements for ARFF personnel.

2-3.3

The complexity of modern aircraft and the variety of types in service make it difficult to train ARFF personnel in all the important design features of each model. However, they should become as familiar as possible with each type of aircraft that normally uses the airport. Particular emphasis should be placed on the following (*see also NFPA Aircraft Familiarization Charts Manual*):

(a) Location and operation of normal and emergency exits, cargo doors, equipment, and galley access doors;

(b) Seating configurations;

(c) Type of fuel and location of fuel tanks;

(d) Location of ejection seats and armament (military aircraft);

(e) Locations of batteries, hydraulic, and oxygen systems;

(f) Positions of break-in points on the aircraft;

(g) Location of rapidly activated standby generators or turbines;

(h) Fire access panels; and

(i) Location of aircraft construction materials that are subject to be releasing hazardous/toxic substances while burning (i.e., carbon fibers, etc.).

2-3.4

Airports are large commercial complexes that contain many potential life and fire hazards. These hazards vary relative to aircraft operations, time of day, weather conditions, construction, or a combination of these factors. It is, therefore, vital that ARFF personnel become extensively knowledgeable about the airport and any changes that occur that could adversely affect immediate response or the efficient performance of their rescue and fire fighting responsibilities. Minimum requirements of knowledge should include:

(a) Water supply locations (hydrants);

(b) Runway identifications and locations;

(c) Taxiway identifications and locations;

(d) Airport lighting systems;

(e) Most effective response routes and alternatives;

(f) Fuel handling and storage areas;

(g) Key airport locations;

(h) Airport service roads;

(i) Gates and fences; and

(j) Airport drainage systems.

2-4 Communications.

2-4.1

All airport emergency vehicles should be provided with multiple channel two-way radios operating on the airport's assigned ground control frequency and other airport emergency frequencies.

2-4.2

It is desirable that airport ARFF vehicles be able to monitor or be in direct voice communications with an aircraft during an emergency situation. This procedure is especially important when airport control towers are not in operation.

2-4.3

At an aircraft accident site, power megaphones can be valuable tools to coordinate flight deck crew/ARFF activities, direct evacuating aircraft occupants to safe locations, etc.

2-4.4

Portable radios can be utilized at an accident site to communicate with the command post, airport emergency dispatcher, airport management, arriving back-up units, etc. Where personnel and vehicles from more than one agency will operate in mutual support, common radio frequencies should be available. If not, pre-incident planning procedures should be established so that portable radios can be exchanged, the use of messengers employed, or methods of relaying messages through the command post utilized. When portable radios are exchanged, consideration should be given to avoiding channel saturation and the maintenance of communication discipline.

2-4.5

Experience from recent accidents has shown that the use of automated voice notification systems greatly facilitates emergency response/mutual aid notification.

2-4.6

The use of cellular telephones in ambulances, in supervisory vehicles, and in command post vehicles can provide significant benefits in command and control functions.

2-5 Mutual Aid Considerations.

2-5.1

As indicated previously, it is essential to have mutual fire fighting assistance agreements with community and regional, off-airport fire departments. Successful rescue operations and handling of aircraft accident fires both on and off the airport depends on pre-incident planning the effective use of mutual aid (*see also Appendix E*). The following considerations are significant:

(a) Special attention should be given to ensuring compatibility in equipment designs (i.e., fire hose threads, communications equipment, etc.) and to fire control operational techniques.

(b) It is important to familiarize structural fire department personnel with the special problems relating to aircraft rescue and fire fighting including methods of access to aircraft operating areas and how to operate vehicles while on the airport.

2-5.2

Airport orientation visits should be arranged by fire departments bordering airports for consultations with the airport fire department, airlines, the military services, and others as appropriate. Their training in airport/aircraft familiarization should include those items listed in 2-3.3 and 2-3.4, diagrams in the NFPA *Aircraft Familiarization Charts Manual*, and grid maps of the airport and surrounding area.

2-5.3

Structural fire fighting vehicles normally carry small amounts of water as compared to the amounts usually carried on major airport ARFF vehicles. However, they can be useful in relaying water from hydrants, reservoirs, or other sources to maintain ARFF vehicle supplies.

2-5.4

Structural fire fighters can be utilized to provide assistance to airport ARFF personnel by handling hose lines, operating tools and equipment, assisting in rescue operations, and protecting exposures.

Chapter 3 Flight Deck Crew and ARFF Personnel Responsibilities

3-1 Areas of Responsibility.

3-1.1

The flight deck crew, flight attendants, and ARFF personnel should have the skills to deal with aircraft emergencies and should be familiar with each others' responsibilities to ensure that all their efforts are clearly directed toward the common goals of life and fire safety.

3-1.2

The prime mission of all concerned is the safety of all persons aboard the aircraft and any others involved in the emergency. Duties and responsibilities can generally be defined as follows:

(a) Flight deck crews hold the primary responsibility for the aircraft and for the safety of its occupants. The final decision to evacuate an aircraft and the manner in which the evacuation is carried out are made by the flight deck crew provided they are able to function in the normal manner at the time.

(b) Flight deck crews and flight attendants share responsibility for the aircraft and for the safety of its occupants. The final decision to evacuate an aircraft and the manner in which the evacuation is carried out are made by the flight deck crews and flight attendants provided they are able to function in the normal manner at the time.

(c) It is the duty of responding ARFF personnel to create conditions in which survival is possible and evacuation or rescue can be conducted. As visibility from within an aircraft is limited, any external features or situations likely to be of significance in the evacuation process should be communicated to the aircraft's crew. Should it become apparent that the crew's incapacity precludes the initiation of evacuation, the officer in charge of the ARFF personnel should take the initiative.

3-1.3

To prevent injury when an emergency aircraft evacuation takes place, consideration should be given to assist occupants using the aircraft slides.

3-2 Communications.

3-2.1

Effective communications between flight deck crew and ARFF personnel is very important during emergencies. Contact should be established at the earliest possible time between persons in charge of each group. Exchange of pertinent information can assist in developing better decisions and plans of action. Several methods of direct communication are generally available such as aircraft interphone, tower relay, direct radio communication via approved frequency or visual signals.

3-2.2

Where aircraft engines are operating, radio communications near the aircraft can be very difficult. Most aircraft are equipped with intercom systems and provided with plug-in jacks normally located under the forward portion of the aircraft near the nose gear. ARFF personnel should be aware of this means of communication and carry the necessary headset and microphone to plug into these facilities. Even with the engines operating, direct communications with the flight deck crew can be established by use of this system as long as the power is on.

3-2.3

Where a more direct means of communication cannot be established, the officer in charge of the responding ARFF personnel should go to the left side of the aircraft nose and establish direct eye contact and voice communications with the captain of the flight deck crew. If engine noise is a problem and a power megaphone is not available, it might be necessary to resort to hand signals to communicate. Figure 3-2.3 depicts standard international ground to aircraft hand signals that should be used by ARFF personnel to communicate with the captain during emergencies.

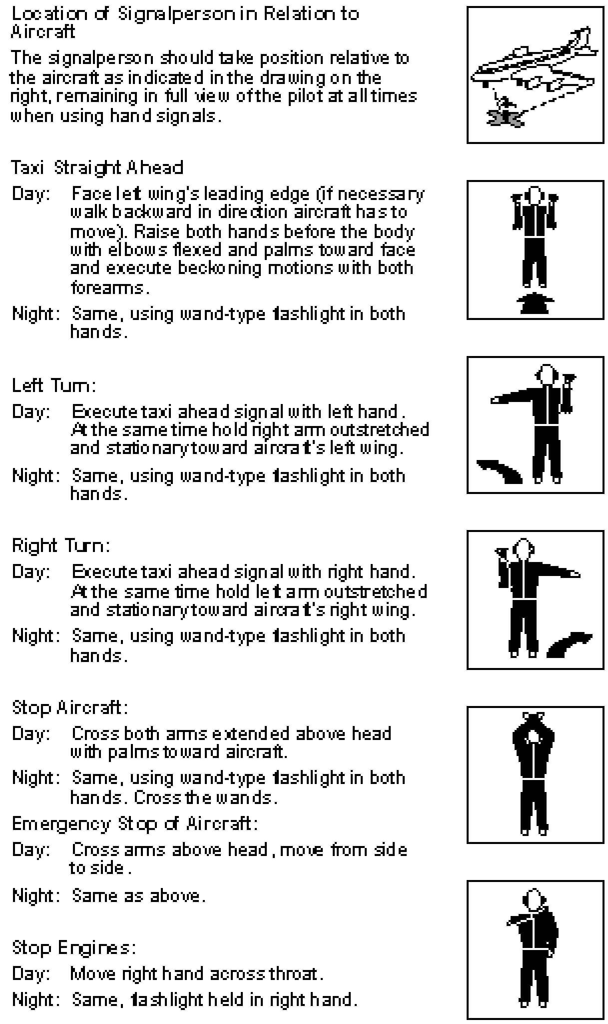

Figure 3-2.3 Standard international ground to aircraft signals.

3-2.4

If aircraft engines are operating, ARFF personnel should use extreme caution when approaching an aircraft for communications purposes as described in 3-2.2 and 3-2.3. The aircraft should be approached only from the front and well ahead of the nose and, if possible, in full view of the captain. Vehicle and hand-held lights should be used in periods of darkness and poor visibility.

Chapter 4 Emergency Response

4-1 General.

4-1.1

The survivable atmosphere inside an aircraft fuselage involved in an exterior fuel fire is limited to approximately 3 minutes if the integrity of the airframe is maintained during the impact. This time is substantially reduced if the fuselage is fractured. When the aluminum skin is directly exposed to flame, burnthrough will occur within 60 seconds or less while the windows and insulation may withstand penetration for up to 3 minutes. Because of this serious life hazard to occupants, rapid fire control is critical. Therefore, whenever flight operations are in progress, ARFF vehicles and personnel should be so located that optimum response and fire control can be achieved within this time frame.

4-1.2

At many airports portions of the critical rescue and fire fighting access areas might be outside the airport boundaries. There also can be obstructions created by natural features, highways, or railroad right-of-ways that would delay or preclude access by ARFF vehicles. Consideration should be given in these instances to providing specialized vehicles where conventional vehicles can be restricted due to unusual terrain characteristics. Any delay in response time is critical, and mutual assistance agreements with off-airport agencies should be established to provide optimum response in problem areas. (*See Figure 4-1.2*.)

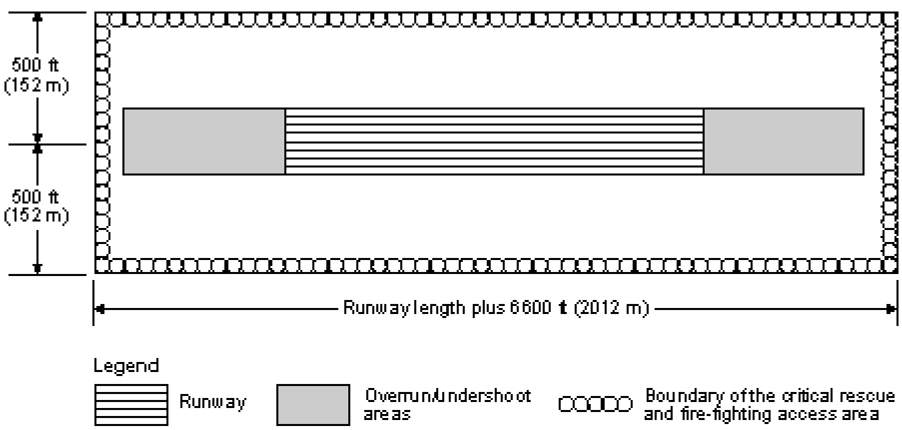

Figure 4-1.2 Critical rescue and fire fighting access area.

4-1.3

To obtain the desired response, pre-incident planning should include a wide range of factors such as adequate alarm systems, fire station locations (or prepositioning of resources), vehicle operator training, and airport familiarization.

4-1.4

Fire stations should be located so that rapid direct access to the operational runway utilizing maximum acceleration rate and top speed of the vehicles is utilized to enable them to reach any point on the runway. The access road to the runway should be as direct as possible.

4-1.5

All-weather access routes to the critical rescue and fire fighting access area suitable for ARFF vehicles should be designated and should be maintained in usable condition while flight operations are in progress.

4-1.6

To minimize response times, operational procedures should exist through which Air Traffic Control (ATC) would stop or divert all aircraft and nonessential traffic that would conflict with responding emergency vehicles.

4-1.7

Airports updating their master plan for airport development should consider obstruction clearance in the critical rescue and fire fighting access area such as ditches, mounds, or vegetation that would cause extensive damage to any overrunning aircraft or obstruct the positioning of the emergency vehicles. Boat launching ramps should be considered in those areas that terminate at large bodies of water.

4-2 Low Visibility Operations.

4-2.1

New and improved techniques for instrument takeoff and landing permit flight operations to continue under adverse weather conditions. Low visibility operations criteria vary from one airport to another depending upon the type of instrument landing system available, the level of natural and manmade obstructions in the surrounding terrain, the type of runway lighting, and the capability of the onboard instrument systems of the aircraft using the airport. Such operational minimums can vary from 3 mi (5 km) visibility to 300 ft (100 m) for landings and with similar restrictions for takeoff. ARFF personnel should ascertain operational restriction levels from the local Air Traffic Control (ATC) agency in order to establish response capability under minimum visibility conditions.

4-2.2

Although aircraft operational navigational weather minimums might not be in effect, fully staffed Alert 1 standby procedures should be initiated when flight operations are in progress and surface visibility and conditions are less than $^1/_2$ mi (800 m). (*See also Section 8-2*.)

4-2.3

Standbys during low visibility operations and adverse weather conditions should have at least one major ARFF vehicle located at a distance no closer than the taxiway hold line adjacent to the midpoint of the active runway unless the fire station(s) location(s) permits effective response times. (*See Figure 4-2.3*.) When on standby, vehicle operators should keep engines running and all emergency lights operating. If the vehicle is equipped with a FLIR system, it should be fully operational with an in-cab display.

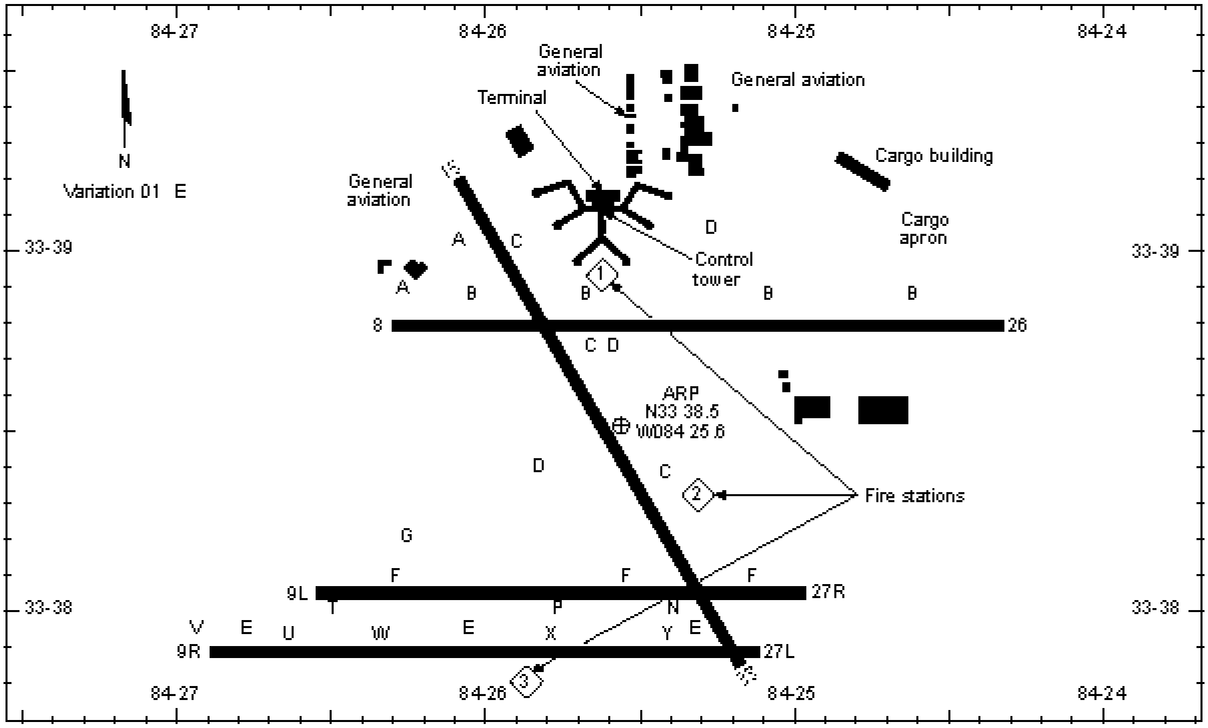

Figure 4-2.3 Example of airport fire station locations.

4-2.4

ARFF personnel assigned to any standby should monitor all applicable radio frequencies.

4-2.5

Air Traffic Control (ATC) should be made aware of the exact location of the ARFF vehicles assigned to standby duty. Where available, surface navigational aids, such as ground radar (ASDE), should be fully utilized through coordination between ARFF personnel and the control tower.

4-2.6

ARFF vehicles can be equipped with an infrared vision system to assist the crew of the vehicles to locate and respond to emergencies in low visibility conditions.

4-2.7

Positioning equipment can be installed on ARFF vehicles to enable the drivers to know their position on the airport at all times.

4-3 Considerations for Airports Adjacent to Water.

4-3.1

Where airports are situated adjacent to large bodies of water such as rivers or lakes, or where they are located on coastlines, special provisions should be made to expedite rescue.

Injured survivors and nonswimmers can drown in water in the same length of time that it takes to die in a fire.

4-3.2

Inclined ramps or docking facilities should be considered by airports located adjacent to large bodies of water to allow rapid response to aircraft accidents. Launch ramps should be located in the overrun areas of the critical rescue and fire fighting area.

4-3.3

For rescue purposes, the vessel should be equipped with flotation platforms and/or life rafts for the maximum number of occupants carried on the largest aircraft regularly scheduled into the airport.

4-3.4

Rescue vessels should be capable of rapid response to the critical rescue and fire fighting area.

Chapter 5 Factors Common to Airport Emergencies

5-1 General.

5-1.1

The primary hazard associated with aircraft accidents is that liquid fuels are likely to be released and ignited during the accident sequence. A secondary hazard is that fuels released but not ignited could subsequently be ignited prior to or during the egress of occupants. In addition, fires involving combustible materials such as interior furnishings, stored goods, and electrical system components can occur. Further complications could result if the aircraft comes to rest in such an attitude that forcible fuselage entry might be required.

5-1.2

During all aircraft emergencies, all persons not directly involved in the ARFF phase of the incident, including the news media, should be required to stay well clear of the site until evacuation, occupant care, full fire control, and site safety security are completed. Responsibility for site security should be preassigned to the airport police and could be augmented by local police, guards, and volunteers as needed.

5-2 Types of Emergency Alerts.

5-2.1

The terms used to describe categories of emergency alerts are not standardized. The Federal Aviation Administration (FAA) terms, Alert I, Alert II, and Alert III, and the International Civil Aviation Organization (ICAO) terms, “Local Standby,” “Full Emergency,” and “Aircraft Accident,” are equivalent. Individual airports might have adopted their own nomenclature for alerts 1, 2, or 3. This must be coordinated with the appropriate authority.

5-2.2 Alert I “Local Standby.”

When an aircraft has, or is suspected to have, an operational defect, the incident should be considered an Alert I. The defect should not normally cause serious difficulty for the aircraft to achieve a safe landing.

5-2.2.1 Under Alert I conditions, at least one ARFF vehicle should be staffed and positioned to permit immediate use in the event of an accident. If the time and conditions permit, ARFF personnel should be advised of the (1) aircraft type, (2) number of passengers and crew, (3) amount of fuel remaining, (4) nature of the emergency, (5) type, amount, and location of dangerous goods aboard, and (6) number and location of nonambulatory passengers onboard, if any. All other in-service ARFF vehicles should remain available for immediate response.

5-2.2.2 An Alert I should also be initiated when an aeromedical evacuation aircraft with patients aboard is approaching or departing the airport.

5-2.2.3 Alert I procedures should be implemented whenever required response times cannot be achieved. Factors that can affect response times include construction work, field maintenance, adverse weather conditions, and low visibility. (*See Chapter 2 and Chapter 4.*)

5-2.2.4 Airports should have management policies for implementation of Alert I procedures during arrival and departure of certain categories of aircraft that do not normally use the airport.

5-2.3 Alert II "Full Emergency."

When an aircraft has, or is suspected to have, an operational defect that affects normal flight operations to the extent that there is danger of an accident, the incident should be considered to be an Alert II, "Full Emergency."

5-2.3.1 When an Alert II emergency is declared, ARFF personnel should be provided with detailed information that allows preparation for likely contingencies. A full response should be made with the ARFF vehicles staffed and in position with engines running and all emergency lights operating so that the fastest response to the accident/incident site can be accomplished.

5-2.3.2 It is important that appropriate radio frequencies be continuously monitored by ARFF personnel. One or more major ARFF vehicles should be able to initiate fire suppression within the briefest period of time after the aircraft comes to rest. Standard standby positions for ARFF vehicles should be established for a variety of anticipated circumstances.

5-2.3.3 ARFF personnel should be informed of any changes in a distressed aircraft's emergency situation that could affect its touchdown point or ultimate behavior after touchdown.

5-2.4 Alert III "Aircraft Accident."

This alert denotes that an aircraft accident has occurred on, or in the vicinity of, the airport.

5-2.4.1 Regardless of the source of an Alert III alarm, full ARFF response should be put into effect. When possible, all known pertinent information should be relayed via radio by Air Traffic Control (ATC) to responding units and include, as accurately as possible, the accident location using landmarks and grid map coordinates.

5-2.4.2 When an accurate accident location is not available, ARFF personnel should anticipate the worst situation and stand by until signs of an accident are evident or better information is given. Mutual aid assistance should be initiated in accordance with the airport/community emergency plan. (*See also NFPA 424, Guide for Airport/Community Emergency Planning, and ICAO Airport Services Manual, Part 7.*)

5-3 Vehicle Response to Aircraft Accidents.

5-3.1

ARFF vehicles should approach any aircraft accident by the route that provides the quickest response time. This might not necessarily be the shortest distance to the scene. Traversing through unimproved areas can take longer than traveling a greater distance on paved surfaces such as taxiways, ramps, and roads. Total response time is vital. Preferred routes, especially those within the critical rescue and fire fighting access area, should be preselected. Practice response runs should be made under both ideal and inclement weather conditions.

5-3.2

In some cases, runways and taxiways are blocked by aircraft awaiting taxi clearance or takeoff. Vehicle operators should be aware of alternate routes that can be used so as not to delay response.

5-3.3

The load-bearing characteristics of the airport soil structure under various weather conditions should be known, and vehicle operators should be trained to deal with off-road driving conditions.

5-3.4

When nearing the accident scene, vehicle operators should be alert to avoid all persons in the area, especially those who might be injured, unconscious, or wandering about in a dazed condition. In darkness, periods of low visibility, or when operating in areas of tall vegetation, extra caution and effective use of spotlights, floodlights, portable lighting, audible warnings, or FLIR systems (if provided) are required.

5-4 Positioning of ARFF Vehicles.

5-4.1

Information from the flight deck crew relative to the nature of the emergency will assist the ARFF personnel to better determine the most advantageous positioning of the vehicles upon arrival at the scene of an aircraft emergency.

5-4.2

Piston-type engine aircraft provide more options for initial positioning of ARFF vehicles than do turbojet aircraft that have swept-back wings and produce a jet blast hazard. ARFF personnel should therefore consider an approach from the nose of jet aircraft. However, this should not become a standard procedure as wind conditions, terrain, type of aircraft, location of engines, cabin configurations, and other factors can dictate the optimum approach in a given circumstance.

5-4.3

Vehicle position should never obstruct aircraft evacuation or interfere with the deployment of evacuation slides. (*See also Chapter 7*.)

5-4.4

Propellers turning on turboprop or piston-type engine aircraft present a hazard to evacuees and ARFF personnel. Turbojet engines present different problems. For example, the areas directly ahead of and for a considerable distance behind the engines should be avoided because of the intake and jet blast hazards. Turbojet engines will rotate for a considerable time after they have been shut down. (*See Figure 5-5.6*.)

5-4.5

When combination cargo/passenger (COMBI) aircraft have declared an emergency, ARFF personnel should be informed of cabin configurations prior to the landing. Since some cargo areas extend over the wings, the overwing exits could be unavailable for use as emergency exits.

5-4.6

The mission of the first-arriving ARFF vehicle and crew is to assist in evacuation of occupants, prevent the outbreak or spread of fire, and perform any rescue operations required. The vehicle should be positioned to protect the principal evacuation route being used by the occupants. When it is obvious that the occupants are evacuating safely without assistance and the fire or threat of fire is controlled, later-arriving vehicles and crews can be strategically positioned and tasks assigned. Caution must be exercised to avoid placing evacuees, ARFF personnel, or vehicles in locations that could become hazardous in the event of a sudden extension of fire.

5-5 Hazards to ARFF Personnel.

5-5.1

ARFF personnel should always remain alert to the possibility of ignition of flammable vapors that are always present in the area of damaged aircraft. Elimination of ignition sources and the maintenance of an unbroken foam blanket is the best procedure in preventing ignition of these vapors.

5-5.2

All ARFF personnel should be provided with and be required to wear proper and complete protective clothing and equipment. Minimum protective clothing and equipment as approved by the authority having jurisdiction. Personnel should be fully trained in the use limitations and value of such protective clothing and equipment by utilizing them in frequent fire fighting drills.

5-5.3

Aircraft structures damaged by fire or impact forces are often very unstable and subject to collapse or rollover. If these conditions are suspected to exist, precautions in the form of blocking or shoring should take place as soon as practicable to ensure the safety of ARFF personnel working in the area. Blocking and shoring nonessential to rescue and fire fighting operations should not be undertaken by ARFF personnel.

5-5.4

If dangerous goods are believed to be involved in an emergency, procedures should be carried out as prescribed in the U.S. Department of Transportation *Emergency Response Guidebook*. This also includes incidents involving agricultural spraying aircraft and the associated pesticides.

5-5.5

Any undercarriage fire creates a potential for aircraft collapse or the explosive disintegration of affected components.

5-5.6

ARFF personnel should stay well clear of an operating jet engine to avoid intake and exhaust hazards. (*See Figure 5-5.6.*)

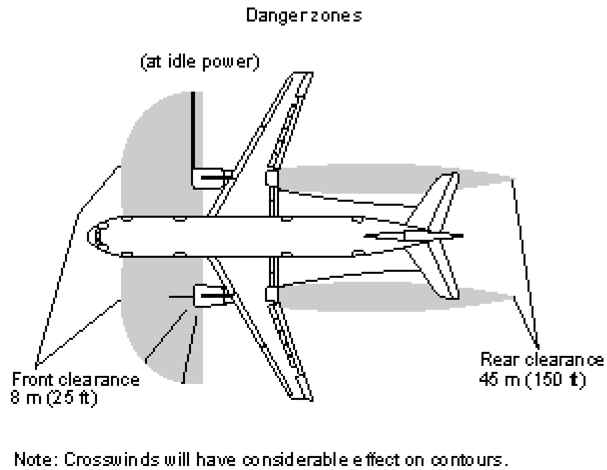

Figure 5-5.6 Engine run danger areas.

5-5.7

The propellers of piston-type engine aircraft should never be moved when at rest, as any movement could, under certain conditions, restart the engine.

5-5.8

Some modern jet aircraft are equipped with Ram Air Turbines (RAT) or Air Driven Generators (ADG) designed to provide back-up electrical and hydraulic power in the event of in-flight failures of primary systems. These devices are often designed to deploy from flush fuselage or engine-mounted storages, and some can deploy with considerable force. ARFF personnel should become aware of aircraft employing these systems and their locations. Serious injury could result should the RAT accidentally deploy and strike a person during emergency operations. (*See Figure 5-5.8.*)

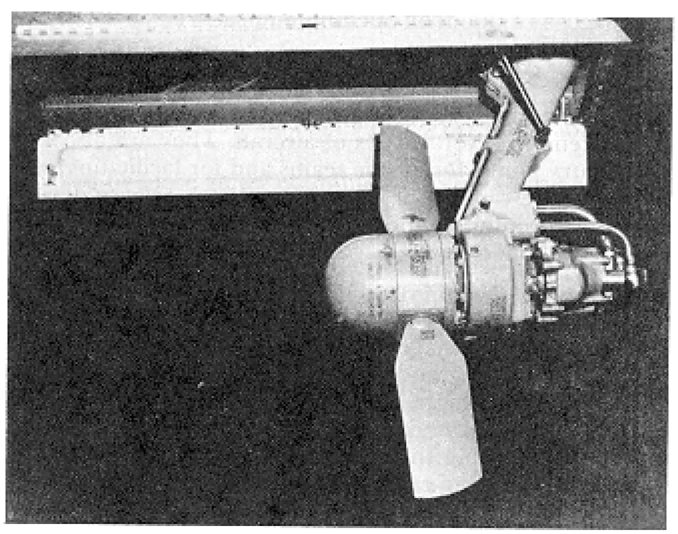

Figure 5-5.8 Ram Air Turbine. Shown is a deployed Ram Air Turbine on a Lockheed 1011 aircraft. It is located at the center underside of the fuselage slightly forward of a point directly in line with the main landing

gears.

5-5.9

On Boeing 767, if the ground spoilers are deployed and an overwing plug is opened, they will rapidly retract down. This is done so that exiting passengers will not be hampered in evacuation. The slide also deploys from the side of the fuselage.

Chapter 6 Aircraft Construction and Materials

6-1 Construction Materials.

6-1.1

ARFF personnel should become familiar with aircraft construction materials. Most of these materials have a low resistance to flame exposure, and their behavior under fire conditions should be understood. They have high resistance to cutting or other forcible entry methods that can sometimes be difficult and time consuming and can virtually impede successful rescue and fire fighting operations.

6-1.2

Much of a modern aircraft structure is aluminum alloy. It is approximately 50 percent lighter than steel, and its normal appearance is light gray or a silvery surface when polished. It is used as sheets for aircraft skin surfaces, as channels for framework, and as plates and castings for bulkheads and fittings. This metal will not contribute to a fire to any significant degree. However, it will melt under the high temperature conditions found in aircraft fires. For this reason it is essential to keep fuselage surfaces cool during rescue operations.

6-1.3

Magnesium alloys are used for wheels, engine mounts, brackets, crankcase sections, cover plates, and other engine parts. The appearance of this metal is silvery-white or grayish, and it is about two-thirds the weight of aluminum. While it is not easily ignited, when it is ignited it burns violently and cannot be easily extinguished. It thus presents a serious reignition source. Sparks developed when the metal comes in contact with paved surfaces, as might occur in a wheels-up landing, have the capability of igniting flammable vapors.

6-1.3.1 Where special extinguishing agents are not available for magnesium fires, water in coarse heavy streams might provide a suitable alternative fire control method. At first, such streams will result in localized intensification of flame and considerable sparking and showering of burning magnesium. Isolated burning pieces of magnesium should be removed from flammable vapor areas.

6-1.4

Steel in various forms, including stainless steel, is used in aircraft engine parts, around engine nacelles, engine fire walls, flap gear, and tubing. The metal presents no fire hazard, nor does it contribute to a fire except that it can create friction sparks when in contact with hard surfaces during a wheels-up landing. The sparks have sufficient energy to ignite flammable vapors. In most forms used in aircraft, steel can be cut with metal cutting saws, but because of the sparks produced, it is a potentially hazardous operation in the presence of flammable vapors.

6-1.5

Titanium is used primarily in engine parts, nacelles, and for engine fire walls. It is a combustible metal but in the forms used in aircraft, it has a high degree of heat and fire resistance. Once ignited, titanium is difficult to extinguish. Water is ineffective. Turbine engine fires involving titanium cannot normally be extinguished by external fire fighting techniques within the time period necessary to complete rescue operations. Titanium metals are a friction spark hazard similar to steel and magnesium. Surfaces of titanium are very difficult to penetrate, even with power equipment.

6-1.6

To improve the payload/vehicle-weight ratio of aircraft without compromising structural strength, increasing use is being made of composite materials. They are made of small, fine fibers embedded in carbon/epoxy materials. The fibers are usually boron, fiberglass, aramid, or carbon in the form of graphite. Composite, fiber-plus-plastic materials have replaced metal in many aircraft components. These materials do not present any unusual fire extinguishment problems.

6-1.7

Many aircraft cabin materials in current and continuing use as well as newer fire-resistive materials can produce high concentrations of toxic gases when heated even though no open flaming is visible. Therefore, it is imperative that positive pressure self-contained breathing apparatus be worn by all fire fighters engaged in rescue, fire fighting, and overhauling operations.

6-2 Aircraft Fuel Tanks.

6-2.1

In some aircraft, where the wing joins the fuselage, there is no substantial separation to provide a desired fire wall. As all aircraft have wing tanks, many without separate metal or synthetic bladders within the wing cavity, vapors are seriously exposed under fire conditions.

6-2.2

Some aircraft carry fuel in the center wing section, which in effect places fuel storage within the fuselage. It is thus possible, under some conditions, for fuel or vapors from tanks damaged due to an aircraft accident to enter the fuselage.

6-2.3

Currently entering commercial service are wide-body aircraft with provisions for additional fuel storage within both the horizontal and vertical stabilizers. Damage to these tanks in the event of an aircraft accident poses a number of problems including those where fuel or vapors might enter occupied sections of the aircraft and become ignited. These additional fuel storage locations can complicate the fire fighting operations and will require additional agent. (*See also NFPA 403, Standard for Aircraft Rescue and Fire Fighting Services at Airports*.)

6-2.4

Wing tanks on some aircraft are located directly above or to the side of landing gear mounts. These tanks have been ruptured during hard landings or other ground accidents.

6-3 Aircraft Exits.

6-3.1

Aircraft exits on transport category aircraft include doors, hatches, and windows of various sizes. These exits will vary with the age, size, and types of the aircraft. ARFF personnel should be familiar with the operation of the various exit types on all makes of aircraft normally using the airport.

6-3.2

Doors on most older, unpressurized aircraft open outward and can be opened from outside and inside the aircraft.

6-3.3

The doors on the majority of U.S. built modern pressurized aircraft are called "plug-type" doors. When these doors open, they push in slightly and then pull out or retract upward into the ceiling. These doors are not operable as long as the cabin remains pressurized [as little as 0.015 psi (103 Pa)].

6-3.4

Aircraft having a door sill higher than 5 ft, with landing gear deployed, are normally equipped with inflatable evacuation slides mounted at the emergency exits. When the system is armed and the emergency exit is opened, the slide can inflate and extend outward in less than 5 seconds with considerable force. ARFF personnel therefore should consult aircraft manufacturer crash charts to be knowledgeable of the areas where those inflatable slides deploy. (*See NFPA Aircraft Familiarization Charts Manual*.)

6-3.5

Doors should be approached and opened with caution, as the slide might deploy either by design or malfunction.

6-3.6

When positioning ladders, elevated platforms, or mobile stairways prior to opening cabin doors from the outside, care should be taken since all aircraft doors do not open in the same direction, or by the same mode of operation.

6-3.7

Opening the doors of most modern-type aircraft from the exterior can be accomplished more readily and safely using an aerial platform or a mobile stairway. If these units are not available, a ground ladder can be raised to a position adjacent to the door control mechanism and, if possible, on the side away from the direction the door is to be opened. Once the door is opened the ladder can then be moved into the door opening and secured at the top to prevent movement.

6-3.8

Overwing exits are part of the emergency evacuation system on several types of aircraft. They might also be useful as entry points for rescue teams and for facilitating ventilation of the cabin. Some overwing exits are equipped with slides that are similar to door exit slides when deployed.

6-3.9

Some aircraft have doors that incorporate stairs on the side of the fuselage or in the tail section to facilitate passenger boarding and deplaning. Although in some circumstances they might be used as such, they are not considered emergency exits. ARFF personnel should know which aircraft using the airport have these types of doors and exercise proper caution when the need arises to open them.

Chapter 7 Evacuation and Rescue

7-1 Aircraft Evacuation.

7-1.1

Evacuation of occupants involved in aircraft accidents and assistance to those who cannot remove themselves should proceed with the greatest possible speed. While care is necessary in the movement of injured occupants so that their injuries are not aggravated, removal from the fire-threatened area is the primary objective.

7-1.2

Flight deck crews receive extensive training in aircraft emergency evacuation procedures. They are in the best position to make optimum decisions relative to evacuation procedures in most emergency situations. They also have immediate contact with those aboard the aircraft and therefore can direct the operations.

7-1.3

Prior to any planned emergency landing, flight deck crews normally will consider passenger relocation within the cabin. This procedure is used to expedite use of potential emergency exits. The practice of placing a crew member, or a person knowledgeable in evacuation procedures, at each exit to assist flight attendants in the direction and movement of occupants is common practice where time and circumstances permit.

Under certain circumstances, flight attendants might have the necessary time prior to impact to more fully instruct passengers on how to survive impact and evacuate the aircraft. Training and check lists provide, among other things, for selection of able-bodied helper passengers to receive instructions pertaining to operation of exits and slides. These persons would then be more capable of assisting the flight attendants. Additionally, ARFF personnel should realize that the first passengers to leave the plane might have received instructions to remain at the bottom of a slide, wing, airstair, etc. ARFF personnel should direct survivors away from the aircraft, and prevent survivors from piling up.

7-1.4

The tendency toward forward exiting is natural since most passengers boarded the aircraft at terminals through forward doors and will instinctively attempt to exit in the same manner. Other exit facilities are apt to be bypassed, especially if persons are under any mental strain or sense of panic. Overwing and other emergency exits requiring physical agility probably will be shunned by those doubting their ability to use them effectively. Access to overwing and some other emergency exits is usually restricted by seating arrangements. Overwing exits are often smaller than door exits, and have caused passengers to become entangled just inside the exit. If visibility in the cabin is impaired due to darkness or dense smoke, orderly evacuation can be further complicated.

7-1.5

Limited evacuation options might be available to the flight deck crew due to circumstances aboard the aircraft. One or more emergency exits could be inoperable as the result of distortion caused by impact. Doors might be blocked by loose galley equipment. Aisles might be difficult to travel due to injured passengers, collapse of overhead panels and partitions, dislodged seats, and carry-on items. Although normal evacuation procedures provide for the use of all available exits, flight deck crews are trained to remain flexible and are prepared to select the best means of exit as circumstances and conditions permit.

7-1.6

Many variations of aircraft accidents are possible, and the flight deck crew can be faced with many decisions in the seconds before or after they occur. ARFF personnel therefore cannot expect that standard procedures will be used in all instances and should remain flexible to provide whatever protection and support evacuees should require. In the event that the flight deck crew becomes incapacitated and evacuation does not begin immediately, ARFF personnel should initiate evacuation procedures.

7-1.7

If fire conditions or fuel spills initially prohibit the use of certain emergency exits, ARFF personnel are usually in a better position to make this observation. The ARFF officer in charge should not hesitate to communicate this information to the flight deck crew.

7-2 Evacuation Slides.

7-2.1

Evacuation slides are provided to expedite occupant egress from aircraft that have normal door sill heights above 5 ft. Because passengers are not trained in proper evacuation slide use, there is a degree of personal injury risk when slides are used. ARFF personnel should expect the occurrence of sprains, bruises, friction burns, and other minor injuries whenever evacuation slides are used. (*See Figure 7-2.1*.)

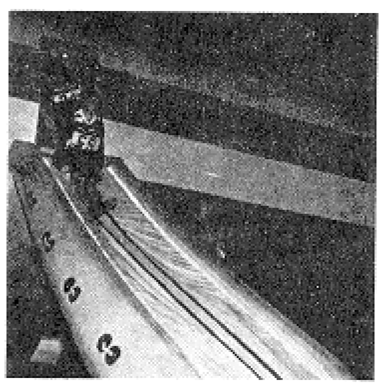

Figure 7-2.1 Photo shows proper entry and use of an evacuation slide.

7-2.2

If, during landing, the nose gear fails, the aircraft might come to rest in a tail-high attitude. The failure of one or more landing gears can result in a nose-high or listing attitude. In these instances, evacuation slides become somewhat ineffective because they do not deploy at the proper angle to the ground. A high percentage of injuries can be expected when evacuation slides are used under these circumstances. ARFF personnel should be able to reduce the amount and severity of injuries and expedite evacuation by manipulating the slides and assisting evacuees. (*See Figure 7-2.2*.)

Figure 7-2.2 Assisting evacuees at the base of an evacuation slide.

7-2.3

Aircraft evacuation slides are susceptible to heat and fire exposure. They are combustible, and when exposed to radiant heat they melt, then deflate, rendering them unusable. ARFF personnel should protect evacuation slides from heat and flame to the best of their ability but should be extremely careful not to apply foam to the operational area of the slide. Foam on the slide makes it very slippery and increases the descent speed of evacuees, possibly causing severe injuries. (*See Figure 7-2.3*.)

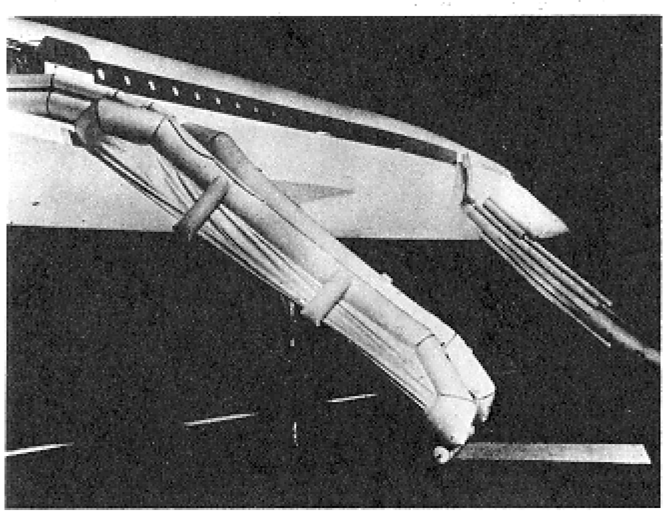

Figure 7-2.3 Photo shows two deployed evacuation slides. Evacuation slides are susceptible to heat and fire exposure.

7-2.4

If time and conditions permit, mobile stairways should be used as an alternative to deploying evacuation slides. This method of evacuation, when there is no immediate danger to aircraft occupants, would prevent many injuries. Response of available mobile stairways should be prearranged between ARFF personnel and one or more of the following:

(a) Airlines;

(b) Airport maintenance facilities;

(c) Airport operations.

7-3 Evacuation Assistance by ARFF Personnel.

7-3.1

The need to assist in aircraft occupant evacuation depends on a variety of factors. When occupants are self-evacuating, ARFF personnel should support the operation and expedite it where possible. In other instances, actions would depend on the degree of occupant survivability, the fire situation, the condition of exits, and the status of evacuation facilities. In any event, rescue efforts should begin with fire prevention/control and should maintain a safe path from egress points. Evacuees should be directed to an upwind location.

7-3.2

Fire prevention/control during evacuation should require strategic positioning of ARFF vehicles and applying foam from turrets to establish a blanket covering the Practical Critical Fire Area (PCA). During this operation, emphasis should be placed on maintaining safe egress paths and eliminating the threat of fire extension into the fuselage. Foam handlines, which are more maneuverable than turret streams, should then be employed to protect evacuees and ARFF personnel, extinguish spot fires, and maintain the integrity of the foam blanket. (*See also Chapter 5*.)

7-3.3

If time and conditions permit, ARFF personnel should assist in the off-loading of evacuees at the base of the evacuation slides to minimize injuries. When high winds or unusual aircraft attitudes cause slides to invert or malposition, an attempt should be made to align them manually.

7-3.4

Ground ladders might be needed to assist occupants who have exited onto wing surfaces and those attempting to exit from openings where evacuation slides are unusable. It is important that assistance be given to evacuees using ladders to ensure that they safely complete their exit and that any one ladder does not become overloaded.

7-4 Aircraft Forcible Entry.

7-4.1

Aircraft involved in accidents can come to rest in almost any attitude. Any abnormal landing force can jam emergency exits. In other instances the fuselage might be broken open by the impact forces, and doors, windows, and hatches can become dislodged. It is difficult to anticipate the various possible accident conditions, and each incident presents unique problems that must be dealt with. ARFF personnel should be thoroughly trained in forcible entry procedures as well as be provided with a wide variety of tools and equipment necessary to accomplish successful entry and extrication of trapped aircraft occupants. Aircraft rescue and fire fighting personnel training programs should include a discussion of methods to be used for a situation that involves an aircraft in an inverted position. Such training should include crash charts that depict, in plan view, the entire underside of the various aircraft using the airport.

7-4.2

In some instances, entry into an aircraft fuselage can only be gained by cutting through the aircraft skin. Knowledge of the aircraft is required to avoid contact with wires, cables, tubing, and heavy structural members. An area of the aircraft normally clear of these features is located in the upper fuselage area above the windows, and any necessary cutting should be attempted in this area. Caution should be exercised to ensure that cutting operations do not endanger trapped occupants.

7-4.3

Turbine-powered aircraft have heavier skins and structures than the older piston aircraft. Due to this heavy construction, the only practical method of entry, other than using normal or emergency exits, is through the use of portable power tools. These tools take the form of electric, pneumatic, hydraulic, or gasoline-powered cutting, spreading, or shifting equipment. At best, this type of entry into a modern jet aircraft fuselage is very difficult and time consuming. These areas should be depicted on aircraft emergency diagrams. (*See NFPA Aircraft Familiarization Charts Manual*.)

7-4.4

Military combat aircraft present additional hazards due to armament, jettison equipment, and ejection seats. This type of aircraft should always be assumed to be armed. Caution should be exercised in the area at the front of this type of aircraft because it can carry fixed guns and rockets. Unlaunched rockets, when exposed to fire, are dangerous from both front and rear if they ignite. As with any ammunition, keep the rockets cool with foam or water. Further unclassified information should be obtained from the commanding officer of the nearest military installation.

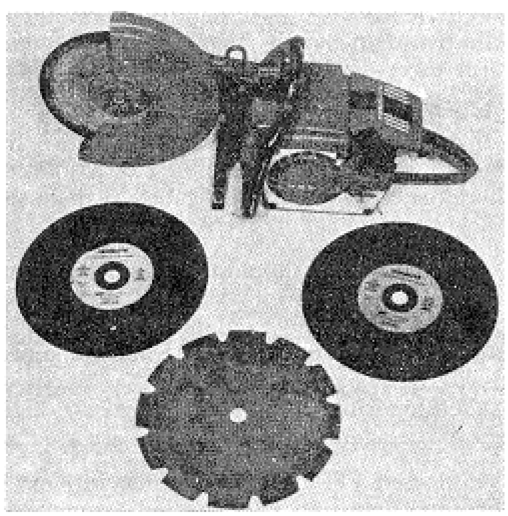

Figure 7-4(a) Rescue saws. Power saws can be used to cut through aircraft skin and structural materials. CAUTION SHOULD BE EXERCISED WHEN USING SPARK-PRODUCING POWER TOOLS WHERE

FLAMMABLE VAPORS EXIST.

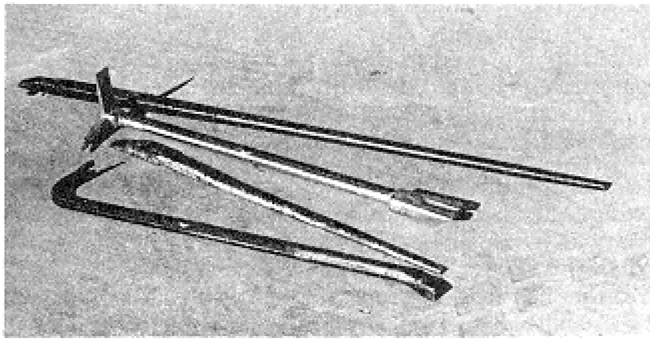

Figure 7-4(b) Prying tools. Claw and pry tools can be used for forcing doors and hatches that are jammed, to pull down panels and partitions, and to dislodge aircraft seats, etc.

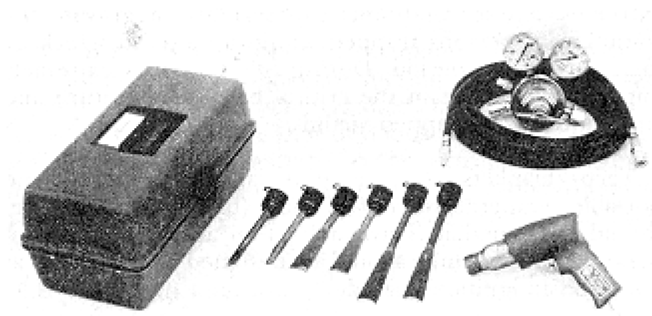

Figure 7-4(c) Air chisel. This tool can be used to cut aluminum and other light metals found on aircraft.

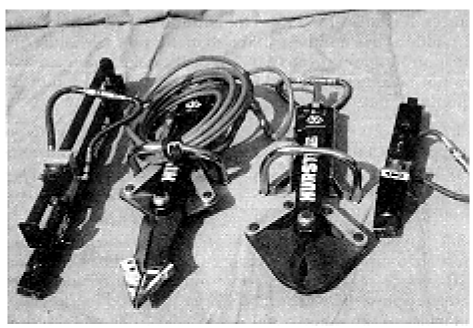

Figure 7-4(d) Hydraulic rescue tool. These tools are used to assist with forcible entry during aircraft accident operations. From left: life or spread (long), spread, cut, and lift or spread (short).

7-5 Extrication and Rescue.

7-5.1

Immediately following the self-evacuation phase of an aircraft accident, a search of the fuselage interior and physical rescue of surviving occupants is crucial. Search and rescue teams should wear full protective clothing and positive pressure self-contained breathing apparatus. They should also be equipped with charged hose lines for their protection and extinguishment of any fire that might have entered the fuselage. A THOROUGH SEARCH OF THE FUSELAGE

INTERIOR AT THIS TIME IS EXTREMELY IMPORTANT. PERSONS, PARTICULARLY INFANTS, CAN BE EASILY OVERLOOKED OR HIDDEN BY DEBRIS.

7-5.2

Rescue operations should be carried out using normal aircraft openings wherever possible. Occasionally, openings caused by airframe separations can be utilized when it is more convenient and safe to do so.

7-5.3

ARFF personnel should have a general knowledge relative to the occupant capacity of the various types of aircraft that use the airport. Initial rescue plans should be based on the assumption that occupant load is at maximum.

7-5.4

The location of occupants in military aircraft can generally be determined by the aircraft type and sometimes by exterior design features such as canopies, gun positions, etc.

7-5.5

Even in survivable aircraft accidents, disruption of the fuselage can be severe, necessitating the improvisation of rescue efforts. ARFF personnel should be skilled in the use of appropriate extrication tools and equipment as well as possessing the basic knowledge and skills to properly stabilize an injured occupant prior to removal from the wreckage.

7-5.6

ARFF personnel rescue and extrication knowledge should include accepted post-aircraft accident procedures, particularly those matters dealing with fatalities and preservation of evidence as described in Chapter 11.

7-5.7

Aircraft accidents can occur during temperature extremes. These conditions can seriously aggravate the condition of persons trapped within an aircraft wreckage for an extended period. During this time it is extremely important to maintain the critical body temperature and vital functions of trapped victims.

Tarps, blankets, portable lights, fans, oxygen units, and portable temperature control units (heating and cooling) should be immediately available at an accident site. Temperature control units should be designed or located so as not to be an ignition hazard.

Chapter 8 Fire Control and Extinguishment

8-1 General.

8-1.1

The risk of fire at an aircraft accident is due to the close proximity of the systems that contain and distribute the fuel and ignition sources such as heated components in engines and undercarriages, damaged electrical circuits, and friction caused by ground slide.

8-1.2

Any post-accident fire can seriously affect the ability of the aircraft occupants to evacuate safely and will reduce the time available to mount a successful fire fighting operation prior to rescue.

8-1.3

Upon impact, or after a period of time, a fire can develop to severe intensity very quickly and can enter the fuselage through opened exits and openings created by the impact.

8-1.4

Aircraft designers are continuously studying design factors and construction material changes that will increase “crashworthiness” and limit the development of fire situations that can impede evacuation. Additional modifications intended to increase the impact survivability of occupants are also being developed. Other changes include improved passenger restraints, reduced combustibility of cabin interiors, better marking of exit routes, upgraded emergency exits, and greater emphasis on the training of flight deck crews.

If these design improvement measures are as successful as anticipated, the prompt and effective intervention by trained ARFF personnel becomes even more important than at present because a greater number of aircraft accident survivors needing assistance can be expected. ARFF personnel should become intimately familiar with all aircraft types using the airport and should pre-incident plan the optimum rescue and fire fighting effort that the fire department can produce with the resources it has at its disposal. Careful consideration of the recommendations in this guide can facilitate the development of practical operational plans.

8-2 Extinguishing Agents for Aircraft Fires.

8-2.1

Aqueous film forming foam (AFFF), film forming fluoroproteins (FFFP), protein foam, and fluoroprotein foam solutions are the primary extinguishing agents preferred for aircraft rescue and fire fighting.

8-2.2

Complementary extinguishing agents consist of approved dry chemicals, Halon 1211, and alternative agents. They are generally best for use on three-dimensional flammable liquid fires or on fires in concealed spaces, such as those occurring behind wall panels, engine nacelles, or wheel wells.

8-2.3

Experience has shown that dry chemical tends to be more effective than halons when used in the open air to extinguish three-dimensional fires, while halons are the preferred agents for electrical fires and in concealed areas.

8-2.4

If dry chemical or halon is used, a fire area, once extinguished, could reflash if exposed to a source of ignition; therefore, a follow-up application of foam is recommended when these agents are used.

8-2.5

AFFF and FFFP should not be mixed with protein-based concentrates. Before film forming foams are used in equipment that formerly contained protein-based foam concentrate, the foam tank and system must be thoroughly flushed with fresh water. The vehicle manufacturer should be consulted to ensure that the agent system design is compatible with the agent to be used.

8-2.6

AFFF and FFFP are compatible with protein and fluoroprotein foams in the applied form and can be applied simultaneously on the same fire area.

8-2.7

AFFF and FFFP agents are compatible with dry chemicals. These agents can be applied simultaneously to improve flame knockdown and control fire spread.

8-2.8

Protein foams should be applied only with compatible dry chemicals. Fluoroprotein foams have demonstrated an improved compatibility with dry chemicals; however, the user should determine that it is adequate to meet operational requirements. If any problems arise, the agent manufacturer should be consulted.

8-2.9

Protein foams should be applied only with compatible dry chemicals.

8-2.10

Fluoroprotein foams have demonstrated an improved compatibility with dry chemicals; however, the user should determine that it is adequate to meet operational requirements. If any problems arise, the agent manufacturer should be consulted.

8-2.11

If foam is being used and the fire is not completely extinguished before the supply is depleted, it might be necessary to complete extinguishment with water streams. When this occurs, avoid applying water or walking in any area that has been secured with foam, as it can break down the established vapor seal that the foam blanket provides.

8-2.12

If the fire has not been completely extinguished by foam, the secured area will “burn back” at a rate that is dependent on the stability of the foam being used. Also under certain circumstances, fire can “flash back” over a portion of an area covered by foam.

8-3 Water and Agent Resupply and Conservation.

Auxiliary water tankers should be dispatched whenever there is any indication of possible need and especially when the aircraft accident site is known to be beyond water relay capability. Prearrangements should be made to ensure that additional supplies of extinguishing agents are brought to the scene. Prudent utilization of agents under these circumstances is particularly important, and application methods should be carefully selected to ensure their most effective use.

8-3.1

It is considered impractical to require airport authorities to provide quantities of extinguishing agents to deal with the worst situation that could arise using only the equipment located on the airport. Therefore, it is necessary for airport emergency plans to contain instructions for requesting support from externally-based fire services following an emergency. It is not easy to specify an operational requirement which makes adequate provision in all circumstances. It is clear that a need for additional water could arise in as little as five minutes, although in this time the initial fire situation should be greatly reduced. If total extinguishment has not been achieved the fire can quickly extend and the equipment must be replenished.

8-3.2

Airports should consider providing additional water as a support facility. There might be exceptions where airports have adequate piped, stored, or natural water supplies, provided that these are available at an accident in sufficient quantity and in time to meet the operational requirement.

8-3.3

In each case the authority having jurisdiction should consult closely with the Chief Fire Officer of the Mutual Aid Fire Service regarding response and supply of additional water supplies. The airport authority will need to assess the suitability of the water resources which can be mobilized to support the airport fire service when a serious and prolonged post-accident fire occurs. Therefore, the speed of mobilization and the rate at which the water can be delivered to the accident site are important factors.

8-4 Rescue Operations.

8-4.1

The primary objective of ARFF personnel at the scene of any aircraft accident is to control and extinguish the fire to enable safe evacuation of the aircraft.

8-4.2

Occupant survival is generally limited to aircraft accidents that are of low impact in nature, where the fuselage is not severely broken up and a fuel fire has not developed. In more severe accidents, even those where fire does develop, ARFF personnel should assume that there is always the possibility of survivors and take aggressive steps to control the fire, initiate evacuation, and rescue those unable to self-evacuate.

8-4.3

Rescue operations should begin as soon as conditions permit and often are a simultaneous function during the fire fighting phase that requires considerable coordination. The rescue team’s mission includes assisting evacuees, accomplishing forcible entry if necessary, completing interior extinguishment, extricating trapped survivors, and removing the injured to safety.

8-4.4

One rescue team method consists of four ARFF personnel equipped with full protective clothing and positive pressure self-contained breathing apparatus (SCBA). Two of the persons are handline operators and precede the other two, who are equipped with appropriate hand-held tools needed for forcible entry, extrication, and making access to hidden fuselage fires behind panels, floors, and compartments.

A procedure preferred by some fire departments is to provide an additional handline operator, similarly attired and equipped with SCBA, operating behind the rescue team with a spray stream, as their protection throughout the entire operation.

8-5 Size-Up (Risk Assessment).

8-5.1

The process called size-up (risk assessment) merely means the gathering of facts in preparation for making decisions. The facts pertaining to an aircraft accident, when mentally assembled, enable the responsible ARFF officer to establish both initial tactics and overall strategy.

8-5.2

The size-up (risk assessment) process is initiated by the first-responding ARFF officer and is carried on throughout the duration of the incident in terms of depth and scope by later-arriving superior officers.

8-5.3

When an aircraft accident occurs, some size-up (risk assessment) information in the form of established facts should be immediately known as the result of training, pre-incident planning, knowledge of available resources, and interpretation of alarm information. Additional facts become known through observation during response and upon arrival at the scene.

8-5.4

Vital operational decisions based upon initial size-up (risk assessment) information should be made without delay. Realistic objectives are critical, and consideration should be given to the capabilities of resources that are immediately available.

8-5.5

Initial assignments of tasks based on the size-up (risk assessment) are generally not fixed and tend to be modified as the incident develops. The size-up (risk assessment) process should continue throughout the duration of the incident, and any changes in strategy or objective that develop should be communicated to key personnel involved in the operation.

8-6 Aircraft Accident — Fire Involvement.

8-6.1

In an aircraft accident, occupants are confined within the fuselage and are surrounded by very large amounts of fuel that, when ignited, can release heat at about five times the rate that develops in the typical structure fire. An aircraft fuselage has a very low resistance to fire, except for engine areas, cargo compartments, and galleys, as fire and smoke barriers are nonexistent.

8-6.2

The priority should be given to aircraft occupant survival. Those who have survived the impact forces then face the exposure to fire and toxic products of combustion. Total extinguishment of the fire is an acceptable initial approach if it is determined to be the most effective method of successfully accomplishing rescue. A resource-conserving alternative would be selective control of fire in areas where occupants are successfully evacuating and maintaining these escape routes until it has been determined that evacuation is complete. A decision as to the precise method of initial fire attach should be made by the ARFF officer in charge immediately upon arrival at the scene. All members of the ARFF team should realize that initial plans are always subject to change and should remain alert for orders that alter operations as conditions dictate.

8-6.3

If upon arrival at an aircraft accident the operator of the first-arriving ARFF vehicle encounters a small fire, the best tactic would be to extinguish it rapidly and then begin to blanket any fuel spill with foam. Later-arriving vehicles should assist in the foam application if needed or perform other tasks as directed by the officer in charge.

8-6.4

If a large fire is in progress upon arrival of the ARFF personnel, foam should be applied using the vehicle turrets. Since initial foam supplies can be exhausted in 2 minutes, turret operators should understand that foam application by this method must be effective and that streams should be shut down on occasion to assess progress and conserve foam. Once a fire has been controlled and any fuel spill blanketed with foam, consideration should be given to employing foam handlines that are more maneuverable and therefore more effective for maintaining a foam blanket and extinguishing small fires.

8-6.5

If foam becomes contaminated by fuel splashing into it, then at some time the foam will become flammable. The degree to which this is a problem depends on the type of foam and the amount of contamination. As solution drains from the foam, the water drains at a faster rate than the fuel, resulting in a fuel-rich foam matrix that can ignite if exposed to a source of ignition. This problem is more evident in AFFF than in other foams because it has a much faster drainage rate and becomes flammable at a lower level of contamination.

8-6.6

Protein and fluoroprotein foaming agents should form a blanket over the surface of a flammable liquid fire in order to extinguish it. The foam should be applied using a dispersed pattern over the surface of the burning fuel to completely cover the spill area. It needs to be applied in such a manner that it does not break up any previously established blanket. If isolated openings in the foam blanket occur, they should be filled in as soon as possible with new foam.

8-6.7

AFFF and FFFP agent solutions can be applied either with aspirating nozzles, turret nozzles used for protein and fluoroprotein foams, or conventional water spray nozzles. Either spray or straight streams can be used as the situation dictates. It is best to approach the fire area as closely as possible and apply the foam in a wide spray pattern initially, changing to a narrower pattern after the heat has been reduced. The stream should be applied in a gentle manner to avoid unnecessary plunging of the stream into the burning fuel. The foam should be applied to the near edge of the fire with a rapid side-to-side sweeping motion to distribute the foam rapidly and thinly over the burning fuel. Advance as the fire is controlled, always applying the foam to the nearest burning fuel surface. Advance only after a continuous, unbroken foam cover is established. The entire foam blanket integrity should be maintained to compensate for voids created by movements of ARFF personnel, evacuees, and equipment, as well as the normal draindown of the foam.

8-7 Extinguishment Techniques.

8-7.1

Vehicle approach to a burning aircraft should be such that turret streams can be applied along the length of the fuselage with efforts concentrated on driving the fire outward while keeping the fuselage cool, protecting occupants as they evacuate, and assisting with the entry of rescue teams.

8-7.2

The location of survivors, if known, and the area of fire will determine where the first streams should be applied. If the fire has penetrated the fuselage, a direct interior attack with handlines should be initiated as soon as possible.

8-7.3

Where it is compatible with the evacuation process, it is best to approach an aircraft fire from the windward side. Agents should be applied from the windward side to provide better reach and greater ability to monitor extinguishing effectiveness, as the heat and smoke will be moving in the opposite direction. When vehicle turrets are in operation on opposite sides of a fuselage, care should be taken so that the fire is not driven underneath from one side to the other.

8-7.4

When an aircraft comes to rest on sloping terrain or adjacent to a gully or wash, circumstances permitting, the fire should be approached from high ground and the burning fuel driven away from the fuselage.

8-7.5

Aircraft accidents do not occur under the best conditions or permit the ideal conditions for combating a fire. It will not always be possible to approach the fire from high ground or the windward side. What is important is an aggressive attack to isolate the fuselage from the fire and efficient fire ground coordination to achieve a successful evacuation of occupants and complete fire extinguishment.

8-7.6

The initial attack on an aircraft fuel fire should normally be by judicious application of foam, or alternatively by the combined use of foam and a complementary agent. A three-dimensional or flowing fire should be extinguished by using an approved dry chemical, Halon 1211, and alternative agents, followed by an application of foam. Even where foam alone is used, a suitable complementary agent should be available to deal with fire inaccessible to direct foam application.

8-7.7

If a fire threatens exposed aircraft, structures, or other combustibles, they should be protected by foam or water spray.

NOTE: Water streams or runoff should not be permitted to destroy any foam blanket in the critical fire area.

8-7.8

If a large fuel spill occurs without igniting, it is important to eliminate as many ignition sources as possible while the spill is being stabilized with a foam blanket. There can be enough residual heat present in jet engines to ignite fuel vapors 30 minutes after shutdown.

8-7.9

Extinguishing agents should be applied in a manner to avoid spot cooling of components that can cause stress failure and disintegration. If possible, streams should be employed so that even surface cooling can result. Approved dry chemicals, Halon 1211, and alternative agents can extinguish fires involving hydraulic fluids or lubricants, but they lack the cooling ability necessary to prevent reignition.

8-8 Turret Operations.

8-8.1

ARFF vehicles should be positioned to make the most effective use of all extinguishing agent systems. The most efficient use can require movement of the vehicle during turret or even handline operations. It is vitally important not to waste available agent. TURRETS SHOULD BE USED ONLY AS LONG AS THEY ARE BEING EFFECTIVE. After initial knockdown of the heat and flame, use of handlines to maintain control of evacuations areas can be the key to a successful rescue operation.

8-8.2

When selecting vehicle positions for applying foam from a turret, remember that wind has a considerable influence upon the quality of the foam pattern and the rate of fire and heat travel. Utilize the wind whenever possible to achieve more effective fire control.

8-8.3

Turret application should never be directed so as to drive fuel or fire toward the fuselage. The main objective is to maintain an escape route for occupants until complete evacuation is achieved.

8-8.4

Usually water supplies are a key factor, and turret operators should concentrate their extinguishing efforts on the escape route from the aircraft.

8-8.5

The “pump and roll” concept, a method of applying agent from a turret while the vehicle is in motion, can be a very effective fire control technique when used correctly.

8-9 Aqueous Film Forming Foam (AFFF) and Film Forming Fluoroprotein (FFFP) for Turret Application.

8-9.1

The basic principle is to distribute a visible AFFF or FFFP blanket of sufficient thickness over the burning fuel to act as a blanket for vapor suppression. The original blanket should not be relied upon to be permanent and should be maintained as necessary until the fuel vapor hazard no longer exists.

8-9.2

Both aspirating and nonaspirating nozzles can be used for AFFF or FFFP application. A nonaspirated nozzle typically provides longer reach and quicker control and extinguishment. However, expansion rates and foam drainage times are generally less when AFFF or FFFP is applied with nonaspirating nozzles, and it should be understood that the foam blanket might be less stable and have a lower resistance to burnback than that formed using aspirating nozzles.

Manufacturers should be consulted for guidance on nozzle performance. Extreme caution should be taken when using the straight stream method as this can cause an increase in the liquid pool surface or cause an opening in the foam blanket, releasing flammable vapors.

8-10 Protein and Fluoroprotein Foam Turret Application.

8-10.1

Protein and fluoroprotein foams should be applied to burning fuel so that they gently form a uniform and cohesive blanket with the least possible turbulence to the fuel surface.

8-10.2

Aspirating nozzles should be used for applying protein and fluoroprotein foams in either the straight stream or dispersed patterns to distribute the foam over a wide area. When using the straight stream method of application, the foam should be applied indirectly using deflection techniques, and special care should be exercised to avoid disturbing the established foam blanket.

8-11 Handline Foam Application.

8-11.1

As soon as the fire has been knocked down by turrets, they should be shut down, perhaps repositioned, and held in a state of readiness to resume operation should the need occur. During this phase of rescue and fire fighting, handlines are more effective than turrets in controlling the fire, maintaining rescue paths for occupants, mopping up spot fires, maintaining the foam blanket, and conserving vital agent supply.

8-11.2

Whether or not there is an immediate need for them, charged handlines should be placed in strategic positions as soon as possible after ARFF personnel arrive on the scene. This practice would ensure their immediate availability for use when the need arises.

8-11.3

Foam application principles are the same for handlines as they are for turrets.

8-12 Aircraft Accident — No Fire Involvement.

At an aircraft accident without fire, appropriate fire prevention measures should be initiated immediately.

(a) All spilled fuel should be covered with foam. Engines and other heated surfaces should be cooled with foam or water fog to prevent ignition. Care should be taken so that the seal established by the foam blanket is not washed away or diluted by the water spray.

(b) The washing of spilled fuel from around the aircraft requires caution. Raw fuel and flammable vapors should be directed away from sources of ignition.

(c) Every effort should be made to prevent sparks whenever there is the possibility of exposed fuel or fuel vapors in the area. Particular care should be taken to prevent sparks due to arcing before the aircraft electrical system can be de-energized.

(d) ARFF need to exercise extreme care when cutting tools are used at the accident site when fuel liquid and vapor is present. A support fire-fighter should be on standby with a fully-charged hoseline to deal with any incipient fire that might develop.

8-13 Exposure Protection.

8-13.1

After rescue of occupants, protection of exposed property should be the next consideration at the scene of an aircraft accident, whether fire exists or not. In addition to airport structures and other aircraft, plans should include preventing contamination and fire spread into drains, sewers, waterways, and any below ground facilities. Authorities should be immediately notified of any exposure to fire or contamination involving property under their control.

8-13.2

Early and effective fire extinguishment ensures the least amount of property loss, and that includes exposed properties whether involved in fire or not. Where resources are limited, conditions will dictate which exposures receive first priority for protection.

Chapter 9 Interior Aircraft Fires

9-1 General.

9-1.1

The recommendations contained in this chapter are provided for the guidance of ARFF personnel encountering interior aircraft fires occurring in both parked, unoccupied aircraft and aircraft with passengers and crew aboard.

9-1.2

The occurrence of interior aircraft fires where passengers and crew are onboard presents a major problem for ARFF personnel. An acute life safety hazard exists in these instances, and the ability to enter the aircraft and extinguish the fire might have to be delayed until evacuation has been completed. Because forcible entry and rescue are discussed in detail elsewhere in this guide, they will not be covered here, and instead emphasis will be on the procedures and techniques of attacking and extinguishing interior aircraft fires.

9-1.3

Aircraft passenger cabin fires normally involve ordinary combustibles such as upholstery, paneling, carpeting, refuse, electrical insulation, and carry-on materials. Generally, a direct attack on the fire with water streams, using structural fire fighting techniques, is effective.

9-1.4

ARFF personnel should understand the structural characteristics of an aircraft fuselage. The absence of fire stops at the floor, behind wall panels, and above ceiling areas permits fires to spread undetected and unchecked through combustible materials once fire has entered those areas. ARFF personnel should always assume, until it is proven otherwise, that fire has moved away from its origin via these concealed spaces. Sections of flooring, wall panels, and ceilings should be removed where fire travel is suspected so that complete extinguishment can be accomplished.

9-1.5

Since the burning of aircraft interior materials creates a toxic atmosphere, ARFF personnel should wear positive pressure self-contained breathing apparatus whenever working inside the fuselage both during the fire fighting stage and later, while overhauling. Additionally, the entire fuselage should be ventilated as quickly as possible by whatever means available. Smoke ejectors can expedite horizontal ventilation, which is usually the only choice of methods since aircraft have no designed vertical openings. [*See Figure 9-5(b).*]

9-1.6

Interior aircraft fire situations can differ widely; therefore, explicit guidance regarding extinguishment techniques is not possible. Points of entry and methods of attack should be dependent upon an evaluation of conditions and assessment of resource capability by the ARFF officer in charge.

9-1.7

An interior aircraft fire location and its intensity can to some degree be determined by observation through cabin windows, smoke characteristics, or aircraft skin that shows buckling or paint blisters.

9-1.8

In the event that an interior aircraft fire cannot be immediately extinguished, foam or water spray should be applied to wing and fuselage fuel tank areas that might be exposed to heat.

9-2 Aircraft Interior Fires Occurring in Flight.

9-2.1

A major hazard of commercial aviation is the in-flight fire that cannot be controlled by onboard portable extinguishers or fixed extinguishing systems.

9-2.2

Aircraft emergency landings or accidents can be the result of uncontrolled fires occurring in flight. The most frequent types of in-flight fires involve:

(a) Engines,

(b) Cabin areas,

(c) Lavatories,

(d) Heaters,

(e) Cargo areas, and

(f) Electrical compartments.

9-2.3

Portable fire extinguishers are required to be mounted at specific locations in the cabin of passenger aircraft, and flight deck crews receive periodic training in their use. The extinguishers are designed to handle incipient fires in accessible areas. However, fires can and do originate in locations not readily accessible from the cabin while the aircraft is in flight. If the area involved in fire is isolated and is not equipped with a fixed extinguishing system, a serious fire can develop and spread rapidly.

9-2.4

When an uncontrolled in-flight fire occurs, the aircraft must make an emergency landing at the nearest suitable airport, and the occupants must be evacuated before being overcome by heat, smoke, and toxic gases. ARFF personnel are usually notified of such emergencies well in advance of the landing and should be prepared to assist in the immediate evacuation and to enter the aircraft and extinguish the fire.

9-2.5

When the aircraft is on the ground and whether or not the air conditioning system is operating, heat, smoke, and gases will build up, creating a toxic atmosphere and setting the stage for a flashover.

9-2.6

After the aircraft has landed and the flight deck crew has initiated emergency evacuation, it should be assumed that some of the occupants might not have the ability to self-evacuate. ARFF personnel should allow normal procedures to be carried out to their full potential without compromising the evacuation process; however, ARFF personnel and vehicles should be placed in strategic positions to effect entry into fuselage to confirm complete evacuation and achieve fire control.

9-2.7

If there is no evidence of occupant evacuation, immediate steps should be taken to make entry for control of the fire and rescue of occupants. Entry will permit an inrush of fresh air into a possibly overheated or unstable atmosphere that could rapidly accelerate the fire. Toxic gases will be present, so ventilation and a thorough search for survivors should take place immediately and simultaneously with the fire fighting effort. In darkness or heavy smoke conditions these efforts will be much more difficult.

9-2.8

Extinguishing agents other than water that can be used on interior aircraft fires include foam, halons, and dry chemicals. However, if onboard oxygen systems have been damaged, creating an oxygen-rich atmosphere, or if there is major interior fire involvement, water streams would be the best agent.

9-3 Interior Fires in Unoccupied Aircraft.

9-3.1

Fires occurring in unoccupied aircraft often result in delayed detection. An unattended aircraft with its doors closed can contain a smoldering fire that can burn unnoticed for an extended period of time. Under these conditions, a build-up of extremely hot fire gases can develop as the fire consumes all the available oxygen. Opening up an aircraft under such circumstances can be very hazardous because when oxygen is introduced into such an atmosphere the entire interior can become immediately ignited, possibly with explosive force. Handlines that fully-charged need to be in place prior to entry into the fuselage.

9-3.2

When arriving at a closed, unoccupied aircraft that is suspected of having an interior fire, the internal atmosphere should be assessed before entry is attempted. If flame cannot be seen, and the windows are hot to the touch and obscured by heavy smoke, it can be expected that a hot, smoldering fire exists and entry of outside air at this time would ignite the entire interior.

9-3.3

If an interior fire in an unoccupied aircraft has not reached the smoldering stage, there is sufficient oxygen present and a free-burning fire can be maintained. Under these circumstances entry should be made and the fire extinguished with water in the conventional manner.

9-3.4

Extinguishment of a hot, smoldering, internal aircraft fire can be very difficult. Where this type of fire exists, one method is worth consideration. It can be referred to as an indirect attack that is made from small fuselage openings such as slightly opened exits or openings made in cabin windows. A coordinated multiple-point attack is more effective than a single point attack and is a necessity when applying the method to fires in wide-body or jumbo aircraft with large volume interiors. It must be remembered that this method is not suitable if there is any possibility of occupants being onboard the aircraft.

9-3.4.1 The extinguishment principle of this indirect method is based on the conversion of water spray into steam as it contacts the super heated atmosphere within an enclosure. The rapid expansion of water spray droplets into minute stream droplets increases the surface area of the water, permitting it to absorb more heat, thus making it more efficient as a cooling agent. Water in this form and under pressure has the ability to penetrate dense burning materials and enter areas behind panels and coverings. When properly applied the method lowers the temperature of the entire fire area to a point where combustion ceases.

9-3.4.2 Should a smoldering, interior aircraft fire occur in compartments below the passenger and flight deck levels, the indirect attack method can also be applied, adapted to the particular circumstances involved. More difficulty can be experienced in achieving convenient openings in these compartments, however. Consideration should be given to attacking fires in these areas through openings in the cabin floor.

9-4 Penetrating Nozzles.

9-4.1

The use of penetrating nozzles is another way of combating aircraft cabin and compartment fires. Most penetrating nozzles are designed so that any agent currently used by ARFF providers can be utilized.

9-4.2

To extinguish an aircraft cabin or compartment fire using penetrating nozzles, the total fire area requiring agent application needs to be considered. For example, to extinguish a large fire in the cabin of a wide-body aircraft, penetrating nozzles injecting agent simultaneously from dispersed, multiple injection points would be required to provide a sufficient amount of agent to effect extinguishment in a timely manner.

9-4.3

Currently, there are a number of penetrating nozzles in use. The manner of application can be slow, awkward, and occasionally dangerous when applied to aircraft fire fighting and should be done with great care. When using this type of penetrating nozzle, ARFF personnel should make certain that they have proper footing and sufficient operating, and have an understanding of aircraft design and construction and emergency access points of entry. (*See Figure 9-4.3*.)

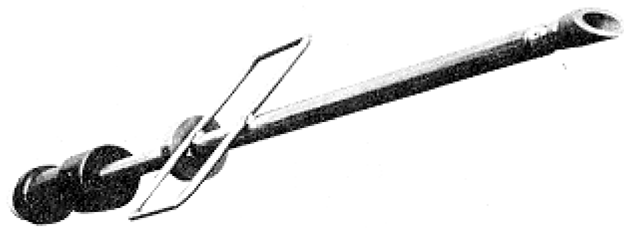

Figure 9-4.3 Aircraft skin penetrator nozzle.

9-4.4

More recently a new type of penetrating nozzle concept has been introduced by the U.S. Air Force. It is referred to as a skin penetrating agent applicator tool (SPAAT). This tool incorporates a pneumatic device that drills through aircraft skin and windows within 10 seconds and can immediately inject any of several agents into the fuselage. (*See Figure 9-4.4*.)

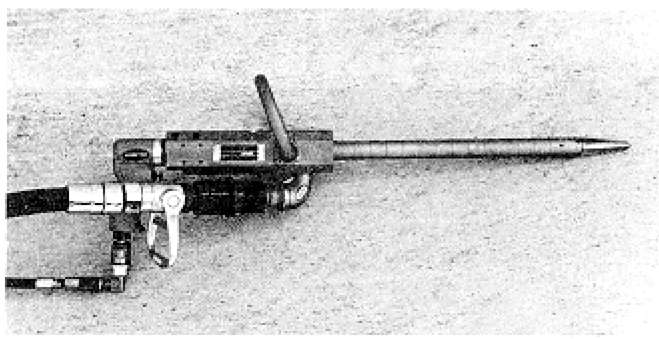

Figure 9-4.4 Skin penetrator agent applicator tool (SPAAT).

9-5 Interior Aircraft Fire Overhaul.

During the overhaul phase of an interior aircraft fire, hose lines should remain charged and available to extinguish any deep-seated fire, hidden uncovered fire, or reignition. Carpeting, wall panels, partitions, and ceiling covering should be removed when necessary to ensure that all fire is extinguished and that there is no threat of reignition. The use of portable lighting units and smoke ejectors will help to make the aircraft interior safer and more tenable for ARFF personnel. [*See Figures 9-5(a) and (b)*.] ANY PERSON ENTERING THE AIRCRAFT DURING THE OVERHAUL PHASE SHOULD USE POSITIVE PRESSURE SELF-CONTAINED BREATHING APPARATUS.

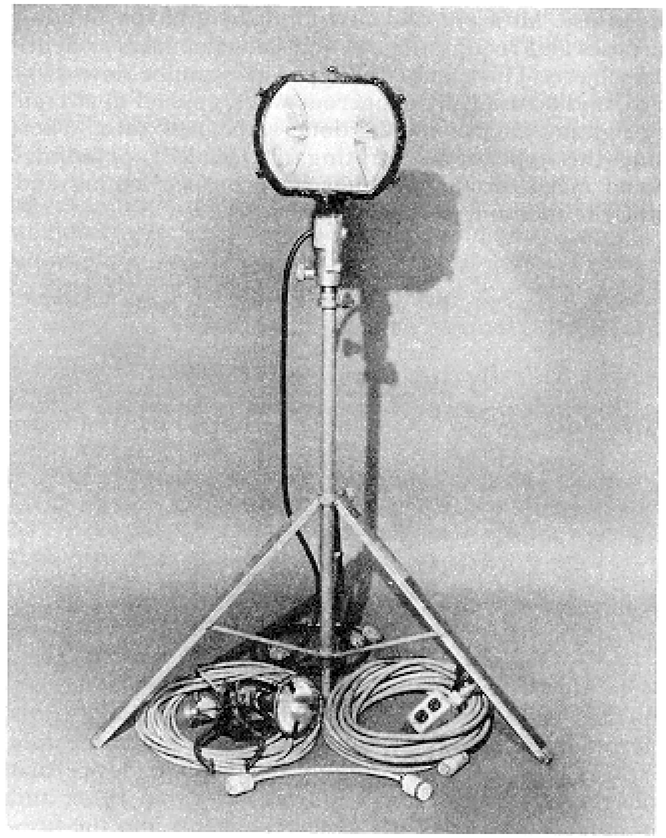

Figure 9-5(a) Portable lighting units.

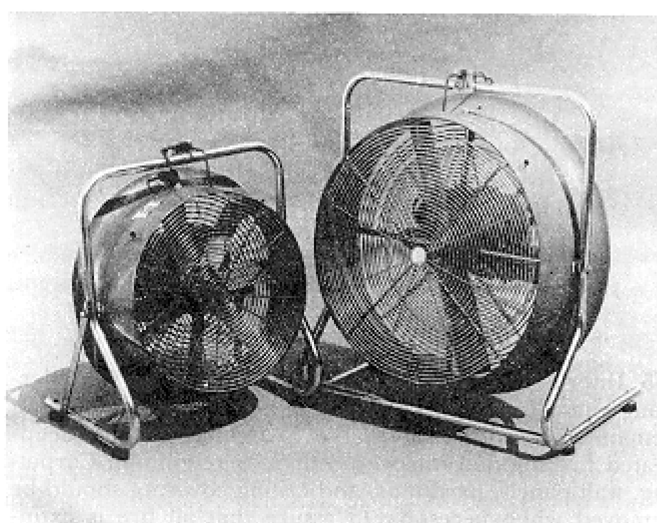

Figure 9-5(b) Smoke ejectors.

Chapter 10 Miscellaneous Aircraft Incidents

10-1 General.

10-1.1

Each year ARFF personnel respond to numerous incidents on airports that are considered "minor." These seemingly routine activities do not make headlines, but the absence of intervention could often result in catastrophic loss of life, serious injuries, and extensive property loss.

10-1.2

Guidance presented in this chapter is intended to inform ARFF personnel of a variety of aircraft incident types and how to deal with them so that the hazards relative to aircraft operations on airports can be safely abated.

10-2 Engine Fires.

10-2.1

It is reasonable for ARFF personnel responding to aircraft engine fires to expect that the following actions have probably been accomplished by the flight deck crew:

(a) Engine shut down;

(b) Engine fire extinguishing system (if any) activated;

(c) Electrical power to the affected engine(s) de-energized; and

(d) Fuel and hydraulic fluid supply to the affected engine(s) shut down.

These actions should be verified as conditions permit. It should be emphasized that turbine engines, following shutoff of power and fuel, can remain a potential hazard during "wind down" with high heat retention continuing for as long as 30 minutes. This heat constitutes a potential ignition source for flammable vapors. On propeller-driven or rotary-wing aircraft, contact with propellers, or entry into their path of rotation, should be avoided during all stages of the emergency.

10-2.2

When jet engines are started or shut down in certain wind conditions, hot starts or tail pipe fires can occur. These fires can usually be controlled by the flight deck crew. In some cases, however, fire department intervention might be necessary.

10-2.3

When reciprocating engine fires are confined within the nacelle, but cannot be controlled by the aircraft extinguishing system, dry chemical or a halon agent should be applied first, as these agents are more effective than water or foam for fires inside an enclosure. Foam or water spray should be used to cool the outside of the nacelle.

10-2.4

Fires confined to the hot section of jet engines can be best controlled by keeping the engine rotating. Such action should be considered in the context of necessary aircraft evacuation and other safety considerations. Fires outside the combustion chambers, but confined within the nacelle, are best controlled with the engine's fixed extinguishing system. If the fire continues after the system has been exhausted, or if reignition occurs, a halon or dry chemical agent should be applied through maintenance openings. The aircraft operator should be advised of the type of extinguishing agent used in order that appropriate maintenance action can be taken later.

10-2.5

Foam or water should not be applied to either the intake or exhaust of a jet engine unless control cannot be secured or confined to the engine nacelle using halon or dry chemical. If foam or water is applied to either the intake or exhaust, ARFF personnel should stand clear to avoid being struck by disintegrating engine parts.

10-2.6

Most jet engines are constructed with magnesium and titanium parts that, if ignited, are very difficult to extinguish. If these fires are contained within the nacelle, they should be permitted to burn themselves out as long as:

(a) There are no external vapors present that cannot be eliminated; and

(b) Sufficient foam or water spray is available to maintain the integrity of the nacelle and surrounding exposed aircraft components.

10-2.7

When tail pipe fires occur in the elevated center engine of three-engine wide-body aircraft or a B-747 auxiliary power unit, special elevating equipment might be required to effectively discharge agent on the fire. (*See also Appendix B.*)

10-3 Aircraft Fuel Servicing Incidents.

10-3.1

A number of aircraft fires have occurred during fuel servicing. Ignition has been caused by static developed in flowing fuel, surface-generated static within an aircraft fuel tank, or refueling vehicle, defective fuel pumps, an external source of ignition, and other improper fueling procedures. Defueling and fuel transfer operations are also serious fire potentials. Standards relative to aircraft fueling procedures and proper equipment maintenance should be diligently enforced by the authority having jurisdiction on the airport.

10-3.2

Fuel spills exterior to the aircraft should be handled in the manner described in NFPA 407, *Standard for Aircraft Fuel Servicing*, when fire does not occur. If fire does occur, it should be handled similar to any other aircraft accident, with primary emphasis on life safety. The practice of fueling occupied transport category aircraft necessitates that, in the event of a fuel spill fire, an immediate check of the interior for occupants is imperative.

10-3.3

Many transport category aircraft have ganged fuel tank vents near wing tips. Vented JET A type fuel (kerosene grades) vapors normally present very little hazard. If tanks are overfilled, the fuel will discharge through the vents, causing a fuel spill. There is a greater potential for a flammable vapor-air mixture being present in the immediate vicinity of wing tip vents when JET B fuel is used. Regardless of which fuel is used, it is good practice not to position or operate vehicles within a 25-ft (8-m) radius of aircraft fuel system vent openings.

10-4 Hot Brakes and Wheel Fires.

10-4.1

The heating of aircraft tires causes overpressure and presents a potential explosion hazard. Good judgment should be exercised in determining the severity of the situation, and this information should be conveyed to the flight deck crew. The flight deck crew in turn can assist the rescue and fire fighting effort by performing necessary procedures (i.e., shut down engines, extend flaps, prepare evacuation, etc.).

10-4.2

In order to avoid endangering ARFF personnel and aircraft occupants and causing unnecessary damage to the aircraft, it is important not to mistake hot brakes for brake fires. Hot brakes normally cool by themselves and do not require an extinguishing agent.

10-4.3

When a hot brake condition occurs on a propeller-driven aircraft, it is usually beneficial to keep the propeller operating that is directly forward of the wheel with hot brakes until the brakes have cooled. Larger, modern aircraft have fusible plugs mounted in the wheels that fuse at approximately 300°F–400°F (282°C–382°C), allowing the tires to deflate before dangerous pressure can develop.

10-4.4

ARFF personnel should remain clear of the sides of aircraft wheel assemblies that are involved in fire and approach only in a fore and aft direction. Since heat is transferred from the brake to the wheel, extinguishing agent should be applied to the brake area. The primary objective is to prevent the fire from spreading upward into the wheel wells, wings, and fuselage.

10-4.5

Foam, water spray, halons, and dry chemical are effective agents for direct application on brake fires.

10-4.6

Dry chemical agents and Halon 1211 might extinguish fires involving hydraulic fluids and lubricants, but reignition can occur since these agents lack sufficient cooling effect. Halon 1211 is particularly effective in extinguishing undercarriage fires; however, where magnesium wheel components are burning, halon agents should not be used.

10-4.7

Effectiveness of any gaseous extinguishing agent can be severely reduced if wind conditions are such that sufficient concentration cannot be maintained to extinguish the fire.

10-4.8

Solid streams of water should be used only as a last resort on wheel fires since the rapid cooling can cause an explosive failure. However, fires involving magnesium wheels have been successfully extinguished by applying large amounts of water from a distance. This method rapidly reduces the heat to a point below the ignition temperature of the magnesium, and the fire is extinguished. ARFF personnel should exercise extreme caution when this method of extinguishment is used, as explosive failure of the wheel components is likely.

10-5 Combustible Metal Fires.

Burning magnesium or titanium parts should be isolated if possible and extinguished by applying a Class D agent. Covering the burning metal with dry, uncontaminated sand can be effective when a Class D agent is not available.

10-6 Broken Flammable Liquid Lines.

Broken fuel, hydraulic, alcohol, and lubricating oil lines should be plugged or crimped when possible to reduce the amount of spill potential.

10-7 Heater Fires.

Heaters located in wings, fuselage, and tail sections of aircraft can be protected with a fixed fire extinguishing system. It can be assumed that in the event of an airborne heater compartment fire, the system would have been activated. After the aircraft has landed, a thorough check of the heater compartment and surrounding area should be made to ensure that there has been no reignition or spread of fire.

10-8 Bomb Threats/Security.

10-8.1

Threats of terrorism have forced airports to enforce strict security measures. These frequently impact the operation of the emergency services.

10-8.2

Arrangements must be made between the airport security authorities and mutual aid responders to enable them to obtain immediate access to the accident site. Care must be taken to ensure that only authorized persons are admitted when a security gate is being used.

10-8.3

When a bomb threat involving an aircraft is declared an emergency, the aircraft should be evacuated without delay. Passengers should be directed to leave their carry-on materials and depart the aircraft as quickly as possible. The situation might dictate the use of the emergency evacuation slides or built-in stairs. Portable stairways positioned by ARFF personnel should be the safest and most practical alternative.

10-8.4

Immediately after evacuation has been completed, the aircraft involved should be moved to a location at least 1000 ft (300 m) away from structures and other aircraft if not already so located.

10-8.5

Airport pre-incident plans should incorporate assignment of initial responsibility in any bomb threat emergency for initiating protective measures, conducting and controlling any search activities, transferring their responsibility, and declaring the termination of the emergency.

10-8.6

The role of the ARFF personnel in bomb threat emergencies should be limited to:

(a) Assisting occupants evacuate the aircraft;

(b) Assuming a standby status and remaining in readiness after evacuation is complete and the aircraft has been moved to a safe location; and

(c) In the event of a bomb detonation, assuming command and control of any rescue operation or fire incident that results.

10-8.7

The airline, where involved, should have the responsibility for the safety and well-being of the passengers and should cooperate and assist the airport police in any needed search of baggage or aircraft.

10-9 Incidents Where Aircraft Fire Warnings Occur.

10-9.1

It is often difficult for the flight deck crew to accurately appraise conditions following actuation of an aircraft fire warning indicator. Therefore, the aircraft should be brought to a stop after clearing the runway and before approaching the terminal. ARFF personnel should inspect the affected area by checking for external evidence of smoke or heat. If no evidence exists, the aircraft should continue on to the terminal where a more thorough inspection can be made.

10-9.2

If there is evidence of fire, immediate access should be made and the fire extinguished. If this occurs the aircraft should be shut down and the decision made as to whether an evacuation of occupants should take place. Airline maintenance personnel and equipment should be requested to respond and assist ARFF personnel in gaining access and operating ground power units, and should assist with portable stairways if needed for evacuation.

10-10 Emergency Landings.

10-10.1

Often, landing gear stuck in the retracted position is the result of broken hydraulic lines or loss of electrical power. Spilled hydraulic fluid can ignite in the wheel wells due to the presence of electrical shorts, friction sparks due to a wheels-up landing, or other heat sources. Should ignition occur, the fire has a tendency to travel up into the fuselage and can rapidly become a major interior fire. ARFF personnel should take immediate steps to ensure the stabilization of this problem even though appearances from the exterior do not immediately indicate the presence of fire.

10-10.2

Hydraulic problems on landing aircraft can involve the brake systems, flaps, spoilers, etc. This has a tendency to lengthen the rollout after touchdown and can also affect the aircraft's directional control. As soon as the aircraft has touched down and passes each ARFF vehicle that is standing by, that vehicle should immediately follow the aircraft and be ready to perform any necessary operation when it comes to a stop. **IT IS EXTREMELY IMPORTANT THAT ALL OTHER AIRPORT VEHICLES AND PERSONNEL REMAIN CLEAR OF THE AIRCRAFT, THUS PERMITTING ARFF VEHICLES AND PERSONNEL TO MANEUVER AND POSITION FOR EFFECTIVE RESCUE AND FIRE FIGHTING**.

10-10.3

At emergencies involving landing gear malfunctions or tire problems, there is always a possibility of the aircraft veering off the runway after landing and hitting standby ARFF vehicles. It is difficult to predict the touchdown point. Therefore, if there are two or more ARFF vehicles available, one vehicle should stand by on the opposite side of the runway, a suitable distance from the edge.

10-11 Aircraft Accidents in the Water.

10-11.1

Many aircraft accidents in the water have occurred in the critical response area off the end of the runway. Where runways terminate adjacent to a significant body of water, special provisions should be made to ensure the rapid response of ARFF services. For any aircraft overrunning or landing short of the runways, response times should be as close as possible to those of land emergencies.

10-11.2

Many transport category aircraft not engaged in intercontinental overwater flights are equipped only with flotation-type seat cushions as emergency flotation devices. Survivability of passengers using this equipment is limited. Survivors are susceptible to hypothermia in water below 70°F (52°C) and ingestion of vapors from floating fuel. Rapid response is extremely important.

10-11.3

In water landing accidents, the possibility of fire is normally reduced because of the cooling of the heated surfaces by the water. In situations where fire occurs, chances of its control and extinguishment are minimal unless the accident occurs within close proximity to shore and extinguishing operations can take place at close range.

10-11.4

Where the distance offshore is within range, fire hose can sometimes be floated into position by scuba divers or boats and used to supplement other means of fire attack.

10-11.5

The impact of an aircraft into water can rupture fuel tanks and lines. It is reasonable to assume that fuel is floating on the water surface. Watercraft having exhausts at or above the waterline can present an ignition hazard and should not enter the area. Advantage should be taken of wind and water currents when dealing with floating fuel. Every effort should be made to keep it from moving into areas where it would be hazardous to rescue operations. As soon as possible, pockets of fuel should either be broken up, moved away with large velocity nozzles, covered with foam, or disposed of by commercial reclaiming enterprises. The local water pollution control agency can be of assistance during this operation.

10-11.6

If fuel on the water has ignited, approach should be made from the direction where wind direction and velocity, water current, and site accessibility create an advantage. Fire can be moved away from an area by using a sweeping technique with hose streams. Foam and other extinguishing agents can be used where practical and necessary.

10-11.7

Scuba diving units should be dispatched to the scene of an aircraft accident in the water. Helicopters can be used to expedite the transportation of divers to the actual area of the accident.

All divers who might be called for this type of service should be qualified in both scuba diving and underwater search and recovery techniques.

10-11.8

In all operations where divers are in the water, standard diver's flags should be flown and all watercraft restricted from the diving area.

10-11.9

Victims in the water are more apt to be found downwind or downstream. Where only the approximate location of the impact site is known upon arrival, divers should use standard underwater search patterns marking the locations of major parts of the aircraft with marker buoys. If sufficient divers are not available, dragging operations should be conducted from surface craft. In no instance should dragging and diving operations be conducted simultaneously.

10-11.10

Life sustaining air can remain in large, submerged, occupied sections of the aircraft. As soon as practicable, entry by divers should be made carefully at the deepest point possible.

10-11.11

Where occupied sections of the aircraft are found floating, great care should be exercised not to disturb their buoyancy, and supplemental floating devices should be attached. Removal of any occupants should be accomplished as smoothly and quickly as possible. Any shift in weight or lapse in time can result in the section sinking. Rescuers should use caution so that they are not injured or trapped should the section capsize or sink.

10-11.12

A command post should be established on an adjacent shore to facilitate implementation of the airport/community emergency plan. (*See NFPA 424, Guide for Airport/Community Emergency Planning*.)

Chapter 11 Post-Aircraft Accident Procedures

11-1 General.

11-1.1

Many local statutes stipulate that it is the duty of the fire department to protect life and property from fire and to extinguish all destructive fires. They further state that no person has the right to interfere with or hinder the fire department in the performance of this responsibility. In aircraft accidents where the investigation of cause is very important, efforts consistent with the duty described above might involve moving parts and operating controls. When this must be done, ARFF personnel should be prepared to subsequently advise responsible authorities of the action they took.

11-1.2

If it is necessary to move portions of a damaged aircraft, either in rescue operations or fire control, caution should be taken to avoid changes in the aircraft's stability. Undue strain on the airframe can liberate fuel from damaged tanks, cause collapse or rollover of the fuselage, or cause greater injuries to trapped occupants.

11-1.3

During the course of the emergency, ARFF personnel should ensure that the “no smoking” rule is rigidly enforced at the scene of an aircraft accident and that all nonessential sources of ignition be prohibited in the immediate vicinity.

11-1.4

ARFF personnel should familiarize themselves with all regulations relating to movement of aircraft wreckage and disposition of accident fatalities. (*See also Appendix D*.)

11-2 Preservation of Evidence.

11-2.1

Following extrication of occupants from an aircraft, preservation of evidence at the site is of vital importance in determining the probable cause. ARFF personnel should be aware of this requirement, and it should be stressed in training exercises.

11-2.2

ARFF personnel should take notice of the condition and position of the aircraft structure prior to beginning any significant cutting or shifting of any portions of the wreckage. If time permits, a photographic record of initial conditions should be made for later study.

11-2.3

Any aircraft accident area should be roped off and perimeter security established to prevent the entry of unauthorized persons. Persons not actively engaged in operations should be denied entry into the area. Those persons inside the controlled area should be fully equipped with the necessary protective clothing and equipment to carry out their duties. (*See also 5-1.2*.)

11-3 Fatalities.

11-3.1

The location of all fatalities in and about the aircraft wreckage should be clearly identified by the use of a flag, stake, or other suitable marking and numbered to coincide with a number securely attached to the body, and photographed if possible. Triage/medical tags can be used for this purpose. (*See also NFPA 424, Guide for Airport/Community Emergency Planning*.)

11-3.2

Removal of fatalities remaining in an aircraft wreckage after the fire has been extinguished should be done only by, or under the direction of, the responsible medical examiner (coroner). Premature body removal can interfere with identification and destroy pathological evidence. If body removal is absolutely necessary to prevent further incineration, the original location and the body should be photographed, identified with a number, and the fact reported to investigators.

11-4 Preservation of Mail, Baggage, and Cargo.

11-4.1

The original location of mail sacks, baggage, and cargo should be observed and this information passed on to investigators. These items should be protected from further damage. If necessary, remove to a safe location such as the command post.

11-4.2

Postal officials normally extend blanket authority to fire departments to remove mail from aircraft involved in an accident for the purpose of saving as much of it as possible. After the responding postal official has been properly identified, the ARFF officer can transfer the custody of the mail.

11-4.3

If it is necessary to remove baggage from an aircraft involved in an accident, it should be placed in the custody of airline officials. Under certain circumstances, customs officials would be granted initial custody. Responsibility for final disposition of baggage belongs to the airline involved.

11-4.4

Cargo manifests should be reviewed for the presence of dangerous goods. If present, they should be examined for leaking containers. If leaks are found, contaminant and decontamination procedures should be initiated immediately by qualified personnel. If cargo is removed from the aircraft, it should be turned over to the responsible agency.

11-4.5

When personal property such as jewelry, purses, watches, etc., is found in the area of an aircraft accident, ARFF personnel should not move it but record the location and notify their commanding officer, who should advise security personnel of the information. These items and their locations can be of great value to the medical examiner in making positive body identifications.

11-5 Flight Data and Cockpit Voice Recorders.

Flight data and cockpit voice recorders are usually located in the aft fuselage area of most commercial aircraft. ARFF personnel should be able to recognize them so that they can be protected from loss or damage until accident investigators assume responsibility. Although no attempt should be made to remove these recorders from the aircraft, as they could be damaged by such efforts, if failure to remove them will result in their total loss, recovery should be made. (*See Figure 11-5*.)

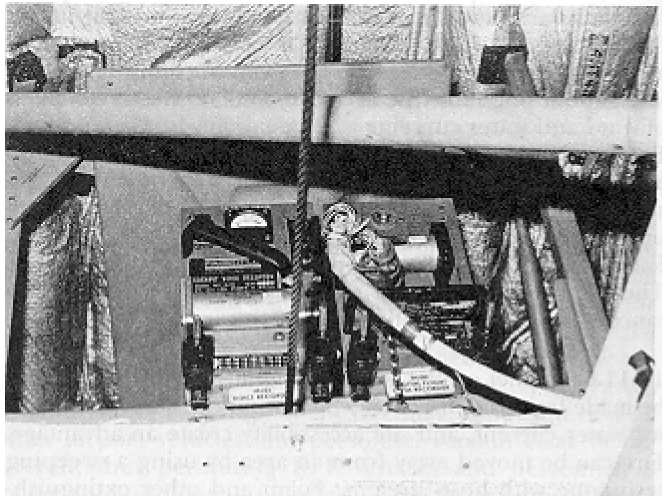

Figure 11-5 A flight data recorder (FDR) and a cockpit voice recorder (CVR) are shown mounted in an aircraft.

11-6 Defueling Accident Aircraft.

11-6.1

Defueling operations should be done under the direct supervision of a qualified aircraft fuel systems specialist. The defueling itself should be performed by qualified technicians using approved methods. (*See NFPA 407, Standard for Aircraft Fuel Servicing, and NFPA 410, Standard on Aircraft Maintenance*.) A standby fire watch should be provided by ARFF personnel during the entire defueling operation.

11-6.1.1 ARFF personnel should be made aware that the issue of defueling an inverted aircraft has very serious potential. The common conclusion of experts in this field is, "If there is no leakage, leave it alone until the rescue operation is completed." Remember that the issue here is defueling an inverted aircraft, not fuel leakage. If there is fuel leakage, it should be dealt with in the same manner as any other fuel leak, regardless of the aircraft's attitude.

11-6.1.2 There are a number of reasons why an inverted aircraft should not or cannot be defueled during the rescue operation:

(a) Ignition can be caused by surface generated static as the fuel flows between the aircraft fuel tank and the fueling vehicle;

(b) Due to the accident, fuel pump access doors and the fuel pumps themselves could have been damaged;

(c) The wing attitude could make it difficult to determine in which tank the fuel is located, in what position, and in what quantity, such that while attempting to defuel, the fuel could be accidentally discharged onto the accident site; and

(d) Fueling normally involves delivery by pressure, and defueling utilizes gravity flow from underwing orifices when the aircraft is on its wheels. Inverted aircraft or those on their bellies do not offer the benefits of gravity flow. This technical problem is compounded by the fact that most fueling vehicles cannot "lift" fuel by suction in the same way as fire vehicles "lift" water from a ground level reservoir up into their water tanks.

11-6.2

To control fuel system leaks prior to completion of aircraft defueling, fuel cell sealant, clay, or other material can be used to make minidams on smooth surfaces to direct the flow of fuel into containers. Crimping, pegs, and plugs should also be used where appropriate. It might also be possible to shovel trenches to direct the fuel to collecting spots where it can be protected from ignition sources.

11-6.3

During defueling operations, an ignition-free area with a radius of at least 50 ft (15 m) from the outer edge of the operating area should be maintained. Persons within the controlled area should be only those necessary for the work being done. Open flames, floodlights, ground power units, and radio transmitters should be prohibited in the operating area. ARFF personnel should also be aware that their vehicles and equipment can be a source of ignition and take necessary precautions.

11-6.4

Concurrent operations such as jacking, shifting, and removing panels should not be conducted during defueling operations. Transfer of fuel during defueling operations can cause changes in weight distribution, balance, and stability of the aircraft. Cribbing, blocking, use of air bags, and other stabilizing methods and equipment should be in place, ready for use if needed. Safe access for fueling vehicles, empty or full, should be provided.

11-6.5

Prior to moving, the interior of the aircraft wreckage should be well ventilated to remove all flammable vapors. After removal of the aircraft, ground surfaces should be thoroughly flushed of any flammable liquids or debris before permitting normal traffic to resume.

11-7 Aircraft Systems Hazards.

ARFF personnel should seek the advice of aircraft systems specialists concerning items that might present problems during overhaul and salvage operations. Advice can include information regarding liquid or pressurized systems that need to be bled off prior to any cutting, bending, or prying around components.

Chapter 12 Structural Fire Department Operations

12-1 General.

12-1.1

A prerequisite for the application of information contained in this chapter is a thorough review of the preceding chapters. Discussed are recommended procedures using apparatus, equipment, and resources available to most structural fire departments. Emphasis is placed on rescue of aircraft occupants.

Figure 12-1(a) On July 2, 1994, a DC-9 with 55 persons onboard collided with trees and a private residence near the Charlotte/Douglas International Airport, Charlotte, North Carolina. The tail section of the DC-9 is lodged in the carport of a house. The nose section is in the lower left. [*See Figure 12-1(b).*]

Figure 12-1(b) The nose of the DC-9 sheared off on impact with trees and skidded down a residential street.

12-1.2

Fire control is often the means by which rescue of aircraft occupants can be accomplished. Aircraft fuel fires require extinguishing agents and techniques common to Class B fires. Structural fire fighters therefore should be trained to effectively combat this type of fire utilizing available equipment and extinguishing agents. IT IS IMPERATIVE THAT FIRE DEPARTMENTS LOCATED NEAR AIRPORTS OR AIRCRAFT FLIGHT PATHS BE THOROUGHLY FAMILIAR WITH THE RECOMMENDATIONS SET FORTH IN THIS GUIDE.

12-1.3

The recommendations presented in this chapter should not be interpreted as an alternative for adequate airport-based rescue and fire fighting services as outlined in NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*.

12-2 Pre-Incident Planning and Training.

12-2.1

Fire departments located near airports should make appropriate arrangements to participate in the airport/community emergency plan. The fire department's services should also be made available to the airport during any special events such as air shows or during periods of unusually heavy aircraft traffic. Since no community is immune to an aircraft accident, all fire departments should implement pre-incident planning and training for this type of incident.

12-2.2

At an aircraft accident, teamwork is so important that fire department officers should review pre-incident planning as the one absolutely indispensable element in aircraft rescue and fire fighting.

12-2.3

The psychological factors involved in aircraft rescue and fire fighting can be successfully overcome only by realistic pre-incident planning and training. Consideration should be given to conducting a critical incident stress debriefing for responding personnel. Each fire department should conduct realistic simulated aircraft fire drills using the types of extinguishing agents and equipment they expect to have available. One important training objective should be to learn the capabilities and limitations of the department's pre-incident plan procedures.

12-2.4

Live fire training is essential in maintaining qualified and certified fire fighters. Traditionally, hydrocarbon fuel from various sources has been the fuel of choice used to conduct this training. However, with stricter environmental laws and improved technology, propane live fire simulators are in use and fulfilling training needs of the fire fighter. The size of the mock-up should come as closely as possible to that of the aircraft utilizing the facility. Training should include interior, engine, wheel brake, exterior pool fire, running fuel, and three-dimensional scenarios. The propane-fired simulator should be equipped with the necessary automatic features to maximize fire fighter safety.

12-2.4.1 An aggressive attack using hose lines with spray nozzles, employing pre-incident planned operating techniques, can develop the confidence necessary to handle these types of incidents successfully.

12-2.5

The volume of smoke, fire, and intense heat accompanying an aircraft fire can appear to be an overwhelming situation to untrained fire fighters. They might be reluctant to attack and control the fire with a limited water supply and conventional equipment for the amount of time required to complete rescue operations. Experience has proven that rescues can be accomplished even where large quantities of spilled aircraft fuel are burning.

12-2.6

Training coordination between military, civil airport, and structural fire departments is strongly recommended. Execution of mutual aid agreements between these agencies will help ensure well-coordinated plans for rescue and fire fighting. In the United States and Canada, military air base commanders are urged to make their training facilities available to nearby fire departments, particularly where those departments are likely to be called upon to assist in rescue and fire fighting operations.

12-2.7

Structural fire department personnel should be thoroughly familiar with the most efficient response routes to the airport and the surrounding area. They should know all the airport's accesses and entrances and be familiar with all rules governing the operational area. They should also be provided with any necessary keys or gate codes. As a minimum, their training should include information relative to items (a) through (j) in 2-3.4 of this guide.

12-2.8

Aircraft familiarization is also an important part of aircraft rescue and fire fighting pre-incident planning. Structural fire departments should contact the airport fire department to arrange qualified persons to take fire fighters through the various aircraft using the airport. When inspecting the aircraft, the following facts should be noted: location of fuel, hydraulic oil, lubricating oils, and other storage locations and capacities; seating arrangements; and emergency exits and hatches and how they can be opened. Also important are the locations of batteries, oxygen storage, and various system shutoffs. (*See also 2-3.3*.)

12-2.9

Fire departments should avail themselves of informational charts of all aircraft types using the airport. Airlines and aircraft manufacturers can provide these charts, which depict most information pertinent to rescue and fire fighting operations. (*See also examples of charts in NFPA Aircraft Familiarization Charts Manual*.)

12-3 Aircraft Accident Operations.

12-3.1

When fire departments receive a report that an aircraft is experiencing an in-flight emergency or that it is down in the vicinity, they should immediately alert the fire forces that could be affected. Fire and police units should coordinate their efforts. Making use of a police helicopter, if available, could help coordinate operations and serve as a communication link between the fire units and the control tower.

12-3.2

Size-up (risk assessment) begins with the fire department's first notification of an incident. Multiple calls from various sources in the vicinity of the airport should alert fire dispatchers of a possible major aircraft accident and warrant an immediate first alarm response. A multiple unit response would ensure arrival at the scene of at least one unit despite the likelihood of blocked access due to debris and traffic. During the initial response, pre-incident plans should be activated, and all pertinent information should be transmitted to the responding units.

12-3.3

The following factors are among those that are important to the size-up (risk assessment) process:

(a) Occupant survival is generally limited to accidents where the fuselage is not severely broken up and a fire has not yet developed.

(b) Environmental and geographical factors have a major impact on response capability. An accident in a wooded area during a winter snowstorm presents different problems than a similar accident on a clear summer afternoon.

(c) Time of day is a factor. An aircraft accident that occurs in a shopping center parking lot has a different life hazard potential at 4:00 a.m. on Sunday than a similar event at 4:00 p.m. on Friday.

(d) The magnitude and nature of the aircraft accident need to be considered. An aircraft accident in an open field can set off a major grass or brush fire, but an accident in a populated area can be more complex. If structures are involved, their occupancy, construction type, and stability need to be evaluated. In addition, an assessment of damage to public utilities and their possible effect on operations should be made. Because of the possibility that water supply from hydrants might not be available due to system damage, it is good practice to include water tanks in the first response.

(e) The nature of the aircraft operation at the time of the accident is of importance. If a crop-dusting aircraft accident occurs, steps need to be taken to protect emergency personnel and limit the spread of pesticide contamination.

(f) Aircraft accidents that occur on takeoff usually involve large amounts of fuel. In addition to the fire problem that could evolve, steps need to be taken to prevent a fire, or fuel or fuel vapors from entering waterways, streets, and underground facilities.

12-4 Basic Fire Control.

12-4.1

Specific implementation of basic aircraft fire control methods should depend upon the fire fighting equipment and types of extinguishing agents available to individual fire departments.

12-4.2

Always assume that there are survivors of an aircraft accident until it is confirmed otherwise. In some instances, however, rescue of occupants cannot be accomplished because of the remoteness of the accident or the severity of the impact forces. In such instances fire fighters should make a thorough search for survivors, protect any exposures, attack and extinguish the fire, and preserve the scene until the proper authorities arrive to assume responsibility.

12-4.3

Fire fighters should have knowledge that aircraft construction differs from most other structures in ways that make fires more dangerous for the occupants and for themselves. Aircraft occupants are enclosed in a thin shell and are surrounded by large amounts of fuel with tremendous heat potential. Large aircraft have hollow wall construction with the void filled with blanket-type insulation. Fire walls and draft stops are nonexistent except for engine, galley, and cargo bay areas. These deterrents to fire spread are not comparable to fire barriers found in building construction.

12-4.4

In all large aircraft and in many smaller models, plumbing, electrical, heating, and cooling services are provided. Consequently there are aircraft equivalents of pipe chases, electrical load centers, buss bars, etc. The aircraft electrical system should be treated with the same safety precautions as those used for a typical residence.

12-4.5

Most aircraft contain pressure hydraulic reservoirs and liquid or gaseous oxygen lines constructed mostly of aluminum. These, as well as brake lines, will rupture quickly under fire conditions. Fuel tanks are interconnected, and fire can propagate through ventilation ducts or manifolds. Fire impingement on empty or near empty fuel spaces often results in a violent rupture of tanks and wings.

12-4.6

Aircraft also differ from other structures in the critical aspect of stability. Most structures are cubical in shape and will collapse in place. Aircraft are cylindrical, conical, and usually on wheels. Therefore, movement, such as tilting and rotation effects, should be considered. Guy lines, chocks, air bags, and cribbing should be required when working around damaged aircraft. Current modern aircraft can weigh 800,000 lb (363,200 kg) or more and have a height greater than a five-story building.

12-4.6.1 Experience has shown that cribbing and shoring material should be unpainted to avoid the inherent slipperiness of painted surfaces when wet and should be made of hard wood so as not to be easily compressed. It should be available and included as a resource in the airport's emergency preparedness plan. It should be of appropriate thickness and length to accommodate the largest aircraft scheduled into the airport. Aircraft recovery manuals should be used to ascertain appropriate cribbing sizes.

12-4.6.2 It should be noted that the training of ARFF personnel to shore unstable aircraft wreckage to facilitate rescue implies the provision of suitable materials. To be effective these materials must be constantly available for immediate deployment. To achieve this, the materials should be stored either in a palletized form (requiring ready access to appropriate lifting and transport equipment) or on a dedicated vehicle, such as a trailer. In either case, a designated responder should be capable of deploying these supplies at all times, under all conditions of weather, visibility, and adverse terrain.

12-4.6.3 As an alternative to the logistics of cribbing, consideration might also be given to the deployment of earth-moving or similar heavy-duty lifting equipment, designed for off-road performance and having the weight and flexibility of electrohydraulics to support or suspend any unstable elements of a damaged aircraft. Skilled operators should also be readily available if this type of equipment is to be used at an aircraft accident site.

12-4.6.4 Regardless of the method or equipment chosen for raising, shoring, or moving a damaged aircraft, the same requirement for guidance based on aircraft structural knowledge is required. It is important to understand that imposing loads at unsuitable locations on the aircraft could merely exacerbate the situation, promoting, rather than preventing, further disruption of the wreckage. It is advantageous for the task to be performed under the supervision of aircraft maintenance personnel, preferably those familiar with the specific type and model of aircraft involved.

12-5 Accidents without Fire.

12-5.1

When an aircraft accident occurs without fire, the following fire prevention procedures should be initiated. Hose lines should always be laid out and charged. Any spilled fuel should be covered with foam. Ignition sources such as hot aircraft components or energized electrical circuits should be eliminated. When moving wreckage, care should be taken to avoid causing sparks.

12-5.2

When foam is not available, water spray can be used to cool hot aircraft components and to move fuel away from the fuselage. However, washing fuel away with water requires that special attention be given to exposures, low areas, and drains where fuel and vapors can flow. The fuel should be directed to an area of containment free from ignition sources where it can later be safely removed.

12-6 Accidents with Fire.

12-6.1

The location of survivors and the sources of heat or flame impingement against the aircraft will determine where hose streams should be applied first. Fire fighters should keep in mind that the heat input into the occupied portion will be reduced if the surfaces of the fuselage exposed to flame or heat can be kept wet. If the fire has penetrated the fuselage, a direct internal attack should be initiated. Care should be taken to see that water runoff does not cause the fire to spread.

12-6.2

Normally, hose streams should be directed along the fuselage and efforts concentrated on driving the flames outward, allowing occupants to escape and permitting entry by fire fighters for rescue operations. The fuselage and fuel tank areas should be kept cool. It might be necessary to create an escape path from an exit point by “sweeping” fire out of the area with spray streams. Once an escape path has been established, it should be maintained for evacuating occupants and fire fighters performing rescue.

12-6.3

All available hose lines should attack the fire from the same general direction. If crews are operating on opposite sides of the fuselage, they should be cautious not to push the fire toward each other. Because prompt action is necessary to effect rescue, the first hose line in operation should be advanced immediately to keep the fuselage cool.

12-6.4

For aircraft rescue and fire fighting, there are too many variables to establish hard and fast rules regarding use of equipment. Spray streams are normally more effective than straight streams in applying water or foam and afford much more personal protection.

12-6.5

The number of handlines will be determined by the availability of the water, equipment, and personnel. Immediately upon arrival, all deployed hose lines should be charged regardless of the fire situation. This cannot be overemphasized.

12-7 Fire Fighting with Water.

12-7.1

If an aircraft accident occurs in a remote area with limited water available on responding apparatus, a supplemental source of water should be established. The use of tank vehicles to shuttle water between the nearest water source and the accident site should be considered.

12-7.2

When using water to combat flammable liquid fires, spray nozzles, operating at approximately 100 psi (689 kPa), should be used. Spray patterns, on initial approach to the fire, should be set at a wide angle momentarily to reduce the heat and flame and then reduced to 30 degrees to attack the fire. The best technique is to sweep the flame off the surface of the fuel by maintaining the lower portion of the spray pattern at the lowest level of the flame. This action also tends to cool the fuel surface and reduce vaporization. However, because there is no vapor seal provided, as when foam is used, chances for reignition remain, and fire fighters should take the necessary precautions to prevent this occurrence (*see Section 12-5*). Additional hose lines, used exclusively for the protection of rescue and fire fighting personnel, are encouraged.

12-7.3

Runoff from water streams can cause the spread of fire to exposures. Straight streams should be used when the heat is too intense to approach initially with spray streams or when the objective is to wash the burning liquid away from the fuselage to an area where there is no exposure.

12-7.4

Trained fire fighters employing proper operating techniques can accomplish a successful rescue operation at an aircraft accident with a limited amount of water if all efforts concentrate on establishing a fire-free evacuation path. Efforts to save the aircraft hull or exposures might have to be delayed until additional resources arrive.

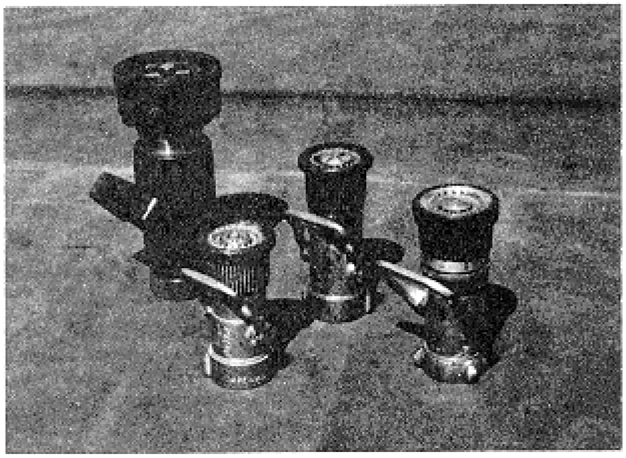

Figure 12-7 Photo shows a variety of typical spray nozzles currently used by structural fire departments. All have the feature of adjustable spray patterns and straight stream settings. Some also have variable flow settings. Most fire chiefs agree that a nozzle setting of 30 degrees provides the best pattern for fighting flammable liquid fires with either water, AFFF, or FFFP solutions.

12-7.5

Addition of a wetting agent might increase the effectiveness of available water; however, certain wet water additives can destroy some foams. Compatibility of the agents should be checked prior to their use.

12-7.6

Approved portable dry chemical, foam, or halon extinguishers can be used to supplement the primary attack with hose streams. These agents are particularly effective on localized fires or in areas that cannot be readily reached by hose streams. In some instances, bulk supplies of dry chemical, foam, or halon are made available to fire departments on an emergency basis. This resource should be considered when pre-incident planning for aircraft accidents.

12-7.7

The technique of using multiple spray nozzles with overlapping 30-degree patterns creates a continuous curtain of water spray. They should be advanced directly to the aircraft, parallel to the fuselage from either the nose or tail section, dependent on wind direction. This procedure will open an area for evacuation and rescue. If possible, hose lines should be advanced with the wind at the fire fighters' backs, as greater reach is possible with the spray streams and less heat is experienced. Progress and stream effectiveness can be monitored more easily from upwind with the smoke moving away. If there is an adequate water supply, a large spray nozzle attached to a deck gun or a portable deluge set can be used to keep the fuselage and fuel tank areas cool.

12-7.8

Protection of exposed property should be considered whether fire exists or not. In addition to structures, exposure protection plans should include drains, sewers, waterways, power lines, and other properties where a flowing fire or unignited fuel could cause fire extension or contamination. Public utility authorities should be notified of any involvement affecting facilities under their control. Master streams from deluge sets, deck guns, or ladder pipes can be used to protect exposures if water supplies are adequate.

12-8 Fire Fighting Foam.

12-8.1

Aqueous film forming foam (AFFF), film forming fluoroprotein foam (FFFP), or protein foam concentrates properly proportioned into fresh water are more effective than just water on flammable liquid fires.

12-8.2

Techniques for the application of foam vary with the type used. Protein and fluoroprotein foam solutions should be applied with an aspirating foam nozzle at a pressure of 100 psi (689 kPa). A constant flow from the nozzle should be maintained to ensure an even pickup of the concentrate. The proper operating pressure should be maintained during the entire foam application for effective results. AFFF and FFFP can be applied using either an aspirating foam nozzle or a conventional spray nozzle operating at 100 psi (689 kPa).

12-8.3

A foam/water solution using protein, fluoroprotein, or AFFF can be made up in the water tank of a structural fire fighting apparatus for direct foam application through hose lines equipped with appropriate nozzles. After draining the appropriate amount of water from the tank, add the required amount of foam-liquid concentrate. Mix the solution by opening the “tank to pump” valve and place the pump in gear; open the “tank fill” valve slightly, and circulate the solution through the pump and tank to assure a good mix. After use, any unused solution should be drained and the entire water system should be well flushed before refilling the water tank for regular use.

12-8.4

Some fire departments have purchased combined agent vehicles for special purposes, such as vehicle accidents and flammable liquid spills. Such combined agent vehicles are a valuable tool for the initial response to an aircraft accident.

12-9 Vehicles.

Fire fighting apparatus designed and intended for use on paved surfaces should not be used for cross-country travel. Extended hose lines from a position on a hard road surface should be used rather than risking immobilization. Once a vehicle has become immobilized, it could not be moved if it became endangered by a developing fire situation. It can also block or delay other emergency vehicles responding to the site.

12-10 Post-Accident Procedures.

Fire department personnel should be familiar with the information contained in Chapter 11 and Appendix D of this guide.

Chapter 13 Referenced Publications

13-1

The following documents or portions thereof are referenced within this guide and should be considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

13-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, 1993 edition.

NFPA 407, *Standard for Aircraft Fuel Servicing*, 1996 edition.

NFPA 410, *Standard on Aircraft Maintenance*, 1994 edition.

NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, 1995 edition.

NFPA 424, *Guide for Airport/Community Emergency Planning*, 1996 edition.

NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*, 1994 edition.

NFPA *Aircraft Familiarization Charts Manual*, 1996.

13-1.2 Other Publications.

13-1.2.1 ICAO Publications. International standards and recommended practices are promulgated by the International Civil Aviation Organization, 1000 Sherbrooke Street West, Montreal, Quebec, Canada H3A-2R2.

Airport Services Manual, Part 7: "Airport Emergency Planning," first edition, 1980.

13-1.2.2 Research and Special Programs Administration Materials Transportation Bureau. Request for single free copy for emergency service organizations may be addressed to: U.S. Department of Transportation, Materials Transportation Bureau, Attention: DMT-11, Washington, DC 20590.

Guidebook for Hazardous Materials Incidents (1984 Emergency Response Guidebook), DOT P 5800.3.

Appendix A Air Transport of Dangerous Goods (Hazardous Materials and Restricted

Articles) and Nuclear Weapons

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

A-1 Commercial Air Transport of Dangerous Goods. The carriage in commercial transport aircraft of dangerous goods is an accepted practice and is closely controlled by national and international regulations.

A-1.1 Definition of Dangerous Goods.

(a) Dangerous goods include explosives and any other article defined as a Combustible Liquid, Corrosive Material, Infectious Substance, Flammable Compressed Gas, Flammable Liquid, Flammable Solid, Magnetized Material, Nonflammable Compressed Gas, Oxidizing Material, Poisonous Article, Radioactive Material, and other restricted articles.

(b) Some unlikely items can come under the heading of dangerous goods; for example, wheel chairs could contain wet-cell batteries, while breathing apparatus might have compressed air cylinders. It is well to be aware of hazards that might not be immediately apparent.

A-2 Radioactive Material. Radioactive materials constitute a particular hazard. They emit certain rays that can be a health hazard and that cannot be detected except by instruments. Radioactive materials transported by air fall into three categories:

(a) Category I — Material emits minimal radiation;

(b) Category II — Emits more radiation and is assigned a transport index up to 1;

(c) Category III — Could have a transport index of 1.1, up to a maximum of 10.

A-3 Transport Index.

A-3.1 The transport index for a package of radioactive material is a simplified expression of the maximum amount of radiation emitted, in millirem per hour, measured one meter from the surface of the package; this number should appear on the notification and such notification received by the pilot-in-command. The sum of the transport indexes is the primary concern, along with the stowage of the packages, to ensure that no living beings are exposed to hazardous radiation.

NOTE 1: In the United States, dangerous goods are transported by air, under authority of the *Code of Federal Regulations*, Title 49, "Transportation," Part 175, published by the Office of the Federal Register National Archives and Records Service, General Services Administration, Washington, DC 20408.

NOTE 2: The International Air Transport Association has issued the IATA *Restricted Articles Regulations*, which is available from IATA Headquarters, Montreal, Canada. Also, the International Civil Aviation Organization has developed technical instructions for the safe transportation of dangerous goods by air (document 9284-AN/905) available from ICAO, 1000 Sherbrooke Street West, Montreal, Quebec, Canada, H3A 2R2.

A-3.2 Dangerous goods are regularly being carried on commercial transport aircraft. This includes passenger aircraft, passenger cargo aircraft (COMBI), and cargo aircraft. While the packaging requirements used to transport these materials are designed for proper containment, the possibility of breakage cannot be overlooked. This introduces the hazards of leaking flammable liquids and poisons, or radioactive contamination at an accident site. By knowing and recognizing dangerous goods labels, fire fighters can be alerted to these hazards.

A-4 Dangerous Goods Warning Labels.

A-4.1 The following dangerous goods warning labels are authorized by the U.S. Department of Transportation based on the United Nations labeling system and are authorized for domestic and foreign shipments. Shippers must furnish and attach an appropriate label(s) to each package of dangerous goods being offered for shipment by air. If the material in a package has more than one danger classification, one of which is Class A poison, or radioactive materials, the package must be labeled for each danger. When two or more dangerous goods of different classes are packed within the same packaging or outer enclosure, the outside of the package must be labeled for each material involved. Radioactive materials requiring labeling must be labeled on two opposite sides of the package and indicate the transport index.

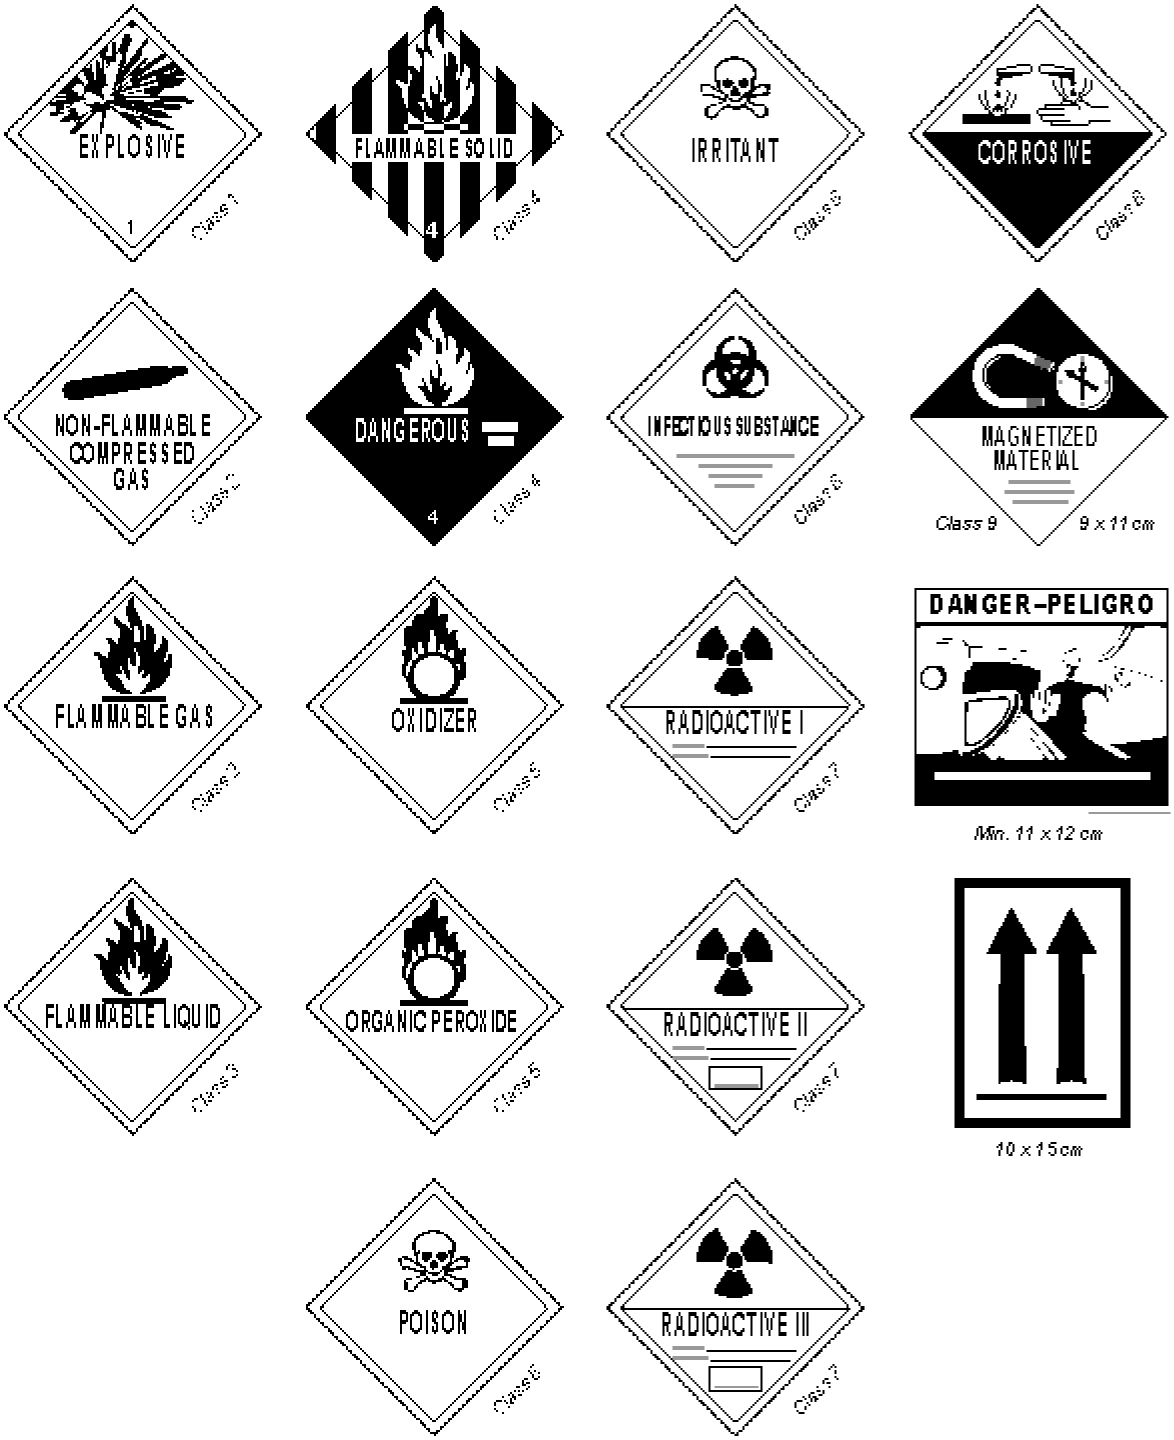

Figure A-1 Warning labels.

Dangerous Goods Class Numbers. Dangerous goods are classified by the UN, ICAO, IATA, and the U.S. DOT as follows:

Class 1	Explosives
Class 2	Gases: compressed, liquefied, dissolved under pressure, or deeply refrigerated
Class 3	Flammable liquids
Class 4	Flammable solids: substances susceptible to spontaneous combustion; substances that, on contact with water, emit flammable gases.
Class 5	Oxidizing substances: organic peroxides
Class 6	Poisonous (toxic) and infectious substances
Class 7	Radioactive materials
Class 8	Corrosives
Class 9	Miscellaneous dangerous goods (including magnetized materials, articles liable to damage aircraft structures, and articles possessing other inherent characteristics that make them unsuitable for air carriage unless properly prepared for shipment).

The bottom half of the DOT diamond-shaped labels can be printed in the language of the country of origin.

A-4.2 The pilot in command of an aircraft should be provided with all relevant information regarding dangerous goods on board the aircraft, and, in the event of an incident, this information should be obtained by airport emergency services either directly from the pilot or through the operations office.

A-4.3 The NFPA publication, *Fire Protection Guide on Hazardous Materials*, provides essential information for those confronted with emergencies such as fire, accidental spills, and aircraft accidents. With the urgency of prompt identification in mind, this guide has been arranged so that the user can get to the information with a minimum of delay.

A-5 Incidents or Accidents Involving Radioactive Materials.

A-5.1 Radioactive materials carried in commercial transport aircraft are packed in rugged containers of varying sizes, such as steel drums, wooden containers, heavy corrugated cardboard, or lead boxes. In the event of an aircraft accident, the possibility of these containers breaking should always be considered.

A-5.2 This introduces the hazard of radioactive contamination of an accident site. The following procedures should then be followed in the United States (similar procedures are followed in other countries):

(a) Notify the nearest Department of Energy office or military base (if military aircraft is involved) of the accident immediately. They in turn will respond with a radiological team to the accident scene.

(b) Restrict the public to as far from the scene as possible. Souvenir collectors should be forbidden in all accidents.

(c) Segregate fire fighters who have had possible contact with radioactive material until they have been examined further by competent authorities.

(d) Remove injured from the area of the accident with as little physical contact as possible and hold them at a transfer point. Take any measure necessary to save lives, but carry out minimal (no more than necessary) first aid and surgical procedures until help is obtained from the radiological team physicians or other physicians familiar with radiation medicine. Whenever recommended by a doctor, an injured individual should be removed to a hospital or office for treatment, but the doctor or hospital should be informed when there is reason to suspect that the injured individual's body or clothing has been contaminated with radiation.

(e) In accidents involving fire, fight fires upwind as far as possible, keeping out of any smoke, fumes, or dust arising from the accident. Handle this as a fire involving toxic chemicals (using positive pressure self-contained breathing apparatus and full protective clothing). Do not handle suspected material until it has been monitored and released by monitoring personnel. Segregate all clothing and tools used at the fire until they can be checked by the radiological emergency team.

(f) Do not eat, drink, or smoke in the area. Do not use food or drinking water that might have been in contact with material from the accident.

(g) The use of instruments such as Geiger counters, ionization chambers, dosimeters, etc., is the only accurate means of determining if radioactive contamination is being given off.

(h) To the extent possible, runoff water and other agents used in fire fighting and cleaning should be channeled, collected, and dammed to prevent entry into water courses and the possible spread of contamination.

A-6 Military Aircraft Carrying Nuclear Weapons.

A-6.1 While most military aircraft will attempt to return to a military airbase in case of emergency, this is sometimes impossible, and landings are frequently made at nonmilitary airports. There are also many cases where "joint-use" airports serve both the military and civil aircraft operations. For these reasons it is advisable for aircraft rescue and fire fighting crews to be familiar with the various types of military aircraft operating in the area. For this purpose, training visits to promote knowledge of the special features of military aircraft at nearby military installations are of value. Such liaison is encouraged by the military.

A-6.2 Any person receiving information of a military aircraft accident should immediately notify the base operations office at the nearest military establishment giving all relevant information. Telephone numbers of such military installations should be kept on hand at civil airports, nearby municipal fire stations, and in airport control towers.

A-6.3 Care should be exercised by the rescue and fire fighting crews when approaching any military aircraft involved in fire. Armament, ejection seats, or hazardous or other dangerous cargoes can present severe hazards during such operation.

A-6.4 The possibility of an atomic explosion from the detonation of a nuclear weapon or warhead involved in a fire, inadvertent release, or impact accident is so small it is practically nonexistent. Safety features and devices have been carefully designed and incorporated in nuclear weapons and warheads to make this assurance possible. The danger of a nuclear weapon is from the high explosives (HE) used plus radiation from the components.

A-6.5 The presence of nuclear weapons in aircraft generally creates no greater hazard than does the presence of conventional high explosives. Most weapons contain a high explosive that could detonate upon moderate to severe impact or when subject to fire. In fact, exposure to heat can make the high explosive more sensitive. In nuclear weapons, the amount of high explosive is considerably less than that found in conventional high explosive bombs. Chemical or radiological hazard might exist during and after an accident or in a fire where a nuclear weapon is involved.

A-6.6 Basically, the same techniques are used for fighting aircraft fires involving nuclear weapons as are those in which conventional high explosive bombs are involved; special extinguishing agents are not required to control and extinguish such fires. The brief amount of time available to control or extinguish the fire before an explosion might be expected is the only special factor to be considered.

A-7 Description. In general, nuclear weapons resemble conventional bombs in that they are enclosed in a shell or casing that is generally cylindrical in shape with tail fins. The weapon or warhead casings are of various thicknesses and might break up upon impact. Most weapons contain a conventional type of high explosive that can detonate upon moderate to severe impact or when subject to fire. The quantity of high explosives involved in a detonation can vary from a small amount to several hundred pounds and constitutes the major hazard in such an accident. If the casing breaks upon impact, the exposed and unconfined pieces of high explosive can ignite and burn or might explode if stepped on or run over. Some minor radiological hazards might exist regardless of the type of weapon, if the weapon burns or if detonation of a high explosive occurs.

A-8 Time Factors. The length of time available to safely fight a fire involving nuclear weapons depends largely upon the physical characteristics of the weapon or warhead case, the intensity of the fire, and the proximity of the fire. Since weapon and warhead cases vary in thickness, fire fighting time factors range from 3 minutes to an indefinite period if the fire impact incident does not detonate the high explosive immediately. The time element for each type of nuclear weapon or component is an important factor in fighting these fires. As soon as fire envelops the weapon area these time factors become effective. For weapons or warheads within a fire impact incident area, and subject to extreme heat but not enveloped in flames, a time factor of 15 minutes will apply; if the fire fighting time factor is unknown to the fire fighters, the minimum time factor of 3 minutes should be observed. Military flight communications procedures normally provide for notification to control towers of pertinent information regarding such time factors. When a weapon or warhead has been involved in a fire and its time factor has expired, even though the fire has been extinguished or burned out, safe evacuation distances should be observed until the arrival of authorized explosive ordinance disposal personnel.

A-9 High Explosive Blast and Fragmentation. The radius of a high explosive blast from a weapon varies, depending on the amount of high explosive that actually detonates. High explosive blast fragmentation distances for these weapons range from a minimum radius of 400 ft (122 m) to a maximum of 1000 ft (305 m). Personnel within these areas can be seriously injured from blast or fragmentation upon detonation of the high explosive. These areas and distances should be considered during the initial fire department approach to an accident where weapons have been enveloped in flames for a period approximating or exceeding the weapon time factor limitations. All except experienced fire fighting personnel should immediately evacuate to a minimum distance of 1500 ft (450 m) for protection against blast or fragmentation.

A-10 Precautionary Measures. Under no circumstances should any high explosive material from ruptured weapons that have been exposed to fire (or any components that have been scattered) be handled, stepped on, driven over, or disturbed in any manner. This material is extremely sensitive to minor detonations from shock or impact and can cause serious injury. Protective clothing and positive pressure self-contained breathing apparatus should be worn during fire fighting operations to provide the fire fighter maximum protection from any chemical or minor radiological hazards that are present. Additional protection is afforded by fighting any fire from an upwind position. All exposed clothing, apparatus, and equipment used during a fire or impact incident where nuclear weapons or components have been involved should be monitored for possible radiological contamination by specialized recovery personnel equipped for this purpose.

A-11 Associated Hazards.

(a) *Radiological.* In the event of a high explosive detonation or burning of a weapon, one has to be concerned principally with Alpha-emitting contamination, which is serious only when ingested. Other types of radiation, which are harmless at the low levels produced in a weapon, can be detected with the use of sensitive detection instruments. (The effect of this radiation can be likened to the effects of radiation emanating from a luminous dial wristwatch.) Since Alpha-emitting particles are so fine that they can be carried as smoke or dust from the burning or high explosive detonation of a nuclear weapon, some Alpha-emitting contamination should be expected in the immediate accident area and downwind. Although this material can present a minor radiation problem, danger from these particles exists only when they are inhaled in significant amounts. Protection against the highest Alpha levels that could be expected from such burning or high explosive detonation incidents is afforded fire fighting personnel by the prescribed protective clothing and self-contained breathing apparatus.

(b) *Fire.* Hazards associated with the burning of nuclear weapons and components are generally the same as those presented by conventional high explosives.

(c) *Impact.* Weapons or warheads can break up, and the high explosive can detonate from impact. Detonation and breakup are contingent to a large degree upon the characteristics of the weapon or warhead case, the impact velocity, and the location of aircraft suspension devices.

(d) *Sympathetic Detonation.* Detonation of a weapon or warhead, by fire or by impact, is also likely to induce detonation (nonnuclear) of any other weapon or warhead in the open within a 50 ft to 300 ft (15 m to 90 m) radius of the incident area.

(e) *High Explosive Burning Characteristics.* Flame and smoke characteristics of burning high explosives vary and provide no specific pattern upon which to determine when the high explosive is about to detonate. Burning high explosives produce flames of various colors; they can be bright red, yellow, greenish-white, or combinations of no predominant color. Some give off a white smoke, while others burn with no trace of smoke.

Appendix B Specialized Vehicles and Equipment

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

B-1 Hovercraft. The Hovercraft in Figure B-1 is typical of many designs available. They are easily operated and maintained with minimum training and can traverse a variety of surfaces such as water, tidal flats, snow, and ice. Payloads of 2000 lb (908 kg) permit up to 20 life rafts to be carried on this model. Piston engine operation offers a unique rescue vehicle at a fraction of the cost of a helicopter.

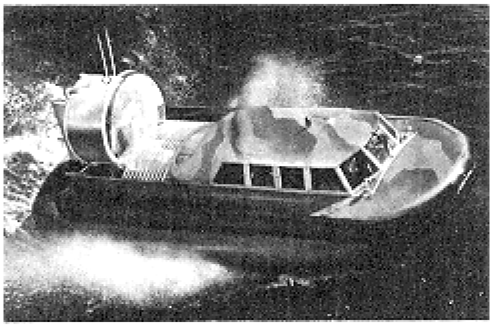

Figure B-1 Hovercraft.

B-2 Elevated Platform. Elevated platform vehicles can provide valuable assistance when emergencies involve “wide-body” style aircraft. When fires occur in the tail section engine of this type of aircraft, fire fighters can be positioned to permit proper application of extinguishing agent on the fire.

Figure B-2 Elevated platform vehicle.

Appendix C Driver's Enhanced Vision System: A Technical Approach for Aircraft Rescue and Fire Fighting Services

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

C-1 Introduction. Several accidents have occurred in poor visibility conditions, and, with the proliferation of category IIIC landing systems, more requirements for fire fighting in low visibility conditions can be expected. Aircraft rescue and fire fighting services currently have no reliable way to locate and navigate crash sites at airports under conditions of poor visibility.

C-2 Background. Aircraft rescue and fire fighting services are required to demonstrate an ability to respond anywhere on the airport operational runway areas as part of earning their annual certificate. This response requirement is considered vital to the ability of ARFF services to gain control of a rapidly growing external post-crash fuel fire and their ability to protect the evacuating passengers from the aircraft fuselage. A response in 3 minutes is dependent on the vehicle's ability to accelerate rapidly from the rescue service's facilities and to maintain approximately a 50-mph (80.5-km/h) approach to the accident site. Accomplishing this task under substandard visibility conditions such as fog and rain prevents the responding vehicles from reaching this speed.

There is a clear need to provide operational equipment in the rescue vehicles that maintains their response ability if low visibility flight operations are to be conducted.

The problem of poor visibility response at airports for rescue and fire fighting services can be broken down into three components:

(a) Locating the accident sites;

(b) Navigating aircraft rescue and fire fighting vehicles to crash sites;

(c) Negotiating terrain and obstacles in low visibility conditions.

Airport fire services need a driver's enhanced vision system (DEVS) that addresses these three components.

Aircraft rescue and fire fighting services should obtain an accurate position fix on the crash site within a time parameter that is comparable to their response time (under 3 minutes). The current system for locating crash sites that are not visible to aircraft rescue and fire fighting services relies on visual observations, estimates, and verbal descriptions of airport landmarks provided by air traffic controllers. This system is prone to human error. The optimal solution to this problem is a system that locates a crash site on a digital map of the airport automatically and transmits this location to aircraft rescue and fire fighting services.

Navigation of aircraft rescue and fire fighting vehicles to crash sites is an issue that can be solved with today's technology. Sophisticated radio navigation systems such as the global positioning system (GPS) provide precise positioning capability. This position information, combined with digital maps of the airport area, can be displayed on a geographic map or heads-up display (HUD) to guide the crews.

Negotiating terrain and locating obstacles in low visibility conditions is an important capability that aircraft rescue and fire fighting services currently do not possess. The only aids that rescue services currently use for improving vision under poor visibility conditions are windshield wipers and headlights. These devices often do not improve visibility enough to allow rescue teams to drive safely at the high speeds necessary to reach a crash site within a reasonable time. One aid that would provide improvement is a forward looking infrared device (FLIR). FLIRs currently are used by the military to improve visibility at night and during severe weather conditions. The FLIR system needs to be fully functional as soon as the fire equipment departs the fire station facility. Exit time typically is under 30 seconds from the time of accident notification. On-line and operational equipment should in no way impede the ability of the aircraft rescue and fire fighting services to respond. Equipment is to be automated and is to necessitate little attention by the truck operator.

C-3 General Requirements. A driver's enhanced vision system (DEVS) is required in an aircraft rescue and fire fighting vehicle for airport emergency equipment. It facilitates faster and safer travel to emergency situations at night and in adverse weather conditions. It provides a substantial increase in the ability to locate people, other aircraft, vehicles, and debris at the emergency site. Its ability to allow the driver to see through flames, smoke, and fog during both the day and night provides ARFF vehicles with a significant increase in effectiveness in every phase of emergency operations.

The DEVS requires a transparent window display (TWD), which is often called a heads-up display (HUD), combined with a global positioning system (GPS) and geographic information system (GIS), on-board sensors, a central data and command RF link (radio communications), and a forward looking infrared (FLIR) sensor. These elements are to be integrated into a single functional system. A validation demonstration program is necessary to provide the quantitative information needed to justify the DEVS and refine it for the ARFF services application.

C-4 Operating Scenarios and Capabilities.

Mission Description

From the moment that an alert is received until the end of the emergency, the ARFF services mission is subject to stress and uncertainty. At any given moment, day or night, the equipment needs to be fully functional within a few seconds, regardless of adverse weather. Often vehicles and aircraft are positioned on the runways and taxiways in unusual or unexpected locations. In the event of an aircraft accident, victims and debris can be present anywhere on the airport. At the same time, the large size of modern airports, with multiple parallel runways and taxiways, places a priority on the ability to travel at high speed to the emergency site.

Once ARFF services have arrived at the location, the ability to assess the situation is crucial to carrying out the mission. The information available to the vehicle operator contributes directly to the level of performance of the ARFF mission. This information needs to be obtained without any increase in the workload. The DEVS reduces the impact of night conditions, adverse weather, fire, and smoke so that the operator's performance approaches that achieved during the optimum daylight scenario.

To achieve this goal, information is to be provided in an easily recognizable form, without the need for vehicle operator intervention. Rescue vehicle location, the location of the emergency, the location of other vehicles (ground and aircraft), the location of people, and the location of debris are the basic data needed (and normally available during the least difficult situations). The condition of the aircraft, location of victims, presence and location of spilled burning fuel, and location of other ARFF personnel also are crucial. In addition, the possible presence of toxic gases caused by spilled or burning cargo needs to be determined to provide for a safe response to the situation. Finally, since multiple vehicles and ARFF crews are always involved in most emergency situations, a centralized command and control system is needed to coordinate the activities of all elements of the emergency response team. The DEVS is one element of this command and control system.

C-5 Required Capabilities. The DEVS provides an increase in the knowledge available to the emergency crew. The crew are able to see through fog, rain, sleet, and snow. The crew are able to see through smoke and flames in and around the burning aircraft, to detect the position of evacuees and trapped passengers, and to distinguish among the debris to move into a position for fire fighting. They are able to apply extinguishing agents to the hottest areas of the burning fire more precisely. They also can track other fire fighters through the smoke and fire while rescue efforts are under way.

The FLIR device provides the ARFF operator with the ability to detect debris and other vehicles (stationary or moving) in the vicinity, as well as to detect passengers evacuating from the aircraft. The FLIR detector can electrocute humans in a smoke or fog environment where normal vision is inadequate. The FLIR stores information for normal driving conditions. The FLIR uses the brighter-than-background standard runway and taxiway lights, which are detected as it travels to the site.

C-6 System Elements. The elements of the DEVS for the ARFF vehicle demonstration include a forward looking infrared device (FLIR), a transparent window display (TWD) or heads-up display (HUD), and a global positioning system (GPS) with geographic information system

(GIS) or mapping.

C-7 Forward Looking Infrared Device. The FLIR is a high resolution infrared detector. It is enhanced with wide dynamic range processing for increased penetration of smoke and fog. The FLIR contains a two-dimensional focal plane array using platinum silicide as the detector material. It operates at wavelengths from 8 micrometers to 12 micrometers and has a sensitivity of 32.2°F (0.1°C). An alternate FLIR of 3 micrometers to 5 micrometers with similar sensitivity also is implemented to establish whether the shorter wavelength provides significant benefits in the smoke environment. A key element in the use of the FLIR device for this application includes a total hands-off automation philosophy. Rapid cool-down is another function dictated by the nature of FLIR detectors. To achieve the best performance, these detectors should be cooled to very low temperatures [in the range of –454°F (270.2°C)]. The cooling systems that have been developed have an operating life of about 2500 hours. Rapid cool-down or extended standby life cycle is considered essential to an ARFF application. Zero (0) or near-zero time start-up is an operational requirement for effectiveness.

C-8 Dynamic Range Issues. To detect people and debris, the FLIR has a sensitivity of approximately 32.2°F (0.1°C). At the same time, the FLIR can be expected to deliver this sensitivity in the presence of flames that couldreach temperatures of 1832°F (1000°C). In order to accomplish this, the FLIR operates over an instantaneous dynamic range of about 10,000: 1.

C-9 Transparent Window Display. The transparent window display system hardware consists of a projector, an optical element, and a symbol generator to provide information to an operational position. The symbol generator provides data to the projector by means of dedicated signal cables. The symbol generator has the capability to receive and to process data links from up to six video inputs and two serial inputs while formatting messages based on a control program. The control program uses the data's priority, refresh rate, and other site-specific criteria to implement the sequence and content of the information presentation.

C-10 Projector. The DEVS projector is a high-brightness CRT, monochrome emitter that creates and projects a focused image onto the window of the ARFF vehicle. The projector is designed to be placed 60 in. to 72 in. (152.4 cm to 182.9 cm) from the window. There are optional mounting schemes that allow the projector to be mounted off-axis from the window to accommodate existing mechanical obstructions. The projector is to be equipped to accept standard signal inputs that include RS-170 to utilize the TWDs as a simple replacement of an existing heads-down display (HDD).

C-11 Optical Element. The optical element is mounted to the window of the ARFF vehicle to act as a dynamic display surface within the truck cab. The optical element should be 6 in.^{2} to 12 in.^{2} (38.7 cm^2 to 77.4 cm^2) and affixed to a selected location on the window with room temperature vulcanizing material. The location should be predefined to reflect data in a uniform manner that is specified by both lateral and vertical angles perpendicular to the plane of the window. The viewing zone should offer a lateral reflection angle of 30 degrees and a vertical reflection angle of 15 degrees. The information is to be presented in a bright green color and is to be focused at the plane of the window. The DEVS is not to obstruct the view to the outside of the vehicle.

C-12 Symbol Generator. The symbol generator is to be a microcomputer-based system designed for rack mounting in an equipment bay. This remote computer offers the capability to interface directly with a selected set of on-board data channels or discrete indicator inputs and is linked with a GPS tracker and a FLIR. The symbol generator is programmed with the mission-specific control scheme and operates in an automatic mode. There is a keyboard and monitor option that supports on-site changes of the data communications and control routines. The symbol generator formats data “pages” and routes this information to the appropriate projector based on priority or currency or on demand. The symbol generator is capable of being configured to accept a variety of standard signal inputs including RS-232, RS-422, and RS-170.

C-13 Global Positioning System. A global positioning system (GPS) receiver is to be mounted on the ARFF vehicle and interfaced with the transparent window display system for display of position information. The GPS is to be a six-channel receiver capable of tracking up to eight satellites. The GPS receiver calculates new position data once every second. Position accuracy is specified at a maximum of 82 ft (25 m), with a typical accuracy of about 32.8 ft to 49.2 ft (10 m to 15 m). An additional ground-based differential transmitter on the airfield provides accuracy from 3.3 ft to 9.8 ft (1 m to 3 m).

C-14 Geographic Information System. The airport mapping system by which the ARFF vehicle is navigated can be developed by several methods. One method being considered is the digital reconstructive method. This is accomplished by taking an aerial photograph of the airport and digitizing it so it then can be displayed on the computer screen for mapping. This method, as it is developed, could provide the increased local terrain and hazards definition needed by the ARFF vehicle to travel on and around the airfield. Additional mapping capability with definitions of 1 mi, 3 mi, and 10 mi (1.6 m, 4.8 m, and 16.1 m) provide for call-up mapping in the event of an accident off the airport operational areas. Digital aerial mapping is an emerging technology that provides three-dimensional hazard definition of streams, swales, and drainage culverts, as well as other hazards that could impede the progress of the rescue.

C-15 Computer Information Enhancements. Once an operational computer is placed in the ARFF vehicle, it provides a host of other fire fighting capabilities. Fire fighters are able to have the complete airport's emergency plan available in the computer with menu-driven software. Toxic and hazardous material indexes can be provided. Complete instructions on emergency door and entryway door operations for every type of commercial aircraft can be provided.

C-16 Vehicle Electrical Upgrade. Because of the need for better power sources, vehicles with new technology equipment need to undergo some modifications to the existing electrical systems. Computers and electronically-controlled devices need smooth-filtered and stable voltage sources. The equipment targeted for installation is modified to operate in the voltage ranges used on the existing vehicles. This usually is 12 v or 24 v dc. Special power converters and voltage stabilizers are to be considered. There also are requirements for the addition of 115 v ac in some cases. Operating off portable generator power sources that might already exist on some of these vehicles does not, in most cases, provide, the smooth, stabilized power sources of these requirements. Transformer rectifiers and power converters do not provide a major challenge for the technological requirements of this program. Low-cost portable battery back-up systems also should be considered to provide power for start-up of the vehicle as well as accidental shutoff of the vehicle system supply. The cost for these required voltage sources is minimal when compared to the trouble-free environment that they provide for the electronic boards and computer systems.

C-17 Final Assessment. The object of this assessment program is to provide information about the new computer-based equipment and vision enhancement devices that help the airport rescue services perform their assigned mission under suboptimal visibility conditions. The cost of installing this equipment can be justified by the need to operate aircraft under these poor visibility conditions. If operations are conducted that allow the aircraft to take off and land under poor visibility conditions, it is reasonable to expect that additional requirements for fire fighting response under low visibility conditions will be established.

The technology needed to perform the driver's enhanced vision system (DEVS) is available now. Although the equipment can be bought off the shelf, installation necessitates some additional research effort because aircraft rescue and fire fighting mission requirements were not considered in the research efforts that produced this technology. In each case, the individual elements of the DEVS considered the fact that the proposed system should require low operational workload by the operator. Each piece of the system endeavors to use current technological equipment with some hardware and software modifications. Finally, the DEVS should be designed for easy installation and a maintenance-free duty life cycle or at the least a modular rack installation design allowing the removal and replacement of components by current maintenance personnel without adding to the personnel burden of a rescue and fire fighting service.

Finally, the most important issue is cost. Historically, this technology is expensive. Some of the reasons for these high costs were dictated by low production runs and the survivability conditions for which the equipment originally was designed. Equipment meeting the rigorous requirements necessary for military applications can add many thousands of dollars to the final purchase price. It is hoped that, with the careful redesign and unique adaptation of existing equipment designs and unit cost price decreases, the cost of using this technology in an aircraft rescue fire fighting vehicle can be reduced substantially in the near future.

C-18 Driver's Enhanced Vision System Guidelines.

C-18.1 DEVS Performance Characteristics. The driver's enhanced vision system (DEVS) is an integrated system of sensors, computers, and navigational equipment designed to improve the response and operation of ARFF crews in low visibility conditions. The DEVS consists of three components: a night or low visibility capability, a vehicle navigation capability, and a vehicle tracking capability, which are integrated using a digital radio data link.

To meet the DEVS requirements, systems need to integrate all three components cohesively. Each component should be integrated into the vehicle's normal operations through a systematic approach of understanding and adapting the technology to the needs of the fire fighting population.

In the sections that follow, the base performance characteristics are detailed. It is important to note that technology development in the enhanced vision area is progressing rapidly; therefore, the criteria that follows should be considered minimal. Questions regarding specific production systems, new performance capabilities, or recommended systems should be directed to the FAA's airports office.

C-18.2 Low Visibility Capability. The intent of the low visibility capability is to provide an enhanced picture of the environmental scene through the use of a chamber or other sensor system displayed inside of the cab. For the immediate future, it appears that forward looking infrared (FLIR) technology holds the most promise for aiding visibility in smoke, fog, and haze and at night. The minimum recommended performance characteristics of the low visibility system are provided below:

(a) **General.**

Expected worst case visibility	0 ft range/0 ft ceiling
Time to operational	≤30 sec
Detection of humans	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 55 mph (88.5 km/h), clear conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 50 mph (80.5 km/h), light fog conditions
	400 ft (121.9 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), heavy fog conditions
	400 ft (121.9 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), smoke conditions
	300 ft (91.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 35 mph (56.3 km/h), rain/snow conditions
Detection of GA aircraft	2500 ft (762.0 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 55 mph (88.5 km/h), clear conditions
	1000 ft (304.8 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 50 mph (80.5 km/h), light fog conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), heavy fog conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), smoke conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 35 mph (56.3 km/h), rain/snow conditions

Detection of objects near fires	People, debris, wreckage, and equipment within 20 ft (6.1 m) of a 6 ft (1.8 m) diameter Jet A fuel fire from a range of 1000 ft (304.8 m)

(b) **FLIR Specific.**

IR waveband	Long wave IR energy (8µm to 12 µm)
Video output	RS-170 or industry standard video
Gain and level controls	Automatic
Horizontal field of view	≥28 degrees (40 degrees preferred)
Vertical field of view	>20 degrees, aspect ratio to match vertical
Lens clearing capability	Windshield wiper, high pressure air, or equivalent
Temperature and humidity changes	Changes in ambient temperature and humidity should not result in condensation inside the FLIR housing or optics assembly
Mounting	On top of vehicle with pan and tilt capability, remote-control equipped, line of sight aligned with driver's line of sight
Video monitor	8 in. to 10 in. (6.2 cm to 25.4 cm) diagonal display mounted near driver's line of sight *Alternative*: Heads-up display with field-of-view to match FLIR

C-18.3 Navigation Capability. The intent of the navigation capability is to allow for accurate positioning of the vehicle on or around the airport surface. The navigation capability should provide a depiction of the vehicle, notable landmarks, roadways, and other guidance aids. Information should be provided to the driver in a meaningful form appropriate to the needs of the fire response.

The navigation capability consists of three main components: a global positioning system (GPS) receiver, a computer system containing supporting maps and navigation information, and a display/control system for driver information.

For full capability on the airport, the DEVS should incorporate both capabilities into the design. The performance characteristics of the components in the above list are as follows:

Position availability	Computed position within 30 sec/hr/day, 7 days/week
Accuracy	Two-dimensional position within 15 ft (4.6 m)

Dead reckoning	Coasting capability when satellite track is lost due to shadowing
Position update rate	< 1/sec
Initialization and operation	Fully automatic
Map — levels of detail	Level 1 — Airport operations area
	Level 2 — Airport property boundary
	Level 3 — 5 mi (8 km) radius of the airport center; either variable or fixed zooms within each level should be provided
Map — orientation	North-up or heading-up, selectable (Note: Heading-up orientation is required for situational awareness in low visibility conditions and unfamiliar areas)
Map — visual orientation cues	Vehicle orientation, vehicle heading, direction of low visibility coverage
Driving cues	Range/bearing indicator in line-of-sight (on FLIR display or separate)
Data link — error checking	Standard error checking
Data link — frequency selection	Selectable to airport location
Display — color	≥ 256 colors

C-18.4 Tracking Capability. The tracking capability components include: Differential GPS (DGPS) correction software, data link hardware/software, and an integrated display/control system for command center operations. The command center can be either fixed or mobile, depending on individual airport ARFF operations. This capability is intrinsically tied to the tracking capability, which allows for the monitoring of the positions of other vehicles, the crash site, identified victims, and other factors, as well as linkage to a centralized display for emergency coordination.

Map — orientation	North-up with dynamic zoom and pan
Data link — error checking	Standard error checking
Data link — frequency selection	Selectable to airport location
Display — color	Large high-resolution monitor [>19 in. (>48.3 cm) diagonal color monitor, 1280 × 1024 resolution]

C-19 Glossary of Technical Terms

Aircraft Rescue and Fire Fighting (ARFF). Formerly known in the fire fighting industry as crash, fire, and rescue.

Cool-Down in the Operational Environment of an Infrared Detector. Term used to describe the period of time needed for the refrigeration unit of the optical sensor to cool the unit to approximately −454°F (−270.2°C) below zero (0). This cool-down mode provides the necessary sensitivity of 10,000: 1 for infrared thermal detection.

Driver's Enhanced Vision System (DEVS). A vision enhancement system utilizing several electronic and computer-based components that aids in improving sight as well as movement or navigation around the airport during reduced visibility operational conditions.

Forward Looking Infrared (FLIR). A heat detector device that allows the viewer to see radiant heat projected from objects. These devices work in the micron band of the infrared spectrum (e.g., 8 µm to 12 µm).

Geographic Information System (GIS). A device that allows an aerial map of the airport to be displayed with markers that move along the image as the vehicle changes position.

Global Positioning System (GPS). A device that picks up signals from orbiting satellites and determines positions of location on earth by reference to longitude and latitude.

Heads-Up Display (HUD). The military name for a device that allows a person to look and operate a device while viewing through the cockpit window of an aircraft. This device displays information on the cockpit window.

Transparent Window Display (TWD). An electronic device that projects an image on a special coated glass or plastic that also allows the viewer to see through the clearplate with a slight reduction in visibility.

Appendix D Civil Aircraft Accident Investigation

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

D-1 In the United States of America, major aircraft accidents are investigated by the National Transportation Safety Board (NTSB), 800 Independence Avenue SW, Washington, DC 20591. In some instances responsibility for investigation is delegated by the Board to the Federal Aviation Administration (FAA).

RESCUE: The occupants.

GUARD: The wreckage — Allow no one inside the wreckage area other than those necessary for occupant removal, fire fighting, and the possible removal of mail and cargo where necessary to protect it from further damage. Items removed for protection must be retained locally for examination by a Federal Air Safety Investigator.

ADVISE: The county coroner/medical examiners — Fatally injured occupants of the aircraft should be held for possible pathological or toxicological examination or both prior to embalment.

IDENTIFY: The position of fatalities — Prior to removing the remains of fatally injured occupants, tag or otherwise identify each body, and mark its location in the wreckage or on the ground (photograph in position, if possible).

PERMIT: News media coverage — Accredited news media may be permitted to enter and photograph the area as long as the wreckage is not disturbed.

NOTIFY: The local authorities, the Safety Board, FAA.

D-2 National Transportation Safety Board Rules.

Title 49 Transportation

Chapter VIII — National Transportation Safety Board

Revised: March 20, 1985

Part 830 Notification and Reporting of Aircraft Accidents or Incidents and Overdue Aircraft, and Preservation of Aircraft Wreckage, Mail, Cargo, and Records.

Authority: Title VII, Federal Aviation Act of 1958, as amended, 72 Stat. 781, as amended by 76 Stat. 921 (49 U.S.C. 1441 et seq.), and the Independent Safety Board Act of 1974, Pub. L. 93-633,88 Stat. 2166 (49 U.S.C. 1901 et seq.).

Subpart A — General.

830.1 Applicability.

This part contains rules pertaining to:

(a) Notification and reporting aircraft accidents and incidents and certain other occurrences in the operation of aircraft when they involve civil aircraft of the United States wherever they occur, or foreign civil aircraft when such events occur in the United States, its territories or possessions.

(b) Preservation of aircraft wreckage, mail, cargo, and records involving all civil aircraft in the United States, its territories or possessions.

830.2 Definitions.

As used in this part the following words or phrases are defined as follows:

“Aircraft accident” means an occurrence associated with the operation of an aircraft which takes place between the time any person boards the aircraft with the intention of flight and all such persons have disembarked, and in which any person suffers death or serious injury, or in which the aircraft receives substantial damage.

"Fatal injury" means any injury which results in death within 30 days of the accident.

"Incident" means an occurrence other than an accident, associated with the operation of an aircraft, which affects or could affect the safety of operations.

"Operator" means any person who causes or authorizes the operation of an aircraft, such as the owner, lessee, or bailee of an aircraft.

"Serious injury" means any injury which (1) requires hospitalization for more than 48 hours, commencing within 7 days from the date the injury was received; (2) results in a fracture of any bone (except simple fractures of fingers, toes, or nose); (3) causes severe hemorrhages, nerve, muscle, or tendon damage; (4) involves any internal organ; or (5) involves second or third degree burns, or any burns affecting more than 5 percent of the body surface.

"Substantial damage" means damage or failure which adversely affects the structural strength, performance, or flight characteristics of the aircraft, and which would normally require major repair or replacement of the affected component. Engine failure or damage limited to an engine if only one engine fails or is damaged, bent fairings or cowling, dented skin, small punctured holes in the skin or fabric, ground damage to rotor or propeller blades and damage to landing gear, wheels, tires, flaps, engine accessories, brakes, or wingtips, are not considered "substantial damage" for the purpose of this part.

Subpart B — Initial Notification of Aircraft Accidents, Incidents, and Overdue Aircraft.

830.5 Immediate notification.

The operator of an aircraft shall immediately, and by the most expeditious means available, notify the nearest National Transportation Safety Board, field office[1] when:

(a) An aircraft accident or any of the following listed incidents occur:

1. Flight control system malfunction or failure;

2. Inability of any required flight crewmember to perform normal flight duties as a result of injury or illness;

3. Failure of structural components of a turbine engine excluding compressor and turbine blades and vanes;

4. In-flight fire; or

5. Aircraft collide in flight.

(b) An aircraft is overdue and is believed to have been involved in an accident.

830.6 Information to be given in notification.

The notification required in section 830.5 shall contain the following information, if available:

(a) Type, nationality, and registration marks of the aircraft;

(b) Name of owner, and operator of the aircraft;

(c) Name of the pilot-in-command;

(d) Date and time of the accident;

(e) Last point of departure and point of intended landing of the aircraft;

(f) Position of the aircraft with reference to some easily defined geographical point;

(g) Number of persons aboard, number killed, and number seriously injured;

(h) Nature of the accident, the weather, and the extent of damage to the aircraft, so far as is known; and

(i) A description of any explosives, radioactive materials, or other dangerous articles carried.

Subpart C — Preservation of Aircraft Wreckage, Mail, Cargo, and Records.

830.10 Preservation of aircraft wreckage, mail, cargo, and records.

(a) The operator of an aircraft involved in an accident or incident for which notification must be given is responsible for preserving to the extent possible any aircraft wreckage, cargo, and mail aboard the aircraft, and all records, including all recording mediums of flight, maintenance, and voice recorders, pertaining to the operation and maintenance of the aircraft and to the airmen until the Board takes custody thereof or a release is granted pursuant to section 831.10(b).

(b) Prior to the time the Board or its authorized representative takes custody of aircraft wreckage, mail, or cargo, such wreckage, mail, or cargo may not be disturbed or moved except to the extent necessary:

1. To remove persons injured or trapped;

2. To protect the wreckage from further damage; or

3. Where it is necessary to move aircraft wreckage, mail, or cargo, sketches, descriptive notes, and photographs shall be made, if possible, of the original position and condition of the wreckage and any significant impact marks.

(c) The operator of an aircraft involved in an accident or incident shall retain all records, reports, internal documents, and memoranda dealing with the accident or incident, until authorized by the Board to the contrary.

Subpart D — Reporting of Aircraft Accidents, Incidents, and Overdue Aircraft.

830-15 Reports and statements to be filed.

(a) *Reports.* The operator of an aircraft shall file a report on Board Form 6120.1 or Board Form 6120.2[2] within 10 days after an accident, or after 7 days if an overdue aircraft is still missing. A report on an incident for which notification is required by section 830.5(a) shall be filed only as requested by an authorized representative of the Board.

(b) *Crewmember Statement.* Each crewmember, if physically able at the time the report is submitted, shall attach a statement setting forth the facts, conditions and circumstances relating to the accident or incident as they appear to him. If the crewmember is incapacitated, he shall submit the statement as soon as he is physically able.

(c) *Where to File the Reports.* The operator of an aircraft shall file any report with the field office of the Board nearest the accident or incident.

NOTE: The reporting and recordkeeping requirements contained herein have been approved by the Office of Management and Budget in accordance with the Federal Report Act of 1942.

Signed at Washington, DC, on September 4, 1980.

James B. King

Chairman

[1]The National Transporation Safety Board field offices are listed under U. S. Government in the telephone directories in the following cities: Anchorage, AK; Atlanta, GA; Chicago, IL; Denver, CO; Fort Worth, TX; Kansas City, MO; Los Angeles, CA; Miami, FL; New York, NY; Seattle, WA.

[2]Forms are obtainable from the Board field offices (see footnote 1), the National Transportation Safety Board, Washington, DC 20594, and the Federal Aviation Administration, Flight Standards District Office.

Appendix E Sample Mutual Aid Agreements

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

E-1 USAF Mutual Aid Agreement (AFR 92-1).

This agreement, entered into this ________ day of______________, 19___, between the Secretary of the Air Force, acting pursuant to the authority of the Act of May 27, 1955 (69 stat, 66), and (fire organization) is for the purpose of securing to each the benefits of mutual aid in fire prevention, in the protection of life and property from fire, and in fire fighting.

It is agreed that:

(a) Upon request to a representative of the ________ Air Force Base Fire Department by a representative of the (fire organization), fire fighting equipment and personnel of the _____________________ Air Force Base Fire Department will be dispatched to any point within the area for which the (fire organization) normally provides fire protection as designated by the representative of the (fire organization).

(b) Upon request to the representative of the (fire organization) by a representative of _________ Air Force Base Fire Department, fire fighting equipment and personnel of the (fire organization) will be dispatched to any point within the fire fighting jurisdiction of the __________ Air Force Base Fire Department as designated by the representative of the __________ Air Force Base Fire Department.

(c) Any dispatch of equipment and personnel pursuant to this agreement is subject to the following conditions:

1. Any request for aid hereunder shall include a statement of the amount and type of equipment and number of personnel requested, and shall specify the location to which the equipment and personnel are to be dispatched, but the amount and type of equipment and number of personnel to be furnished shall be determined by a representative of the responding

organization.

2. The responding organization shall report to the officer in charge of the requesting organization at the location to which the equipment is dispatched and shall be subject to the orders of that official.

3. A responding organization shall be released by the requesting organization when the services of the responding organization are no longer required or when the responding organization is needed within the area for which it normally provides fire protection.

4. In the event of a crash of aircraft owned or operated by the United States or military aircraft of any foreign nation within the area for which the (fire organization) normally provides fire protection, the Chief of the ___________________ Air Force Base Fire Department or his representative may assume full command upon his arrival at the scene of the crash.

(d) Each party waives all claims against every other party for compensation for any loss, damage, personal injury, or death occurring as a consequence of the performance of this agreement.

(e) No party shall be reimbursed by any other party for any costs incurred pursuant to this agreement.

(f) All equipment used by (fire organization) in carrying out this agreement will, at the time of action hereunder, be owned by it; and all personnel acting for (fire organization) under this agreement will, at the time of such action, be an employee or volunteer member of (fire organization).

E-2 Typical Civil Airport Department Mutual Aid Agreement.

The following mutual aid agreement example is based on procedures used by the Seattle-Tacoma International Airport supplied through the courtesy of R. E. Smith, Fire Chief.

This agreement, made and entered into this __________ by and between the___________________________________ and the____

WITNESSETH:

WHEREAS, each of the parties hereto maintains equipment and personnel for the suppression of fires within its own jurisdiction and areas, and

WHEREAS, the parties hereto desire to augment the fire protection available in their establishments, district agencies and municipalities in the event of large fires, conflagrations, and natural or technological disasters, and

WHEREAS, the agencies entering into this Agreement have an interest in providing mutual assistance in emergencies for which each respective fire department has the capabilities to respond, and

THEREFORE BE IT AGREED THAT:

(a) Whenever it is deemed advisable by the commanding officer of a fire department belonging to a party to this Agreement, or whenever the commanding officer of any such fire department is actually present at an emergency incident, such commanding officer may request assistance for the purpose of extinguishing, controlling, or aiding in the extinguishing or controlling of fires, or in the mitigation of emergency medical service incidents from the fire departments which are signatory to this Agreement. Under the terms of this Agreement, such commanding officer is authorized to make such a request and the commanding officer of the department receiving the request or authorized subordinates, shall forthwith take the following action:

1. Immediately determine if apparatus and personnel can be spared in response to the call;

2. What apparatus and personnel might most effectively be dispatched;

3. The exact mission to be assigned in accordance with the detailed plans and procedures of operation drawn in accordance with this Agreement by the managing representatives of the fire department concerned;

4. Dispatch such apparatus and personnel as the responsible officer receiving the call reasonably believes should be sent, with complete instructions as to the mission, in accordance with the terms of this Agreement and pursuant to the instructions received in the request for assistance.

(b) The tendering of assistance under the terms of this Agreement shall not be mandatory, but the party receiving the request of assistance should immediately inform the requesting agency if, for any reason, assistance cannot be rendered.

(c) Each party to this Agreement waives all claims against the other party or parties for compensation for any loss, damage, personal injury, or death occurring in consequence of the performance of this Agreement.

(d) Each party to this Agreement shall maintain its own insurance coverage for equipment and personnel.

(e) All services performed under this Agreement shall be rendered without reimbursement of either party or parties.

(f) The commanding officer of the fire department requesting assistance shall not relinquish responsibility for mitigating the emergency incident to those officers responding pursuant to the terms of this Agreement. A senior officer of a responding mutual aid department will make him/herself available to the commanding officer for consultation as a resource person, to assist in tactical or strategical decisions during the emergency. As often as is practically possible, the mutual aid departments will remain intact under the direct supervision of the highest ranking officer from their own department. Direction for the responding department’s fire fighters’ and subordinate officers’ activities will, however, come from the commanding officer of the fire department initiating the request for assistance.

(g) The chief fire officers and personnel of the fire departments of both parties to this Agreement are invited and encouraged, on a reciprocal basis, to frequently visit each other’s activities for guided familiarization tours consistent with local security requirements and, as feasible, to jointly conduct pre-fire planning inspections and drills.

(h) The commanding officers of the fire departments of the parties of this Agreement are authorized to meet and draft any detailed plans and procedures of operation necessary to effectively implement this Agreement. Such plans and procedures of operations shall become effective upon ratification by the signatory parties.

(i) This Agreement shall become effective upon the date hereof and shall remain in full force and effect until cancelled by mutual agreement of the parties hereto or by written notice by one party to the other party, giving ten (10) days notice of said cancellation.

IN WITNESS THEREOF, the parties hereto have executed this Agreement at ________________________, Washington, on the day and year first above written.

PORT OF SEATTLE FIRE DEPARTMENT

Appendix F Referenced Publications

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

F-1 The following documents or portions thereof are referenced within this guide for informational purposes only and thus should not be considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

F-1.1 NFPA Publication. National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 422, *Guide for Aircraft Accident Response*, 1994 edition.

Fire Protection Guide on Hazardous Materials.

F-1.2 IATA Publication. International Air Transport Association Headquarters, IATA Building, 2000 Peel Street, Montreal, Canada H3A 2R4.

Restricted Articles Regulations.

F-1.3 U.S. Government Publication. Office of the Federal Register, National Archives and Records Service, General Services Administration, Washington, DC 20408.

Title 49, *Code of Federal Regulations*, Part 175, “Transportation.”

F-2 Bibliographical References. *The following publications are included in the Appendix for informational purposes only*.

F-2.1 ICAO Publications. International standards and recommended practices are promulgated by the International Civil Aviation Organization, 1000 Sherbrooke Street West, Montreal, Quebec, Canada H3A 2R2.

Aerodromes (Annes 14), 8th edition, March 1983.

Airport Services Manual, Part 1: "Rescue and Fire Fighting," second edition, 1984.

Emergency Response Guidance for Aircraft Incidents Involving Dangerous Goods, first edition, March 1987.

F-2.2 U.S. Government Publications. Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

F-2.2.1 FAR Part 139. Part 139 is sold on a subscription basis by the Superintendent of Documents. Subscribers will receive changes to this part automatically.

F-2.2.2 Federal Aviation Administration Publications. Available from Department of Transportation, Distribution Unit, M-494.3, Washington, DC 20590.

Advisory Circulars. This listing is limited to those free advisory circulars relating to aircraft rescue and fire fighting services. For a complete listing of FAA advisory circulars, write to the address above and request a copy of the latest "Advisory Circular Checklist and Status of Other FAA Publications." This checklist is also published periodically in the Federal Register.

150/5200-12A, *Fire Department Responsibility in Protecting Evidence at the Scene of an Aircraft Accident* (4-8-85) (AAS-100). Furnishes general guidance for airport employees, airport management, and other personnel responsible for fire fighting and rescue operations, at the scene of an aircraft accident, on the proper presentation of evidence.

150/5200-15C, Announcement of Availability — International Fire Service Training Association's Manual 206, *Aircraft Fire Protection and Rescue Procedures* (second edition, 1978) (8-26-82) (AAS-100). Explains the nature of the manual and tells how it can be obtained.

150/5200-18A, *Airport Safety Self-Inspection* (12-18-85) (AAS-310). Suggests functional responsibility, procedures, a checklist, and schedule for an airport safety self-inspection.

150/5200-21A, Announcing the Availability of U.S. Air Force Technical Order (T.O. 00-105E-9) *Aircraft Emergency Rescue Information* (2-24-81) (AAS-100). Explains the nature of the Technical Order and tells how it can be obtained.

150/5210-2A, *Airport Emergency Medical Facilities and Services* (11-27-84) (AAS-300). Provides information and advice so that airports can take specific voluntary pre-incident planning actions to ensure at least minimum first aid and medical readiness appropriate to the size of the airport in terms of permanent and transient personnel.

150/5210-6C, *Aircraft Fire and Rescue Facilities and Extinguishing Agents* (1-28-85) (AAS-100). Outlines scales of protection considered as the recommended level compared with the minimum level in Federal Aviation Regulation Part 139.49 and tells how these levels were established from test and experience data.

150/5210-13, *Water Rescue Plans, Facilities, and Equipment* (5-4-72) (AAS-300). Suggests planning procedures, facilities, and equipment to effectively perform rescue operations when an aircraft lands in a body of water, swamp, or tidal area where normal aircraft fire fighting and rescue service vehicles are unable to reach the accident scene.

150/5210-14, *Airport Fire and Rescue Personnel Protective Clothing* (3-12-86) (AAS-100). Developed to assist airport management in the development of local procurement specifications for an acceptable, cost-effective proximity suit for use in aircraft rescue and fire fighting operations.

150/5210-15, *Airport Rescue and Fire Fighting Station Building Design* (7-30-87) (AAS-100). Provides standards and guidance for planning, designing, and constructing and airport rescue and fire fighting station.

150/5210-58, *Painting, Marking, and Lighting of Vehicles Used on an Airport* (7-11-86) (AAA-120). Provides guidance, specifications, and standards, in the interest of airport personnel safety and operational efficiency, for painting, marking, and lighting of vehicles operating in the airport air operations areas.

150/5210-78, *Aircraft Fire and Rescue Communications* (4-30-84) (AAS-120). Provides guidance and information for planning and implementing an airport communications system for airport fire and rescue service.

150/5220-4A, *Water Supply Systems for Aircraft Fire and Rescue Protection* (12-11-85) (AAS-120). Provides guidance for the water source selection and standards for a water distribution system designed to support aircraft rescue and fire fighting (ARFF) service operations on airports.

150/5220-9, *Aircraft Arresting Systems for Joint Civil/Military Airports* (4-6-70) (AAS-300). Updates existing policy and describes and illustrates the various types of military aircraft emergency arresting systems that are now installed at various joint civil/military airports. It also informs users of criteria concerning installations of such systems at joint civil/military airports.

150/5220-10, *Guide Specification for Water/Foam Type Aircraft Fire and Rescue Trucks* (5-26-72) (Consolidated reprint incorporates changes 1 and 2) (AAS-100). Assists airport management in the development of local procurement specifications.

150/5220-14A, *Airport Fire and Rescue Vehicle Specification Guide* (2-25-85) (AAS-100). Assists airport management in the development of local procurement specifications.

150/5230-4, *Aircraft Fuel Storage, Handling, and Dispensing on Airports* (8-27-82) (AAS-300). Provides information on aviation fuel deliveries to airport storage and the handling, cleaning, and dispensing of fuel into aircraft.

150/5230-4, Chg. 1 (2-20-86).

150/5230-4, Chg. 2 (7-1-87).

150/5280-1, *Airport Operations Manual* (6-16-72) (AAS-310). Sets forth guidelines to assist airport operators in developing an Airport Operations Manual in compliance with the requirements of FAR Part 139.

150/5280-1, Chg. 1 (3-24-81).

150/5280-3, *Fire Fighting Exemptions Under the 1976 Amendment to the Federal Aviation Act* (2-4-77) (AAS-100). Outlines the type of information that can be used as justification in supporting petitions for exemption from a portion or all of the fire fighting and rescue requirements of Part 139.

150/5325-5C, *Aircraft Data* (6-29-87) (AAS-100). Presents a listing of principal aircraft weights and dimensions which affect airport facility design. It is to be used for guidance in airport development. Data presented are for common civil aircraft and those military aircraft which frequently utilize civil facilities.

150/5340-1E, *Marking of Paved Areas on Airports* (11-4-80) (AAS-200). Describes standards for marking paved runways, taxiways, closed and/or hazardous areas on airports.

150/5340-18B, *Standards for Airport Sign Systems* (8-21-84) (AAS-200). Contains the Federal Aviation Administration standards for use on airports.

150/5355-1A, *International Signs to Facilitate Passengers Using Airports* (11-3-71) (AAS-100). Informs airport authorities of the desirability to provide international signs and diagrammatic maps within terminal buildings and of the need of clearly marked road signs for airports.

150/5355-2, *Fallout Shelters in Terminal Buildings* (4-1-69) (AAS-100). Furnishes guidance for the planning and design of fallout shelters in airport terminal buildings.

150/5360-12, *Airport Signing and Graphics* (12-23-85) (AAS-110). Provides guidance on airport related signs and graphics.

150/5370-2C, *Operational Safety on Airports During Construction* (5-31-84) (AAS-300). Concerning operational safety on airports with special emphasis on safety during periods of construction activity, to assist airport operators in complying with Part 139.

150/5380-5A, *Debris Hazards at Civil Airports* (2-25-81) (AAS-100). Discusses problems of debris at airports, gives information on foreign objects, and tells how to eliminate such objects from operational areas.

F-2.2.3 United States Military Publications.

Air Force: Technical Manual 00-105E-9, *Aircraft Emergency (Fire Protection Information)*, available from HQ WR-ALC (MMEOTD), Robbins AFB, GA 31093.

Navy and Marine: NAVAIR 00-80R-14, *Aircraft Fire Fighting and Rescue Manual for US Naval and Marine Air Stations and Facilities*, available from Naval Air Technical Services Facility, 700 Robins Avenue, Philadelphia, PA 19111.

Army: *Technical Manual 5-315,* available from Superintendent of Public Documents, Public Documents Department, U.S. Government Printing Office, Washington, DC 20402.

F-2.3 Miscellaneous.

ASTM E 380, *Standard for Metric Practice*, 1993, American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

Advanced Techniques in Impact Protection and Emergency Egress from Air Transport Aircraft, R.G. Snyder Report, HEARD-AG 221, National Transportation Safety Board Accident Reports.

NFPA 403

1993 Edition

Standard for Aircraft Rescue and Fire Fighting Services at Airports

1993 Edition

This edition of NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at*

Airports, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc. at its Annual Meeting held May 24-27, 1993, in Orlando, FL. It was issued by the Standards Council on July 23, 1993, with an effective date of August 20, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 403

Committee work leading to the development of a recommended practice by the Association commenced in 1947 following a request from the Civil Aeronautics Board (U.S.A.) for information on what constituted "adequate" ground fire fighting equipment and personnel for airports served by air carrier aircraft.

NFPA Committee work continued during 1948, and in 1949 the Association adopted a tentative text at its Annual Meeting held in San Francisco, CA. In 1952 a revised text was submitted for adoption by the Association, and unanimously accepted. Since its original adoption, this text has been revised periodically with editions issued in 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1965, 1966, 1967, 1970, 1971, 1972, 1973, 1974, 1975, and 1978.

The 1988 edition comprised a complete revision to the text of the document to make it a standard and to segregate mandatory requirements from advisory material. Prior to the 1988 edition, all editions were recommended practices.

A Standing Subcommittee responsible for revising this standard was appointed by the Standards Council. This Standing Subcommittee was dissolved in 1992 with a change to the *Regulations Governing Committee Projects*. The work of revising this standard was continued by a Task Group appointed by the chairman. The following is a list of the members of the Task Group:

Task Group on Aircraft Rescue and Fire Fighting Services at Airports

Paul R. Robinson, Kennesaw, GA, Rep. Air Line Pilots Assn., Chair; Brian Boucher, Canadian Air Line Pilots Assn., Ontario, Canada; Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA; William M. Carey, Underwriters Laboratories Inc., IL; Bob Casey, BDM International, VA; Robert L. Darwin, Dept. of the Navy, DC; B. V. Hewes, Airport Safety Services, GA; William D. Killen, Naval Facilities Engr. Command (18-F), VA; Joan M. Leedy, 3M Company, MN; Robert J. Manley, Int'l Federation of Airline Pilots, WA; Bertrand F. Ruggles, FAA Dept. of Transportation, DC; Mark T. Conroy, NFPA Staff Liaison.

This edition is a partial revision.

Technical Committee on Aircraft Rescue and Fire Fighting

John F. Rooney, *Chair*

Tucson, AZ

James F. O'Regan, *Vice Chair*
Westboro, MA

Edward B. (Ned) Aksim, Chubb Nat'l Foam, PA

Brian Boucher, Canadian Air Line Pilots Assn., Ontario, Canada
Rep. Canadian Air Line Pilots Assn.

Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA

Robert L. Darwin, Dept. of the Navy - Fire Protection Div., DC

Robert J. Donahue, Massport, MA

B. V. Hewes, Airport Safety Services, GA

Paul O. Huston, Amerex Corp., AL
Rep. Fire Equipment Mfrs. Assn., Inc.

L. M. Krasner, Factory Mutual Research Corp., MA

Dan Lanzdorf, Oshkosh Truck Corp., WI

Thomas J. Lett, Albuquerque Fire & Safety Assoc. Inc., NM
Rep. NFPA Fire Service Section

D. Robin Maryon, Simon Gloster Saro Ltd., UK

John J. O'Sullivan, British Airways, UK

Davis R. Parsons, Los Angeles City Fire Dept., CA

Gaetan Perron, Dept. of Nat'l Defence, Ontario, Canada

Robert E. Reyff, U.S. Air Force, FL

Paul R. Robinson, Kennesaw, GA
Rep. Air Line Pilots Assn.

Bertrand F. Ruggles, FAA Dept. of Transportation, DC

Joseph L. Scheffey, Hughes Assoc. Inc., MD

John M. Schuster, 3M Co., MN

John X. Stefanki, John X. Stefanki, Inc., CA

William J. Wenzel, Voorheesville, NY
Rep. Walter Truck Corp.

Ronald O. Wikander, Lockheed Aeronautical Systems Co., GA

Larry E. Williams, Williams Training Assoc., AR

Richard Winnie, Emergency One, Inc., FL

Joseph A. Wright, DOT/FAA Technical Center, NJ
Rep. Atlantic City Int'l Airport, NJ

William E. Moore, U.S. Federal Aviation Admin., CO
(Alt. to B. F. Ruggles)

Bruce A. Warner, ICI Americas Inc., DE
(Alt. to P. O. Huston)

William S. Weeks, Air Line Pilots Assn., NC
(Alt. to P. R. Robinson)

Nonvoting

Bernard Brown, Civil Aviation Authority, UK

John E. Lodge, Lodge Fire Protection Consultancy Ltd., UK
(Member Emeritus)

Edward F. Mudrowsky, Nat'l Transportation Safety Board, DC

Committee Scope: This Committee shall have primary responsibility for the criteria for aircraft rescue and fire fighting services and equipment, procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. This Committee shall also develop aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 403

Standard for Aircraft Rescue and Fire Fighting Services at Airports

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 8 and Appendix B.

Chapter 1 Administration

1-1 Scope.

This standard contains the minimum requirements for aircraft rescue and fire fighting (ARFF) services at airports. Requirements for other airport fire protection services are not covered in this document.

1-2 Purpose.

1-2.1

This standard is prepared for the use and guidance of those charged with providing and maintaining aircraft rescue and fire fighting services at airports.

1-2.2

The principal objective of a rescue and fire fighting service is to save lives. For this reason, the provision of means of dealing with an aircraft accident or incident occurring at, or in the immediate vicinity of, an airport assumes primary importance because it is within this area that there are the greatest opportunities of saving lives. This must assume at all times the possibility of, and need for, extinguishing a fire that may occur either immediately following an aircraft accident or incident, or at any time during rescue operations.

1-2.3

The most important factors bearing on effective rescue in a survivable aircraft accident are: the training received, the effectiveness of the equipment, and the speed with which personnel and equipment designated for rescue and fire fighting purposes can be put to use.

1-3 Definitions.

For the purpose of this standard, the following terms shall have the meanings given below.

ARFF Personnel. Personnel actively engaged in the pursuit of rescue and fire fighting at the scene of an airport incident.

Actual Response Time. The total period of time measured from the time of an alarm until the first ARFF vehicle arrives at the scene of an aircraft accident and is in position to apply agent.

Aircraft Accident. An occurrence associated with the operation of an aircraft that takes place between the time any person boards the aircraft with the intention of flight and until all such persons have disembarked and in which any person suffers death or serious injury or in which the aircraft receives substantial damage.

Aircraft Fire Fighting. The control or extinguishment of fire adjacent to or involving an aircraft following ground accidents/incidents. Aircraft fire fighting does not include the control or extinguishment of airborne fires in aircraft.

Aircraft Incident. An occurrence, other than an accident, associated with the operation of an aircraft, that affects or could affect continued safe operation if not corrected. An incident does not result in serious injury to persons or substantial damage to the aircraft.

Aircraft Rescue. The fire fighting action taken to prevent, control, or extinguish fire involving, or adjacent to, an aircraft for the purpose of providing maximum fuselage integrity and escape area for its occupants. Rescue and fire fighting personnel, to the extent possible, will assist in evacuation of the aircraft using normal and emergency means of egress. Additionally, rescue and fire fighting personnel will, by whatever means necessary, and to the extent possible, enter the aircraft and provide all possible assistance in the evacuation of the occupants.

Airport Air Traffic Control. A service established to provide air and ground traffic control for airports.

Airport Fire Chief. The individual normally having operational control over the airport's rescue and fire fighting personnel and equipment, or a designated appointee.

Airport Fire Department Personnel. Personnel under the operational jurisdiction of the chief of the airport fire department assigned to aircraft rescue and fire fighting.

Airport Manager. The individual having managerial responsibility for the operation and safety of an airport. The manager may have administrative control over aircraft rescue and fire fighting services, but normally does not exercise authority over operational fire and rescue matters.

Approved.* Acceptable to the "authority having jurisdiction."

Authority Having Jurisdiction.* The "authority having jurisdiction" is the organization, office or individual responsible for "approving" equipment, an installation or a procedure.

Critical Rescue and Fire Fighting Access Area. The rectangular area surrounding a runway within which aircraft movements can be expected to occur on airports. Its width extends 500 ft (150 m) from each side of the runway centerline, and its length is 3,300 ft (1,000 m) beyond each runway threshold.

Fixed Base Operator (FBO). An enterprise based on an airport that provides storage, maintenance, or service for aircraft operators.

Flight Service Station (FSS). An air traffic facility that briefs pilots, processes, and monitors flight plans and provides in-flight advisories.

Foam. An aggregation of small bubbles used to form an air-excluding, vapor-suppressing blanket over the surface of a flammable liquid fuel.

Foam, Alcohol-Resistant. Used for fighting fires involving water-soluble materials or fuels that are destructive to other types of foam. Some alcohol-resistant foams may be capable of forming a vapor-suppressing, aqueous film on the surface of hydrocarbon fuels.

Foam, Aqueous Film Forming (AFFF). A concentrated aqueous solution of one or more hydrocarbon and/or fluorochemical surfactants that forms a foam capable of producing a vapor-suppressing, aqueous film on the surface of hydrocarbon fuels. The foam produced from AFFF concentrates is dry chemical compatible and is therefore suitable for use in combination with that agent.

Foam Concentrate. A concentrated liquid foaming agent that is mixed with water and air in designated proportions to form foam.

Foam, Film Forming Fluoroprotein (FFFP). A protein-based foam concentrate incorporating fluorinated surfactants that forms a foam capable of producing a vapor-suppressing, aqueous film on the surface of hydrocarbon fuels. This foam may show an acceptable level of compatibility to dry chemicals and may be suitable for use with those agents.

Foam, Fluoroprotein (FP). A protein-based foam concentrate with added fluorochemical surfactants that forms a foam showing a measurable degree of compatibility with dry chemical extinguishing agents and an increase in tolerance to contamination by fuel.

Foam, Protein (P). A protein-based foam concentrate that is stabilized with metal salts to make a fire-resistant foam blanket.

Foam Solution. The solution that results when foam concentrate and water are mixed in designated proportions prior to aerating to form foam.

Fuselage. The main body of an aircraft.

International Civil Aviation Organization (ICAO). An international body charged with matters dealing with the development, coordination, and preservation of international civil aviation.

May. This term is used to state a permissive use, or an alternative method to a specified requirement.

Movement Area. Those parts of the airport used for taxiing, takeoff, and landing of aircraft, exclusive of parking areas.

Mutual Aid. Reciprocal assistance by emergency services under a prearranged plan.

Rapid Response Area (RRA).* A rectangle that includes the runway and the surrounding area extending to but not beyond the airport property line. Its width extends 500 ft (152 m) outward from each side of the runway centerline, and its length is 1650 ft (500 m) beyond each runway end. (*See Figure A-1-3.*)

Shall. Indicates a mandatory requirement.

Should. This term, as used in the Appendix, indicates a recommendation or that which is advised but not required.

Table-Top Training. A workshop-style of training involving a realistic emergency scenario and requiring problem-solving participation by personnel responsible for management and support at emergencies.

Chapter 2 Organization of Aircraft Rescue and Fire Fighting (ARFF) Services

2-1 Administrative Responsibilities.

2-1.1

The airport management shall be responsible for the provisions of ARFF services on the airport.

2-1.2

Regardless of the functional control of ARFF services on the airport, a high degree of mutual aid shall be prearranged between such services on airports and any off-airport fire or rescue agencies serving the environs of the airport.

2-1.3

The aircraft owner/operator shall ensure that provisions have been made for the security of the aircraft until such time as a legally appointed accident investigation authority assumes responsibility. The airport manager or authority having jurisdiction may assist or assume the authority in the absence of the aircraft owner/operator.

2-2 Emergency Preparedness.

2-2.1*

Airports shall prepare a disaster plan, taking into account airport emergency services and mutual aid services available in the event of a disaster.

2-2.2

Full-scale airport disaster plans shall be tested at least every other year. In addition, table-top training shall be conducted at least annually.

2-3 Categorizing Airports for ARFF Services.

2-3.1*

The authority having jurisdiction shall determine the level of protection based on the largest aircraft scheduled into the airport. Airports shall be categorized for ARFF services in accordance with Table 2-3.1.

Table 2-3.1 Airport Category by Overall Length and Width of Aircraft

Airport Category U.S.			Overall Length of Aircraft up to but Not Including		Maximum Exterior Width up to but Not Including	
NFPA	FAA	ICAO	Feet	Meters	Feet	Meters
1	GA-1	1	30	9	6.6	2
2	GA-1	2	39	12	6.6	2
3	GA-2	3	59	18	9.8	3
4	A	4	78	24	13.0	4
5	A	5	90	28	13.0	4
6	B	6	126	39	16.4	5
7	C	7	160	49	16.4	5
8	D	8	200	61	23.0	7
9	E	9	250	76	23.0	7
10			300	91	25.0	8

2-3.2*

The airport category for a given aircraft shall be based on the overall length of the aircraft or the fuselage width. If, after selecting the category appropriate to the aircraft's overall length, the aircraft's fuselage width is greater than the maximum width given in Table 2-3.1, then the category for that aircraft shall be the next one higher.

Chapter 3 Extinguishing Agents

3-1 Primary Agents.

3-1.1*

One or more of the following types of primary agents shall be used for aircraft fire fighting involving hydrocarbon fuels.

(a) Aqueous film forming foams (AFFF)

(b) Fluoroprotein foam (FP) or film forming fluoroprotein foam (FFFP)

(c) Protein foam (P).

3-1.2*

All foam concentrates shall be approved or listed based on the following performance test requirements.

3-1.2.1* Aqueous film forming foam agents shall meet the applicable fire extinguishment and burnback performance requirements for the 50 sq ft (4.6 m^2) fire test in accordance with Military Specification MIL-F-24385.

3-1.2.2 Film forming fluoroprotein foam (FFFP), protein foam (P), and fluoroprotein foam (FP) agents shall meet the applicable fire extinguishment and burnback performance requirements of Underwriters Laboratories Inc. Standard UL-162 (Type 3 application).

3-1.2.3 Any primary agent used at the minimum quantities and discharge rates for AFFF in Tables 3-3.1(a) and 3-3.1(b) shall meet the applicable fire extinguishment and burnback performance requirements of 3-1.2.1.

3-2 Complementary Agents.

Either one or both of the following complementary agents shall be available for aircraft fire fighting:

(a)* Potassium bicarbonate dry chemical

(b)* Halon 1211.

3-3 Quantity of Agents.

3-3.1

The minimum amounts of water for foam production, and the minimum amounts of complementary agents necessary shall be as specified in Tables 3-3.1(a) or 3-3.1(b) based on the system of categorizing airports listed in Table 2-3.1.

Table 3-3.1(a) Minimum Extinguishing Agent Quantities and Discharge Rates

	AFFF		Fluoroprotein or Film Forming Fluoroprotein Foam		Protein Foam		Potassium Bicarbonate		Halon 1211

3-3.2

Sufficient foam concentrate shall be provided to proportion, at the prescribed percentage of foam concentrate to water, into double the quantity of water specified in Table 3-3.1(a) or 3-3.1(b).

3-3.3*

Water equal to 100 percent of that required by 3-3.1 shall be available to replenish the primary fire fighting vehicle(s).

3-4 Compatibility of Agents.

3-4.1*

Chemical compatibility shall be ensured between foam and complementary agents where used simultaneously or consecutively.

3-5 Combustible Metal Agents.

3-5.1*

Extinguishing agents for combustible metal fires shall be provided in portable fire extinguishers that are rated for Class D fires in accordance with Section 1-4 of NFPA 10, *Standard for Portable Fire Extinguishers*. At least one nominal 20-lb (9.1-kg) extinguisher shall be carried on each vehicle specified in Table 4-1.1.

3-6 Agent Discharge Capabilities.

3-6.1

The discharge capabilities of extinguishing agents shall not be less than the rates specified in Table 3-3.1(a) or 3-3.1(b), and Sections 2-15.6, 3-13.9, and 4-13.9, as applicable, of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*.

3-6.2

Other than at Category 1, 2, and 3 airports, where the handline nozzles can be used, the discharge rates for foam shall be met using only the ARFF vehicle turret(s).

Chapter 4 Aircraft Rescue and Fire Fighting (ARFF) Vehicles

4-1 Rescue and Fire Fighting Vehicles.

4-1.1*

The minimum number of ARFF vehicles provided at each airport shall be as specified in Table 4-1.1.

Table 4-1.1 Minimum Number of ARFF Vehicles

Airport Category	1	2	3	4	5	6	7	8	9	10
Number of Vehicles	1	1	1	1	2	2	3	3	4	4

4-1.2*

ARFF vehicles shall be constructed to comply with the provisions of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, and Table 3-3.1(a) or 3-3.1(b).

4-1.3

Consideration shall be given to the provision of an additional vehicle or vehicles in order that minimum requirements are maintained during periods when a vehicle is out of service.

4-1.4

All foam-producing ARFF vehicles shall be tested at least annually in accordance with NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

4-2* Tools and Equipment.

Vehicles shall be provided with tools and equipment to effectively support rescue and fire fighting operations.

Chapter 5 Airport Emergency Communications

5-1 Communications and Alarms.

5-1.1

Airport ARFF services communications shall have a capability that is consistent with the airport's operational needs.

5-1.2*

The operational communications system shall provide a primary and, where necessary, an alternate effective means for direct communication between the following, as applicable:

(a) The alerting authority such as the control tower or flight service station, airport manager, fixed-base operator, or airline office and the airport ARFF service;

(b) Air traffic control tower or flight service station and ARFF vehicles enroute to an aircraft emergency or at the accident/incident site;

(c) The fire department alarm room and ARFF vehicles at the accident/incident site;

(d) The airport ARFF services and appropriate mutual aid organizations located on or off the airport, including an alert procedure for all auxiliary personnel expected to participate; and

(e) The ARFF vehicles.

5-1.3

To ensure that the communications system is operational under a variety of airport emergency conditions, provisions shall be made for an emergency standby power source or alternate backup communication system.

5-1.4

A preventive maintenance program shall be carried on to keep all communications equipment in a fully serviceable condition.

5-1.5

The functional performance of all communications systems shall be tested at intervals not exceeding 24 hours.

Chapter 6 ARFF Personnel and Protective Clothing

6-1 Personnel.

6-1.1

A person shall be appointed to direct the airport ARFF services. The responsibilities of this person shall include overall administrative supervision of the organization, effective training of personnel, and operational control of emergencies involving aircraft within the airport jurisdiction.

6-1.2

During flight operations, sufficient trained personnel shall be readily available to staff the rescue and fire fighting vehicles and to perform fire fighting and rescue operations. These trained personnel shall be deployed in a way that ensures that minimum response times can be achieved and that continuous agent application at the appropriate rate can be fully maintained.

6-1.3

Responding units shall include personnel trained and equipped for cabin interior fire fighting.

6-1.4*

All ARFF personnel shall meet the requirements of NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*.

6-1.5

All ARFF and other authorized personnel shall be given suitable uniforms or identifying insignia to prevent any misunderstanding as to their right to be in the fire area or the aircraft movement area of an airport during an emergency.

6-2 Protective Clothing.

6-2.1*

Approved protective clothing and equipment including protective coat, protective trousers, helmet, gloves, and self-contained breathing apparatus (SCBA) shall be provided, maintained, and readily available for use by all ARFF personnel.

6-2.2*

SCBA for ARFF personnel shall meet the requirements of NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*.

6-2.3

Station/work uniforms worn by ARFF personnel shall meet the requirements of NFPA 1975, *Standard on Station/Work Uniforms for Fire Fighters*.

6-2.4

Other than ARFF vehicle driver/operators, all ARFF personnel engaged in any rescue or fire fighting operation shall wear complete protective clothing including SCBA and shall not remove any protective clothing or SCBA until they are in a safe area and so directed by the officer in charge.

Chapter 7 Airport Fire Station Location and Response Capability

7-1 Siting and Response.

7-1.1*

ARFF vehicles shall be garaged at one or more strategic locations as needed to meet required response times.

7-1.2*

Emergency equipment shall have immediate and direct access to critical aircraft movement areas and the capability of reaching all points within the Rapid Response Area (RRA) in the time specified. Therefore, the location of the airport fire station shall be based on minimizing response time to aircraft accident and incident high-hazard areas. Locating the airport fire station for structural fire fighting utility is of secondary importance.

7-1.3*

The demonstrated response time of the first responding vehicle to reach any point on the operational runway shall be 2 minutes or less and to any point remaining within the on-airport portion of the rapid response area shall be no more than $2^1/_2$ minutes, both in optimum conditions of visibility and surface conditions. Other ARFF vehicles necessary to achieve the agent discharge rate listed in Table 3-3.1(a) or 3-3.1(b) shall arrive at intervals not exceeding 30 seconds.

Chapter 8 Referenced Publications

8-1

The following documents or portions thereof are referenced within this standard and shall be

considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the NFPA issuance of this document.

8-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

Fire Extinguishing Agent, Aqueous Film-Forming Foam (AFFF), Liquid Concentrate, for Fresh and Sea Water, Revision F, January 7, 1992, U.S. Military Specification MIL-F-24385, Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, PA 19120.

Standard for Foam Equipment and Liquid Concentrates, 6th edition, March 7, 1989, Underwriters Laboratories Inc., Standard UL-162.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for information purposes only.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect or certify any installations, procedures, equipment, or materials nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations which is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner since jurisdictions and “approval” agencies vary as do their responsibilities. Where public safety is primary, the “authority having jurisdiction” may be a federal, state, local or other regional department or individual such as a fire chief, fire marshal, chief of a fire prevention bureau, labor department, health department, building official, electrical inspector, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the “authority having jurisdiction.” In many circumstances the property owner or his designated agent assumes the role of the “authority having jurisdiction”; at government installations, the commanding officer or departmental official may be the “authority having jurisdiction.”

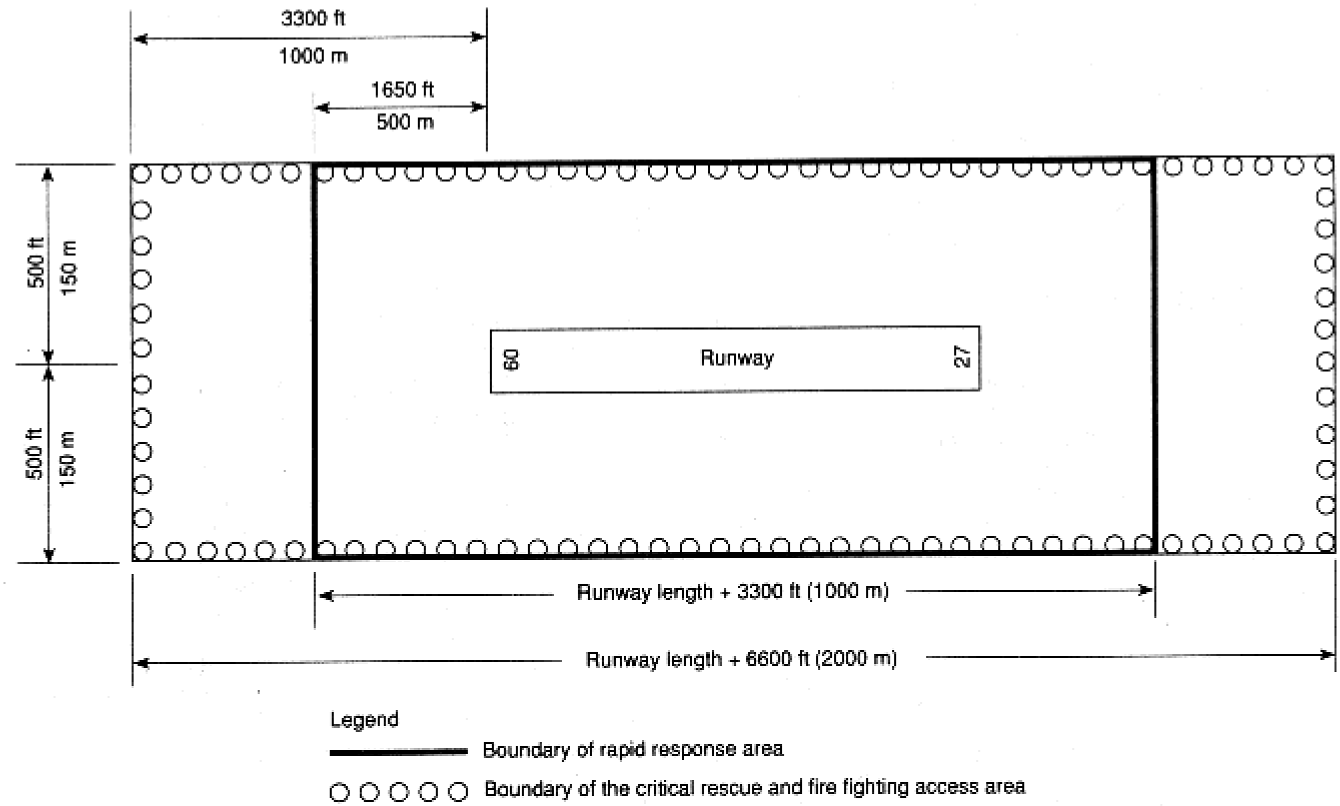

Figure A-1-3 Response and access areas.

A-1-3 Rapid Response Area (RRA).

Approximately 85 percent of the accidents as historically recorded in the CRFFAA occurred within the boundary of the RRA and response time to the on-airport portion of the RRA should meet the times specified in 7-1.3. (*See Figure A-1-3.*)

A-2-2.1

See NFPA 424M, *Manual for Airport/Community Emergency Planning*, for comprehensive guidance.

A-2-3.1 Background.

Area Concept. The first meeting of the Rescue and Fire Fighting Panel (RFFP-I) was convened by the International Civil Aviation Organization (ICAO) in Montreal, Canada, from March 10 to 20, 1970.

At that time, the method contained in Annex 14, Attachment C (5th edition) for the determination of the level of protection (agent quantities and number of vehicles) to be provided at airports for fixed wing aircraft was based on the fuel load and passenger capacity of the aircraft. As a result of correspondence exchanged among the Panel members there was general agreement that a new or revised method for specifying the quantity of extinguishing agents and rescue equipment to be provided was needed.

The Panel unanimously agreed that the concept for determining the level of protection should be the “critical area.” This was an area to be protected in any post-accident situation that would permit the safe evacuation of the aircraft occupants. The purpose of the critical area concept was not to define fire attack procedures. Instead, it was to serve as the basis for calculating the quantities of extinguishing agents necessary to achieve protection within an acceptable period of time.

The Panel also unanimously agreed that the critical area should be a rectangle having as one dimension the length of the fuselage. The logic being that passenger capacity was related to length. However, a wide division of opinion existed as to what width should be used. The RFF Panel’s report documents five proposed means of defining the width of the critical area.

It was finally agreed that there was no single system that could be used to express the area to be protected for all sizes of aircraft. In the end, the Panel agreed that the critical area should be a rectangle, having as one dimension the overall length of the aircraft and as the other dimension the overall length of the aircraft for aircraft with wing spans of less than 30 m (100 ft) and to be 30 m (100 ft) for aircraft with wing spans of 30 m (100 ft) or more. A standard fuselage width of 6 m (20 ft) was assumed. Using this approach, the aircraft in service at that time were grouped into a series of eight categories. Beginning with category one, each successive category represented a logical progression in aircraft length.[1]

[1]Hewes, B. V., Chairman, “Report of the First Meeting of the ICAO Rescue and Fire Fighting Panel (RFFP-I),” March 10-20, 1970, Montreal, Canada, WP/28, Section 2.1 Area Concept, p. 2-1.

The concept of using graduated aircraft categories as a means of assessing fire protection needs has survived to the present time with only minor revisions to reflect changes in the operating aircraft fleet. This general concept has been adopted worldwide by both consensus standard writing organizations and national regulatory authorities.

By correspondence following RFFP-I, the members agreed that the use of the area concept for determining the level of fire fighting agents and equipment needed to combat an aircraft accident fire was based on the facts that:

(a) the quantity of agent necessary to control or cover the fire area could be relatively accurately determined; and

(b) the rate of application of the agents to control the fire in the most effective time period could also be determined.

Hence, when RFFP-II convened in 1972 the Panel confirmed the critical area concept where one dimension of the area would be the length of the aircraft. However, there was no consensus as to length of the other side. In addition, the Panel concluded that there was a need to distinguish between the “theoretical critical area” within which it might be necessary to control a fire and a “practical critical area” that was representative of actual aircraft accident conditions. Although the Panel had not agreed on the dimensions, it did agree that the theoretical critical area should be defined as follows:

Theoretical critical area: The theoretical area adjacent to an aircraft in which fire must be controlled for the purpose of ensuring temporary fuselage integrity and providing an escape area for its occupants.

The RFFP-II had benefit of large test fire experiments conducted by a member country aimed at estimating the size of the theoretical critical fire area.[2] That study paid particular attention to the width on each side of the fuselage, which would have to be secured to protect the aircraft's skin from melting under severe fire conditions. On the basis of the data presented in that report, the Panel agreed that the theoretical critical area should be a rectangle having as one dimension the overall length of the aircraft, and as the other dimension:

(a) for aircraft with an overall length of less than 20 m (65 ft), 12 m (40 ft) plus the width of the fuselage; and

(b) for aircraft with an overall length of 20 m (65 ft) or more, 30 m (100 ft) plus the width of the fuselage.[3]

The theoretical critical area serves only as a means for categorizing aircraft in terms of the magnitude of the potential fire hazard in which they may become involved. It is not intended to represent the average, maximum, or minimum spill fire size associated with a particular aircraft. The original formula for the maximum theoretical critical area, as presented in the RFFP-II report, was given as follows:[4]

[2]Geyer, G. B., "Evaluation of Aircraft Ground Fire Fighting Agents and Techniques," Report No. AGFSRS-71-1, Tri-Service Systems Program Office Aircraft Ground Fire Suppression and Rescue, Wright-Patterson AFB, OH 45433, February 1972. NTIS No. AD 741 881, Section VIII, p. 172ff.

[3]Harley, R. A., Chairman, "Report of the Second Meeting of the ICAO Rescue and Fire Fighting Panel (RFFP-II)," June 5-16, 1972, Montreal, Canada, Section 3.1 and 3.2, p. 3-1f.

[4]Ibid., Recommendation 3/2 Guidance Material on the Critical Area Concept, p. 3-16.

$A_T = L \times (30 + w)$ where $L > 20$ m,

or

$A_T = L \times (100 + w)$ where $L > 65$ ft, and

$A_T = L \times (12 + w)$ where $L < 20$ m,

or

$A_T = L \times (40 + w)$ where $L < 65$ ft

where

L = the overall length of the aircraft,

w = the width of the aircraft fuselage, and

A_T = the theoretical critical area (TCA).

The data analyzed by RFFP-II in its effort to respond to the issue of TCA versus practical critical area (PCA) appeared to indicate that the PCA was approximately two-thirds of the TCA. This had been verified by a study conducted by one of the member countries of actual spill fire sizes and aircraft accidents.[5] Another analysis of aircraft rescue and fire fighting operation had not included the study of the PCA as compared to the TCA.[6] However, that study did compare the actual amount of water used for foam at those accidents with the amounts recommended by RFFP-I and it was found that out of 106 accidents for which this information was available, in 99 cases or 93 percent the amounts recommended by the Panel were in excess of those required in the actual aircraft accident. In light of the above, the Panel decided to use two-thirds of the TCA as the PCA.[7] See Figure A-2-3.1(a) for a graphic display of this concept. The formula for the PCA developed by RFFP-II for fixed-wing aircraft can be expressed as:

$$PCA = (0.67) \times (TCA).$$

Control Time. After defining the critical area to be protected and developing a system of fire protection categories, RFFP-I turned its attention to the issues of discharge rates and the extinguishing agents to be applied to the critical area. The Panel concluded that fire control time and fire extinguishment time within the critical area should be considered individually and defined as follows:

Control time is the time required from the arrival of the first fire fighting vehicle to the time the initial intensity of the fire is reduced by 90 percent.

Extinguishment time is the time required from arrival of the first fire fighting vehicle to the time the fire is completely extinguished.[8]

RFFP-II confirmed these definitions and, based on an analysis of accident data furnished by member countries, it considered that the equipment and techniques to be used should be capable of controlling the fire in the PCA in 1 minute.[9] This concept not only survived to the present time, but it has, with minor revisions from time to time to update changes in the operating aircraft fleet, been adopted worldwide by both consensus standards-making organizations and national regulatory authorities.

RFFP-II was unable to identify a recommended time period for the extinguishment time. This was due to the numerous variables involved at each aircraft accident such as the size of the aircraft, area of fire, and three-dimensional fires.[9]

[6] Harley, op. cit., Section 1.2, Review of Reports, p. 1-1.

[7] Ibid., Section 3.3, Practical Critical Area, p. 3-3.

[8] Hewes, op. cit., Section 2.2, Control Time, p. 2-2.

[9] Harley, op. cit., Section 3.5, Control and Extinguishment Time, p. 3-4.

Discharge Rate. At RFFP-I, the Panel agreed that discharge rates should be designed to achieve the lowest possible fire control time that is consistent with the objective of preventing the fire from melting through the fuselage or causing an explosion of the fuel tanks. The Panel also agreed that the equipment and techniques to be used should be capable of controlling the fire in the critical area in 1 minute and of extinguishing the fire within another minute. Using available fire extinguishment test data based on protein foam, the Panel concluded that for a single agent attack an application rate of 8.2 (L/min)/m^2 (0.2 U.S. gpm/ft^2) for 2 minutes would be sufficient to meet the fire control and fire extinguishment time requirements. The Panel also agreed that when dual agent attack techniques were used (foam and dry chemical, CO_2, or a halocarbon), a reduced application rate could be used. A minimum of 6.1 (L/min)/m^2 (0.15 U.S. gpm/ft^2) was recommended.

Based on the consideration that the lighter construction of small aircraft increased their vulnerability to fire penetration, the Panel also recommended that the same discharge rates be used for small aircraft.

All of the discussions and recommendations at RFFP-I were based on the performance of protein foam only. The Panel's report recognized the existence of both fluoroprotein and aqueous film forming foams and indicated that some member countries were starting to use them. However, the Panel generally agreed that there was insufficient documentation of performance upon which to base recommendations. The report also indicated a general understanding among Panel members that the suitability of other agents and their relationship with protein foam would be considered later.[10]

At RFFP-II, the Panel confirmed the application rate for protein foam recommended by RFFP-I and agreed that an application rate of 5.3 (L/min)m^2 (0.13 U.S. gpm/ft^2) for aqueous film forming foam was suitable. The Panel could not agree on a suitable recommendation for fluoroprotein due to the wide variety of foams. However, it did recognize them as useful aircraft fuel fire fighting foams and left the application rate to the authority having jurisdiction; to be based on test data for the individual foams.[11]

Quantities of Agent to Be Provided. By multiplying the TCA corresponding to the upper limit of the airport category times the recommended protein foam application rate, times a factor of two for the recommended discharge time, RFFP-I produced a table of recommended water quantities for foam production. The table also included recommended weights for complementary agents and the recommended discharge rates for both single and dual agent attack for eight airport categories.[12]

[10]Hewes, op. cit., Section 2.3, Discharge Rate, p. 2-2.

[11]Harley, op. cit., Sections 3.6, Application Rate & 3.7 Discharge Rate, p. 3-4f.

[12]Hewes, op. cit., Section 2.4, Quantities of Agent, p. 2-3. and Table C-2, Minimum Amounts of Extinguishing Agents, p. 2-17.

At RFFP-II, the Panel agreed that when determining the amounts of extinguishing agents to be provided, the amounts required to control and to extinguish a fire should be determined separately. The quantities were named and defined as follows:

Quantity Q_1. The quantity required to obtain a 1-minute control time in the PCA.

The formula for the water required for control in the PCA (Q_1) can be expressed as:

$$Q_1 = PCA \times R \times T$$

where

PCA = the practical critical area,

R = the rate of application for the specific foam, and

T = time of application.

Quantity Q_2. The quantity required for continued control of the fire after the first minute or for complete extinguishment of the fire or for both.

The Panel concluded that the amount of water required for Q_2 could not be calculated exactly, as it depended on a number of variables. Those variables considered of primary importance by the Panel were:

(a) maximum gross weight,

(b) maximum passenger capacity,

(c) maximum fuel load, and

(d) previous experience (analysis of aircraft rescue and fire fighting operations).

These factors were used by RFFP-II to generate Q_2 values for each airport category where $Q_2 = f \times Q_1$. The values of f ranged from 3 percent for Category 1 airports through 170 percent for Category 8 airports.[13]

13Harley, op. cit., Recommendation 3/2 Guidance Material on the Critical Area Concept, p. 3-16 ff.

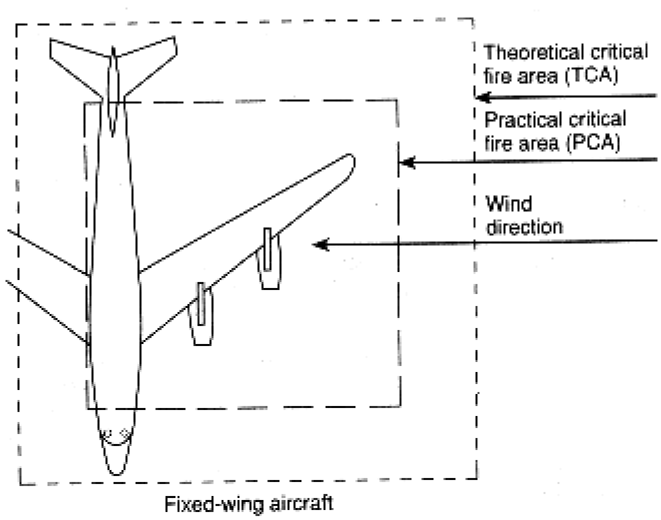

Figure A-2-3.1(a) Theoretical critical fire area (TCA) relative to practical critical fire area (PCA).

Today's Situation:

The basic concepts developed by the ICAO RFFPs are still considered valid. However, the variables mentioned above that are used to develop the f factor for Q_2 have been refined over time and are now expressed as follows:

(a) *Aircraft Size.* Aircraft size reflects the potential level of risk. This risk factor is a composite of the passenger load, the potential internal fire load, flammable liquid fuel capacity, and the fuselage length and width. Careful consideration of all these factors allows the identification of a meaningful operational objective, i.e., the area to be rendered fire-free (controlled or extinguished).

(b) *Relative Effectiveness of Agent Selected.* This is accounted for by the specific application rate identified for each of the common generic foam concentrate types.

(c) *Time Required to Achieve PCA Fire Control.* Information from reliable large-scale fire tests, empirical data from a wide variety of sources, and field experience worldwide indicates that 1 minute is both a reasonable and a necessary operational objective.

(d) *Time Required to Maintain the Controlled Area Fire-Free or to Extinguish the Fire.* An operational objective that provides a safety factor for the initial fire attack on the PCA while waiting for the arrival of backup support or to complete extinguishment of remaining fires outside the PCA.

The quantity of water for foam production required for 1 minute fire control of the PCA is still referred to as Q_1. However, data collected in the ensuing years now permits us to specify the required application rates for three generic foam types needed to extinguish fire in one square meter or one square foot of the PCA as follows:

(a) AFFF = 5.5 (L/min)/m^2 or 0.13 gpm/ft^2

(b) FP = 7.5 (L/min)/m^2 or 0.18 gpm/ft^2

(c) PF = 8.2 (L/min)/m^2 or 0.20 gpm/ft^2.

Over time the changes in aircraft size factor have required revisions to the values of both Q_1 and Q_2 and the introduction of a third component, Q_3, which make up the total quantity of water (Q) required for the production of foam.

For example, Q_1 changes as a function of the accepted foam application rates and the size of the operational aircraft common to the various airport categories. And, since Q_2 is a function of Q_1, it too is impacted by changes in aircraft size and requires revision from time to time to accurately reflect the changes in the operational aircraft fleet.

The operational significance of the components making up Q is substantial in that Q relates to both the specific quantities of fire suppression agents required to control fire in the PCA and to the requirement that the specified quantity of agent be applied to the PCA within a time frame of 1 minute. In turn, Q_2 relates to the need to have sufficient fire suppression agents available to maintain conditions that do not pose a threat to life in the PCA until such time as rescue operations are completed. The secondary role of Q_2 is to extinguish all fires in and peripheral to the PCA.

The development of the requirement for these two quantities of water is based on exterior aircraft fuel spill fire control parameters. Information from actual incidents in recent years has shown that with increased aircraft crash worthiness, water for interior fire fighting operations is also necessary. This quantity of water, called Q_3, is based on the need for hand lines to be used for interior fire fighting. Hence, the total quantity of water (Q) is now defined as follows:

$$Q = Q_1 + Q_2 + Q_3$$

where

Q_1 = water requirement for control of PCA,

Q_2 = water requirement to maintain control or extinguish the remaining fire or both, and

Q_3 = water requirement for interior fire fighting.

(*See Figure A-2-3.1(b)*.)

The method for calculating the values for each component of Q are presented below.

(1) $Q_1 = PCA \times R \times T$

where

PCA = (0.67) × TCA, TCA = L × (K + W), and L = length of aircraft;

W = width of fuselage,

R = application rate of selected agent,

T = time of application (1 minute), and

K = values shown below.

Feet	**Meters**
K = 39 where L = less than 39	K = 12 where L = less than 12
= 46 where L = 39 up to but not including 59	= 14 where L = 12 up to but not including 18
= 56 where L = 59 up to but not including 79	= 17 where L = 18 up to but not including 24
= 98 where L = 79 and over	= 30 where L = 24 and over

(2) The current values of Q_2 as a percentage of Q have been determined to be:

Airport Category	**Q_2% Q_1**	**Airport Category**	**Q_2% Q_1**
1	0	6	100
2	27	7	129
3	30	8	152
4	58	9	170
5	75	10	190

(3) The values of Q_3 are based on accepted water flow requirements for the type of fire fighting operations to be experienced when combating an interior aircraft fire. They are determined as follows:

Airport Category	**Q_3 Equals (U.S. gal)**
1	0

2	0
3	60 gpm × 5 min = 300 gal
4	60 gpm × 10 min = 600 gal
5	125 gpm × 10 min = 1250 gal
6	125 gpm × 10 min = 1250 gal
7	125 gpm × 10 min = 1250 gal
8	250 gpm × 10 min = 2500 gal
9	250 gpm × 10 min = 2500 gal
10	250 gpm × 10 min = 2500 gal

Sample Calculation Using Airport Category 4 and AFFF Foam:

$TCA = L \times (K + W)$

$= 68.5 \times (56 + 11.4) = 4617\ ft^2$

$PCA = {}^2/_3 \times TCA = {}^2/_3 \times 4617\ ft^2 = 3078\ ft^2$

$Q_1 = 0.13\ gpm/ft^2 \times 3078\ ft^2 \times 1 = 400\ gal$

$Q_2 = 58\% \times Q_1 = 0.58 \times 400 = 232\ gal$

$Q_3 = 600$

now

$Q = Q_1 + Q_2 + Q_3$

$= 400 + 232 + 600 = 1232\ gal$

or

$Q = 1200\ gal$ (rounded off)

This quantity is shown in the second column of Table 3-3.1(a).

The example is given to illustrate the logic and the factors used to arrive at the quantity of water for foam production required for an airport Category 4. For example, the aircraft length (L) and the aircraft external cabin width (W) are the midpoint length and width for Category 4.

Airport categories are used in the calculations to eliminate the need for calculating specific quantities of extinguishing agents for each type of aircraft.

Although only water is normally necessary for interior hand line attack, logistically and tactically it should be discharged as foam and is therefore added to the quantities of water necessary for foam production in Tables 3-3.1(a) and 3-3.1(b).

A-2-3.2 See Table A-2-3.2.

Table A-2-3.2 Representative Aircraft by Airport Categories

		Overall Fuselage Length		External Fuselage Width	
Airport Category	**Aircraft Type**	**feet**	**meters**	**feet**	**meters**
1	Beech Bonanza 35	26.33	8.01	3.05	1.07

A-3-1.1

Foams used for control and extinguishment of aircraft fires involving fuel spills are produced by incorporation of air into a solution of foam concentrate and water. Their characteristics, as indicated by expansion and drainage rate, are influenced by the amount of mechanical agitation to which the water, foam concentrate, and air are subjected. They extinguish fire by physically separating the fuel vapors from the heat and oxygen necessary for combustion, spreading over the surface of the fuel to effectively suppress vaporization and secure an extinguished area by protecting it from reignition. Foam, being essentially water, cools the surface of the fuel and any metal surfaces in the fuel. The solution drainage from some foams forms an aqueous film on most aviation fuels. It is advantageous for a foam blanket to reseal if disrupted, and essential that either the foam has good thermal and mechanical stability or that provision is made to renew the foam blanket from time to time during a lengthy rescue operation.

Foam liquid concentrates of different types or of different manufacturers should not be mixed unless it is first established that they are compatible. Protein and fluoroprotein foam concentrates, in particular, are generally not compatible with AFFF concentrates and should not be mixed, although foams generated separately from these concentrates are compatible and can be applied simultaneously to a fire. All foams used as primary agents are available for use at 3 percent and 6 percent concentrations, usually in either fresh or salt water, and some are for use at other concentrations such as 1 percent or 5 percent.

Foam can be produced in a number of ways. The method of foam production selected should be carefully weighed, considering the techniques best suited for the equipment concerned, the rates and patterns of discharge desired and the manpower needed to properly utilize the foam capabilities of the vehicles. The principal methods of foam production are given in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

The quality of water used in making foam can affect the foam performance. Locally available water might require adjustment of the proportioning device to achieve optimum foam quality. No corrosion inhibitors, freezing point depressants, or any other additives should be used in the water supply without prior consultation and approval of the foam concentrate manufacturer.

CAUTION: Converting aircraft crash fire fighting and rescue vehicles to use a type of foam concentrate other than that for which they were initially designed should not be accomplished without consultation with the equipment manufacturer and without a thorough flushing of the agent and the complete foam delivery system. Particular attention should be given to ensuring that the system component materials are suitable for the particular concentrate being substituted and that, where necessary, the proportioning equipment is recalibrated and reset.

CAUTION: Any salvageable aircraft that comes in contact with foam agents during fire fighting or fuel spill securing operations should be thoroughly flushed with fresh water as soon as practicable. Both the foam manufacturer and the airframe manufacturer should be contacted for any additional requirements that may be associated with specific foam agents or aircraft components.

A-3-1.2

The two test methods cited in 3-1.2 have wide application in North America but may not be recognized in other areas of the world. In particular, ICAO has developed guidance that references foam evaluation methods having significantly different test parameters such as test fuel, application rate, and extinguishment density. The intent of this standard is that primary foam agents meet minimum performance criteria. It is the intent that aqueous film forming foams achieve a level of performance consistent with the MIL-F-24385, when the lowest discharge rates/quantities in Tables 3-3.1(a) and 3-3.1(b) are used. The national (ICAO State) civil aviation authority having jurisdiction may adopt or reference standards recognized in that particular part of the world. It is incumbent on the national (ICAO State) authority to determine that alternate test methods are consistent with the minimum agent rates/quantities they have adopted. The national (ICAO State) civil aviation authority having jurisdiction should make this determination to prevent inconsistencies at the local or regional level.

A-3-1.2.1 Fresh water or sea water may be used for the fire test.

A-3-2(a) There are a number of chemical compounds offered on a proprietary basis that are referred to as dry chemical fire extinguishing agents. Historically, sodium bicarbonate-based compounds were initially so described, but in recent years, a number of other chemicals have been tested and potassium bicarbonate-based powders have proven most effective as a means of quickly extinguishing flammable liquid fires when applied with a proper technique and at an adequate rate. Potassium bicarbonate has good flooding characteristics and can penetrate to otherwise inaccessible areas. Dry chemicals, as currently used in aircraft rescue and fire fighting, can be used to extinguish three-dimensional liquid fuel or running fires where foam is present on the ground.

A-3-2(b) Halogenated extinguishing agents are hydrocarbons in which one or more hydrogen atoms have been replaced by atoms from the halogen series: fluorine, chlorine, bromine, or iodine. This substitution confers not only nonflammability but flame extinguishment properties to many of the resulting compounds. Halogenated agents are used both in portable fire extinguishers and in extinguishing systems. The three halogen elements commonly found in extinguishing agents are fluorine (F), chlorine (Cl) and bromine (Br).

The extinguishing mechanism of the halogenated agents is not clearly understood. However, there is undoubtedly a chemical reaction that interferes with the combustion processes. Halogenated agents act by chemically interrupting the continuing combination of the fuel radicals with oxygen in the flame chain reactions. This process is known as “chain breaking.”

The discharge of Halon 1211 may create hazards to personnel such as dizziness, impaired coordination, reduced visibility, and exposure to toxic decomposition products. In any proposed use of Halon 1211 where there is a possibility that people may be trapped in or enter into atmospheres made hazardous, suitable safeguards should be provided to ensure prompt evacuation of and to prevent entry into such atmospheres and also to provide means for prompt rescue of any trapped personnel. Breathing apparatus should be worn.

Halon 1211 is a liquefied gas discharged as an 85 percent liquid stream that forms a vapor cloud when in contact with the fire, which permits penetration of obstructed and inaccessible areas. Halon 1211 leaves no agent residue and is the preferred agent for aircraft tire fires, engine fires, interior aircraft fires, electrical component fires, and flightline vehicle/equipment engine fires. Halon agent is, however, included in the Montreal Protocol on Substances that Deplete the Ozone Layer, signed September 16, 1987. The protocol permits continued availability of halongenated fire extinguishing agents at reduced production levels until the year 1994. Halon use should be limited to extinguishment of unwanted fire and should not be used for routine training of personnel.

A-3-3.3

Fire fighting vehicles meeting the requirements of 3-3.2 carry a sufficient quantity of foam concentrate for one refill, therefore rapid water resupply is of prime importance. The reserve water supply may be maintained in tankers or structural equipment. Hydrants may be considered if they are adequately located. Mutual aid services can be considered for this purpose if they are capable of responding in the critical time required to maintain the fire attack.

A-3-4.1

It is important that the compatability of the foam and dry chemical agents be established if they are to be used together. Halon 1211 is compatible with all foams.

A-3-5.1

A variety of metals burn when heated to high temperatures by friction or exposure to external heat; others burn from contact with moisture or in reaction with other materials. Because accidental fires can occur during the transportation of these materials, it is important to understand the nature of the various fires and hazards involved. The most common combustible metals used in aircraft are magnesium and titanium.

The hazards involved in the control or complete extinguishment of combustible metal fires include extremely high temperatures, steam explosions, hydrogen explosions, toxic products of combustion, explosive reaction with some common extinguishing agents, breakdown of some extinguishing agents with the liberation of combustible gases or toxic products of combustion, and dangerous radiation in the case of certain nuclear materials. Some agents displace oxygen, especially in confined spaces. Therefore, extinguishing agents and methods for their specific application should be selected with care. Some combustible metal fires should not be approached without suitable self-contained breathing apparatus and protective clothing, even if the fire is small. Other combustible metal fires can be readily approached with minimum protection.

Numerous agents have been developed to extinguish combustible metal (Class D) fires, but a given agent does not necessarily control or extinguish all metal fires. Although some agents are valuable in working with several metals, other agents are useful in combating only one type of metal fire. Despite their use in industry, some of these agents provide only partial control and cannot be classified as actual extinguishing agents. Certain agents that are suitable for other classes of fires should be avoided in the case of combustible metal fires, because violent reactions can result (e.g., water on sodium; vaporizing liquids on magnesium fires).

Certain of the combustible metal extinguishing agents have been in use for years, and their success in handling metal fires has led to the terms “approved extinguishing powder” and “dry powder.” These designations have appeared in codes and other publications where it was not possible to employ the proprietary names of the powders. These terms have been accepted in describing extinguishing agents for metal fires and should not be confused with the name “dry chemical,” which normally applies to an agent suitable for use on flammable liquid (Class B) and live electrical equipment (Class C) fires.

A-4-1.1

It is desirable to have more than one vehicle available to facilitate attacking aircraft fires from more than one point or quarter, as an aid to expedite rescue, to reduce the potential seriousness of vehicle breakdown, and to minimize the “out of service” consequences when a vehicle is in need of routine maintenance or repairs. Having at least two fire fighting vehicles available is particularly important when dealing with transport-type aircraft due to the need to rapidly cover any burning fuel spill to protect the aircraft and its occupants from radiated heat during the evacuation and rescue period, and to maintain the secure area around the fuselage to permit the safe evacuation and rescue of the occupants.

A-4-1.2

The capacity of each vehicle with regard to fire fighting, rescue equipment, and staffing should be compatible with the desired performance characteristics established for vehicles in the various catagories specified in NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*. It is particularly important that the vehicle not be overloaded so as to reduce the required acceleration, top speed, or vehicle flotation below the acceptable minimums set forth in NFPA 414.

The off-pavement performance capability of each ARFF vehicle should be established by tests at each airport during the various weather and terrain conditions experienced at that airport to establish, prior to an actual emergency, the capabilities and limitations of the vehicle for off-pavement response to accident/incident locations. In addition, periodic tests should be conducted to ensure that the performance requirements of the vehicle are as originally designed, and that the skill levels of the driver/operators remain high.

Where climatic or geographic conditions exist that considerably reduce the effectiveness of conventional wheeled vehicles, it is often necessary to carry extinguishing agents in a specialized vehicle suitable for traveling the airport terrain, such as a tracked, amphibious, air-cushioned, or high-mobility wheeled vehicle. Where these difficult operational conditions exist, experts should be consulted to develop a vehicle specification that matches the vehicle's performance capabilities to the unique conditions present at the airport.

Overall vehicle dimensions should be within practical limits with regard to local highway practices, width of gates and height and weight limitations of tunnels and bridges, and other local considerations.

Simplicity of vehicle operation with emphasis on operation of the extinguishing agent discharge devices is extremely important due to the time restrictions imposed for successful aircraft rescue and fire fighting operations and the need to keep the fire fighting crew to the minimum required for safe and efficient operations. Successful control of the fire in the PCA is essential using the minimum amount of agent necessary to secure the objective. To control an aircraft fire it is necessary to apply extinguishing agents at a rate higher than the fire is capable of destroying the control effort. Hand hose lines are usually not adequate for fire involving larger types of aircraft due to their limited discharge rate and are used primarily for protection of rescue parties, maintaining control of the fire in the PCA area, and combating fires in aircraft interiors. For these reasons, turrets are needed to rapidly knock down the fire and secure the evacuation routes.

Improvements in vehicle and equipment design over recent years have increased the fire fighting efficiency of these units and have outdated older rescue and fire fighting vehicles. Before procuring any used vehicle for an airport rescue and fire fighting service, the possible savings in initial cost should be carefully weighed against the lower maintenance cost, the reduced manpower requirements, and the greater fire fighting efficiency that can be expected from new vehicles and equipment built in accordance with NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*. Secondhand vehicles might have been subjected to abusive service, components may have been overstressed, and repair parts might be impossible to obtain. Foam fire fighting equipment purchased for this service should be tested in accordance with NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

Specialized vehicles such as elevated platform devices or aerial water towers might be needed at some airports to allow fire fighters to reach elevations above the normal range of airport ARFF vehicles. Provision of escape slides or other rapid evacuation systems on these vehicles might be invaluable in effecting a rapid rescue.

All essential vehicles should be provided with two-way radio communications with air traffic control (ATC) or the airport controlling facility, e.g., air-radio, flight service station, etc.

A-4-2

The following equipment should be carried on each ARFF vehicle:

(a) One ladder of overall length appropriate to the aircraft using the airport. This ladder is to be of lightweight alloy, aluminum or magnesium, 16-in. (40.6-cm) minimum width, mounted in quick-release brackets on the apparatus and readily accessible. This ladder is not intended for evacuation use.

(b) Rapid intervention vehicles and Class 1 major fire fighting vehicles should be equipped with a ladder capable of extending to a length of at least 16 ft (4.9 m).

Class 2, 3, and 4 major fire fighting vehicles should be equipped with a ladder capable of extending to a length of at least 20 ft (6.1 m).

(c) Two portable 6-volt electric, weatherproof, hand-held lanterns having a minimum 25,000 beam candle power rating with carrying straps.

(d) One 6-lb crash axe with a serrated cutting edge and designed to prevent full penetration.

(e) One adjustable hydrant wrench capable of accommodating up to a 1.75-in. (4.4-cm) pentagon nut and up to a 1.25-in. (3.2-cm) square nut.

(f) One set of double male and double female connectors to fit each tank fill connection size provided on the vehicle. The connector material should be specified.

(g) Appropriate coupling wrenches for each size of hose carried on the vehicle.

(h) Two approved fire extinguishers having a minimum 80B:C UL rating of either dry chemical or Halon 1211. The dry chemical extinguishers should be the external propellant cartridge type.

(i) One 36-in. (91.4-cm) crowbar.

(j) One “D” handle pike pole with a shaft of fiberglass or other nonconductive material of similar density.

(k) One rubber mallet suitable for removing long-handled pipe caps.

(l) One 36-unit first-aid kit.

(m) One general-purpose cutter with capacity to cut up to 0.38 in. diameter hardened steel (Bhn 300) bolts.

(n) Two Dzus fastener keys.

(o) One tool roll to include at least the following equipment:

(1) One aircraft cable cutter, 14-in. (35.6-cm), capacity to $^{1}/_{4}$ in. (0.6 cm).

(2) One lineman’s pliers, heavy duty, 8 in. (20.3 cm) long.

(3) One grappling hook and rope sling, 40 in. (101.6 cm) long.

(4) One hacksaw frame, adjustable 8 in. to 12 in. (20.3 cm to 30.5 cm).

(5) Three hacksaw blades, 10-in. (25.4-cm) steel.

(6) Six fuel line plugs: 3 hardwood, 3 neoprene.

(7) One rescue knife with “V” blade.

(8) One vise grip wrench, 10 in. (25.4 cm) long.

(9) One metal cutting saw, 20-in. (50.8-cm) blade.

(10) Two industrial grade slot-type screwdrivers [one 4- (10.2-cm) and one 6-in. (15.2-cm) blade].

(11) Two industrial grade Phillips screwdrivers [one 4- (10.2-cm) and one 6-in. (15.2-cm) blade].

(12) One hand axe with serrated face and insulated handle.

One hydraulic rescue kit should be carried on an in-service ARFF vehicle.

A-5-1.2

At those locations where the primary alerting authority (such as a control tower) is not operational during all the hours that the airport is open to aircraft traffic, a secondary alerting authority should be designated and trained. Appropriate communications and alarm control devices should be available at the secondary alerting authority’s operating location and be operational during all times that the primary alerting authority is not available.

At those locations where a city/town/county off-airport fire department furnishes the airport rescue and fire fighting personnel, and the alerting/dispatch of those personnel for airport emergencies is handled by an emergency direct-line telephone between the airport alerting authority and the off-airport alarm room, the airport fire station alarm(s) should ring upon activation of the direct emergency line. If possible, this type of “third party” dispatching of airport fire fighting and rescue services should be avoided.

Because the majority of the calls for aircraft ARFF services are initiated by or first received by air traffic controllers, the airport fire department alarm room and the control tower, the flight service station or other air traffic control point should be linked by two-way radio and direct-line telephone to enhance the response time of the fire and rescue crews.

The emergency direct-line telephone should not pass through any intermediate automated switchboard or operator that could subject the alert calls to delays.

The tone of the emergency telephone bell (or buzzer) should be distinctly different from all other communications signaling devices within hearing of personnel in the alarm room, on the apparatus floor, or in living quarters as applicable.

Protection against delays due to telephone bell/buzzer failure should be provided by use of redundant warning lights activated by the same input signal as the telephone ringer. The lights should be strategically located throughout the alarm room, the apparatus floor, and living space as dictated by the fire station design and the normal activities of the fire and rescue service personnel.

The fire station alarm should be linked to the emergency telephone so that a call on the emergency telephone circuit simultaneously actuates the audible alarm throughout the fire station.

Consideration should be given to having the alarm circuitry open the vehicle bay doors in the fire station upon sounding the alarm. However, some climatic conditions can make this impractical, or noise when doors are opened can interfere with hearing the dispatch.

The notification of all units designated to respond to an aircraft emergency on a large airport should be done through the use of a “conference” circuit that allows simultaneous notification. This “conference” circuit should include, as appropriate, the following units or offices:

(a) Control tower, flight service station, or other control point;

(b) Rescue and fire fighting;

(c) Airport police;

(d) Airport management;

(e) Airline station manager(s) as appropriate;

(f) Military units (joint-use airports); and

(g) Other authorities on or off the airport as required by the airport's emergency plan.

At airports with several air carriers, the notification of the appropriate station manager might be accomplished more effectively by the use of individual paging devices.

Fire stations where personnel are normally present for duty, but may be preoccupied with "housekeeping" or training duties, should be equipped with a public address system. This is particularly important in fire stations where the alarm room, training room, and living quarters are physically separated from the apparatus floor. Such a system should significantly enhance response time and fire fighter effectiveness by providing vital details of the emergency to each fire fighter during response, e.g., location of accident or incident site, type of aircraft, number of persons involved, aircraft fuel load, preferred vehicle routing, etc.

At airports with a main fire station and one or more substations, an interconnected public address system should be provided.

At airports employing dual function personnel or auxiliary fire fighters, an audible alarm should be installed in all areas where auxiliary fire fighting personnel are employed to notify them of any emergency recall for fire and rescue duties. It should be a distinctly different sound and loud enough to be clearly heard above the normal noise level.

At airports equipped with ground-to-air radio, the person authorized to receive in-flight emergency messages should be provided with a device for actuating these alarms.

Alarm actuating stations should be provided near hangars, shops, fueling stations, and aircraft parking areas.

Individual paging devices, although potentially more expensive, can be used. This method has the advantage of notifying those persons with assigned rescue fire fighting duties.

A reliable voice communications capability should be available between the airport rescue and fire fighting service and any off-airport organizations expected to participate in the airport-community mutual-aid plan.

Each emergency response vehicle on an airport should be equipped with two-way voice radio communication between the alerting authority, all other aircraft rescue and fire fighting vehicles, and the designated command post.

On airports with a control tower the communications channel between vehicles and the tower should be on the assigned standard ground control frequency, or as designated in the Airport Emergency Plan Letter of Agreement between airport management, the control tower and/or flight service station.

On airports without a control tower but having another means of ground-to-air communications, the rescue and fire fighting vehicles should be equipped to communicate on a frequency common with the control point.

Where practicable, the two-way radio capability on the airport fire and rescue service vehicle(s) should not be “tied into” Public Service frequencies (City-County or Airport Maintenance). This independent communications network will help ensure interruption-free communication in an emergency situation.

On-scene commanders (OSC) should have a communication capability while outside or remote from their vehicle communications systems. Portable radios can be used by the OSC for direct contact with the airport fire services and air traffic control services.

A reliable form of communication should be provided between the aircraft commander, the OSC, ARFF services, and the airport alerting authority to preclude unnecessary aircraft emergency evacuation or misunderstandings.

Direct communications can be established between the flight deck and the OSC or ARFF personnel by use of flight-deck-to-ground lines. Normally this communication capability results from the use of a ground service headset that is plugged into a wheel well or nose interphone jack.

The airport rescue and fire fighting service alarm room should be designed and operated in such a manner that an alarm can be received, evaluated, and acted upon with a minimum of activity or consultation.

For an alarm room to serve its intended function, provisions should be made to ensure that all personnel assigned to alarm room duties are trained in communication equipment operations, proper communication procedures, and local emergency plan implementation procedures.

A-6-1.4

A carefully organized training program should be developed to meet the qualification requirements of NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*. The following guidelines are offered for structuring such a program.

The objectives of a training program for aircraft rescue and fire fighting personnel at airports should be to:

(a) Teach the safe application of recognized practices and procedures.

(b) Develop and maintain the confidence and competency of all personnel assigned ARFF duties;

(c) Instill the concept of professionalism;

(d) Serve as a source of accurate technical information whereby the lessons gained from aircraft accidents or incidents are properly analyzed and the information disseminated to others concerned with ARFF operations; and

(e) Enhance the esprit de corps of aircraft rescue and fire fighting personnel by creating an appreciative awareness of the hazards and dangers they may face in carrying out ARFF operations.

Control and Planning.

The complete training and educational program for aircraft rescue and fire fighting personnel should be under the direction of one officer of the airport fire department for planning, development, and supervision.

Resources for Training.

Training material resources for a training program oriented specifically to meet the needs of aircraft rescue and fire fighting personnel should take into consideration providing suitable amounts of extinguishing agents, such as foam concentrate, dry chemical, and Halon 1211; and fuel for training fires.

Phases of Training.

Training of aircraft rescue and fire fighting personnel should include seven phases. Training in all phases should be conducted for support personnel used as auxiliary fire fighters and for full-time aircraft rescue and fire fighting personnel. Because of the factor of time availability for schooling, the depth into which subjects are covered will vary, but the scope should not be reduced for auxiliary fire fighters.

Indoctrination.

Indoctrination training should include the following:

(a) The rules and regulations applicable to ARFF services;

(b) Knowledge of the basic duties and responsibilities and those of co-workers;

(c) Emergency response procedures;

(d) The command structures for administration and operations; and

(e) The importance of practicing occupational safety.

Operating ARFF Equipment.

All aircraft rescue and fire fighting personnel should be capable of effectively handling fire and rescue equipment under varied conditions of terrain and weather. The aim of training should be to ensure that every fire fighter is so well versed in handling all types of appliances and tools used in ARFF operations that under stressful conditions individual fire fighters can take effective action without the need for specific direction. Among the items that should be covered are:

(a) Complete knowledge of each tool and piece of equipment;

(b) The location of each piece of equipment and tool carried on each vehicle;

(c) The method of using each piece of equipment and tool, with emphasis on personal safety factors;

(d) Special handling precautions for the use of power tools;

(e) Knowledge of, and training in, the use of breathing apparatus and other protective equipment;

(f) The techniques employed in utilizing the available communication equipment;

(g) Knowledge of the apparatus, its built-in equipment, including the pump and its performance capabilities, the agents carried and their delivery systems;

(h) Actual operation of all vehicle controls and behind-the-wheel driver training under circumstances including negotiating obstacles and muddy or snow-covered soil conditions. This is done to provide a degree of assurance that the vehicle will not get bogged down or damaged during emergencies.

(i) Knowledge of departmental policies on positioning of apparatus for tactical service at accidents/incidents under the variety of possible conditions to be encountered; and

(j) Recordkeeping to document the efficiency and effectiveness of the various vehicles utilized by the airport fire department.

Fire Behavior and Fire Suppression.

Aircraft rescue and fire fighting personnel should possess a sound knowledge of fire behavior.

Instruction in this phase should include:

(a) The principles of combustion, with emphasis on the types of aircraft fuels;

(b) How fire propagates through the effects of heat conduction, convection, and radiation;

(c) The influence of fuel distribution on heat production;

(d) The principles of fire suppression by the various types of agents utilized in aircraft rescue and fire fighting operations;

(e) Live fire exercises that include but are not limited to exterior fuel fires, interior fires, engine fires, wheel fires, and fires involving on-board auxiliary power units; and

(f) The effects of heat exposure on individuals.

Training should be given covering the advantages and disadvantages of each fire extinguishing agent employed. Every opportunity should be taken to use the agents on realistic training fires. Each routine equipment test should be used as a training exercise to provide experience in the proper handling of the equipment, and to establish the proper technique of application of each agent available.

Rescue and Fire Fighting Procedure.

Care should be taken to ensure that aircraft rescue and fire fighting personnel fully understand that to achieve the objective of safeguarding the lives of those involved in an aircraft accident requires that fire in the practical critical area be controlled quickly and that this area be kept secure. Strict discipline should be maintained to ensure that fire suppression agents are not expended on fire outside the PCA until it is positively established that the immediate and long-term security of the PCA will not be jeopardized.

Personnel should be given thorough instructions in the following subject areas:

(a) The standard operating procedures (SOP) to be expected from the aircraft crew members under specified circumstances;

(b) The locations within aircraft where victim concentration may be anticipated under accident conditions of various types;

(c) Behavior patterns of individuals involved in major disasters;

(d) Means of preventing or minimizing panic;

(e) Means of gaining entry through normal aircraft openings;

(f) Locations most suitable for forcible entry into the aircraft;

(g) Requirements of setting up triage and treatment areas that should be part of the Airport/Community Emergency Plan (*see NFPA 424M, Manual for Airport/Community Emergency Planning*); and

(h) Methods of carrying injured persons (one-person and by teams).

Familiarization with Local Terrain.

A thorough knowledge of the terrain of the airport and its immediate vicinity is essential. The existence of any areas that may from time to time become impassable because of weather or other conditions (tides, growth of brush, etc.) should be known to all crew members. Training should include actual ARFF vehicle operations over primary and secondary travel routes on the airport and runway overrun areas. Familiarization with areas outside the airport boundary to which the on-airport ARFF equipment might be authorized to respond can be accomplished with other vehicles. Personnel should also receive training during periods of diminished visibility.

The instruction program should include:

(a) Locations of obstacles both temporary and permanent;

(b) Locations of exit points (gates and/or frangible sections) in the security fence;

(c) Location of rendezvous points for mutual-aid apparatus as planned in the airport/community emergency plan;

(d) Areas that might become impassable in inclement weather;

(e) Availability of helicopters, boats, swamp buggies, air-cushion vehicles or other off-road conveyances; and

(f) The operation of each ARFF vehicle and its capability to negotiate the existing terrain under the various conditions that may be anticipated.

Aircraft Familiarization Training.

Aircraft rescue and fire fighting personnel should be familiar with:

(a) Locations of phone jacks on different types of aircraft;

(b) The availability and method of operation of aircraft escape devices;

(c) The location of aircraft batteries, and means of disconnect;

(d) The amount and type of aircraft fuel carried and the fuel storage locations in each aircraft;

(e) The location and quantity of oxygen carried;

(f) Access to wheel wells, engine accessory compartments, and other areas of critical concern; and

(g) The fire behavior characteristics and locations in the aircraft of combustible metals (magnesium, titanium), plastics (cabin liners, seating), combustible insulation (for electrical wiring and sound deadening), hydraulic fluids, lubricating oil, rubber, and similar combustibles and flammable materials.

Emergency Medical Training.

Every member of the airport ARFF services should be given initial and recurrent training in emergency medical procedures.

A-6-2.1

Although NFPA 1971, *Standard on Protective Clothing for Structural Fire Fighting*; NFPA 1972, *Standard on Helmets for Structural Fire Fighting*; and NFPA 1973, *Standard on Gloves for Structural Fire Fighting*, do not apply to ARFF protective clothing, ARFF protective clothing should at least meet the minimum requirements of these standards. Guidance and proximity of protective clothing can be found in FAA Advisory Circular 150/5210-14, dated 12 March 1986.

Fire entry suits are not recommended for civil airport application. Rapid fire control afforded by present fire fighting equipment and short times for survival without fire control make the fire entry suit unnecessary and inappropriate.

A-6-2.2

Tests have shown that many toxic gases are produced when aircraft cabin interior finish materials are burned or charred. These gases include carbon monoxide, hydrogen chloride, chlorine, hydrogen cyanide and other cyanogen components, and carbonyl chloride (phosgene). A principal cause of difficulty lies in the fact that the supply of breathing air is greatly reduced by combustion of these cabin finish materials. It is, therefore, necessary that ARFF personnel who enter or operate in the vicinity of an aircraft during the fire sequence be equipped with self-contained breathing equipment. Helmets or hoods should be designed to accommodate the SCBA facepiece without interference; most existing proximity hoods do not have this provision.

A-7-1.1

Factors that influence response time include:

(a) The means of notification of the ARFF force;

(b) The completeness of the information in the activation message;

(c) The location of the fire station;

(d) The acceleration, top speed, on-road handling, and off-road mobility characteristics of the vehicles;

(e) The degree of preparatory training;

(f) The provision of emergency access roads; and

(g) Climatic conditions.

A-7-1.2

The geographical center of an airport might not be the best location for siting the airport fire station. Before selecting the actual location, time trials should be run to determine the optimum location that ensures the quickest response to all potential accident sites. Also, an evaluation should be placed on present and future usage of the airport movement areas to ensure proper selection of the fire station site. [*See Figures A-7-1.2(a) and (b)*.]

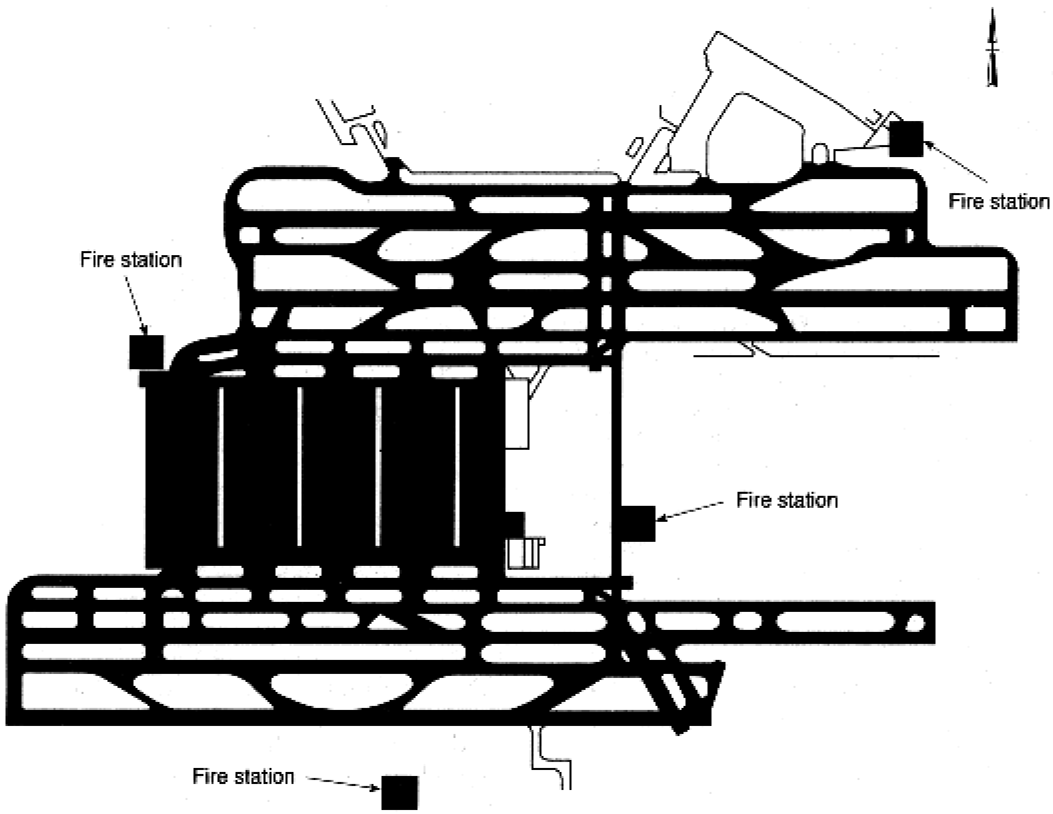

Figure A-7-1.2(a) Example of category 9 airport fire station locations.

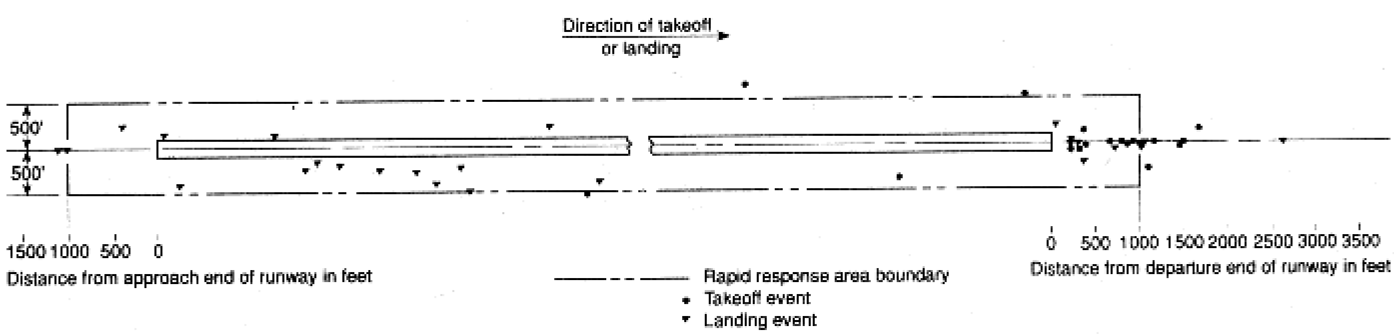

Figure A-7-1.2(b) Rapid response area (RRA) boundary.

Care should be taken to ensure that access to or from the airport fire station cannot and will not be blocked by taxiing or parked aircraft or vehicular traffic.

Airport fire stations located close to taxiways and runways or adjacent to flight patterns should have soundproof training rooms, living quarters, and an alarm room. The high noise level of turbine engines can cause damage to hearing; accordingly, at airports handling turbine-powered aircraft, fire fighters on duty outside of soundproofed areas should be provided with aural protection. Where high noise levels are encountered it might be necessary to supplement audible signals with visual signals, such as flashing lights, to alert fire fighters.

Where airport response plans call for response outside the airport fences, suitable exits should be provided around the perimeter of the airport for ARFF vehicles. Particular attention should be given to the provision of ready access to the RRA and CRFFAA. The critical rescue and fire fighting access area (CRFFAA) is the rectangular area surrounding any given runway. Its width extends 500 ft (150 m) outward from each side of the runway centerline, and its length is 3,300 ft (1000 m) beyond each runway end. This is the area where accidents historically have occurred. [*See Figure A-7-1.2(b).*]

A-7-1.3

Two or more airport fire stations should be strategically located on the airport where a centrally located fire station cannot meet the response criteria given in 7-1.3.

Advisory Circulars. This listing is limited to advisory circulars of substance concerning aircraft rescue and fire fighting. For complete listing of FAA advisory circulars write the FAA and request a copy of latest “Advisory Circular Checklist and Status of Federal Aviation Regulations.” This checklist is published periodically in the Federal Register.

150/5200-12A, Fire Department Responsibility in Protecting Evidence at the Scene of an Aircraft Accident (4-8-85). Guidance on the proper preservation of evidence at the scene of an aircraft accident.

150/5200-31, Airport Emergency Plan (1-27-89). (AAS-310). Provides guidance for the preparation of emergency plans at civil airports.

150/5210-2, Airport Emergency Facilities and Services (11-27-84). Provides information and advice so that airports may take specific voluntary preplanning actions to ensure at least minimum first-aid and medical readiness appropriate to the size of the airport in terms of permanent and transient personnel.

150/5210-5B, Painting, Marking, and Lighting of Vehicles Used on an Airport (7-11-86). Provides guidance, specifications, and standards, in the interest of airport personnel safety and operational efficiency, for painting, marking, and lighting of vehicles operating in the airport air operations area.

150/5210-G, Aircraft Fire and Rescue Facilities and Extinguishing Agents (1-28-85). Outlines scales of protection considered as the recommended minimum level.

150/5210-7B, Aircraft Fire and Rescue Communications (4-30-84). Provides guidance for planning and implementing an airport communications system for airport fire and rescue service.

150/5210-13A, Water Rescue Plans, Facilities, and Equipment (5-31-91). Provides guidance to assist airport operators in preparing for water rescue operations.

150/5210-14, Airport Fire and Rescue Personnel Protective Clothing (3-12-86). Developed to assist airport management in the development of local procurement specifications for an acceptable, cost-effective proximity suit for use in aircraft rescue and fire fighting operations.

150/5210-15, Airport Rescue and Fire Fighting Station Building Design (7-30-87). (AAS-100). Provides standards and guidance for planning, designing, and constructing an airport rescue and fire fighting station.

150/5210-16, Announcement of Availability: Standardized Basic Aircraft Rescue and Fire Fighting Curriculum (A Basic ARFF Training Course) (2-21-89). (AAS-314). Announces availability of subject course.

150/5220-4A, Water Supply Systems for Aircraft Fire and Rescue Protection (12-11-85). (AAS-120). Provides guidance for the water source selection and standards for a water distribution system designed to support aircraft rescue and fire fighting (ARFF) service operations on airports.

150/5220-10A, Guide Specification for Water/Foam Aircraft Rescue and Fire Fighting Vehicles (7-3-91). (AAS-120). Contains performance standards, specifications, and recommendations for the design, construction, and testing of a family of aircraft rescue and fire fighting (ARFF) vehicles.

150/5220-17A, Design Standards for an Aircraft Rescue and Fire Fighting Training Facility (1-31-92). (AAS-100). Contains standards, specifications, and recommendations for the design of an aircraft rescue and fire fighting training facility.

150/5230-4, Aircraft Fuel Storage, Handling, and Dispensing on Airports (8-27-82). (AAS-300). (Consolidated reprint includes changes 1 and 2). Provides information on aviation fuel deliveries to airport storage and the handling, cleaning, and dispensing of fuel into aircraft.

150/5370-2C, Operational Safety on Airports During Construction (5-31-84). Title is self-explanatory.

150/5390-2, Heliport Design (1-4-88). (AAS-100). Contains FAA guidelines, recommendations, and design standards for heliports and helistops developed after the date of this publication.

20-42C, Hand Fire Extinguishers for Use in Aircraft (3-7-84). (ACE-110). Provides methods acceptable to the administrator for showing compliance with the hand fire extinguisher provisions in FAR 25, 29, 91, 121, 125, 127, and 135 and provides updated general information.

NFPA 407

1996 Edition

Standard for Aircraft Fuel Servicing

1996 Edition

This edition of NFPA 407, *Standard for Aircraft Fuel Servicing*, was prepared by the Technical Committee on Aircraft Fuel Servicing and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 13-15, 1995, in Chicago, IL. It was issued by the Standards Council on January 12, 1996, with an effective date of February 2, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 407 was approved as an American National Standard on February 2, 1996.

Origin and Development of NFPA 407

Active work by the National Fire Protection Association leading toward the development of this standard began in 1951. Since then, the technical committee responsible has made every effort to keep the text up-to-date, and subsequent editions have been published almost every year from 1955 to 1975. The 21st edition was issued in 1980, and the technical committee completed a partial revision in 1984.

The 1990 edition was a complete rewrite that reorganized the design and operational requirements into separate chapters. The requirements for grounding were deleted, and the requirements for bonding were clarified.

This edition is a partial revision. Requirements for self-service fueling and rapid refueling of helicopters were added.

Technical Committee on Aircraft Fuel Servicing

John A. Park, Burns & McDonnell Engr Co., Inc., MO

Claude Taucher, American Airlines, OK

Committee Scope: This Committee shall have primary responsibility for documents on fire-safe procedures, equipment, and installations for aircraft fuel servicing.

NFPA 407

Standard for Aircraft Fuel Servicing

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 4 and Appendix B.

Chapter 1 Administration

1-1 Scope.

This standard applies to the fuel servicing of all types of aircraft using liquid petroleum fuel. It does not apply to the following:

(a) In-flight fueling;

(b) Fuel servicing of flying boats or amphibious aircraft on water; or

(c) Draining or filling of aircraft fuel tanks incidental to aircraft fuel system maintenance operations or manufacturing.

1-2* Purpose.

1-2.1

The purpose of this standard is to establish reasonable minimum fire safety requirements for procedures, equipment, and installations for the protection of persons, aircraft, and other property during ground fuel servicing of aircraft using liquid petroleum fuels. These requirements are based upon sound engineering principles, test data, and field experience.

1-2.2

The fire hazard properties of aviation fuels vary; however, for the purpose of this standard, the same fire safety precautions are specified for all types.

1-3 Definitions.

Aircraft. A vehicle designed for flight that is powered by liquid petroleum fuel.

Aircraft Fueling Vehicle. A fuel servicing hydrant vehicle or an aircraft fuel servicing tank vehicle.

Aircraft Fuel Servicing. The transfer of fuel into or from an aircraft.

Aircraft Fuel Servicing Hydrant Vehicle (Hydrant Vehicle). A vehicle equipped with facilities to transfer fuel between a fuel hydrant and an aircraft.

Aircraft Fuel Servicing Ramp or Apron. An area or position at an airport used for the fuel servicing of aircraft.

Aircraft Fuel Servicing Tank Vehicle (Fueler). A vehicle having a cargo tank (tank truck, tank full trailer, tank semitrailer) designed for or used in the transportation and transfer of fuel into or from an aircraft.

Airport Fueling System. An arrangement of aviation fuel storage tanks, pumps, piping, and associated equipment, such as filters, water separators, hydrants and station, or aircraft fuel servicing vehicles, installed at an airport and designed to service aircraft at fixed positions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Aviation Fuel.* Any petroleum fuel for use in aircraft engines.

Baffle. A non-liquidtight transverse partition in a cargo tank.

Bulkhead. A liquidtight transverse closure between compartments of a cargo tank.

Burst Pressure. See Pressure.

Cargo Tank. A container used for carrying aircraft fuels and mounted permanently or otherwise secured on a tank vehicle. The term “cargo tank” does not apply to any container used solely for the purpose of supplying fuel for the propulsion of the vehicle on which it is mounted.

Cathodic Protection. A method of controlling or impressing an electrical current to prevent corrosion of metal components of airport fueling systems that are in contact with the ground.

Compartment. A liquidtight division in a cargo tank.

Deadman Control. A device that needs a positive continuing action by a person to allow the flow of fuel.

Electric Hand Lamp. A portable lamp other than a flashlight.

Emergency Fuel Shutoff. A function performed to stop the flow of fuel in an emergency.

Fueler. See Aircraft Fuel Servicing Tank Vehicle (Fueler).

Fuel Servicing Station. A unit that includes all necessary equipment to enable the transfer of fuel into or from an aircraft or fueler. This unit can be installed in a cabinet above or below the ground.

Head. A liquidtight transverse closure at the end of a cargo tank.

Hydrant Valve. An outlet of an airport fueling system that includes a deadman-controlled valve and adapter assembly to which a coupler on a hose or other flexible conduit on an aircraft fuel servicing vehicle can be connected.

Hydrant Vehicle. See Aircraft Fuel Servicing Hydrant Vehicle (Hydrant Vehicle).

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Misfueling. The accidental fueling of an aircraft or refueling vehicle tank with an improper grade of product.

Overshoot. The quantity of fuel passing through the valve after the deadman control is released.

Pressure.

Burst Pressure. The pressure at which a component ruptures.

Test Pressure. The pressure to which a system or a component of a system is subjected to verify the integrity of the system or component.

Working Pressure. The maximum allowable pressure, including momentary surge pressure, to which a system, hose, or other component can be safely subjected while in service.

Pressure Fuel Servicing. A system used to fuel an aircraft by close coupling under pressure.

Self-service Fueling. The dispensing of aviation fuels into aircraft fuel tanks by persons other than the facility owner/operator.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Tank Full Trailer. A vehicle that is not self-propelled and that has a cargo tank for the transportation of aviation fuel mounted thereon or built as an integral part thereof. It is so constructed that its weight and load rest on its own wheels.

Tank Semitrailer. A vehicle that is not self-propelled and that has a cargo tank for the transportation of aviation fuel mounted thereon or built as an integral part thereof. It is so constructed that, when drawn by a tractor by means of a fifth wheel connection, some of its load and weight rests upon the towing vehicle.

Tank Truck. A self-propelled vehicle having a cargo tank for the transportation of aviation fuel.

Tank Vehicle. Any tank truck, tank full trailer, or tractor and tank semitrailer combination.

Test Pressure. See Pressure.

Working Pressure. See Pressure.

1-4 Units.

Where the value for a measurement as specified in this standard is followed by an equivalent value in other units, the first value shall be regarded as the requirement. The equivalent value could be approximate.

Chapter 2 Design

2-1 General.

2-1.1 Fueling Hose Apparatus.

Nozzle receptacles and hose storage apparatus shall be arranged to avoid kinks and short loops in hoses.

2-1.2 Electrostatic Hazards and Bonding.

2-1.2.1 A provision for bonding shall be incorporated in the design of fuel servicing vehicles and systems to prevent differences in electrostatic potential in accordance with Section 3-4.

2-1.2.2 Bonding cables shall be constructed of conductive, durable, and flexible material.

2-1.2.3 Bonding connections shall be electrically and mechanically firm. Jacks, plugs, clamps, and connecting points shall be clean, unpainted metal to provide a positive electrical connection.

2-1.2.4 API BULL 1529, *Aviation Fueling Hose*, Type C hose, or BS 3158, *Rubber Hoses and Hose Assemblies for Aircraft Ground Fueling and Defueling*, Type C (conductive) hose, shall be used to prevent electrostatic discharges but shall not be used to accomplish required bonding. API BULL 1529, Type A, BS 3158, Type A, and hose having a static wire in the hose wall shall not be used.

2-1.2.5* The design shall incorporate the provision of a 30-second relaxation period between the filter separator and the discharge outlet.

Exception: This requirement shall not apply to systems designed for fuels with static dissipater additives.

2-1.3 No Smoking Signs.

Entrances to fueling areas shall be posted with "no smoking" signs.

2-1.4 Radar Equipment.

2-1.4.1 Aircraft Radar Equipment.

2-1.4.1.1 Surveillance radar equipment in aircraft shall not be operated within 300 ft (90 m) of any fueling, servicing, or other operation in which flammable liquids, vapors, or mist might be present.

2-1.4.1.2 Weather-mapping radar equipment in aircraft shall not be operated while the aircraft in which it is mounted is undergoing fuel servicing.

2-1.4.2* Ground Radar Equipment.

2-1.4.2.1 Antennas of airport flight traffic surveillance radar equipment shall be located so that the beam will not be directed toward any fuel storage or loading racks within 300 ft (90 m). Aircraft fuel servicing shall not be conducted within this 300-ft (90-m) distance.

2-1.4.2.2 Antennas of airport ground traffic surveillance radar equipment shall be located so that the beam will not be directed toward any fuel storage or loading racks within 100 ft (30 m). Aircraft fuel servicing or any other operations involving flammable liquids or vapors shall not be conducted within 100 ft (30 m) of such antennas.

2-1.5 Emergency Fire Equipment Accessibility.

Accessibility to aircraft by emergency fire equipment shall be considered in establishing aircraft fuel servicing positions.

2-1.6 Portable Fire Extinguishers.

2-1.6.1* Portable extinguishers shall be provided in accordance with 2-3.8 and Section 3-13.

2-1.6.2 Extinguishers shall conform to the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

2-1.7* Deadman Controls.

2-1.7.1 The valve that controls the flow of fuel to an aircraft shall have a deadman control. The deadman control device shall be arranged to accommodate the operational requirements of Section 3-15. The fuel flow control valve shall be one of the following:

(a) The hydrant pit valve;

(b) At the tank outlet on a tank vehicle;

(c) A separate valve on the tank vehicle; or

(d) On the hose nozzle for overwing servicing.

2-1.7.2 Deadman controls shall be designed to preclude defeating their intended purpose.

2-1.8 Pressure Fuel Servicing System Controls.

The system shall be designed to minimize surge pressure. The overshoot shall not exceed 5 percent of actual flow rate from the time the deadman is released until the flow stops completely. The control valve shall be located and designed so that it will not be rendered inoperative by a surface accident, power failure, or spill. It shall be fail-safe by closing completely in the event of control power loss.

2-2* Aircraft Fueling Hose Requirements.

2-2.1 Performance Requirements.

Hose shall comply with the requirements of API BULL 1529, *Aviation Fueling Hose*, or BS 3158, *Rubber Hoses and Hose Assemblies for Aircraft Ground Fueling and Defueling*. Couplings shall comply with the requirements of API BULL 1529.

2-2.2 Additional Requirements.

2-2.2.1 Each coupled length of hose shall be tested at the same minimum proof pressure rating for that grade of hose as defined in API BULL 1529, *Aviation Fueling Hose*.

2-2.2.2 A test certificate shall be provided for each coupled length of hose and shall state the following:

(a) Manufacturer's name (hose);

(b) Manufacturer's name (couplings);

(c) Hose type;

(d) Hose grade;

(e) Size and length of hose;

(f) Serial number or reference number of hose;

(g) Quarter and year of manufacture of hose;

(h) Model number of couplings;

(i) Sizes of coupling ferrules;

(j) Hydrostatic test pressures;

(k) Coupled length serial number;

(l) Identification of individual responsible for coupling the hose;

(m) Name and address of company responsible for coupling the hose;

(n) Date of certification.

2-2.2.3 The coupling tests as specified in API BULL 1529, *Aviation Fueling Hose*, shall be performed for each hose grade, type, and manufacturer.

2-2.2.4 Each coupling of a coupled length of hose shall be permanently marked with a serial number corresponding to its hydrostatic test certificate.

2-2.2.5 The hose at the end of each coupling ferrule shall be permanently marked prior to hydrostatic testing to serve as a reference to determine whether a coupling has slipped during testing or while in service.

2-2.3 Hydrostatic Testing.

Hydrostatic testing shall be in accordance with ASTM D 380, *Standard Test Methods for Rubber Hose*.

2-2.3.1 Following a hydrostatic test, all of the water shall be drained and the hose shall be dried internally. The open ends, including the threads of the couplings, shall be suitably covered to protect the threads and to prevent contamination.

2-2.3.2 A hose that is recoupled for any reason shall be hydrostatically tested and recertified to the same criteria as a newly coupled hose.

2-3 Aircraft Fuel Servicing Vehicles.

Aircraft fuel servicing tank vehicles that are used on public highways also shall comply with NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*.

2-3.1 Materials.

2-3.1.1 In addition to any specific requirements in this chapter, only materials safe for use in the service intended and compatible with fuel applications shall be used in the construction of aircraft fuel servicing vehicles.

2-3.1.2 Magnesium shall not be used in the construction of any portion of an aircraft fuel servicing vehicle.

2-3.2 Vehicle Cargo Tanks.

Every cargo tank shall be supported by and attached to, or shall be a part of, the tank vehicle upon which it is carried in accordance with NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*.

2-3.3 Static Protection.

2-3.3.1 All metallic components and vehicle chassis shall be electrically bonded to prevent a difference in their electrostatic potential.

2-3.3.2 A provision shall be made for the bonding of the tank to the fill pipe or the loading rack as specified in 3-20.2.1. Electrical continuity between the loading rack and fill pipe shall be accomplished as specified in Section 3-4.

2-3.3.3 Cables shall be provided on the vehicle to allow the bonding operations specified in Section 3-4.

2-3.3.4 A cable with a clip or plug shall be attached to each overwing nozzle to facilitate compliance with 3-4.2.

2-3.4 Containers and Systems for Flammable Liquids Other than Cargo Tanks.

2-3.4.1 Vehicle fuel tanks and containers for other flammable liquids shall be made of metal and shall be designed, constructed, and located in a manner that precludes hazardous arrangements. Tanks shall be substantially protected by their location, and fill pipes shall not project beyond the vehicle profile. Tanks and containers shall vent away from sources of ignition during filling. Any arrangement not protected by location shall be listed for such use. The fuel tank arrangement shall allow for drainage without the tank's removal from its mountings.

2-3.4.2 Gravity feed systems shall not be used.

2-3.4.3 All portions of the flammable liquid feed system shall be constructed and located to minimize the fire hazard. The lines shall be made of materials not adversely affected by the fluid or by other materials likely to be encountered; shall be of adequate strength for the purpose; and shall be secured to avoid chafing or undue vibration.

2-3.4.4 The engine air intake shall retain the manufacturer's configuration to prevent the emission of flame in case of backfiring.

2-3.4.5 Where provided, the sediment bowl in the fuel supply line shall be of steel or material of equivalent fire resistance.

2-3.5 Engine Exhaust System.

2-3.5.1 The engine exhaust system shall be designed, located, and installed to minimize the hazard of fire in the event of the following:

(a) Leakage of fuel from the vehicle fuel tank or fuel system;

(b) Leakage from the fuel dispensing system of the vehicle;

(c) Spillage or overflow of fuel from the vehicle fuel tank or the cargo tank; or

(d) Spillage of fuel during the servicing of an aircraft.

2-3.5.2 Exhaust system components shall be secured and located clear of components carrying flammable liquids and separated from any combustible materials used in the construction of the vehicle.

2-3.5.3 Suitable shielding shall be provided to drain possible fuel spillage or leakage away from exhaust system components safely.

2-3.5.4 Exhaust gases shall not be discharged where they could ignite fuel vapors that might be released during normal operations or by accidental spillage or by leakage of fuel.

2-3.5.5 A muffler (or silencer) cutout shall not be provided.

2-3.6 Vehicle Lighting and Electrical Equipment.

2-3.6.1 Wiring shall be of adequate size to provide the required current-carrying capacity and mechanical strength. It shall be installed to provide protection from physical damage and from contact with spilled fuel either by its location or by enclosing it in metal conduit or other oil-resistant protective covering. All circuits shall have overcurrent protection. Junction boxes shall be weatherproofed.

2-3.6.2 Spark plugs and other exposed terminal connections shall be insulated to prevent sparking in the event of contact with conductive materials.

2-3.6.3* Motors, alternators, generators, and associated control equipment located outside of the engine compartment or vehicle cab shall be of a type listed for use in accordance with NFPA 70, *National Electrical Code*®, Class I, Division 1, Group D locations.

2-3.6.4 Electrical equipment and wiring located within a closed compartment shall be of a type listed for use in accordance with NFPA 70, *National Electrical Code*, Class I, Division 1, Group D locations.

2-3.6.5 Lamps and switching devices, other than those covered in 2-3.6.3 and 2-3.6.4, shall be of the enclosed, gasketed, weatherproof type. Other electrical components shall be of a type listed for use in accordance with NFPA 70, *National Electrical Code*, Class I, Division 2, Group D locations.

2-3.6.6 Electrical service wiring between a tractor and trailer shall be designed for heavy duty service. The connector shall be of the positive-engaging type. The trailer receptacle shall be mounted securely.

2-3.7 Cabinets.

All cabinets housing vehicle auxiliary equipment shall have expanded metal flooring, perforated metal grating-type flooring, or open floor to facilitate air circulation within the enclosed space and to prevent the accumulation of fuel.

2-3.8 Fire Extinguishers for Aircraft Fuel Servicing Vehicles.

2-3.8.1 Each aircraft fuel servicing tank vehicle shall have two listed fire extinguishers, each having a rating of at least 20B with one extinguisher mounted on each side of the vehicle.

2-3.8.2 There shall be one listed extinguisher having a rating of at least 20B installed on each hydrant fuel servicing vehicle.

2-3.8.3 Extinguishers shall be readily accessible from the ground. The area of the paneling or tank adjacent to or immediately behind the extinguisher(s) on fueling vehicles shall be painted with a contrasting color.

2-3.8.4 Extinguishers shall be kept clear of elements such as ice and snow. Extinguishers located in enclosed compartments shall be readily accessible, and their location shall be marked clearly in letters at least 2 in. (50 mm) high.

2-3.9 Full Trailers and Semitrailers.

2-3.9.1 Trailer connections shall be designed to secure the trailer firmly and to prevent the towed vehicle from swerving from side to side at the speeds anticipated so that the trailer essentially remains in the path of the towing vehicle.

2-3.9.2 Full trailers and semitrailers shall be equipped with brakes on all wheels.

2-3.10 Smoking Restrictions.

2-3.10.1 A “no smoking” sign shall be posted prominently in the cab of every aircraft fuel servicing vehicle.

2-3.10.2 Smoking equipment such as cigarette lighters and ash trays shall not be provided. If a vehicle includes such equipment when initially procured, it shall be removed or rendered inoperable.

2-3.11 Cargo Tanks.

2-3.11.1 Cargo tanks shall be constructed in accordance with NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*.

2-3.11.2 Aluminum alloys for high strength welded construction shall be joined by an inert gas arc welding process using filler metals R-GR40A, E-GR40A (5154 alloy), R-GM50A, and E-GM50A (5356 alloy) in accordance with AWS A5.10, *Specification for Bare Aluminum and Aluminum Alloy Welding Electrodes and Rods*.

2-3.11.3 Tank outlets shall be of substantial construction and shall be attached securely to the tank.

2-3.11.4 Every cargo tank or compartment over 90 in. (2286 mm) long shall be provided with baffles, the total number of which shall be such that the distance between any two adjacent baffles, or between any tank head or bulkhead and the baffle closest to it, shall in no case exceed 60 in. (1524 mm). The cross-sectional area of each baffle shall be not less than 80 percent of the cross-sectional area of the tank, and the thickness of a baffle shall be not less than that required for the heads and bulkheads of the cargo tank in which it is installed.

2-3.11.5 Venting shall be in accordance with NFPA 385, *Standard for Tank Vehicles for Flammable and Combustible Liquids*.

2-3.11.6 Cargo drawoff valves or faucets projecting beyond the frame of a tank vehicle shall be protected against damage.

2-3.12 Fill Openings and Top Flashings.

2-3.12.1 Dome covers shall be provided with a forward-mounted hinge and self-latching catches and shall be fitted with watertight fuel-resistant seals or gaskets (designed to prevent spillage or leakage from overturn and to prevent water entry). Dome covers shall automatically close and latch with the forward motion of the vehicle.

2-3.12.2 Drains from top flashing shall divert spilled fuel from possible sources of ignition, including the engine, the engine exhaust system, the electrical equipment, or an auxiliary equipment enclosure.

2-3.12.3 The tank fill openings shall be protected against overturn damage by a rigid member(s) fixed to the tank and extending a minimum of 1 in. (25 mm) above any dome cover, handle, vent opening, or projection of the unit. Overturn protection shall be braced adequately to prevent collapse. The overturn protection shall be designed to channel rain water, snow, or fuel to the exterior of the cargo tank.

2-3.13 Piping, Joints, Flanged Connections, and Couplings.

2-3.13.1 Product piping shall be metal and rated for the system working pressure or at least 125 psi (860 kPa), whichever is greater.

2-3.13.2 Except as provided in 2-3.13.3, all joints shall be welded. Elbows and fittings shall be kept to a minimum and, where used, shall be of the preformed welding type.

2-3.13.3 Flanged connections or approved couplings shall be provided to avoid the need for cutting and welding where components are serviced or replaced. Gaskets in flanged connections shall be of a material and design that resist fire exposure for a time comparable to the flange and bolts.

2-3.13.4 Piping shall be supported adequately.

2-3.14 Outlet Valves and Emergency Shutoff Controls.

2-3.14.1 The outlets of each cargo tank or compartment, including water drawoffs, shall be equipped with shutoff valves located inside the shell, or in the sump where it is an integral part of the shell. The cargo tank outlet shall be designed so that the valve needs to be kept closed except during loading and unloading operations. The water drawoff connection shall be of a type that cannot be blocked open.

2-3.14.2 The operating mechanism for each tank outlet valve shall be adjacent to the fuel delivery system operating controls and shall be arranged so that the outlet valve(s) can be closed simultaneously and instantly in the event of a fire or other emergency. There shall be at least two emergency shutoff controls, one mounted on each side of the vehicle. These controls shall be quick-acting to close the tank outlet valve in case of emergency. They also shall be remote from the fill openings and discharge outlets and shall be operable from a ground-level standing position. In addition, all vehicles equipped with a top deck platform shall have an emergency shutoff control operable from the deck.

2-3.14.3 Emergency fuel shutoff controls shall be placarded “EMERGENCY FUEL SHUTOFF” in letters at least 2 in. (50 mm) high and shall be of a color that contrasts with the placard background for visibility. The method of operation shall be indicated by an arrow or by the word “PUSH” or “PULL,” as appropriate. The words “EMERGENCY FUEL SHUTOFF” shall not be used to identify any control or device on the vehicle other than the emergency fuel shutoff controls.

2-3.14.4 Each outlet valve shall be provided with a fusible device that causes the valve to close automatically in case of fire.

2-3.14.5 A shear section shall be provided between shutoff valve seats and discharge outlets that breaks under strain unless the discharge piping is arranged to afford the same protection and leave the shutoff valve seat intact.

2-3.14.6 Openings in cargo tank compartments that are connected to pipe or tubing shall be fitted with a spring-loaded check valve, a self-closing valve, or similar device to prevent the accidental discharge of fuel in case of equipment malfunction or line breakage. Unless such valves are located inside the tank, they shall be equipped with a shear section as described in 2-3.14.5.

2-3.15 Fuel Dispensing System.

2-3.15.1 The valve that controls the flow of fuel from an aircraft fuel servicing vehicle to an aircraft shall have a deadman control(s) in accordance with the requirements of 2-1.7.

2-3.15.2 The deadman flow control in the nozzle shall be permitted for overwing fueling. Notches or latches in the nozzle handle that could allow the valve to be locked open shall be prohibited. Each overwing servicing nozzle shall have a cable with a plug or clip for bonding to the aircraft. (*See 3-4.2.*)

2-3.15.3 Nozzles for underwing fueling shall be designed to be attached securely to the aircraft adapter before the nozzle can be opened. It shall not be possible to disengage the nozzle from the aircraft adapter until the nozzle is fully closed.

2-3.15.4 Fuel servicing pump mechanisms shall be designed and arranged so that failure or seizure does not cause rupture of the pump housing, a tank, or of any component containing fuel. Fuel pressure shall be controlled within the stress limits of the hose and plumbing by means of either an in-line pressure controller, a system pressure relief valve, or other suitable means. The working pressure of any system component shall equal or exceed any pressure to which it could be subjected.

2-3.15.5 On tank full trailer or tank semitrailer vehicles, the use of a pump in the tractor unit with flexible connections to the trailer shall be prohibited unless the following conditions exist:

(a) Flexible connections are arranged above the liquid level of the tank in order to prevent gravity or siphon discharge in case of a break in the connection or piping; or

(b) The cargo tank discharge valves required by 2-3.15.1 are arranged to be normally closed and to open only when the brakes are set and the pump is engaged.

2-3.15.6 Hose shall be connected to rigid piping or coupled to the hose reel in a manner that prevents kinks or undue bending action or mechanical stress on the hose or hose couplings.

2-3.15.7 Aircraft fuel servicing vehicles shall have an integral system or device that prevents the vehicle from being moved unless all fueling nozzles and hydrant couplers are properly stowed and mechanical lifts are lowered to their stowed position.

2-3.16 Tests.

2-3.16.1 Cargo tanks, at the time of manufacture, shall be tested by a minimum air or hydrostatic pressure of 5 psi (24.4 kg/m^2) applied to the whole tank (or each compartment thereof if the tanks are compartmented). Such pressure shall be maintained for a period of at least 5 minutes during which, if the test is by air pressure, the entire exterior surface of all joints shall be coated with a solution of soap and water, heavy oil, or other substance that causes foaming or bubbling that indicates the presence of leaks. Hydrostatic pressure, if used, shall be gauged at the top of the tank. The tank shall be inspected at the joints for the issuance of liquid to indicate leaks. Any leakage discovered by either of the methods described, or by any other method, shall be considered evidence of failure to meet these requirements.

2-3-16.2

At the time of manufacture, the section of the fuel dispensing system that is under pressure during service shall be subjected to a hydrostatic test pressure equal to 150 percent of the working pressure of the system for at least 30 minutes and shall be proven tight before it is placed in service. Hose connections shall be permitted to be plugged during this test.

2-3.17 Product Identification Signs.

Each aircraft fuel servicing vehicle shall have a sign on each side and the rear to identify the product. The sign shall have letters at least 3 in. (75 mm) high and shall be of a color contrasting sharply with the sign background for visibility. The word "FLAMMABLE" and the name of the product carried, such as "JET A," "JET B," "GASOLINE," or "AVGAS" shall appear on the sign.

2-3.18 Loading.

2-3.18.1 No cargo tank or compartment shall be loaded to the point where it is liquid full. The ullage expansion space shall not be less than 1 percent of the volume of the tank compartment. Where local climatic conditions warrant, the ullage expansion space shall be increased to prevent leakage or overflow from expansion of the contents due to a rise in atmospheric temperature or direct exposure to the sun.

2-3.18.2 A heat-actuated shutoff valve shall be provided in the piping immediately upstream of the loading hose or swing arm connection.

2-3.19 Top Loading.

2-3.19.1 Drop tubes used in top loading or overhead loading of tank vehicles shall be designed to minimize turbulence. Drop tubes shall be metallic.

2-3.19.2 Fixed drop tubes permanently mounted in the vehicle tank shall extend to the bottom of the tank or to the inside of the sump to maintain submerged loading and avoid splashing of the fuel.

2-3.19.3 Drop tubes attached to loading assemblies extending into the vehicle tank shall extend to the bottom of the tank and shall be maintained in that position until the tank is loaded to provide submerged loading and avoid splashing or free fall of fuel through the tank atmosphere.

2-3.19.4 Loading arms shall be counterbalanced properly.

2-3.19.5 A deadman control shall be provided and located so that the operator can observe the liquid level in the tank as it fills.

2-3.20 Bottom Loading.

2-3.20.1 Loading hose shall conform to the requirements of Section 2-2. Swivel connections shall be provided at each end of the hose to allow free movement to compensate for changes in the position of the vehicle connection during loading.

2-3.20.2 Swinging loading arms shall be counterbalanced properly. Swivel joints shall be used to allow free movement and to compensate for changes in the attitude of the vehicle during loading.

2-3.20.3 The connection between the tank truck and the arm or hose shall be a dry-break coupler that cannot be opened until it is engaged to the vehicle tank adapter. It shall not be possible to disconnect the hose coupler from the tank vehicle connection until the internal valves of the vehicle adapter and coupler are fully closed.

2-3.20.4* The bottom loading fitting of the tank vehicle shall be a spring-loaded check valve that remains in a closed position until opened by connecting the coupler.

2-3.20.5 Aircraft fuel servicing vehicles shall incorporate an integral brake interlock system that prevents the vehicle from being moved until the bottom loading coupler has been disconnected from the vehicle.

2-3.20.6 The supply piping terminating at the loading hose or swing arm shall be supported to carry the loads imposed.

2-3.20.7 The filling of the vehicle cargo tank shall be controlled by a deadman control so that a fueling operator can monitor the operation while activating the control. In addition, a float-actuated shutoff or other automatic sensing device shall be provided. Any liquid bled from a sensing device during loading shall be piped to the bottom of the cargo tank.

2-3.20.8 The fill pipe and valving on bottom-loaded tank vehicles shall be arranged to prevent fuel spray and turbulence in the cargo tank.

2-3.21 Emergency Remote Control Stations.

2-3.21.1 Each tank vehicle loading station shall be provided with an emergency fuel shutoff system. This requirement is in addition to the deadman control required by 2-3.19.5 for top loading and by 2-3.20.7 for bottom loading. It shall be the purpose of this system to shut down the flow of fuel in the entire system or in sections of the system if an emergency occurs. This system shall be of a fail-safe design.

2-3.21.2 Each emergency fuel shutoff station location shall be placarded “EMERGENCY FUEL

SHUTOFF" in letters at least 2 in. (50 mm) high. The method of operation shall be indicated by an arrow or by the word "PUSH" or "PULL," as appropriate. Any action necessary to gain access to the shutoff device (e.g., "BREAK GLASS") shall be shown clearly. Lettering shall be of a color contrasting sharply with the placard background for visibility. Placards shall be weather resistant, shall be located at least 7 ft (2.1 m) above grade, and shall be positioned so that they can be seen readily from a distance of at least 25 ft (7.6 m).

2-4 Airport Fuel Systems.

2-4.1 Design Approval.

Work shall not be started on the construction or alteration of an airport fuel system until the design, plans, and specifications have been approved by the authority having jurisdiction.

2-4.2 System Approval.

The authority having jurisdiction shall inspect and approve the completed system before it is put into service.

2-4.3 General Requirements.

2-4.3.1 Each installation planned shall be designed and installed in conformity with the requirements of this standard and with any additional fire safety measures deemed necessary by the authority having jurisdiction.

2-4.3.2 The system and each of its components shall be designed for the working pressure of the system.

2-4.3.3 The emergency fuel shutoff system shall be designed and installed as an integral part of the airport fuel system. Operating controls for emergency fuel shutoff of the system shall be located to be accessible readily and safely in the event of an accident or spill.

2-4.3.4 In establishing each aircraft fuel dispensing location, consideration shall be given to the accessibility of the location in an emergency by fire-fighting personnel and equipment.

2-4.4 Fuel Storage Tanks.

2-4.4.1* Fuel storage tanks shall conform to the applicable requirements of NFPA 30, *Flammable and Combustible Liquids Code*.

2-4.4.2 The authority having jurisdiction shall determine the clearances required from runways, taxiways, and other aircraft movement and servicing areas to any aboveground fuel storage structure or fuel transfer equipment with due recognition given to national and international standards establishing clearances from obstructions. Tanks located in designated aircraft movement areas or aircraft servicing areas shall be underground or mounded over with earth. Vents from such tanks shall be constructed in a manner to preclude collision hazards with operating aircraft. Aircraft operators shall be consulted regarding the height and location of such vents to avoid venting flammable vapors in the vicinity of ignition sources, including operating aircraft and automotive equipment permitted in the area.

2-4.5 Emergency Fuel Shutoff Systems.

2-4.5.1 Each fuel system, as required by 2-4.3.3, shall have means for quickly and completely shutting off the flow of fuel in an emergency. This requirement is in addition to the requirement in 2-1.7 for deadman control of fuel flow.

2-4.5.2* The method of fuel transfer (gravity, pumping, or use of hydraulic or inert gas pressure) shall be considered in the design of the emergency fuel shutoff system and the location of the emergency fuel shutoff valve.

2-4.5.3 The emergency fuel shutoff system shall include shutoff stations located outside of probable spill areas and near the route that normally is used to leave the spill area or to reach the fire extinguishers provided for the protection of the area.

2-4.5.4* At least one emergency shutoff control station shall be conveniently accessible to each fueling position.

2-4.5.5 The emergency fuel shutoff system shall be designed so that operation of a station shuts off fuel flow to all hydrants that have a common exposure.

2-4.5.6 Emergency fuel shutoff systems shall be designed so that they shut off the flow of fuel if the operating power fails.

2-4.5.7 Each emergency fuel shutoff station shall be placarded "EMERGENCY FUEL SHUTOFF" in letters at least 2 in. (50 mm) high. The method of operation shall be indicated by an arrow or by the word "PUSH" or "PULL," as appropriate. Any action necessary to gain access to the shutoff device (e.g., "BREAK GLASS") shall be shown clearly. Lettering shall be of a color contrasting sharply with the placard background for visibility. Placards shall be weather resistant, shall be located at least 7 ft (2.1 m) above grade, and shall be positioned so that they can be seen readily from a distance of at least 25 ft (7.6 m). Valves used to shut off a hydrant for maintenance purposes shall not have placards that could create confusion in an emergency.

2-4.6 Transfer Piping.

2-4.6.1 Underground piping shall be used in the vicinity of aircraft movement areas unless the piping is protected by a substantial barrier guard. Piping shall be protected by suitable sleeves or casings to protect the pipe from shock hazards where it crosses sewer manholes, service tunnels, catch basins, or other underground services. Piping shall be laid on firm supports using clean, noncorrosive backfill.

2-4.6.2 Transfer piping located within buildings not specifically designed for the purpose of fuel transfer shall be located within a steel casing of a pressure rating equal to that of the carrier pipe. This casing shall extend beyond the building and terminate at a low point(s) with an automatic leak detection system. The casing shall be capable of being drained to a safe location.

2-4.6.3 Fuel piping that runs under a building or a passenger concourse shall be protected by a steel casing that encloses only the piping.

2-4.6.4 Piping, valves, and fittings shall be of metal, suitable for aviation fuel service, and designed for the working pressure and mechanically and thermally produced structural stresses to which they could be subjected and shall comply with ANSI B31.3, *Chemical Plant and Petroleum Refinery Piping.* Deviations from ANSI B31.3 can be authorized by the authority having jurisdiction where engineering data can be presented to justify such deviations.

2-4.6.5 Cast-iron, copper, and galvanized steel piping, valves, and fittings shall not be permitted. Ductile iron valves shall be permitted.

2-4.6.6 Aluminum piping, valves, and fittings shall be used only where specifically approved by the authority having jurisdiction.

2-4.6.7 In the selection of pipe, valves, and fittings, the following shall be considered:

(a) Working pressure;

(b) Bending and mechanical strength requirements (including settlement);

(c) Internal and external corrosion;

(d) Impact stresses;

(e) Method of system fabrication and assembly;

(f) Location of piping and accessibility for repair or replacement;

(g) Exposure to mechanical, atmospheric, or fire damage;

(h) Expected period of service and effect of future operations.

2-4.6.8 Gaskets in flanged connections shall resist fire temperatures for a duration comparable to the temperature resistance of the flange and bolts.

2-4.6.9 Allowances shall be made for thermal expansion and contraction by the use of pipe bends, welded elbows, or other flexible design. Pressure relief valves shall be provided in lines that can be isolated.

2-4.6.10 Welded joints shall be made by qualified welders in accordance with the standards of the American Welding Society and ANSI B31.3, *Chemical Plant and Petroleum Refinery Piping*.

2-4.6.11* Isolation valves or devices shall be provided to facilitate dismantling portions of the fueling system. These valves shall be capable of being locked closed.

2-4.6.12 Buried flanges and valves shall not be permitted.

2-4.7 Fuel Flow Control.

2-4.7.1 Hydrant valves shall be designed so that the flow of fuel shall shut off when the hydrant coupler is closed. Hydrant valves shall be of the self-closing, dry-break type.

2-4.7.2 The flow control valve shall be an integral part of the hydrant valve or coupler. The fuel control valve shall be arranged so that it is not rendered inoperative by a surface accident, spill, or malfunction and shall shut off the flow of fuel if the operating energy fails. The fuel control system shall be designed to minimize overshoot. The system shall be designed to shut off fuel flow quickly and effectively, even if there is a reduction of pressure downstream of the flow control valve such as could result from a major line or hose break. A screen shall be provided ahead of the valve to trap foreign material that could interfere with complete closure of the valve. The hydrant valve that allows the flow of fuel to the aircraft shall have a deadman control. The use of any means that allows fuel to flow without the operator activating this control shall not be permitted. The deadman control shall be arranged so that the fueling operator can observe the operation while activating the control.

2-4.7.3* The pressure of the fuel delivered to the aircraft shall be automatically controlled so that it is not higher than that specified by the manufacturer of the aircraft being serviced.

2-4.8 Filter Vessels.

All sections of the filtering system shall have electrical continuity with adjoining piping and equipment. In freezing climates, filter separator sumps and associated piping that could contain water shall be protected to prevent freezing and bursting. Heaters shall be constructed of noncorrosive materials.

2-4.9 Electrical Equipment.

All electrical equipment and wiring shall comply with the requirements of NFPA 70, *National Electrical Code*, Article 515, utilizing the Class I liquids requirements for all applications.

2-4.10 Fuel Servicing Hydrants, Pits, and Cabinets.

2-4.10.1 Piping, valves, meters, filters, air eliminators, connections, outlets, fittings, and other components shall be designed to meet the working pressure requirements of the system.

2-4.10.2 Fueling hydrants and fueling pits that are recessed below a ramp or apron surface and are subject to vehicle or aircraft traffic shall be fitted with a cover designed to sustain the load of vehicles or aircraft that taxi over all or part of them.

2-4.10.3 Fueling hydrants, cabinets, and pits shall be located at least 50 ft (15.2 m) from any terminal building, hangar, service building, or enclosed passenger concourse (other than loading bridges).

2-4.11 Drainage.

2-4.11.1 Aircraft servicing ramps or aprons shall be sloped and drained in accordance with NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*. The ramp or apron shall slope away from the rim or edge of fueling hydrants or fueling pits to prevent flooding.

2-4.11.2 Fueling hydrant boxes or fueling pits that are connected to a ramp drainage system shall be fitted with vapor-sealing traps.

2-4.12* Cathodic Protection.

Systems provided with cathodic protection shall have appropriate signs, located at points of entry, warning against separation of units without prior deenergization or without proper jumpers across the sections to be disconnected. Isolation flanges shall be installed as required to separate components protected by a cathodic system from those required to be grounded for other electrical requirements.

2-4.13 Hydrostatic Test.

After completion of the installation (including fill and paving) the airport fuel systems shall be subjected to a temperature-compensated hydrostatic test pressure equal to 150 percent of the system working pressure for at least 4 hours and shall be proven tight before they are placed into service.

2-5 Fueling at Rooftop Heliports.

Fueling on rooftop heliports shall be permitted only where approved by the authority having jurisdiction.

2-5.1 General Limitations.

2-5.1.1 In addition to the special requirements in this chapter, the heliport shall comply with the requirements of NFPA 418, *Standard for Heliports*.

2-5.1.2 Facilities for dispensing fuel with a flash point below 100°F (37.8°C) shall not be permitted at any rooftop heliport.

2-5.2 Fueling Facilities.

2-5.2.1 In addition to the special requirements of this chapter, the fuel storage, piping, and dispensing system shall comply with the requirements of NFPA 30, *Flammable and Combustible Liquids Code*, and with applicable portions of this standard.

2-5.2.2 The entire system shall be designed so that no part of the system is subjected to pressure above its working pressure.

2-5.2.3 The fuel storage system shall be located at or below ground level.

2-5.3 Pumps.

2-5.3.1 Pumps shall be located at or below ground level. Relay pumping shall not be permitted.

2-5.3.2 Pumps installed outside of buildings shall be located not less than 5 ft (1.5 m) from any building opening. They shall be substantially anchored and protected against physical damage from collision.

2-5.3.3 Pumps installed within a building shall be in a separate room with no opening into other portions of the building. The pump room shall be adequately ventilated. Electrical wiring and equipment shall conform to the requirements of NFPA 70, *National Electrical Code*, Article 515.

2-5.4 Piping.

Piping above grade shall be steel and, unless otherwise approved by the authority having jurisdiction, shall be suitably cased or shall be installed in a duct or chase. Such piping duct or chase shall be constructed so that a piping failure does not result in the entry of fuel liquid or vapor entering the building. All pipe casings, ducts, and chases shall be drained. Piping shall be anchored and shall be protected against physical damage for a height of at least 8 ft (2.4 m) above the ground. An isolation valve shall be installed on the suction and discharge piping of each pump. In addition, a check valve shall be installed at the base of each fuel piping riser to automatically prevent the reverse flow of the fuel into the pump room in the event of pump seal failure, pipe failure, or other malfunction. (*See 2-4.6.*)

2-5.4.1 Piping within buildings shall comply with 2-4.6.2.

2-5.4.2 Piping above grade exterior to buildings shall be of steel. Piping shall be located within a steel casing. The pressure rating of the pipe casing shall be equal to that of the carrier pipe. The casing shall be capable of being drained to a safe location. An automatic leak detection system shall be provided at the casing low point(s).

2-5.4.3 Piping shall be anchored and shall be protected against physical damage for a height of at least 8 ft (2.4 m) above the ground.

2-5.4.4 An isolation valve shall be installed on the suction and discharge piping of each pump. In addition, a check valve shall be installed at the base of each fuel piping riser to automatically prevent the reverse flow of fuel into the pump room in the event of a pump seal failure, pipe failure, or other malfunction.

2-5.5 Nozzles.

2-5.5.1 Overwing nozzles shall conform to 2-3.15.2.

2-5.5.2 Underwing nozzles shall conform to 2-3.15.3.

2-5.6 Hose.

Hose shall comply with the requirements of Section 2-2.

2-5.7 Static Electricity.

The provisions of 2-1.2 shall apply, as appropriate, to guard against electrostatic hazards during helicopter fuel servicing operations.

2-5.8 Deadman Control.

Each fuel dispensing hose shall have a deadman-controlled fuel shutoff conforming to the requirements of 2-1.7 and 2-1.8.

2-5.9 Emergency Fuel Shutoff Stations.

2-5.9.1 A system shall be provided to completely shut off the flow of fuel in an emergency. The system shall shut off the fuel at the ground level. The emergency fuel shutoff controls shall be in addition to the normal operating controls for the pumps and deadman control.

2-5.9.2 At least two emergency fuel shutoff stations located on opposite sides of the heliport at exitways or at similar locations shall be provided. An additional emergency fuel shutoff station shall be located at ground level and shall be near, but at least 10 ft (3 m) from, the pumps.

2-5.9.3 Each emergency fuel shutoff station location shall be placarded "EMERGENCY FUEL SHUTOFF" in letters at least 2 in. (50 mm) high. The method of operation shall be indicated by an arrow or by the word "PUSH" or "PULL," as appropriate. Any action necessary to gain access to the shutoff device (e.g., "BREAK GLASS") shall be shown clearly. Lettering shall be of a color contrasting sharply with the placard background for visibility. Placards shall be weather resistant, shall be conspicuously located, and shall be positioned so that they can be seen readily from a distance of at least 25 ft (7.6 m).

2-5.10 Fire Protection.

Fire protection shall conform to the requirements of NFPA 418, *Standard for Heliports*.

2-5.11 Personnel Training.

All heliport personnel shall be trained in the operation of emergency fuel shutoff controls and in the use of the available fire extinguishers.

2-6 Self-service Aircraft Fueling.

2-6.1

Self-service fueling shall be permitted, subject to the approval of the authority having jurisdiction.

2-6.2 Fueling Facilities.

In addition to the special requirements of this chapter, the fuel storage, piping, and dispensing system shall comply with the requirements of NFPA 30, *Flammable and Combustible Liquids Code*, and with applicable portions of this standard.

2-6.3 Dispensing Devices.

2-6.3.1 Listed or approved dispensing devices shall be used.

2-6.3.2 Access to dispensing equipment shall be controlled by means of mechanical or electronic devices designed to resist tampering and to prevent access or use by unauthorized persons.

2-6.3.3 Dispensing devices shall have a listed or approved emergency shutoff valve, incorporating a fusible link or other thermally actuated device designed to close automatically in case of fire. This valve also shall incorporate a shear section that automatically shuts off the flow of fuel due to severe impact. This valve shall be rigidly mounted at the base of the dispenser in accordance with the manufacturer's instructions.

2-6.3.4 Dispensing devices shall be located on an island to protect against collision damage or shall be suitably protected with pipe bollards or other suitable protection.

2-6.3.5* Dispensing devices or cabinets shall be designed so that a proper bond between the aircraft and the fueling equipment can be established in accordance with Section 3-4.

2-6.4

Hose shall comply with the requirements of Section 2-2. Two or more lengths of hose shall not be coupled together.

2-6.5 Nozzles.

2-6.5.1 Overwing nozzles shall conform to 2-3.15.2.

2-6.5.2 Underwing nozzles shall conform to 2-3.15.3.

2-6.6 Emergency Fuel Shutoff System.

2-6.6.1 A system conforming with 2-4.5 shall be provided to shut off the flow of fuel completely in an emergency. The emergency fuel shutoff controls shall be in addition to the normal operating controls for the dispenser and deadman control.

2-6.6.2 The controls shall be designed to allow only authorized personnel to reset the system after an emergency fuel shutoff.

2-6.6.3 The emergency fuel shutoff controls shall be installed in a location acceptable to the authority having jurisdiction and shall be more than 20 ft (7 m) but less than 100 ft (30 m) from the dispensers.

2-6.7

A clearly identified means to notify the fire department shall be provided and shall be located in the immediate vicinity of each emergency fuel shutoff control.

2-6.8

Each facility shall have a minimum of one fire extinguisher with a rating of at least 20-B:C located at the dispenser and one fire extinguisher with a rating of at least 20-B:C at each emergency fuel shutoff control.

2-6.9

In addition to the warning signs specified in 2-4.5.7 and 3-8.1, emergency instructions shall be conspicuously posted in the dispensing area and at the emergency fuel shutoff control and shall provide the address of the site and incorporate the following or equivalent wording:

EMERGENCY INSTRUCTIONS:

In case of fire or spill:
1. Use emergency fuel shutoff.
2. Report accident by calling (specify local fire emergency reporting number) on phone.
3. Report address of site (list address of site here).

2-6.10 Operating Instructions.

Operating instructions shall be posted. The instructions shall include the proper operation and use of all equipment, correct bonding procedures, the procedures that are to be employed to dispense fuel safely, the location and use of the emergency fuel shutoff controls, the use of the available fire extinguishers, and the procedures to be used in the event of an emergency.

Chapter 3 Operations

3-1 General.

3-1.1

Only authorized personnel trained in the safe operation of the equipment they use, in the operation of emergency controls, and in the procedures to be followed in an emergency shall fuel or defuel aircraft.

3-1.2

Where a valve or electrical device is used for isolation during maintenance or modification of the fuel system, it shall be tagged/locked. The tag/lock shall not be removed until the operation is completed.

3-2* Prevention and Control of Spills.

3-2.1

Fuel servicing equipment shall comply with the requirements of this standard and shall be maintained in safe operating condition. Leaking or malfunctioning equipment shall be removed from service.

3-2.2

Fuel nozzles shall not be dragged along the ground.

3-2.3

Pumps, either hand operated or power operated, shall be used where aircraft are fueled from drums. Pouring or gravity flow shall not be permitted from a container with a capacity of more than 5 gal (18.9 L).

3-2.4

Where a spill is observed, the fuel servicing shall be stopped immediately by release of the deadman controls. In the event that a spill continues, the equipment emergency fuel shutoff shall be actuated. In the event that a spill continues from a hydrant system, the system emergency fuel shutoff shall be actuated. The supervisor shall be notified at once, and the operation shall not be resumed until the spill has been cleared and conditions are determined to be safe.

3-2.5

The airport fire crew shall be notified if a spill covers over 10 ft (3 m) in any direction or is over 50 ft^2 (5 m^2) in area, continues to flow, or is otherwise a hazard to persons or property. The spill shall be investigated to determine the cause, to determine whether emergency procedures were properly carried out, and to determine the necessary corrective measures.

3-2.6

Transferring fuel by pumping from one tank vehicle to another tank vehicle within 200 ft (61 m) of an aircraft shall not be permitted.

3-2.7

Not more than one tank vehicle shall be permitted to be connected to the same aircraft fueling manifold.

Exception: Where means are provided to prevent fuel from flowing back into a tank vehicle because of a difference in pumping pressure.

3-3 Emergency Fuel Shutoff.

3-3.1

Access to emergency fuel shutoff control stations shall be kept clear at all times.

3-3.2

A procedure shall be established to notify the fire department serving the airport in the event of a control station activation.

3-3.3

If the fuel flow stops for any reason, it first shall be presumed that an emergency fuel shutoff system has been actuated. The cause of the shutoff shall be corrected before fuel flow is resumed.

3-3.4

Emergency fuel shutoff devices shall be operationally checked at least every 3 months.

3-3.5

Suitable records shall be kept of tests required by this section.

3-4* Bonding.

3-4.1

Prior to making any fueling connection to the aircraft, the fueling equipment shall be bonded to the aircraft by use of a cable, thus providing a conductive path to equalize the potential between the fueling equipment and the aircraft. The bond shall be maintained until fueling connections have been removed, thus allowing separated charges that could be generated during the fueling operation to reunite.

3-4.2

In addition to the above, where fueling overwing, the nozzle shall be bonded with a nozzle bond cable having a clip or plug to a metallic component of the aircraft that is metallically connected to the tank filler port. The bond connection shall be made before the filler cap is removed. If there is no plug receptacle or means for attaching a clip, the operator shall touch the filler cap with the nozzle spout before removing the cap in order to equalize the potential between the nozzle and the filler port. The spout shall be kept in contact with the filler neck until the fueling is completed.

3-4.3*

Where a funnel is used in aircraft fueling, it shall be kept in contact with the filler neck as well as the fueling nozzle spout or the supply container to avoid the possibility of a spark at the fill opening. Only metal funnels shall be used.

3-4.4

Where a hydrant servicer or cart is used for fueling, the hydrant coupler shall be connected to the hydrant system prior to bonding the fuel equipment to the aircraft.

3-4.5

Bonding and fueling connections shall be disconnected in the reverse order of connection.

3-4.6

Conductive hose shall be used to prevent electrostatic discharge but shall not be used to accomplish required bonding.

3-5 Operation of Aircraft Engines and Heaters.

3-5.1

Fuel servicing shall not be performed on a fixed wing aircraft while an onboard engine is operating. (*See Section 3-21.*)

Exception: In an emergency resulting from the failure of an onboard auxiliary power unit on a jet aircraft and in the absence of suitable ground support equipment, a jet engine mounted at the rear of the aircraft or on the wing on the side opposite the fueling point shall be permitted to be operated during fueling to provide power, provided that the operation follows written procedures approved by the authority having jurisdiction.

3-5.2

Combustion heaters on aircraft (e.g., wing and tail surface heaters, integral cabin heaters) shall not be operated during fueling operations.

3-6 Internal Combustion Engine Equipment Around Aircraft (Other than Aircraft Fuel Servicing Vehicles).

3-6.1

Equipment, other than that performing aircraft servicing functions, shall not be permitted within 50 ft (15 m) of aircraft during fuel servicing operations.

3-6.2

Equipment performing aircraft servicing functions shall not be positioned within a 10-ft (3-m) radius of aircraft fuel system vent openings.

3-6.3

During overwing aircraft fuel servicing where aircraft fuel system vents are located on the upper wing surface, equipment shall not be positioned under the trailing edge of the wing.

3-7* Electrical Equipment Used on Aircraft Servicing Ramps.

3-7.1

Battery chargers shall not be connected, operated, or disconnected while fuel servicing is performed on the aircraft.

3-7.2*

Aircraft ground-power generators or other electrical ground-power supplies shall not be connected or disconnected while fuel servicing is performed on the aircraft.

3-7.3

Electric tools or similar tools likely to produce sparks or arcs shall not be used while fuel servicing is performed on the aircraft.

3-7.4

Photographic equipment shall not be used within 10 ft (3 m) of the fueling equipment or the fill or vent points of aircraft fuel systems.

3-7.5

Battery-powered vehicle equipment shall not be operated within 10 ft (3 m) of fueling equipment or spills.

3-7.6

Communication equipment used during aircraft fuel servicing operations within 10 ft (3 m) of the fueling equipment or the fill or vent points of aircraft fuel systems shall be intrinsically safe in accordance with UL 913, *Standard for Intrinsically Safe Apparatus and Associated Apparatus for Use in Class I, II, and III Division 1, Hazardous (Classified) Locations*.

3-8 Open Flames on Aircraft Fuel Servicing Ramps.

3-8.1

Entrances to fueling areas shall be posted with “no smoking” signs.

3-8.2

Open flames on aircraft fuel servicing ramps or aprons within 50 ft (15 m) of any aircraft fuel servicing operation or fueling equipment shall be prohibited.

3-8.3

The category of open flames and lighted open-flame devices shall include, but shall not be limited to, the following:

(a) Lighted cigarettes, cigars, pipes;

(b) Exposed flame heaters, liquid, solid, or gaseous devices, including portable and wheeled gasoline or kerosene heaters;

(c) Heat-producing, welding, or cutting devices and blowtorches;

(d) Flare pots or other open-flame lights.

3-8.4

The authority having jurisdiction might establish other locations where open flames and open-flame devices shall not be permitted.

3-8.5

Personnel shall not carry lighters or matches on their person while engaged in fuel servicing operations.

3-8.6

Lighters or matches shall not be permitted on or in fueling equipment.

3-9* Lightning Precautions.

3-9.1

Fuel servicing operations shall be suspended where there are lightning flashes in the immediate vicinity of the airport.

3-9.2

A written procedure shall be established to set the criteria for where fueling operations must be suspended at each airport as approved by the fueling agent and the airport authority.

3-10 Aircraft Fuel Servicing Locations.

3-10.1

Aircraft fuel servicing shall be performed outdoors. Aircraft fuel servicing incidental to aircraft fuel system maintenance operations shall comply with the requirements of NFPA 410, *Standard on Aircraft Maintenance.*

3-10.2*

Aircraft being fueled shall be positioned so that aircraft fuel system vents or fuel tank openings are not closer than 25 ft (8 m) from any terminal building, hangar, service building, or enclosed passenger concourse other than a loading walkway. Aircraft being fueled shall not be positioned so that the vent or tank openings are within 50 ft (15 m) of any combustion and ventilation air-intake to any boiler, heater, or incinerator room.

3-10.3

Accessibility to aircraft by emergency fire equipment shall be established for aircraft fuel servicing positions.

3-11 Aircraft Occupancy During Fuel Servicing Operations.

3-11.1

If passengers remain onboard an aircraft during fuel servicing, at least one qualified person trained in emergency evacuation procedures shall be in the aircraft at or near a door at which there is a passenger loading walkway, integral stairs that lead downward, or a passenger loading stair or stand. A clear area for emergency evacuation of the aircraft shall be maintained at not less than one additional exit. Aircraft operators shall establish specific procedures covering emergency evacuation under such conditions for each type of aircraft they operate. All "no smoking" signs shall be displayed in the cabin(s) and the no smoking rule shall be enforced.

3-11.2

For each aircraft type, operators shall determine the areas through which it could be hazardous for boarding or deplaning passengers to pass while the aircraft is being fueled. Controls shall be established so that passengers avoid such areas.

3-12 Positioning of Aircraft Fuel Servicing Vehicles.

3-12.1

Aircraft fuel servicing vehicles shall be positioned so that a clear path of egress from the aircraft for fuel servicing vehicles shall be maintained.

3-12.2

The propulsion or pumping engine of aircraft fuel servicing vehicles shall not be positioned under the wing of the aircraft during overwing fueling or where aircraft fuel system vents are located on the upper wing surface. Aircraft fuel servicing vehicles shall not be positioned within a 10-ft (3-m) radius of aircraft fuel system vent openings.

3-12.3

Parking brakes shall be set on fuel servicing vehicles before operators leave the vehicle cab.

3-13* Portable Fire Extinguishers.

3-13.1

During fueling operations, fire extinguishers shall be available on aircraft servicing ramps or aprons.

3-13.2

Each aircraft fuel servicing tank vehicle shall have two listed fire extinguishers, each having a rating of at least 20-B:C, with one extinguisher mounted on each side of the vehicle.

3-13.3

There shall be one listed fire extinguisher having a rating of at least 20-B:C installed on each hydrant fuel servicing vehicle.

3-13.4

Where the open hose discharge capacity of the aircraft fueling system or equipment is more than 200 gal per minute (750 L/min), at least one listed wheeled extinguisher having a rating of not less than 80-B:C and a minimum capacity of 125 lb (55 kg) of agent shall be provided.

3-13.5*

Extinguishers shall be kept clear of elements such as ice and snow. Extinguishers located in enclosed compartments shall be readily accessible and their location shall be marked clearly in letters at least 2 in. (50 mm) high.

3-13.6*

Fuel servicing personnel shall be trained in the use of the available fire extinguishing equipment they might be expected to use.

3-14 Defueling.

3-14.1

The transfer of fuel from an aircraft to a tank vehicle through a hose generally is similar to fueling, and the same requirements shall apply. In addition, each operator shall establish procedures to prevent the overfilling of the tank vehicle, which is a special hazard when defueling.

3-14.2

Where draining residual fuel from aircraft tanks incidental to aircraft fuel system maintenance, testing, manufacturing, salvage, or recovery operations, the procedures of NFPA 410, *Standard on Aircraft Maintenance*, shall apply.

3-15 Deadman Control Monitoring.

3-15.1

The fueling operator shall monitor the panel of the fueling equipment and the aircraft control panel during pressure fueling or shall monitor the fill port during overwing fueling.

3-15.2

Fuel flow shall be controlled by use of a deadman control device. The use of any means that defeats the deadman control shall be prohibited.

3-16* Aircraft Fueling Hose.

3-16.1

Aircraft fueling hose shall be inspected before use each day. The hose shall be extended as it normally would be for fueling and checked for evidence of blistering, carcass saturation or separation, cuts, nicks, or abrasions that expose reinforcement material, and for slippage, misalignment, or leaks at couplings. If coupling slippage or leaks are found, the cause of the problem shall be determined. Defective hose shall be removed from service.

3-16.2

At least once each month the hose shall be completely extended and inspected as required in 3-16.1. The hose couplings and the hose shall be examined for a length approximately 12 in. (305 mm) adjacent to the couplings. Structural weakness shall be checked by pressing the hose in this area around its entire circumference for soft spots. Hoses that show evidence of soft spots shall be removed from service. The nozzle screens shall be examined for rubber particles. The presence of such particles indicates possible deterioration of the interior, and the hose shall be removed from service. With the hose still completely extended, it shall be checked at the working pressure of the fueling equipment to which it is attached. Any abnormal twisting or ballooning during this test indicates a weakening of the hose carcass, and the hose shall be removed from service.

3-16.3

A hose assembly that has been subjected to abuse, such as severe end-pull, flattening or crushing by a vehicle, or sharp bending or kinking, shall be removed from service. It shall be hydrostatically tested prior to use. (*See 2-2.2.1.*)

3-16.4

If inspection shows that a portion of a hose has been damaged, the damaged portion shall be cut off and the undamaged portion recoupled. Two lengths of hose shall not be coupled together. Only couplings that are an exact match for the interior and exterior dimensions of the hose shall be used. Recoupled hose assemblies shall be hydrostatically tested. (*See 2-2.2.1*.)

3-16.5

Before any hose assembly, new or recoupled, is placed in service, it shall be visually inspected for evidence of damage or deterioration.

3-16.6

Kinks or short loops in fueling hose shall be avoided.

3-16.7

Suitable records shall be kept of required inspections and hydrostatic tests.

3-17 Maintenance of Aircraft Fuel Servicing Vehicles.

3-17.1

Aircraft fuel servicing vehicles shall not be operated unless they are in proper repair and free of accumulations of grease, oil, or other combustibles.

3-17.2

Leaking vehicles shall be removed from service, defueled, and parked in a safe area until repaired.

3-17.3

Maintenance and servicing of aircraft fuel servicing vehicles shall be performed outdoors or in a building approved for the purpose.

3-18 Parking Aircraft Fuel Servicing Tank Vehicles.

Parking areas for unattended aircraft fuel servicing tank vehicles shall be arranged to provide the following:

(a) Dispersal of the vehicles in the event of an emergency;

(b) A minimum of 10 ft (3 m) of clear space between parked vehicles for accessibility for fire control purposes;

(c) Prevention of any leakage from draining to an adjacent building or storm drain that is not suitably designed to handle fuel;

(d) A minimum of 50 ft (15 m) from any parked aircraft and buildings other than maintenance facilities and garages for fuel servicing tank vehicles.

3-19 Parking Aircraft Fuel Servicing Hydrant Vehicles.

Parking areas for unattended aircraft fuel servicing hydrant vehicles shall be arranged to provide the following:

(a) Dispersal of the vehicles in the event of an emergency;

(b) Prevention of any leakage from draining to an adjacent building or storm drain that is not suitably designed to handle fuel.

3-20 Loading of Aircraft Fuel Servicing Tank Vehicles.

3-20.1 General Requirements.

3-20.1.1 Filling of the vehicle cargo tank shall be under the observation and control of a qualified and authorized operator at all times.

3-20.1.2 The required deadman and automatic overfill controls shall be in normal operating condition during the filling operation. They shall not be blocked open or otherwise bypassed.

3-20.1.3 The engine of the tank vehicle shall be shut off before starting to fill the tank.

3-20.1.4 To prevent leakage or overflow from expansion of the contents due to a rise in atmospheric temperature or direct exposure to the sun, no cargo tank or compartment shall be loaded to the point where it is liquid full.

3-20.2 Top Loading.

3-20.2.1 Where loading tank trucks through open domes, a bond shall be established between the loading piping and the cargo tank to equalize potentials. The bond connection shall be made before the dome is opened and shall be removed only after the dome is closed.

3-20.2.2 Drop tubes attached to loading assemblies extending into the vehicle tank shall extend to the bottom of the tank and shall be maintained in that position until the tank is loaded to provide submerged loading and avoid splashing or free fall of fuel through the tank atmosphere. The flow rate into the tanks shall not exceed 25 percent of the maximum flow until the outlet is fully covered.

3-20.2.3 The level in the tank shall be visually monitored at all times during top loading.

3-20.3 Bottom Loading.

3-20.3.1 A bonding connection shall be made between the cargo tank and the loading rack before any fuel connections are made and shall remain in place throughout the loading operation.

3-20.3.2 The operator shall initiate fuel flow by means of a deadman control device.

3-20.3.3 The operator shall perform the precheck on each compartment shortly after flow has started to ensure that the automatic high-level shutoff system is functioning properly.

3-21 Rapid Refueling of Helicopters.

3-21.1

Only turbine engine helicopters fueled with Jet A or Jet A-1 fuels shall be permitted to be fueled while an onboard engine is operating.

Helicopters permitted to be fueled while an onboard engine is operating shall have all sources of ignition of potential fuel spills located above the fuel inlet port(s) and above the vents or tank openings. Ignition sources shall include, but shall not be limited to, engines, exhausts, APUs, and combustion-type cabin heater exhausts.

3-21.2

Helicopter fueling while onboard engines are operating shall be permitted only under the following conditions:

(a) An FAA-licensed helicopter pilot shall be at the aircraft controls during the entire fuel servicing process.

(b)* Passengers shall be deboarded to a safe location prior to rapid refueling operations. Where the pilot in command deems it necessary for passengers to remain onboard for safety reasons, the provisions of 3-11.1 shall apply.

(c) Passengers shall not board or deboard during rapid refueling operations.

(d) Only designated personnel, properly trained in rapid refueling operations, shall operate the equipment. Written procedures shall include the safe handling of the fuel and equipment.

(e) All doors, windows, and access points allowing entry to the interior of the helicopter that are adjacent to, or in the immediate vicinity of, the fuel inlet ports shall be closed and shall remain closed during refueling operations.

(f) Fuel shall be dispensed into an open port from approved deadman-type nozzles, with a flow rate not to exceed 60 gpm (227 L/min), or it shall be dispensed through close-coupled pressure fueling ports. Where fuel is dispensed from fixed piping systems, the hose cabinet shall not extend into the rotor space. A curb or other approved barrier shall be provided to restrict the fuel servicing vehicle from coming closer than within 10 ft (3 m) of any helicopter rotating components. If a curb or approved barrier cannot be provided, fuel servicing vehicles shall be kept 20 ft (6 m) away from any helicopter rotating components, and a trained person shall direct fuel servicing vehicle approach and departure.

3-22 Self-service Fueling.

Occupancy of the aircraft during self-service fueling shall be prohibited.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-2 Fire Hazards in Aircraft Fuel Servicing.

(a) Aircraft fuel servicing involves the transfer of a flammable or combustible liquid fuel between a bulk storage system and the fuel tanks of an aircraft. It includes both fueling and defueling. The transfer is usually accomplished by using a tank vehicle, a hydrant vehicle, a fuel servicing cabinet, or a fueling pit. Drums and pumps sometimes are used.

The movement of the fuel through the pumps, piping, and filters of the transfer system causes the fuel to be charged electrostatically.

If the charge on the fuel is sufficiently high when it arrives at the fuel tank, a static spark could occur that might ignite the fuel vapor.

(b) During overwing fueling, the fuel is discharged into an opening in the aircraft fuel tank using a hose with a hand-held nozzle. The flow and splashing of fuel causes the generation of static electricity and the production of flammable mists and vapors. Top loading of tank vehicles creates similar hazards.

(c) Underwing servicing, hydrant servicing, and bottom loading of tank vehicles use hoses or flexible connections of metal tubing or piping, as well as devices to allow temporary connection of fuel transfer lines. These methods minimize the charge generation and misting hazards associated with overwing fueling and top loading.

(d) Other potential sources of ignition that could present a hazard during aircraft fuel servicing include:

1. Operating aircraft engines, auxiliary power units, and heaters.

2. Operating automotive or other internal combustion engine servicing equipment in the vicinity.

3. Arcing of electrical circuits.

4. Open flames.

5. Energy from energized radar equipment.

6. Lightning.

(e) The autoignition temperatures of turbine fuels (*see A-1-3, "Aviation Fuel"*) are such that the residual heat of aircraft turbine engines after shutdown or the residual heat of turbine aircraft brakes following hard use can ignite such fuels if they are spilled or sprayed on these surfaces before they have cooled below the autoignition temperatures of the fuels.

(f) Aircraft fuel tank vents usually are located some distance above ground level. Under normal conditions, fuel vapors from the vents are quickly dissipated and diluted safely. Fuel spilling from the vents of an overfilled tank is a much more serious hazard. Spills resulting from leaks or equipment failure also are a hazard.

(g) Fire prevention measures in aircraft fuel servicing are directed principally toward the following:

1. Prevention of fuel spillage;

2. Elimination or control of potential ignition sources.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-3 Aviation Fuel.

The fire hazard properties of aviation fuels are best described by analyzing the following:

I. Susceptibility to or Ease of Ignition.

(a) *Flash Point.*

1. The flash point of standard grades of aviation gasoline has been established at approximately -50°F (-46°C) at sea level by the Tag closed-cup method. The flash point of JET B turbine fuel is not regulated by specification, but samples have been tested by the closed-cup method and have been found to be as low as -10°F (-23°C) at sea level. JET A or kerosene grade turbine fuels have a minimum flash point of 100°F (38°C).

2. Aviation gasoline and JET B turbine produce large volumes of vapor and are capable of forming ignitible mixtures with air even at very low temperatures. Kerosene grades of turbine fuel (JET A) do not produce ignitible mixtures with air at normal temperatures and pressures, but when a JET A turbine fuel is heated above its flash point (or exists in the form of a mist), the mixture can be ignited. This condition can develop where temperatures are 100°F (38°C) or higher.

(b) *Flammability Conditions.*

1. The lower limit represents the minimum concentration while the upper limit defines the maximum amount of fuel vapors in air that allows combustion. The generally accepted flammability range by volume for most gasolines is 1.4 percent to 7.6 percent. The average range for JET B turbine fuels is 1.16 percent to 7.63 percent. The average range for kerosene grade (JET A) turbine fuels is 0.74 percent to 5.32 percent.

2. More significant than the strict flammability range is the temperature range in which it is possible for such flammable vapor-air mixtures to form. At sea level in a storage tank, such a temperature range for aviation gasoline is approximately -50°F to 30°F (-46°C to -1°C); for JET B turbine fuels, the range is approximately -10°F to 80°F (-23°C to 27°C); and, for kerosene grade (JET A) turbine fuels, the range is approximately 100°F to 165°F (38°C to 74°C). It is evident that JET B turbine fuels represent the most serious practical hazard under normal temperature conditions.

3. Air enters as vented tanks are drained, and, during such periods, the flammable vapor conditions can change drastically. The same change occurs when the aircraft descends in altitude. These facts are important in assessing the degree of hazard that could exist in a tank containing any of these volatile products during or after such air mixing.

4. Under aircraft crash impact conditions where fuel mists are created following tank failures, all of the fuels are readily ignitible at essentially all ambient temperatures. Under these conditions, fuel in mist form presents a hazard equal to fuel in vapor form with respect to flammability limits.

(c) *Vapor Pressure.*

1. The vapor pressure of these fuels is the pressure of the vapor at any given temperature at which the vapor and liquid phases of the substance are in equilibrium in a closed container. Such pressures vary with the temperature, but, most commonly, information on hydrocarbon mixtures is obtained using the Reid method, in which the pressures are measured at 100°F (38°C) [*see ASTM D 323, Standard Test Method for Vapor Pressure of Petroleum Products (Reid Method)*]. The Reid vapor pressures of average grades of aviation gasoline have a range of 5.5 psi to 7.0 psi (38 kPa to 48 kPa). For JET B turbine fuels, the Reid vapor pressure range is 2.0 psi to 3.0 psi (14 kPa to 21 kPa). JET A (kerosene grade) turbine fuels have a Reid vapor pressure range of approximately 0.1 psi (0.7 kPa).

2. The practical significance of this characteristic of the three grades of fuel is that the standard grades of aviation gasoline do produce flammable vapors in ignitible amounts at normal temperatures and pressures. However, where these vapors are confined, the vapor-air mixture over the liquid surface most often is too rich to be ignited by sparks, since it is above the upper flammability limit. With JET B turbine fuel, due to its relatively low vapor pressure, the vapor-air mixture above the liquid surface under normal temperature and pressure conditions frequently is within the flammability range. This means that ignition of JET B turbine fuel vapors either within or exterior to a tank can cause violent combustion within the confined space if flame enters. The JET A (kerosene grade) turbine fuels do not produce flammable vapors in ignitible amounts unless the fuel temperature is above 100°F (38°C).

(d) *Autoignition Temperature.*

1. The autoignition temperature is the minimum temperature of a substance which will initiate or cause self-sustained combustion independently of any sparks or other means of ignition.

2. Under one set of test conditions, standard grades of aviation gasoline have ignition temperatures approximating 840°F (449°C). Turbine fuels have ignition temperatures among the lowest found for hydrocarbons and are considerably lower than those for aviation gasoline. For example, the autoignition temperature of a JET B turbine fuel was measured using the same test procedure at approximately 480°F (249°C). A JET A (kerosene grade) turbine fuel tested under the same method was found to have an autoignition temperature approximating 475°F (246°C). Temperatures in this range can exist for a considerable period in turbine engines after shutdown or on brake surfaces following hard use.

3. It should be noted that these temperatures are derived from reproducible laboratory test procedures, whereas, in actual field conditions, these ignition temperatures might be higher.

(e) *Distillation Range.*

1. The initial and the end boiling points of standard grades of aviation gasoline are approximately 110°F and 325°F (43°C and 163°C), respectively. The initial boiling point of JET B turbine fuels is approximately 135°F (57°C) and the end point is approximately 485°F (252°C). The only marked difference in the distillation ranges of the three fuels under consideration occurs in the JET A or kerosene grades of turbine fuels that have initial boiling points of approximately 325°F (163°C) and end points of approximately 572°F (300°C).

NOTE: Initial and end boiling points should be determined by ASTM D 86, *Standard Test Method for*

Distillation of Petroleum Products.

2. The boiling range, along with the flash points and vapor pressures of the fuels, indicates the relative volatility of the fuels; the initial and end boiling points indicate the overall volatility of a fuel through its entire distillation range; the flash point and vapor pressures measure the initial tendency of the fuel to vaporize.

II. Fire Severity After Ignition.

(a) *Heat of Combustion.*

1. The net heat of combustion of gasoline normally is quoted as approximately 19,000 Btu/lb (44.19 kJ/kg). For JET B turbine fuels, the average is approximately 18,700 Btu/lb (43.50 kJ/kg), while for the JET A (kerosene grades) of turbine fuels it is approximately 18,600 Btu/lb (43.26 kJ/kg).

2. These figures for heat of combustion clearly indicate that there is little difference in the heats of combustion for these various hydrocarbons that are of significance with regard to fire safety.

(b) *Rate of Flame Spread.*

Where fuel is spilled, there is a marked difference in the rates of flame spread over pools of JET A or kerosene grades of turbine fuel as compared with the other two types. Under these conditions, a direct relationship exists between the rate of flame spread and the vapor pressures of the materials. A report dated October 1973 entitled "An Evaluation of the Relative Fire Hazards of JET A and JET B for Commercial Flight" (N74-10709) states that the rate (of flame spread) for JP-4 (JET B) is about 30 times greater than for aviation kerosene (JET A) at the temperatures most often encountered. This is an important factor in evaluating the severity of the fire hazard encountered under these conditions and also is a factor that affects the ease of fire control under similar conditions.

This slower rate of flame propagation for JET A or kerosene grades of turbine fuel does not occur, however, where the fuel is released as a fuel mist, as frequently results in aircraft impact accidents or where the fuels are heated to or above their flash point. If a flammable or combustible liquid exists in mist form or is at a temperature above its flash point, the speed of flame spread in the mist or vapor is essentially the same, regardless of the liquid spilled.

III. Fire Control Factors.

(a) *Relative Density.*

1. The relative density of a material is commonly expressed as related to water at 60°F (16°C). All these fuels are lighter than water; the relative density of aviation gasolines is normally quoted at about 0.70, JET B turbine fuels at about 0.78, and the JET A (kerosene grade) fuels at about 0.81.

2. This means that, with respect to fire control, all of the fuels float on water. This can be a handicap during fire-fighting operations under certain conditions where sizable quantities of spilled fuel are involved.

(b) *Solubility in Water.*

1. All three of the fuels are essentially nonsoluble in water. Fires involving all three fuels

can be handled with regular foam concentrates (as opposed to alcohol types).

2. The amount of water that is entrained in the fuel due to water contamination is not particularly significant from a fire hazard viewpoint, except for the fact that the amount of water increases the static generation hazard of the fuel.

(c) *Standard Grades of Aviation Fuels.* Standard grades of aviation fuels include:

1. Aviation gasoline (AVGAS) includes all gasoline grades of fuel for reciprocating engine-powered aircraft of any octane rating. It has the general fire hazard characteristics of ordinary automotive gasoline (MOGAS).

2. JET A and JET A-1 are kerosene grades of fuel for turbine engine-powered aircraft, whatever the trade name or designation. JET A has a -40°F (-58°C) freezing point (maximum); JET A-1 incorporates special low temperature characteristics for certain operations having a -53°F (-47°C) freezing point (maximum). JP-8 (identical to JET A except for the additive package) and JP-5 (slightly less volatile than either JET A or JET A-1) are used by certain U.S. military forces. Jet A and JP-8 are known in the United Kingdom and in many former UK areas of influence as AVTUR, whereas JP-5 is similar to the UK designated AVCAT.

3. JET B is a blend of gasoline and kerosene grades of fuel for turbine engine-powered aircraft, whatever the trade name or designation. JET B is a relatively wide boiling range volatile distillate having a -60°F (-51°C) freezing point (maximum). JP-4 is one grade of JET B fuel used by the U.S. military forces; JP-4 has identical specifications to JET B as they relate to fire hazards. This fuel is known in the United Kingdom as AVTAG.

A-1-3 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1.2.5 The charge on the fuel can be reduced by the use of a static dissipater additive that increases the electrical conductivity of the fuel and thereby allows the charge to relax or dissipate more quickly, or by the use of a relaxation chamber that increases the residence time of the fuel downstream of the filter to at least 30 seconds, thereby allowing most of the charge to dissipate before the fuel arrives at the receiving tank.

API RP 2003, *Protection Against Ignitions Arising Out of Static, Lightning, and Stray Currents*, recommends a 30-second relaxation time for loading tank trucks and refuelers. However, it has not been a common practice to require a similar relaxation time for aircraft refueling, primarily because of the relatively few electrostatic incidents that have occurred during aircraft fueling.

In filling tank trucks or storage tanks, API RP 2003 recommends that at least 30 seconds of residence time be provided downstream of a filter in order to allow static charges generated in flowing fuel to relax before fuel enters the tank.

The reason it is possible to fuel aircraft safely with low conductivity fuel without providing 30 seconds relaxation time is due primarily to the difference in the geometry of aircraft tanks as compared with tank truck compartments. Flow into the aircraft normally is subdivided into several tanks simultaneously and also distributed into adjoining compartments of each tank by a multihole inlet. Bachman and Dukek[1] conducted full-scale research using a simulated large aircraft tank and concluded that none of the tanks or compartments hold sufficient fuel to allow enough charges to accumulate and create large surface voltages. Slower fill rates per compartment also allow more charge to relax.

---

[1]Bachman, K.C. and Dukek, W. G., "Static Electricity in Fueling Superjets," 1972. Exxon Research & Eng. Co. Brochure, Linden, NJ.

Additionally, the inlet system of most aircraft tanks directs fuel towards the bottom of the tank to avoid splashing that generates more charge. Finally, while the hoses that connect the fueler to the aircraft provide only a few seconds of residence time for charge relaxation at high rates of flow, the actual relaxation volume in the system is significantly greater where a coated screen is used as a second stage water barrier. In this case, the vessel's volume after the first stage filter coalescer might represent an additional 15 seconds of residence time for charge relaxation. (The coated screen, unlike other water barriers, does not generate charge.)

A flammable vapor space in the tank due to the presence of Jet B or JP-4 fuels still constitutes a potential hazard. Therefore, to minimize the chance for static ignition, FAA regulations require that fueling be conducted at half of the rated flow where civil aircraft have used such fuels.

A-2-1.4.2 Radar Ignition Hazards.

(a) The beam of radar equipment has been known to cause ignition of flammable vapor-air mixtures from inductive electric heating of solid materials or from electrical arcs or sparks from chance resonant conditions. The ability of an arc to ignite flammable vapor-air mixtures depends on the total energy of the arc and the time lapse involved in the arc's duration, which is related to the dissipation characteristics of the energy involved. The intensity or peak power output of the radar unit, therefore, is a key factor in establishing safe distances between the radar antenna and fueling operations, fuel storage or fuel loading rack areas, fuel tank truck operations, or any operations where flammable liquids and vapors could be present or created.

(b) Most commercially available weather-mapping airborne radar equipment operates at peak power outputs, varying from 25 kW to 90 kW. Normally this equipment should not be operated on the ground. Tests have shown that the beam of this equipment can induce energy capable of firing flash bulbs at considerable distances. If the equipment is operated on the ground for service checking or for any other reason, the beam should not be directed toward any of the hazards described in A-2-1.4.2(a) that are located within 100 ft (30 m). (WARNING: Higher power radar equipment can require greater distances.)

(c) Airport surface detection radar operates under a peak power output of 50 kW. It is fixed rather than airborne equipment.

(d) Airborne surveillance radar of the type currently carried on military aircraft has a high peak power output. Aircraft carrying this type of radar can be readily distinguished by radomes atop or below the fuselage, or both.

(e) Aircraft warning radar installations are the most powerful. Most of these installations are, however, remotely located from the hazards specified in A-2-1.4.2(a) and therefore are not covered herein. Ground radar for approach control or traffic pattern surveillance is considered the most fire hazardous type of radar normally operating at an airport. The latter type of equipment has a peak power output of 5 MW. Where possible, new installations of this type of equipment should be located at least 500 ft (150 m) from any of the hazards described in A-2-1.4.2(a).

A-2-1.6.1 Multipurpose dry chemical (ammonium phosphate) should not be selected due to corrosion concerns relative to the agent. Carbon dioxide extinguishers should not be selected due to their limited range and effectiveness in windy conditions.

A-2-1.7

Deadman controls should be designed so that the operator can use them comfortably while wearing gloves and hold them for the time needed to complete the operation. A pistol grip deadman device that is squeezed to operate is preferable to a small button that needs to be held by a thumb or finger.

A-2-2

The section on aircraft refueling hose has been altered extensively by referencing API BULL 1529, *Aviation Fueling Hose*. NFPA 407 formerly contained many requirements for hose, but it was intended only to address features that might be related to a fire or the results of a fire. It was not until 1982 that a comprehensive aircraft refueling hose specification was published by API. Prior to that time, NFPA 407 was the only document in existence that addressed this subject.

API BULL 1529 deals with all aspects of hose safety, including the couplings that are acceptable.

NFPA 407 recognizes the need for an extensive document such as API BULL 1529 and requires hoses that meet that standard. However, it is important to recognize that API does no testing and it does not regulate those manufacturers who claim to sell hose that meets API BULL 1529. The hose user and the cognizant authority in charge might find it prudent to require hose manufacturers to produce copies of test reports or documents that certify that hoses using the identical construction and compounds have been tested and have passed all requirements of API BULL 1529 satisfactorily.

A-2-3.6.3 Electrical Equipment in Aircraft Fuel Servicing Vehicle Engine Compartments. Equipment contained in the engine compartment or vehicle cab and located 18 in. (457 mm) or more aboveground may be permitted to be of the general purpose type.

A-2-3.20.4 Optional Precautions Against Misfueling of Aircraft Fuel Servicing Tank Vehicles. The coupler and truck fitting should be equipped with coded lugs or a mechanical device to ensure product selection and to prevent mixing of products. This might not be feasible on over-the-road-type tank vehicles.

A-2-4.4.1 Optional Guidance on Fuel Storage Tanks. Where pressure tanks are used, details on construction, spacing, and location should be in accordance with industry good practice and approved by the authority having jurisdiction. When AVGAS, MOGAS, or JET B turbine fuels are stored in bulk quantities in aboveground tanks, they should be stored in floating roof-type tanks. Covered floating roof tanks minimize the hazardous flammable vapor-air space above the liquid level. The vapor spaces of underground tanks storing fuels should not be interconnected.

A-2-4.5.2 Discussion of Fuel Transfer Methods. Fuel transfer by pumping is the more common procedure and normally is preferred from a fire protection standpoint, since it allows rapid shutdown of fuel flow through pump shutdown. Gravity transfer is the simplest method but normally is limited to relatively low flow rates. Because the static head does exert some pressure in the system, a safety shutdown should include a valve or valves located as close to the tank as practicable.

A-2-4.5.4 Alarms for Emergency Shutoff System. The operation of the emergency shutoff control should sound an alarm at the airport fire crew station and at the fuel storage facility.

A-2-4.6.11 System Component Isolation Guidance. Flanged connections should be provided for ease of dismantling and to avoid cutting and welding after the system has been placed in service. The location of these isolation devices depends upon the size and character of each system, but the following locations generally apply (*see Figure A-2-4.6.11*):

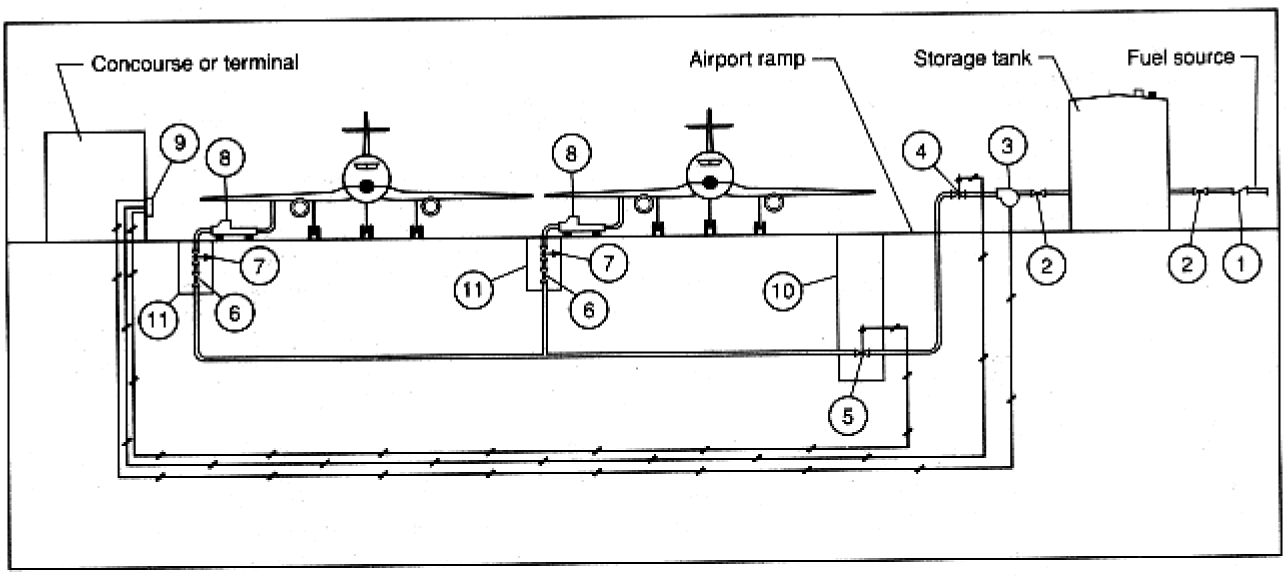
(a) At each storage tank;

(b) At each pump;

(c) At each filter separator;

(d) At each hydrant or on each hydrant lateral;

(e) At each flow regulator or pressure control valve.



NOTE: No dimensional relationship exists between elements in this figure. Refer to this standard, NFPA 30, *Flammable and Combustible Liquids Code*, NFPA 70, *National Electrical Code*, and FAA Regulations for separations and clearances.

1. Check valve at tank inlet
2. Isolation valve at tank inlet/outlet
3. Pumping system
4. Pump discharge control valve or hydrant system shutoff valve (alternate location)
5. Hydrant system shutoff valve (alternate location)
6. Hydrant shutoff valve
7. Hydrant pit valve
8. Hydrant fueling servicing vehicle
9. Emergency fuel shutoff station
10. Valve box
11. Hydrant pit

Figure A-2-4.6.11 Typical fixed airport fueling system isolation valving — operating and emergency controls.

A-2-4.7.3 Location of Surge Suppressors. Where surge suppressors are necessary, they should be located so that exposure to vehicular traffic, weather conditions, and the result of accidental rupture is minimized.

A-2-4.12

Cathodic protection is recommended for metal components of airport fueling systems and fuel storage facilities that are in contact with the ground. There are two types of cathodic protection as follows:

(a) The galvanic anode method, which generates its own current;

(b) The impressed current method, which has an external current source.

A-2-6.3.5 Although it is not technologically possible to have a bonding system that is 100 percent fail-safe, there are devices available that can help ensure that a proper bond has been established before fueling.

A-3-2 Handling Fuel Spills.

The following actions are appropriate in the event of a fuel spill, although each spill should be treated as an individual case due to such variables as the size of the spill, type of flammable or combustible liquid involved, wind and weather conditions, equipment arrangement, aircraft occupancy, emergency equipment, and personnel available.

(a) The flow of fuel should be stopped, if possible. If the fuel is discovered leaking or spilling from fuel servicing equipment or hoses, the emergency fuel shutoff should be operated at once. If the fuel is discovered leaking or spilling from the aircraft at the filler opening, vent line, or tank seams during fueling operations, fueling should be stopped immediately. Evacuation of the aircraft should be ordered when necessary. The aircraft then should be thoroughly checked for damage or entrance of flammable liquid or vapors into any concealed wing or fuselage area, and corrective action should be taken as necessary before it is returned to normal operational service.

(b) The airport fire crew should be notified if the spill presents a fire hazard. The only routine exceptions are for small spills. Supervisory personnel should be notified to ensure that operations in progress can be continued safely or halted until the emergency is past and that corrective measures can be taken to prevent recurrence of a similar accident.

(c) It might be necessary to evacuate the aircraft if the spill poses a serious fire exposure to the aircraft or its occupants. Walking through the liquid area of the fuel spill should not be permitted. Persons who have been sprayed with fuel or had their clothing soaked with fuel should go to a place of refuge, remove their clothing, and wash. Individuals whose clothing has been ignited should be wrapped in blankets, coats, or other items or should be told to or forced to roll on the ground.

(d) Mobile fueling equipment and all other mobile equipment should be withdrawn from the area or left as is until the spilled fuel is removed or made safe. No fixed rule can be made, as fire safety varies with circumstances. Shutting down equipment or moving vehicles can provide a source of ignition if no fire immediately results from the spillage.

(e) Aircraft, automotive, or spark-producing equipment in the area should not be started before the spilled fuel is removed or made safe. If a vehicle engine is running at the time of the spill, it normally is good practice to drive the vehicle away from the hazard area unless the hazard to personnel is judged too severe. Fuel servicing vehicles in operation at the time of the spill should not be moved until a check is made to verify that any fuel hose that might have been in use or connected between the vehicle and the aircraft is safely stowed.

(f) If any aircraft engine is operating at the time of the spill, it normally is good practice to move the aircraft away from the hazard area unless air currents set up by operating power plants would aggravate the extent or the nature of the existing vapor hazard.

(g) If circumstances dictate that operating internal combustion engine equipment within a spill area that has not ignited should be shut down, engine speeds should be reduced to idle prior to cutting ignition in order to prevent backfire.

(h) The volatility of the fuel can be a major factor in the initial severity of the hazard created by a spill. Gasoline and other low flash point fuels at normal temperatures and pressures produce vapors that are capable of forming ignitible mixtures with the air near the surface of the liquid, whereas this condition does not normally exist with kerosene fuels (JET A or JET A-1) except where ambient temperatures are 100°F (38°C) or above or where the liquid has been heated to a similar temperature.

(i) Spills of gasoline and low flash point turbine fuels (JET B) greater than 10 ft (3 m) in any dimension and covering an area of over 50 ft^2 (5 m^2) or that are of an ongoing nature should be blanketed or covered with foam. The nature of the ground surface and the existing exposure conditions dictate the exact method to be followed. Such fuels should not be washed down sewers or drains. The decision to use a sewer or drain should be made only by the chief of the airport fire brigade or the fire department. If fuels do enter sewers, either intentionally or unintentionally, large volumes of water should be introduced to flush such sewers or drains as quickly as possible to dilute the flammable liquid content of the sewer or drain to the maximum possible extent. Normal operations involving ignition sources (including aircraft and vehicle operations) should be prohibited on surface areas adjacent to open drains or manholes from which flammable vapors might issue due to the introduction of liquids into the sewer system until it can be established that no flammable vapor-air mixture is present in the proximity.

NOTE: See NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*, for further information on aircraft fueling ramp drainage designs to control the flow of fuel that might be spilled on a ramp and to minimize the resulting possible danger.

(j) Spills of kerosene grades of aviation fuels (JET A or JET A-1) greater than 10 ft (3 m) in any dimension and covering an area of over 50 ft^2 (5 m^2) or that are of an ongoing nature and that have not ignited should be blanketed or covered with foam if there is danger of ignition. If there is no danger of ignition, an absorbent compound or an emulsion-type cleaner can be used to clean the area. Kerosene does not evaporate readily at normal temperatures and should be cleaned up. Smaller spills can be cleaned up using an approved, mineral-type, oil absorbent.

(k) Aircraft on which fuel has been spilled should be inspected thoroughly to ensure that no fuel or fuel vapors have accumulated in flap well areas or internal wing sections not designed for fuel tankage. Any cargo, baggage, express, mail sacks, or similar items that have been wetted by fuel should be decontaminated before being placed aboard any aircraft.

A-3-4 Bonding.

Hydrocarbon fuels, such as aviation gasoline and JET A, generate electrostatic charge when passing through the pumps, filters, and piping of a fuel transfer system. (The primary electrostatic generator is the filter/separator that increases the level of charge on a fuel by a factor of 100 or more as compared with pipe flow.) Splashing, spraying, or free-falling of the fuel further enhances the charge. When charged fuel arrives at the receiving tank (cargo tank or aircraft fuel tank) one of two possible events will occur:

(a) The charge will relax harmlessly to ground; or

(b) If the charge or the fuel is sufficiently high, a spark discharge can occur. Whether or not an ignition follows depends on the energy (and duration) of the discharge and the composition of the fuel/air mixture in the vapor space (i.e., whether or not it is in the flammable range).

The amount of charge on a fuel when it arrives at the receiving tank, and hence its tendency to cause a spark discharge, depends on the nature and amount of impurities in the fuel, its electrical conductivity, the nature of the filter media (if present), and the relaxation time of the system [i.e., the residence time of the fuel in the system between the filter (separator) and the receiving tank]. The time needed for this charge to dissipate is dependent upon the conductivity of the fuels; it could be a fraction of a second or several minutes.

No amount of bonding or grounding prevents discharges from occurring inside of a fuel tank. Bonding ensures that the fueling equipment and the receiving tank (aircraft or fueler) are at the same potential and provides a path for the charges separated in the fuel transfer system (primarily the filter/separator) to combine with and neutralize the charges in the fuel. Also, in overwing fueling and in top loading of cargo tanks, bonding ensures that the fuel nozzle or the fill pipe is at the same potential as the receiving tank, so that a spark does not occur when the nozzle or fill pipe is inserted into the tank opening. For this reason, the bonding wire must be connected before the tank is opened.

Grounding during aircraft fueling or refueler loading is no longer required because:

(a) It does not prevent sparking at the fuel surface (*see NFPA 77, Recommended Practice on Static Electricity*).

(b) It is not required by NFPA 77, *Recommended Practice on Static Electricity*.

(c) The static wire might not be able to conduct the current in the event of an electrical fault in the ground support equipment connected to the aircraft and could constitute an ignition source if the wire fuses. If ground support equipment is connected to the aircraft or if other operations are being conducted that necessitate electrical earthing, then separate connections should be made for this purpose. Static electrical grounding points can have high resistance and, therefore, are unsuitable for grounding.

For a more complete discussion of static electricity in fuels, see NFPA 77, *Recommended Practice on Static Electricity*.

A-3-4.3

Ordinary plastic funnels or other nonconducting materials can increase static generation. The use of chamois as a filter is extremely hazardous.

A-3-7 Electric Hand Lamps.

Electric hand lamps used in the immediate proximity of the fueling operation should be of the type approved for use in NFPA 70, *National Electrical Code*, Class I, Division 1, Group D hazardous locations. There is no supportable basis for requiring in the petroleum industry the use of approved, listed, or permitted two- or three-cell flashlights to avoid igniting Class I, Group D vapors.

A-3-7.2 Aircraft Ground-Power Generators.

Aircraft ground-power generators should be located as far as practical from aircraft fueling points and tank vents to reduce the danger of igniting flammable vapors that could be discharged during fueling operations at sparking contacts or on hot surfaces of the generators.

A-3-9

It is impossible to establish precise rules for fueling when there are electrical storms in the vicinity of the airport. The distance of the storm from the airport, the direction in which it is traveling, and its intensity are all factors to be weighed in making the decision to suspend fueling operations temporarily. Experience and good judgment are the best guides. Sound travels approximately $^{1}/_{5}$ mi/sec (322 m/sec). The approximate number of miles to the storm can be determined by counting the seconds between a flash of lightning and the sound of thunder and dividing by 5.

A-3-10.2 Aircraft Fuel Servicing Locations.

The precautions in 3-10.2 are intended to minimize the danger of the ignition of any flammable vapors discharged during fueling and of fuel spills by sources of ignition likely to be present in airport terminal buildings.

A-3-13 Portable Fire Extinguishers on Aircraft Servicing Ramps or Aprons.

Fire extinguishers for ramps where fueling operations are conducted are intended to provide an immediate means of fire protection in an area likely to contain a high concentration of personnel and valuable equipment. The prominent and strategic positioning of portable fire extinguishers is essential in order for them to be of a maximum value in the event of an emergency. Extinguishers should not be located in probable spill areas. For normal, single parking configurations, extinguishers specified for protection of fuel servicing operations should be located along the fence, at terminal building egress points, or at emergency remote control stations of airport fixed-fuel systems. To provide accessibility from adjoining gates, particularly where more than one unit is specified, extinguishers may be permitted to be located approximately midway between gate positions. Where this is done, the maximum distance between extinguishers should not be over 300 ft (90 m). Where the specified extinguishers are not located along the fence but are brought into the servicing area prior to the fueling operation, they should be located upwind not over 100 ft (30 m) from the aircraft being serviced. For protection of fuel servicing of aircraft that are double parked or triple parked, extinguishers should be located upwind not over 100 ft (30 m) from the aircraft being serviced.

A-3-13.5 Protection of Extinguishers Against Inclement Weather.

During inclement weather, extinguishers not in enclosed compartments may be permitted to be protected by canvas or plastic covers. If icing occurs, the extinguisher should be sprayed with deicing fluid.

A-3-13.6 Training of Personnel in the Utilization of Extinguishers.

Fuel servicing personnel should be given adequate training with extinguishers so that such equipment is used effectively in an emergency. Such training should be given on fires of the type that could be encountered on the job. To ensure prompt action in the event of a spill or other hazardous condition developing during fueling operations, aircraft servicing personnel also should be trained in the operation of emergency fuel shutoff controls. Each new fuel servicing employee should be given indoctrination training covering these and similar safety essentials that are related to the job. Follow-up and advanced training should be given as soon as the employee is sufficiently acquainted with the work to benefit from such training. Supervisors should be given training in the more technical aspects of fire safety so that they understand the reason for these and similar requirements and have an appreciation for the responsibility of a supervisor or the safety of an operation.

A-3-16

Failure of aircraft fueling hose in service is a potential source of fuel spillage and a potential fire hazard. The principal reasons for failure of aircraft fueling hoses include:

(a) Using damaged hoses.

(b) Using aged hoses.

(c) Exceeding pressure limits.

(d) Improper installation.

A-3-21.2

(b) If passengers remain onboard an aircraft during fuel servicing, at least one person trained in emergency evacuation procedures is required to be aboard (*see 3-11.1*). It is not intended that the pilot in command perform this function.

NFPA 408

1994 Edition

Standard for Aircraft Hand Portable Fire Extinguishers

1994 Edition

This edition of NFPA 408, *Standard for Aircraft Hand Portable Fire Extinguishers*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 16-18, 1994, in San Francisco, CA. It was issued by the Standards Council on July 14, 1994, with an effective date of August 5, 1994, and supersedes all previous editions.

The 1994 edition of this document has been approved by the American National Standards

Institute.

Origin and Development of NFPA 408

Work on this standard started in 1947 after requests were received by the National Fire Protection Association for recommendations on aircraft hand fire extinguishers. During the intervening years, prior to the adoption of the first draft of this text in 1955 by the Association, a number of proposals were prepared and circulated for comment and criticism. In 1956 a revision was adopted incorporating an appendix on air crew training. Revisions were made in 1964, 1965, 1970, and 1973.

The 1984 document was completely revised to recognize state-of-the-art developments in extinguishing agents and to bring the document into form with the NFPA *Manual of Style*.

The 1989 edition was a reconfirmation of the 1984 edition. This edition is a complete revision and was developed by a task group made up of the following individuals:

Task Group on Aircraft Hand Fire Extinguishers

John J. O'Sullivan, British Airways, Heathrow Airport (London), England, Chair; Paul E. Calderwood, Everett Fire Dept., MA; Paul O. Huston, Amerex Corp., AL; Gaetan Perron, Dept. of Nat'l Defence, Ottawa, ON, Canada; Bertrand F. Ruggles, US FAA Dept. of Transportation, Washington, DC; John M. Schuster, 3M Co., MN; John X. Stefanki, John X. Stefanki Inc., CA; Mark T. Conroy, NFPA Staff Liaison.

Technical Committee on Aircraft Rescue and Fire Fighting

John F. Rooney, *Chair*
Tucson, AZ

James F. O'Regan, *Vice Chair*
Westboro, MA

Robert J. Donahue, *Secretary*
Massport, MA

Brian Boucher, Canadian Air Line Pilots Assn., Canada
Rep. Canadian Air Line Pilots Assn.

Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA

David F. Short, Carmichael Int'l Ltd, England

Mark T. Conroy, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on aircraft rescue and fire-fighting services and equipment, procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports, with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. The Committee shall develop aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 408
Standard for
Aircraft Hand Portable Fire Extinguishers

1994 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.

Information on referenced publications can be found in Chapter 6 and Appendix B.

Chapter 1 Administration

1-1 Scope.

1-1.1

This standard specifies requirements for the type, capacity, rating, number, location, installation, and maintenance of aircraft hand portable fire extinguishers to be provided for the use of flight crew members or other occupants of an aircraft for the control of incipient fires in the areas of aircraft that are accessible during flight.

1-1.2

This standard also includes requirements for training flight crew members in the use of these extinguishers.

1-1.3

This standard does not cover fire detection and fixed fire extinguishing systems installed in an aircraft, or fire detection and fire extinguishing systems for the protection of ground maintenance operations.

1-1.4

Specific protection for Class D fires, and fires in hazardous materials, is beyond the scope of this standard.

1-2 Purpose.

1-2.1

This standard is intended for use by those responsible for selecting, purchasing, installing, approving, and maintaining aircraft hand portable fire extinguishers and for those responsible for training personnel in their use.

1-2.2*

The specific requirements established in this standard are intended for the particular environment of an aircraft where fire extinguishment must be the first priority.

1-2.3*

Hand portable fire extinguishers, as specified in NFPA 10, *Standard for Portable Fire Extinguishers*, have the general purpose of serving as first aid fire-fighting appliances. Accordingly, the requirements of Chapters 4 and 5 of NFPA 10, *Standard for Portable Fire Extinguishers*, are applicable to the aviation environment, and are supplemental to the specific requirements of this standard.

1-3* Definitions.

Aircraft Hand Portable Fire Extinguisher. An approved, portable device carried and operated by hand containing an extinguishing agent that can be expelled under pressure for the purpose of suppressing or extinguishing fire.

Approved. Acceptable to the authority having jurisdiction.

NOTE: The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Bar. See Galley.

Buffet. See Galley.

Cargo Aircraft. An aircraft that is configured solely to carry cargo and no personnel other than the flight crew and any additional crew required for the care of the cargo.

Cargo/Baggage Compartment. An enclosed compartment within, or attached to, an aircraft fuselage and separate from the passenger and flight crew areas. It almost always is accessible only from the exterior of the fuselage.

Class A Fire. A fire that involves ordinary solid combustible materials such as wood, cloth, paper, rubber, and many plastics.

Class B Fire.* A fire that involves a flammable or combustible liquid such as oil, fat, alcohol, gasoline, and hydraulic fluid. Some plastics behave like Class A combustibles up to a point, but then they develop many attributes of a Class B fire.

Class C Fire.* A fire that involves energized electrical equipment or wiring.

Class D Fire.* A fire that involves combustible metals such as magnesium, titanium, zirconium, sodium, lithium, and potassium.

Cockpit. See Flight Deck.

COMBI. An aircraft designed to transport both passengers and cargo on the same level within the fuselage.

Extinguisher(s). See Aircraft Hand Portable Fire Extinguisher.

Flight Crew. Those members of the aircraft crew whose responsibilities include the operation and management of the aircraft flight controls, engine(s), and systems, i.e., pilot in command (captain), first officer (co-pilot), second officer (flight engineer), etc.

Flight Deck. The area of an aircraft arranged for use of the flight crew in operating the aircraft. Berths, galleys, and lavatory facilities may be associated with the flight crew compartment but are not included in the term "flight deck."

Galley. An area of an aircraft used for storing, refrigerating, heating, and dispensing food and beverages. Such areas typically include areas for storing plastic trays, plastic dinnerware utensils, and paper napkins.

Halogenated Agents. Halogenated agents referenced in this standard are bromotrifluoromethane (Halon 1301), bromochlorodifluoromethane (Halon 1301), and mixtures of Halon 1211 and Halon 1301 (Halon 1211/1301). Approved, listed, and labeled extinguishers containing clean evaporating type HCFC or HFC halogenated replacement agents also shall be permitted to be used to comply with the requirements of this standard.

NOTE: Halon 1211 and Halon 1301 are included in the "Montreal Protocol on Substances that Deplete the Ozone Layer" signed September 16, 1987. The 1992 amendments to the protocol call for a cessation of production of Halon 1211 and Halon 1301 worldwide.

Halon 1211. The chemical name is bromochlorodifluoromethane, $CBrClF_2$. Halon 1211 is a multipurpose, Class ABC-rated agent effective against flammable liquid fires. Due to its relatively high boiling point (+25°F/-4°C), Halon 1211 discharges as an 85 percent liquid stream offering long agent throw range.

Halon 1301. The chemical name is bromotrifluoromethane, $CBrF_3$. Halon 1301 is recognized as an agent having Class ABC capability in total flooding systems; however, Halon 1301 offers limited Class A capability when used in hand portable fire extinguishers.

Hand Fire Extinguisher(s). See Aircraft Hand Portable Fire Extinguisher.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed. Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Maximum Certificated Occupant Capacity. The maximum number of persons that can be carried as certified for each specific aircraft model by the authority having jurisdiction. (In the United States the authority having jurisdiction is the Federal Aviation Administration.)

May. This term is used to state a permissive use or an alternative method to a specified requirement.

Passenger Aircraft. An aircraft designed for the primary function of carrying passengers.

Rated/Rating. A numerical value assigned to an extinguisher based upon its fire extinguishing capability in accordance with ANSI/UL 711, *Standard for Rating and Fire Testing of Fire Extinguishers*.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Types and Capacities

2-1 General.

2-1.1

Hand portable fire extinguishers should meet or exceed all of the requirements of one of the fire test standards and one of the appropriate performance standards listed below.

2-1.1.1 Extinguishers installed in the United States shall meet the requirements of the following ANSI standards:

(a) Fire Test Standard: ANSI/UL 711

(b) Performance Standards

1. Dry Chemical Types: ANSI/UL 299
2. Water Types: ANSI/UL 626
3. Halon Types: ANSI/UL 1093
4. Film Forming Types: ANSI/UL 8

2-1.1.2 Extinguishers installed in Canada shall meet the requirements of the following Canadian standards:

(a) Fire Test Standard: CAN/ULC S508-M90

(b) Performance Standards

1. Dry Chemical Types: CAN/ULC-S504-M88

2. Water Types: CAN4-S507-M83

3. Halon Types: CAN/ULC-S512-M87

2-1.2

Identification of the listing and labeling organization, with ratings and classifications, including the performance standard that the extinguisher meets or exceeds, shall be clearly marked on each extinguisher.

2-1.2.1 An organization listing, labeling, and marking extinguishers used to comply with the requirements of this standard shall utilize a third-party certification program for hand portable fire extinguishers that meets or exceeds the requirements of ANSI/UL 1803, *Standard for Factory Follow-Up on Third Party Certified Portable Fire Extinguishers.*

Exception No. 1: Extinguishers manufactured prior to January 1, 1989.

Exception No. 2: Certification organizations accredited by the Standards Council of Canada.

2-1.3*

All aircraft hand fire extinguishers shall function properly at temperature ranges from -40°F to 120°F (-40°C to 49°C).

2-1.4*

Water extinguishers having a capacity of $1^{3}/_{8}$ qt (2 L), and having special approval of the authority having jurisdiction, shall not be required to be labeled, and shall comply with 2-1.1, 2-1.2, and 2-1.3 of this chapter.

2-2 Water.

2-2.1

Water-based extinguishers shall have a minimum 1-A rating and shall be equipped with either a spray or straight stream nozzle.

2-2.2

Water-based extinguishers shall not be used on Class B or Class C or Class D fires.

2-2.3

Cargo compartments shall have a water-based extinguisher(s) with a minimum rating of 2-A.

2-3 Halogenated Agents.

2-3.1*

Only halogenated agents specified in this standard shall be used in hand fire extinguishers in aircraft.

2-3.2

Halon 1211 purchased for recharging extinguishers shall meet the requirements of Military Specification MIL-B-38741.

2-3.3

Halon 1301 purchased for recharging extinguishers shall meet the requirements of Military Specification MIL-M-12218C.

2-3.4* Halon 1211 Extinguishers.

2-3.4.1* For occupied spaces on aircraft, Halon 1211 extinguishers shall not be less than $2^1/_2$ lb (1.2 kg) capacity, and shall not be more than 5 lb (2.3 kg) capacity. These extinguishers shall have a minimum 5-B:C rating, not less than 8-sec effective discharge time, not less than a 10-ft (3-m) liquid range, and may be equipped with a discharge hose.

2-3.4.1.1* For occupied spaces on small aircraft only, with a maximum certificated occupant capacity of one to four persons including the pilot, a Halon 1211 extinguisher with a minimum 2-B:C rating shall be permitted to be used as an option to the Halon 1301 extinguishers specified in Table 3-1.1.

2-3.4.2 For accessible cargo compartments of COMBI aircraft and cargo aircraft, Halon 1211 extinguishers shall not be less than 13 lb (5.9 kg) capacity, and shall have a minimum 2-A: 40-B:C rating.

2-3.4.3 The total Halon 1211 agent available in all extinguishers in any single compartment, if discharged simultaneously, shall not be capable of producing a concentration greater than 2 percent by volume at 120°F (49°C) in the compartment.

2-4 Carbon Dioxide.

2-4.1

For occupied spaces on aircraft, carbon dioxide (CO_2) extinguishers shall not be used.

2-4.2

For cargo compartments of COMBI aircraft and cargo aircraft, CO_2 extinguishers shall not be used.

2-5 Dry Chemical.

2-5.1*

For occupied spaces on aircraft, dry chemical extinguishers shall not be used.

2-5.2

For cargo compartments of COMBI aircraft and cargo aircraft, dry chemical extinguishers shall not be less than 10-lb (4.5-kg) capacity, and shall have a minimum 2-A: 40-B:C rating.

2-6 Dry Powder.

2-6.1*

For occupied spaces on aircraft, dry powder extinguishers for Class D fires shall not be used.

2-6.2

For accessible cargo compartments of COMBI aircraft and cargo aircraft, dry powder extinguishers for Class D fires may be provided in addition to required extinguishers specified in 3-2.2 of this standard.

2-7 Other Agents.

2-7.1

Hand portable fire extinguishers carrying non- halogenated-type agents developed to replace halon shall be listed and labeled.

Chapter 3 Distribution of Extinguishers

3-1 Passenger Aircraft.

3-1.1

Aircraft hand portable fire extinguishers shall be placed in occupied spaces on aircraft as specified in Table 3-1.1.

Table 3-1.1 Distribution of Extinguishers in Occupied Spaces on Aircraft

Maximum Certificated Occupant Capacity	Number of Extinguishers	Type of Extinguisher	Location
1-4 (including pilot)	1	Halon 1301	Within Reach of Seated Pilot
		Halon 1211 optional	
		(See 2-3.4.1.1, 2-3.4.3, 2-3.4.3)	
5-30	1	Halon 1301 or Halon 1211	Within Reach of Seated Pilot
	1	Halon 1211	Cabin
31-60	1	Halon 1301 or Halon 1211	Flight Deck
	2	One water and one Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
61-120	1	Halon 1301 or Halon 1211	Flight Deck
	3	One water and two Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
121-200	1	Halon 1301 or Halon 1211	Flight Deck
	4	Two water and two Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
201-275	1	Halon 1301 or Halon 1211	Flight Deck
	5	Two water and three Halon 1211	Cabin

	1	Halon 1211	Each Galley (See 3-1.2)
276-400	1	Halon 1301 or Halon 1211	Flight Deck
	8	Four water and four Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
Greater than 400	1	Halon 1301 or Halon 1211	Flight Deck
	10	Five water and five Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
COMBI Aircraft	1	Halon 1301 or Halon 1211	Flight Deck
Wide-body	5	Two water and three Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
	4	Halon 1211	Cargo (PAX level)
	2	Water	
COMBI Aircraft	1	Halon 1301 or Halon 1211	Flight Deck
Narrow-body	4	Two water and two Halon 1211	Cabin
	1	Halon 1211	Each Galley (See 3-1.2)
	2	Halon 1211	Cargo (PAX level)
	2	Water	

3-1.2

Where an extinguisher, other than a water extinguisher, is located within 5 ft (1.5 m) of a galley opening and on the same floor level, an additional extinguisher shall not be required for the galley.

3-1.3

Where distances between extinguishers, as measured by normal aisle travel, exceed 60 ft (18 m), extinguishers in addition to those required by Table 3-1.1 shall be provided so that no travel distance to an extinguisher exceeds 30 ft (9 m).

3-1.4

Where aircraft passenger compartments, galleys, or lounge areas are on a separate level, such compartments or areas shall have extinguishers in accordance with Table 3-1.1.

3-1.5

Extinguishers in passenger compartments shall be readily accessible, mounted for quick removal, and shall be installed on bulkheads wherever possible. Where installation is necessary in overhead storage spaces, extinguishers shall be located so that carry-on luggage cannot interfere with extinguisher accessibility, and extinguisher locations shall be clearly marked and shall be visible to occupants of the compartment.

3-1.6

Personal breathing equipment (PBE) approved and maintained as specified by the authority having jurisdiction shall be provided. The PBE shall be provided within 3 ft (0.9 m) laterally of all hand portable fire extinguishers.

3-2 Cargo Aircraft.

3-2.1 Occupied Spaces on Aircraft.

3-2.1.1 The flight deck of cargo aircraft shall be provided with one Halon 1211 extinguisher.

3-2.2 Cargo Compartment.

3-2.2.1 Where fixed extinguishing systems provide protection for the entire cargo compartment(s), or where cargo compartment(s) are not accessible during flight, hand portable fire extinguishers shall not be required for the cargo compartment(s).

3-2.2.2* Where fixed extinguishing systems do not provide protection for the entire cargo compartment(s), a minimum of one hand portable fire extinguisher having a minimum capacity of 10 lb (4.5 kg) and a minimum rating of 2-A: 40-B:C shall be provided, and shall be equipped with a discharge hose or wand with a minimum length of 12 in. (304 mm).

3-2.2.3 The hand portable fire extinguisher specified in 3-2.2.2 shall be located and accessible inside the cargo compartment at the interior access entry. Any additional hand portable fire extinguishers provided for cargo compartment use shall also be located in the cargo compartment.

3-2.2.4 A self-contained breathing apparatus (SCBA), approved and maintained as specified by the authority having jurisdiction, with a minimum rated service life of 15 min and equipped with a full facepiece shall be provided. The SCBA shall be accessible in a clearly marked location outside the cargo compartment positioned adjacent to the access entry point.

3-3 COMBI Aircraft.

3-3.1

Aircraft hand fire extinguishers shall be placed in the flight deck passenger cabin and cargo compartment on aircraft as specified in Table 3-1.1.

3-3.2

Where an extinguisher other than a water extinguisher is located within 5 ft (1.5 m) of a galley opening and on the same floor level, an additional extinguisher shall not be required for the galley.

3-3.3

The number of hand portable fire extinguishers necessary for the cargo compartment are as specified in Table 3-1.1.

3-3.4

Hand portable fire extinguishers shall be placed adjacent to the entrance door of passenger deck (cargo compartment) and adjacent to the rear exit door of the aircraft.

Chapter 4 Inspection, Maintenance, and Hydrostatic Testing

4-1 Preflight Inspection.

4-1.1

Flight crew member(s) shall make a preflight inspection of all extinguishers.

4-1.2

The inspection shall determine that all required extinguishers are provided, ready for use, in proper location, and properly secured. Where provided, extinguisher pressure gauges shall indicate acceptable pressure, and seals and seal wires shall not be broken.

4-2 Maintenance.

4-2.1

Extinguishers shall be maintained in accordance with Chapter 4 of NFPA 10, *Standard for Portable Fire Extinguishers*, and records shall be kept in accordance with these requirements.

4-2.2

Recharging procedures shall follow the requirements of Chapter 4 of NFPA 10, *Standard for Portable Fire Extinguishers*.

4-2.3

Extinguishers that are out of service for maintenance or recharge shall be replaced with extinguishers having the same agent, rating, and operating procedure.

4-3 Hydrostatic Testing.

4-3.1

Extinguisher shells and appurtenant devices such as nozzles, hoses, and pressure cartridges shall be hydrostatically tested in accordance with Chapter 5 of NFPA 10, *Standard for Portable Fire Extinguishers*.

Chapter 5 Flight Crew Training

5-1 General.

5-1.1

Initially, before assignment, and at least annually thereafter, flight crew members shall receive theoretical and practical training in the basics of fire extinguishment. Instruction on location and use of hand portable fire extinguishers on the aircraft for which flight crew members will be qualified shall be provided.

5-1.2

Training shall be conducted by instructors who are knowledgeable of the aircraft environment experienced in the extinguishment of fire using hand portable fire extinguishers.

5-1.3

Training shall include:

(a) Classroom instruction;

(b) Practical use of hand portable fire extinguishers;

(c) Extinguishment of a hot fire;

(d) Movement in a smoke-filled environment;

(e) Wearing of personal breathing equipment, within a replica of an aircraft cabin environment. Halon shall not be discharged during training, as per 5-3.3.3.

5-2* Classroom/Fire Scenario Instruction.

5-2.1

Classroom instruction shall be given to flight crews concerning all types of extinguishers discussed in this standard. Classroom instruction shall include the following topics as a minimum:

(a) Chemistry of fire and fire extinguishment;

(b) Severity potential of aircraft fires;

(c) Types of combustibles available in aircraft;

(d) Identification and choice of proper extinguisher;

(e) Consequences of misapplication of extinguishers;

(f) Relative effectiveness of extinguishers;

(g) Inspection requirements; and

(h) Health and operational safety concerns.

5-2.2 Practical Smoke Training.

On aircraft types in which it is provided, training shall be given on the use of appropriate breathing equipment (PBE) when using an extinguisher in a cosmetic smoke-filled environment.

5-3 Manipulative Skills Training.

5-3.1

Training shall be administered to flight crews sufficient to have each crew member demonstrate operation and use of hand portable extinguishers.

5-3.2

Training shall be representative of an interior aircraft fire, using the relevant type of hand portable fire extinguishers carried on the aircraft.

5-3.3*

Each flight crew member shall demonstrate the knowledge and skill required to select the appropriate hand portable fire extinguisher for various fire scenarios and to properly apply the agent.

5-3.3.1 The overall training plan shall include representative aircraft fires of Class A, B, C, and combined Class A and B fires.

5-3.3.2 Fire scenarios shall include galley, lavatory or closed compartment, flight deck, open cabins, and flammable liquid fires.

5-3.3.3 Extinguishers containing halon shall not be discharged during routine manipulative skills training. Halon agent shall be conserved and be used only to combat unwanted fires. Suitable substitutes may be used for training. This shall be agreed on with the authority having jurisdiction.

5-3.3.4 Any alternative agent used shall have to be approved by the authority having jurisdiction, listed, and correctly labeled.

5-4* COMBI Aircraft.

5-4.1

The following items shall form the basis of the required course of instruction for flight crew involving COMBI aircraft operations:

(a) Explanation of fire risks with COMBI operations;

(b) Chemistry of fire;

(c) Theory of extinguishing agents;

(d) Aircraft layout;

(e) Cargo loading requirements;

(f) Hazardous cargo consignments;

(g) Scale of COMBI fire fighting equipment (*see Table 3-1.1*);

(h) Designated fire fighter duties

- Preflight audit
- In-flight inspection
- Fire control techniques
- Post fire information feedback;

(i) Practical demonstration and use of portable controlled fire extinguishers;

(j) Practical exercises involving simulated fire situations.

5-4.2

The facility used for training flight crews shall be representative of actual fire conditions to include:

(a) An enclosed environment in which the trainee can experience the effects of fire and heat.

(b) Demonstrate the effectiveness of fire extinguishers when correctly applied to an actual fire.

(c) A facility to demonstrate an electrical fire shall be provided.

(d) One exercise shall include dressing in the protective clothing and personnel breathing equipment provided on-board the aircraft and entering a simulated smoke-filled environment carrying a hand portable fire extinguisher as carried on the aircraft.

5-5 Recurrent Training and Testing.

5-5.1

Recurrent training shall include discussions on recent on-board aircraft fire incidents. This is particularly important when crews are assigned to more than one aircraft type.

5-5.2

Recurrent training shall be provided at intervals not exceeding 3 years.

Chapter 6 Referenced Publications

6-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

Military Specification for Halon 1301, *MIL-M-12218C*.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-2.2

In an aircraft fire, the integrity of the aircraft must be preserved and the flight crew must retain their physiological ability to fly the airplane (e.g., vision and consciousness). The overall threat to life must be held at the lowest possible level.

A-1-2.3

Additional information on the effectiveness and suitability of various aircraft hand portable fire extinguishers may be found in DOT/FAA/CT-82/42, "Study of Hand-Held Fire Extinguishers Aboard Civil Aviation Aircraft," 1982.

A-1-3

European fire class designations are as follows:

1. Class A — Wood, paper, cloth, etc;
2. Class B — Flammable liquids;
3. Class C — Flammable gases;
4. Class D — Metal fires;
5. Class E — Electrical fires.

NOTE: European fire extinguisher ratings are not comparable with U.S. or Canadian ratings. In the U.K. the applicable standards are British Standard 5306 - Part 3 - *Selection, Installation, and Maintenance of Portable Fire Extinguishers*, and British Standard 5423 -*Rating Extinguishers by Fire Tests*.

The classification of fire extinguishers consists of one or more LETTERS that indicate the classes of fire on which an extinguisher has been found to be effective. The letters (A and B only) are preceded by a rating NUMBER that indicates the relative extinguishing effectiveness.

A-2-1.3

Aircraft hand portable fire extinguishers must perform in an environment substantially more varied and critical than those approved for use in most land surface applications. Design consideration for extinguisher body, valves, fittings, and associated hardware, including mounting brackets, also should include pressure variations, positive and negative accelerations, vibration, corrosion, and ambient temperature variations.

A-2-1.4

In the United States, the authority having jurisdiction is the Federal Aviation Administration. In Europe it is the Joint Aviation Authority. In Canada it is Transport Canada.

A-2-3.1

Exposure to decomposed halogenated agents may produce varied central nervous system effects depending upon exposure concentration and time. Halogenated agents also will decompose into more toxic products when subjected to flame or hot surfaces at approximately 900°F (482°C). See NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*, and NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*, for detailed information.

A-2-3.4 Halon 1211.

Halon 1211 extinguishers have their greatest effectiveness on Class B and C fires. Extinguishers with 9 lb (4 kg) or greater capacity also are rated for Class A fires. Extinguishers with capacity less than 9 lb (4 kg), although not rated for use on Class A fires, have been shown to be effective in extinguishing surface Class A fires. Detailed information on Halon 1211 agent characteristics, concentration requirements, health hazards, and extinguishing limitations may be found in NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*.

A-2-3.4.1 Halon 1211 extinguishers of less than 9 lb (4 kg) capacity are not always furnished with a discharge hose. However, for access to underseat, overhead, and other difficult-to-reach locations, consideration should be given to using extinguishers with a discharge hose of a minimum length of 12 in. (304 mm). Also, the discharge hose is more likely to result in the extinguisher being properly held in an upright position during use.

A-2-3.4.1.1 For occupied spaces on small aircraft where natural state halon concentrations will be approaching allowable limits, Halon 1301 is the halogenated agent of choice for the following reasons:

(a) Halon 1211 decomposes when exposed to flame, producing toxic products of decomposition. Halon 1211 produces some decomposition products that are not produced by Halon 1301 and is therefore also considered more toxic in the decomposed state.

(b) Health and safety advantages associated with similar volume occupied spaces on larger aircraft (flight decks) do not usually exist for the smaller aircraft. These advantages are a forced ventilation system, availability of oxygen masks, and availability of a second individual capable of flying the aircraft.

A-2-5.1

Dry chemical agent causes visibility problems in occupied spaces and potentially severe contamination of aircraft electrical components.

A-2-6.1

Dry powder agent causes visibility problems in occupied spaces and potentially severe contamination of aircraft electrical components.

A-3-2.2.2 The hose or wand will provide effective reach of the contents of the extinguisher to any part of the cargo.

A-5-2

Discussion of health and safety aspects should include hazards and warnings concerning toxicity of combustion products, as well as the effects of short, intermediate, and long-term exposure to the undecomposed agents. See Appendix A of NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*, as appropriate.

A-5-3.3

It is highly recommended that live fire training on representative aircraft fires be conducted for all flight crew members during both initial and recurrent training sessions. Live fire training provides flight crews with psychological conditioning, fire fighting techniques, and knowledge of extinguishing agent capabilities and limitations under actual fire situations. The live fires used should be the scenarios required in 5-3.3.2.

A-5-4

On completion of the course, flight deck crews and flight attendants should be confident in the procedures and practical use of equipment while working under conditions of smoke and heat. Numbers of personnel receiving training at any one time should be limited in order to ensure that each individual receives adequate practical experience and that his/her performance can be assessed by instructional staff.

NFPA 409

1995 Edition

Standard on Aircraft Hangars

1995 Edition

This edition of NFPA 409, *Standard on Aircraft Hangars,* was prepared by the Technical Committee on Airport Facilities and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 409 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 409

The original fire protection recommendations for the construction and protection of airplane hangars were published by the National Board of Fire Underwriters (now the American Insurance Association) in 1930. Revisions were issued by the NBFU in 1931, 1943, 1945, and 1950. During the period 1943 through 1954, these recommendations were published as NBFU Pamphlet 85. In 1951, the National Fire Protection Association, Inc. organized a Committee on Aircraft Hangars to which the National Board of Fire Underwriters and other interested groups lent their support. The NFPA's first standard was adopted in 1954, and the NBFU adopted the same text, rescinding their earlier 1950 standard. Revisions were made in 1957 and 1958 by this NFPA Committee. In 1959, a reorganization of the NFPA aviation activities resulted in the assignment of this standard to the Sectional Committee on Aircraft Hangars and Airport Facilities. The 1960, 1962, 1965, 1966, 1967, 1969, 1970, 1971, 1972, 1973 and 1975 editions were prepared by this sectional committee. The sectional committee was reorganized as the Technical Committee on Airport Facilities and completed a revision to NFPA 409 in 1978. The document underwent extensive editorial revision and partial technical revision in 1984. This standard was revised in 1990 and 1995.

Mark T. Conroy, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire safety for the construction and protection at airport facilities involving construction engineering but excluding airport fixed fueling systems.

NFPA 409
Standard on
Aircraft Hangars

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix B.

Chapter 1 Administration

1-1 Scope.

This standard contains the minimum requirements for the proper construction and protection of aircraft hangars from fire.

1-2 Purpose.

1-2.1*

The purpose of this standard is to provide a reasonable degree of protection from fire for life and property in aircraft hangars, based on sound engineering principles, test data, and field experience.

1-2.2

No part of this standard is intended to restrict new technologies or alternate arrangements, provided the level of safety prescribed by the standard is not lowered.

1-3 Definitions.

Aircraft Access Door. Any opening through which any portion of the aircraft is passed to gain entry to the hangar.

Aircraft Hangar. A building or other structure inside any part of which aircraft are housed or stored, and in which aircraft might undergo service, repairs, or alterations. For the purposes of this standard, aircraft hangars are classified as follows:

Group I Aircraft Hangar. A hangar having at least one of the following features and operating conditions:

(a) An aircraft access door height over 28 ft (8.5 m),

(b) A single fire area in excess of 40,000 ft^2 (3716 m^2), or

(c) Provision for housing an aircraft with a tail height over 28 ft (8.5 m).

Group II Aircraft Hangar. A hangar having both of the following features:

(a) An aircraft access door height of 28 ft (8.5 m) or less, and

(b) A single fire area for specific types of construction in accordance with Table 1-3.

Table 1-3

Single Fire Area

Type of Construction	Equal or Greater Than Ft^2	Equal or Greater Than (M^2)	But Not Larger Than Ft^2	But Not Larger Than (M^2)
Type I (443) and (332)	30,001	(2,787)	40,000	(3,716)
Type II (222)	20,001	(1,858)	40,000	(3,716)
Type II (111), Type III (211), and Type IV (2HH)	15,001	(1,394)	40,000	(3,716)
Type II (000)	12,001	(1,115)	40,000	(3,716)
Type III (200)	12,001	(1,115)	40,000	(3,716)
Type V (111)	8,001	(743)	40,000	(3,716)
Type V (000)	5,001	(465)	40,000	(3,716)

Group III Aircraft Hangar.* A Group III hangar can be a freestanding unit for a single aircraft, a row hangar with a common structural wall and roof system, and a hanger that houses multiple aircraft as well as having door openings for each aircraft, or an open bay hangar capable of housing multiple aircraft.

A Group III hangar shall have both of the following features:

(a) An aircraft access door height of 28 ft (8.5 m) or less, and

(b) A single fire area that measures up to the maximum square footage permitted for specific types of construction in accordance with Table 1-3(a).

Table 1-3(a) Maximum Fire Areas for Group III Hangars

Type of Construction	Maximum Single Fire Area Ft^2	(M^2)
Type I (443) and (332)	30,000	(2,787)
Type II (222)	20,000	(1,858)
Type II (111), Type III (211), and Type IV (2HH)	15,000	(1,394)
Type II (000)	12,000	(1,115)
Type III (200)	12,000	(1,115)
Type V (111)	8,000	(743)
Type V (000)	5,000	(465)

Aircraft Storage and Servicing Area. That part of a hangar normally used for the storage and servicing of one or more aircraft, not including any adjacent or contiguous areas or structures, such as shops, storage areas, and offices.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Demand Calculation Method. Hydraulic calculation procedure for determining the minimum theoretical flow and pressure required to produce a minimum specified total discharge from a specific configuration of piping and discharge devices.

Detection System. A system consisting of detectors; controls; control panels; automatic and manual actuating mechanisms; all wiring, piping, and tubing; and all associated equipment that is used to actuate an extinguishing system.

Fire Area. An area within an aircraft hangar subject to loss by a single fire because of lack of internal subdivisions as specified in Section 2-2 or Section 5-2 of this standard, as appropriate.

Fire Wall. A wall separating buildings or subdividing a building to prevent the spread of fire and having a fire resistance rating and structural stability.

Foam-Water Deluge System. A system having a pipe connected to and including a source of foam concentrate and a water supply. Water and foam concentrate [protein, fluoroprotein, or aqueous film-forming foam (AFFF)] are delivered to open discharge devices for extinguishing agent discharge and for distribution over the area to be protected. The piping is connected to the water supply through an automatic valve that is actuated by the operation of a detection system installed in the same areas as the discharge devices. When this valve opens, water flows into the piping system, foam concentrate is injected into the water, and the resulting discharge of foam solution through the foam-water discharge devices generates and distributes foam. Upon exhaustion of the foam concentrate supply, water discharge will follow the foam and continue until shut off manually.

Hangar Building Cluster. A group of buildings with more than one area for the storage and servicing of aircraft and all attached or contiguous structures, or structures not separated as specified in 2-3.2 or 5-2.1 of this standard, as appropriate.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Single Hangar Building. A building with one area for the storage and servicing of aircraft and any attached, adjoining, or contiguous structure, such as a lean-to, shop area, or parts storage area not separated as specified in 2-3.2 or 5-2.1 of this standard, as appropriate.

Supply Calculation Method. Hydraulic calculation procedure for determining the maximum theoretical flows and pressures in a system with a specific configuration of piping and discharge devices supplied by a water distribution system.

Unfueled Aircraft. An aircraft whose fuel system has had flammable or combustible liquid removed such that no tank, cell, or piping contains more than $^1/_2$ percent of its volumetric capacity.

Tail Height. The maximum tail height as stated in aircraft manufacturers' specifications.

Chapter 2 Construction of Group I and Group II Aircraft Hangars

2-1 Types of Construction.

2-1.1*

Group I hangars shall be either Type I or Type II construction in accordance with NFPA 220, *Standard on Types of Building Construction*. Group II hangars shall be constructed of any of the types of construction specified in NFPA 220, *Standard on Types of Building Construction*, or any combination thereof.

2-1.2*

Mezzanines, tool rooms, and other enclosures within aircraft storage and servicing areas shall be constructed of noncombustible material or limited-combustible material as defined in NFPA 220, *Standard on Types of Building Construction*, in all hangars except those of Type V (111) and (000) construction.

2-2 Internal Separations.

2-2.1*

Where aircraft storage and servicing areas are subdivided into separate fire areas, the separation shall be by a fire wall having not less than a 3-hour fire resistance rating. Any openings in such fire walls communicating directly between two aircraft storage and servicing areas shall be provided with a listed 3-hour fire door or 3-hour shutter actuated from both sides of the wall. Where areas are of different heights, the tallest wall shall have a fire resistance rating of not less than 3 hours.

2-2.2

Where two or more aircraft storage and servicing areas constituting separate fire areas are separated by continuous offices, shops, and parts storage areas, one of the two walls between the aircraft storage and servicing areas and the offices, shops, and parts storage areas shall comply with 2-2.1. The other wall shall comply with 2-2.3.

2-2.3*

Partitions and ceilings separating aircraft storage and servicing areas from all other areas, shops, offices, and parts storage areas shall have at least a 1-hour fire resistance rating with openings protected by listed fire doors or shutters having a minimum fire resistance rating of 45 minutes.

2-2.4

Where a storage and servicing area has an attached, adjoining, or contiguous structure, such as a lean-to, shop, office, or parts storage area, the wall common to both areas shall have at least a 1-hour fire resistance rating, with openings protected by listed fire doors having a minimum fire resistance rating of 45 minutes and actuated from both sides of the wall.

2-3 Clear Space Distance Requirements Around Hangars.

2-3.1

Precautions shall be taken to ensure ready access to hangars from all sides. Adequate separation shall be provided to reduce fire exposure between buildings. The clear spaces specified in Tables 2-3.2 and 2-3.3 shall not be used for the storage or parking of aircraft or concentrations of combustible materials, nor shall buildings of any type be erected therein.

2-3.2

For single hangar buildings, the clear space distances specified in Table 2-3.2 shall be maintained on all sides of the single hangar. Where mixed types of construction are involved, the less fire-resistant type of construction shall be used to determine the clear space required. Where the minimum clear space specified in Table 2-3.2 is not met, the buildings shall be considered a hangar building cluster.

Table 2-3.2

Type of Construction	Minimum Separation Required
Type I (443) and (332)	50 ft (15m)
Type II (222)	50 ft (15m)
Type II (111), Type III (211), and Type IV (2HH)	50 ft (15 m)
Type II (000)	50 ft (15 m)
Type III (200)	50 ft (15 m)
Type V (111) and (000)	75 ft (23 m)

2-3.2.1 Where both exposing walls and openings therein of adjacent single hangar buildings have a minimum fire resistance rating of at least 3 hours, no minimum separation distance shall be required. These buildings shall be considered a hangar building cluster.

2-3.2.2 Where the exposing wall and any openings therein of one hangar have a minimum fire resistance rating of at least 2 hours, the minimum separation distance shall be permitted to be reduced to not less than 25 ft (7.5 m) for single hangar buildings.

2-3.2.3* Where the exposing walls of both buildings have a minimum fire resistance rating of at least 2 hours, with all windows protected by listed glass in fixed steel sash having a minimum fire resistance rating of $^{3}/_{4}$ hour, with outside sprinkler protection and each doorway protected with one automatically operated listed fire door having a minimum fire resistance rating of $1^{1}/_{2}$

hours, the clear space distance shall be permitted to be reduced to not less than 25 ft (7.5 m) between single hangar buildings. Under such conditions, the glass area in the exposing walls shall be not more than 25 percent of the wall area.

2-3.3

The clear space distances specified in Table 2-3.3 shall be maintained on all sides of the hangar building clusters. Where mixed types of construction are involved, the less fire-resistant type of construction shall be used to determine required clear space differences.

Table 2-3.3

Type of Construction	Minimum Separation Required
Type I (443) and (332)	75 ft (23 m)
Type II (222)	75 ft (23 m)
Type IV (2HH)	75 ft (23 m)
Type II (III) and Type III(211)	100 ft (30 m)
Type II (000)	100 ft (30 m)
Type III (200)100 ft (30 m)	100 ft (30m)
Type V (III) and (000)	125 ft (38 m)

2-3.3.1 Where the exposing wall and any openings therein of one hangar have a minimum fire resistance rating of at least 2 hours, the clear space distance shall be permitted to be reduced to not less than 50 ft (15 m) between hangar building clusters.

2-3.3.2* Where the exposing walls of both buildings have a minimum fire resistance rating of at least 2 hours, with all windows protected by listed glass in fixed steel sash having a minimum fire resistance rating of hour, with outside sprinkler protection and each doorway protected with one automatically operated listed fire door having a minimum fire resistance rating of $1^1/_2$ hours, the clear space shall be permitted to be reduced to not less than 50 ft (15 m) between hangar building groups. Under such conditions, the glass area in the exposing walls shall be not more than 25 percent of the wall area.

2-4 Floors.

2-4.1

The surface of the grade floor of aircraft storage and servicing areas, regardless of type of hangar construction, shall be noncombustible and above the grade of the approach or apron at the entrance to the hangar.

2-4.2*

The floors of adjoining areas that pose flammable or combustible liquid spill hazards, and connect with aircraft storage and servicing areas, shall be noncombustible and shall be designed to prevent a spill from entering the aircraft storage and servicing area.

2-4.3

Floor openings in multistoried sections of hangars shall be enclosed with partitions or protected with construction having a fire resistance rating not less than that required for the floor construction where the opening is made.

2-5 Roofs.

2-5.1

Roof coverings shall be of an approved type of tile, slate, metal, or asphalt shingle, or of built-up roofing finished with asphalt, slate, gravel, or other approved material. Roof coverings shall be listed as Class A or Class B when tested in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.

2-5.2

Where insulated metal deck assemblies are used, they shall be equivalent to FM Class 1, or UL Fire Classified ratings.

2-5.3*

Spaces under roofs created where suspended ceilings are provided in aircraft storage and servicing areas shall be cut off from the area below so that the space cannot be used for storage or other occupancy. The space shall be provided with ventilation louvers to ensure air circulation therein.

2-5.4

Permanent exterior ladders to hangar roofs shall be provided on all hangars exceeding 25,000 ft^2 (2323 m^2) in area, or exceeding 40 ft (12 m) in height, or exceeding 100 ft (30 m) in their smallest dimension.

Exception: Permanent exterior ladders to hangar roofs shall not be required where enclosed stairs leading directly to the roof of aircraft storage and servicing areas are available from the exterior of the hangar.

2-6 Columns.

2-6.1

In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, column protection shall be required in accordance with 2-6.2 through 2-6.4.

2-6.2

All main steel structural columns of the aircraft storage and servicing areas shall be made fire resistant using listed materials and methods to provide a fire-resistive rating of not less than 2 hours.

2-6.3*

Fixed water or foam-water systems shall be permitted to be used in lieu of a 2-hour fire resistance rating, if such systems are designed specifically to protect the columns.

2-6.4

All fire-resistant materials used to protect structural steel columns shall be of a type that resists damage from discharge of the fixed fire protection system.

2-7 Doors.

2-7.1

Hangar doors that accommodate aircraft shall be of noncombustible construction where hangars are of any Type I or Type II construction as specified in 2-1.1 of this chapter.

2-7.2

The power source for hangar doors shall operate on independent circuits and shall not be deenergized when the main disconnect switches for general hangar power are shut off.

2-7.3*

Vertical traveling doors shall be counterbalanced, and horizontal slide or accordion-type doors shall be arranged, so that manual or auxiliary operation by means of winches or tractors, for example, is feasible.

2-7.4

In areas where freezing temperatures can occur, door tracks or the bottom edges of doors shall be protected by heating coils or equivalent means to prevent ice formation that might prevent or delay operation.

2-8 Curtains.

Where curtains are used to enclose a work area, they shall be of a listed flame-retardant type.

2-9 Landing Gear Pits, Ducts, and Tunnels.

2-9.1*

Landing gear pits, ducts, and tunnels located below floor level shall be designed on the premise that flammable liquids and vapor will be present at all times. Materials and equipment shall be impervious to liquids and shall be fire resistant or noncombustible.

2-9.2

Electrical equipment for all landing gear pits, ducts, and tunnels located below hangar floor level shall be suitable for use in Class I, Division 1, Group D hazardous locations in compliance with Article 501 of NFPA 70, *National Electrical Code*®.

2-9.3

All landing gear pits, ducts, and tunnels shall be provided with a positive mechanical exhaust ventilation system capable of providing a minimum rate of five air changes per hour during normal operations and be designed to discharge externally to the hangar.

2-9.4

Upon the detection of flammable vapors, the ventilation system shall be capable of providing a minimum ventilation rate of 30 air changes per hour for the landing gear pit and all associated ducts or tunnels.

2-9.5

The ventilation system shall be controlled by an approved continuous-reading combustible gas analyzing system that is arranged to operate the ventilation system at the rate specified in 2-9.4 automatically upon detection of a specified flammable vapor concentration that is below the lower flammable limit. The detection system shall have sensors located throughout all ducts and tunnels.

2-9.6

As entry of fuel, oil, and water into landing gear pits is inevitable, drainage or pumping facilities shall be provided. Water-trapped vapor seals and appropriate separator fuel traps shall be provided. Where automatic pumping facilities are necessary, they shall be suitable for use with aviation fuel and water. The drainage shall be fully enclosed pipe runs if drainage is routed through ventilation or access tunnels to external discharge points.

2-9.7*

Explosion protection shall be provided in landing gear pits and communicating ducts and tunnel areas in the form of pressure-relief venting or by a listed explosion prevention system installed in accordance with NFPA 69, *Standard on Explosion Prevention Systems*.

2-9.8*

An approved fire protection system shall be installed to protect each pit unless the hangar fire protection required by either Chapter 3 or Chapter 4 of this standard is adequate to protect each pit.

2-10 Exposed Interior Insulation.

2-10.1

Exposed interior insulation attached to walls and roofs in an aircraft storage and servicing area of a hangar not provided with a sprinkler system designed in accordance with Chapter 3 or Chapter 4 of this standard, as applicable, shall be noncombustible as defined in Chapter 2 of NFPA 220, *Standard on Types of Building Construction*.

2-10.2

In an aircraft storage and servicing area of a hangar equipped with an approved sprinkler system designed in accordance with Chapter 3 or Chapter 4 of this standard, as applicable, exposed interior insulation attached to walls and roofs shall be noncombustible or limited-combustible as defined in Chapter 2 of NFPA 220, *Standard on Types of Building Construction*.

2-11 Drainage of Aprons and Hangar Floors.

2-11.1

The apron or approach at the entrance to the hangar shall slope away from the hangar with a minimum grade of one-half of one percent (1:200) for the first 50 ft (15 m). Ramps used for aircraft fueling adjacent to hangar structures shall comply with NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*. In establishing locations for nearby aircraft parking, consideration shall be given to the drainage pattern of the apron.

2-11.2 Hangar Floor Drainage.

2-11.2.1 In aircraft storage and servicing areas of hangars housing other than unfueled aircraft floor drainage in accordance with 2-11.2.2 through 2-11.2.12 shall be provided.

2-11.2.2* Floor drainage systems shall be provided to restrict the spread of fuel in order to reduce the fire and explosion hazards from fuel spillage.

2-11.2.3 Drainage systems shall be designed to reduce fire and explosion hazards within the systems to the maximum extent by the use of noncombustible underground piping, and by routing drainage as directly as possible to a safe outside location. Such systems shall be designed with suitable traps or be provided with adequate ventilation to prevent vapor mixtures from forming within the underground drainage system.

2-11.2.4* Drainage systems in aircraft storage or servicing areas shall be designed and constructed so that they have sufficient capacity to prevent buildup of flammable liquids and water over the drain inlet when all fire protection systems and hose streams are discharging at the design rate.

2-11.2.5 The pitch of the floor shall be a minimum of one-half of one percent. The floor pitch provided shall be calculated taking into consideration the towing requirements of the aircraft and the factors of aircraft weight, balance checking, and maintenance.

2-11.2.6 Each drainage system shall be calculated separately, taking into consideration the maximum rated discharge based on the supply calculation method for the fire protection systems and hose lines.

2-11.2.7 The size of drainage piping shall be determined by the hydraulic demands placed on the system throughout its length.

2-11.2.8 Curbs, ramps, or drains shall be provided at all openings from aircraft storage and servicing areas, or the slope of the floor shall be such so as to prevent the flow of liquids through openings.

2-11.2.9 Pits for service facilities, such as for compressed air, electrical outlets, etc., shall drain into the floor drainage system.

2-11.2.10 Oil separators shall be provided for the drainage systems serving all aircraft storage and servicing areas. These separators can serve each hangar drainage system, a group of hangar drainage systems, or be installed as part of a general airport drainage system.

2-11.2.11 In aircraft storage and servicing areas protected by water sprinkler systems or foam-water systems, a bypass shall be provided around the separator to allow for emergency direct disposal of water and flammable liquids. Separator systems shall discharge flammable liquid products to a safely located tank, cistern, or sump.

2-11.2.12 Grates and drain covers shall be of sufficient strength to support the point loading of the heaviest type aircraft or equipment that the hangar might serve. Grates and covers shall be removable to facilitate cleaning and flushing.

2-12 Heating and Ventilating.

2-12.1*

Heating, ventilating, and air conditioning equipment shall be installed, as applicable, in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; NFPA 54, *National Fuel Gas Code*; NFPA 90B, *Standard for the Installation of Warm Air Heating and Air Conditioning Systems;* and NFPA 58, *Standard for the Storage and Handling of Liquefied*

Petroleum Gases.

2-12.2

In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, or sections communicating therewith, no heating, ventilating, and air conditioning equipment employing an open flame or glowing element shall be installed, other than as provided for in 2-12.5 of this section.

2-12.3

In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, hangar heating plants that are fired with gas, liquid, or solid fuels not covered under 2-12.5 of this section and that are not located in a detached building shall be located in a room separated from other parts of the hangar by construction having at least a 1-hour fire resistance rating. This separated room shall not be used for any other hazardous purpose or combustible storage, and shall have no direct access from the aircraft storage or servicing area. Openings in the walls of such rooms communicating with other portions of the hangar shall be restricted to those necessary for ducts or pipes. Penetrations of the 1-hour fire resistance rated enclosure shall be firestopped with an approved material properly installed and capable of maintaining the required fire resistance rating for the enclosure. Each such duct shall be protected with a listed automatic fire damper or door. All air for combustion purposes entering such separated rooms shall be drawn from outside the building.

2-12.4*

In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, heating, ventilating, and air conditioning systems employing recirculation of air within aircraft storage and servicing areas shall have return air openings not less than 10 ft (3 m) above the floor. Supply air openings shall not be installed in the floor and shall be at least 6 in. (152 mm) from the floor measured to the bottom of the opening.

Where automatic fire protection systems are installed in aircraft storage and servicing areas, fans for furnace heating systems shall be arranged to shut down automatically by means of the operations of the interior automatic fire protection system. One or more manual fan shutoff switches shall be provided. Shutoff switches shall be accessible and clearly placarded.

2-12.5 Suspended or Elevated Heaters.

2-12.5.1 In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, listed electric, gas, or oil heaters shall be permitted to be used if installed as specified in 2-12.5.2, 2-12.5.3, and 2-12.5.4.

2-12.5.2 In aircraft storage and servicing areas, heaters shall be installed at least 10 ft (3 m) above the upper surface of wings or of the engine enclosures of the highest aircraft that might be housed in the hangar. The measurement shall be made from the wing or engine enclosure, whichever is higher from the floor, to the bottom of the heater.

2-12.5.3 In shops, offices, and other sections of aircraft hangars communicating with aircraft storage or servicing areas, the bottom of the heaters shall be installed not less than 8 ft (2.4 m) above the floor.

2-12.5.4 In all hangars, suspended or elevated heaters shall be located in spaces where they shall not be subject to injury by aircraft, cranes, movable scaffolding, or other objects. Provisions shall be made to ensure accessibility to suspended heaters for recurrent maintenance purposes.

2-12.6

Where a mechanical ventilating system is employed in hangars or shops, the ventilating system shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*.

2-12.7

Where blower and exhaust systems are installed for vapor removal, the systems shall be installed in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

2-13 Lighting and Electrical Systems.

2-13.1

Artificial lighting shall be restricted to electric lighting.

2-13.2*

Electrical services shall be installed in compliance with the provisions for aircraft hangars contained in Article 513 of NFPA 70, *National Electrical Code*.

2-13.3

In aircraft storage and servicing areas of hangars housing other than unfueled aircraft, main distribution panels, metering equipment, and similar electrical equipment shall be located in a room separated from the aircraft storage and servicing areas by a partition having at least a 1-hour fire resistance rating. The partition shall not be penetrated except by electrical raceways, which shall be protected by approved sealing methods maintaining the same fire resistance rating as the partition.

2-14* Lightning Protection.

Where provided, lightning protection shall be installed in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

2-15 Grounding Facilities for Static Electricity.

2-15.1*

Aircraft storage and servicing areas of hangars housing other than unfueled aircraft shall be provided with grounding facilities for removal and control of static electrical accumulations on aircraft while aircraft are stored or undergoing servicing in a hangar in accordance with 2-15.2 and 2-15.3.

2-15.2

An adequate number of floor-grounding receptacles shall be provided. The receptacles shall be either grounded through individual driven electrodes or electrically bonded together in a grid system and the entire system grounded to underground metal piping, such as cold water or sprinkler piping, or driven electrodes. Where driven electrodes are used, they shall consist of $^5/_8$ in. (15.9 mm) diameter or larger metal rods driven at least 5 ft (1.5 m) into the ground. Floor-grounding receptacles shall be designed to minimize the tripping hazard.

2-15.3*

Grounding wires shall be bare and of a gauge that is satisfactorily durable to withstand mechanical strains and usage.

2-16 Exit and Access Requirements.

2-16.1

Means of egress from the aircraft hangar shall comply with NFPA *101®*, *Life Safety Code®*.

2-16.2

Aisles and clear space shall be maintained to ensure access to sprinkler control valves, standpipe hose, fire extinguishers, and similar equipment.

2-17* Materials for Draft Curtains.

Where provided, draft curtains shall be constructed of noncombustible materials not subject to disintegration or fusion during the early stages of a fire and shall be tightly fitted to the underside of the roof or ceiling. Any opening in draft stops shall be provided with self-closing doors constructed of materials equivalent in fire resistance to the draft stop itself.

Chapter 3 Protection of Group I Aircraft Hangars

3-1 General.

3-1.1

Group I aircraft hangar storage and servicing areas of hangars housing other than unfueled aircraft shall be equipped with an approved automatic foam-water deluge system, as specified in Section 3-2 of this chapter, as the primary protection system. In addition, a supplementary protection system as specified in Section 3-3 of this chapter shall also be provided where applicable.

3-1.2

Group I aircraft hangar storage and service areas housing unfueled aircraft shall be provided with automatic sprinkler protection as specified in Sections 4-2 and 4-7.

3-1.3

Automatic sprinkler protection shall be provided inside separate shop, office, and storage areas located inside aircraft maintenance and servicing areas, unless they are otherwise provided with automatic fire protection systems.

3-1.4

Each sprinkler system shall be designed and installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, as applicable, and in accordance with the requirements of this chapter.

3-1.5

Additional protection, as specified in Sections 3-4 and 3-6 of this chapter, shall be provided in all Group I aircraft hangars in addition to other protection systems required by this chapter.

3-2 Deluge Foam-Water Sprinkler System Design and Performance.

3-2.1 Plans and Specifications.

3-2.1.1* Before systems are installed, complete specifications and working plans shall be drawn to scale showing all essential details, and plans shall be easily reproducible to provide necessary copies.

3-2.1.2 Information supplied in these plans and specifications shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and shall include the following:

(a) The design purpose of the system;

(b) The discharge densities and the period of discharge;

(c) The hydraulic calculations;

(d) The details of tests of the available water supply;

(e) The details of proposed water supplies;

(f) The detailed layout of the piping and of the detection systems;

(g) The make and type of discharge devices, operating equipment, and foam concentrate to be installed;

(h) The location and spacing of discharge devices;

(i) The pipe hanger and bracing location and installation details;

(j) The location of draft curtains;

(k) The accurate and complete layout of the area to be protected; and

(l) The details of any foam concentrate, its storage and injection, and other pertinent data to provide a clear explanation of the proposed design.

3-2.2 Pipe and Fittings.

Piping and fitting materials shall be in accordance with NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*.

3-2.2.1 In aircraft storage and servicing areas, each sprinkler system shall be designed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, as applicable, and in accordance with this chapter.

3-2.2.2* In aircraft storage and servicing areas, the maximum projected floor area under an individual deluge system shall not exceed 15,000 ft^2 (1394 m^2).

3-2.2.3 In aircraft storage and servicing areas, the protection area as projected on the floor shall be limited to 130 ft^2 (12.1 m^2). The maximum distance between sprinklers either on branch lines or between branch lines shall be 12 ft (3.7 m).

3-2.2.4 System piping shall be hydraulically designed using two separate calculation methods. The demand calculation method shall be performed to determine the adequacy of the water supply. The supply calculation method shall be performed to determine the amount of foam concentrate required. Where steel pipe is installed, the coefficient C in the Hazen and Williams formula shall be taken as 120 in the calculations.

3-2.2.5 In other portions of hangars protected by sprinklers, the spacing shall be in accordance with the hazard requirements of the areas involved.

3-2.2.6 Uniform sprinkler discharge shall be based on a maximum variation of 15 percent between the sprinkler providing the lowest density and the sprinkler providing the greatest density within an individual deluge system as specified in 3-2.2.12 or 3-2.2.13. Variation below the required density shall not be permitted. Orifice plates, sprinklers of different orifice sizes, piping of less than 1 in. diameter, or multiple fittings installed between a branch line fitting and an individual sprinkler for the sole purpose of increasing pressure loss shall not be permitted as a means to limit discharge.

Exception: Local application protection for columns.

3-2.2.7 Where open hangar doors result in interference with the distribution of overhead systems, additional devices shall be provided to ensure effective floor coverage.

3-2.2.8 Foam-water deluge systems discharge devices shall be either air-aspirating or non air-aspirating and shall have deflectors designed to produce water discharge patterns closely comparable to those of spray sprinklers as defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*, when discharging at the same rates of flow.

3-2.2.9 The discharge devices shall generate foam where supplied with the foam solution under pressure and shall distribute the foam in a pattern essentially similar to that of water discharging therefrom.

3-2.2.10 The discharge devices shall have a minimum nominal $^1/_4$-in. (6.4-mm) orifice and shall be listed for use with the particular type of foam concentrate to be used in the system.

3-2.2.11 Strainers shall be installed in accordance with NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler Systems and Foam-Water Spray Systems*.

3-2.2.12 The discharge density from air-aspirating discharge devices using protein-type, fluoroprotein-type, or AFFF-type foam solutions shall be a minimum of 0.20 gal of foam solution per min per ft^2 (8.1 L/min/m^2) of floor area.

3-2.2.13 The discharge density from non air-aspirating discharge devices using AFFF-type foam solutions shall be a minimum of 0.16 gal of foam solution per min per ft^2 (6.5 L/min/m^2) of floor area.

3-2.3* Foam Concentrate Supply.

3-2.3.1 The quantities of foam concentrate, either protein foam, fluoroprotein, or AFFF, shall be sufficient for a 10-minute foam discharge based on the supply calculation in 3-2.2.4.

3-2.3.2 A reserve supply of foam concentrate of compatible type for the system shall be directly connected to the system and readily available. The reserve supply shall be in the same quantity as the main supply.

To prevent accidental depletion of this reserve supply, it shall be available to the system only by intentional manual operation.

3-2.4 Foam Concentrate Pumps.

3-2.4.1* Where foam concentrate is introduced into the water stream by pumping, the total foam concentrate pumping capacity shall be such that the maximum flows and pressures can be met with the largest foam concentrate pump out of service.

3-2.4.2 Power supply for the drivers of foam concentrate pumps shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and NFPA 70, *National Electrical Code.*

Power supplies shall be arranged such that disconnecting power to the protected facility during a fire shall not disconnect the power supply to the foam concentrate pump feeder circuit.

3-2.4.3 Controllers for foam concentrate pumps shall be as follows:

(a) For electric drive foam concentrate pumps greater than 30 horsepower, a listed fire pump controller shall be used.

(b) For electric drive foam concentrate pumps greater than 15 horsepower but not exceeding 30 horsepower, a listed fire pump controller or listed limited service controller shall be used.

(c) For electric drive foam concentrate pumps less than 15 horsepower, a listed limited service controller shall be used.

(d) For diesel engine drive foam concentrate pumps, a listed fire pump controller shall be used.

3-2.4.4 Piping shall be arranged so that maximum foam concentrate demand can be supplied from either primary or reserve foam concentrate tanks.

3-2.5 Water Supply.

3-2.5.1* The water supply shall be capable of furnishing water for the largest number of systems that possibly could be expected to operate.

3-2.5.1.1 Where draft curtains meeting the requirements of Section 2-17 are not provided, water supply requirements shall be calculated on the premise that all systems in the aircraft storage and servicing area not subdivided by fire walls will operate.

3-2.5.1.2 In aircraft storage and servicing areas having a maximum roof or ceiling height of 25 ft (7.5 m) or less, the water supply shall be sufficient for the operation of the largest number of systems. Sufficient water supply requirements are determined by assuming that a fire at any point will operate all the systems in every draft-curtained area that is wholly or partially within a 50-ft (15-m) radius of that point measured horizontally.

3-2.5.1.3 In aircraft storage and servicing areas having a maximum roof or ceiling height in excess of 25 ft (7.5 m) but not more than 75 ft (22.5 m) above floor level, the water supply shall be sufficient for the operation of the largest number of systems. Sufficient water supply requirements are determined by assuming that a fire at any point will operate all the systems in every draft-curtained area that is wholly or partially within a 75-ft (22.5-m) radius of that point measured horizontally.

3-2.5.1.4 In aircraft storage and servicing areas having a maximum roof or ceiling height in excess of 75 ft (22.5 m) above the floor level, the water supply shall be sufficient for the operation of the largest number of systems. Sufficient water supply requirements are determined by assuming that a fire at any point will operate all the systems in every draft-curtained area that is wholly or partially within a 100-ft (30-m) radius of that point measured horizontally.

3-2.5.2 The water supply shall be capable of maintaining water discharge at the design rate and pressure for a minimum of 60 minutes covering the entire area protected by systems expected to operate simultaneously as determined by 3-2.5.1 of this section, unless protection is provided as specified in 3-2.5.3 of this section.

3-2.5.3 Where foam-water systems are installed, and where applicable additional protection is installed in accordance with Section 3-3 of this standard, the water supply duration shall be for a minimum of 45 minutes.

3-2.5.4 The water supply shall be capable of satisfying the requirements of Section 3-4 of this chapter for interior hose stations. The calculated demand shall be the demand at a point where supply piping for the interior hose station(s) connects to the system piping or fire protection underground.

3-2.5.5 Where the water supply for the system also serves as a supply for exterior hose streams, a hose stream allowance of 500 gpm (1893 L/min) shall be included in the water supply hydraulic calculations. Calculations for hose streams shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

3-2.5.6* Where a single reservoir is used for the basic water supply, such reservoir shall be divided into approximately equal sections, arranged so at least one-half of the water supply will always be maintained in service in order to increase the reliability of the water supply. The suction line from each section shall be sized to deliver the maximum water supply requirement.

3-2.6 Fire Pumps.

3-2.6.1 Fire pumps shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and in accordance with the provisions of 3-2.6.2 through 3-2.6.6.

3-2.6.2 The total pumping capacity shall be such that maximum demand can be met with the largest fire pump out of service.

3-2.6.3 Pump houses and rooms shall be of fire-resistive or noncombustible construction. Where internal combustion engines used for driving fire pumps are located inside the fire pump house or room, protection shall be provided by automatic sprinklers installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

3-2.6.4* Fire pumps shall be started automatically by either a drop in water pressure or a signal from the detection control panel. Where two or more electrically driven fire pumps supplied from the same electrical feeder are used, they shall be electrically controlled to prevent simultaneous starting.

3-2.6.5 Frequent operation of fire pumps shall be avoided by the installation of a small auxiliary pressure maintenance pump or other suitable means to maintain normal system pressures.

3-2.6.6 Once started, fire pumps shall be arranged to run continuously until they are stopped manually. There shall be an audible “pump running” alarm in a continuously attended area.

3-2.7* Flushing Underground Pipe.

Underground mains and each lead-in connection shall be flushed as specified in NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*.

3-2.8 Acceptance Tests.

3-2.8.1 The following tests shall be performed prior to final acceptance of any fire protection system in an aircraft hangar.

3-2.8.1.1 Hydrostatic pressure tests shall be conducted on each sprinkler system as specified in NFPA 13, *Standard for the Installation of Sprinkler Systems*, or NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*, as applicable.

3-2.8.1.2 Full-flowing tests with water only shall be made on each foam-water deluge system as a means of checking the sprinkler distribution and to ensure against clogging of piping and sprinklers by foreign matter carried by the water. The maximum number of systems that possibly could be expected to operate in case of fire, including supplementary systems, shall be in full operation simultaneously to provide a check on the adequacy and condition of the water supply. Suitable gauge connections and gauges shall be provided to verify hydraulic calculations.

3-2.8.1.3 The smallest single foam-water deluge system shall be discharged using foam concentrate. This test shall be run for a length of time sufficient to stabilize discharge before test samples are taken to determine foam concentrate percentage.

3-2.8.1.4 The maximum number of systems expected to operate shall be simultaneously discharged with foam. This test shall be run for a length of time sufficient to stabilize discharge before test samples are taken to determine foam concentrate percentage.

3-2.8.1.5 Any proportioner not tested under the requirements of 3-2.8.1.3 or 3-2.8.1.4 shall be individually tested with foam concentrate to determine concentrate percentage.

3-2.9 Final Approval.

The installing company shall furnish a written statement that the work has been completed in accordance with 3-2.1 of this section, and tested in accordance with the provisions of 3-2.8 of this section.

3-2.10 Conversion of Existing System.

In converting one type of system to another, all provisions of this chapter pertaining to new systems shall apply.

3-2.10.1 If water supplies are greater than necessary, the uniform discharge requirement of 3-2.2.6 of this section shall be permitted to be waived if the required minimum discharge rate in gal per min per sq ft is available in all areas.

3-2.10.2 Where existing systems are designed with a discharge density higher than the minimum required discharge density [0.16 gpm/ft^2 (6.5 L/min/m^2)], a proportionate reduction in the time of discharge shall be permitted but shall not be less than 7 minutes.

3-2.10.3 Converted systems shall be tested in accordance with 3-2.8 of this section.

3-2.11 Detection System Design.

3-2.11.1 Detectors for actuating the primary protection systems shall be rate-of-rise, fixed temperature, or rate compensation types.

3-2.11.2 Detection systems shall be provided with complete supervision.

3-2.11.3* Manual actuation stations shall be located so that each system can be individually operated from both inside and outside the aircraft storage and servicing area. The manual stations shall be installed so that they are unobstructed, readily accessible, and located in the normal paths of exit from the area.

3-3 Supplementary Protection Systems.

3-3.1*

Hangars housing aircraft having wing areas in excess of 3,000 ft^2 (279 m^2) shall be protected with a listed supplementary protection system.

3-3.2*

Each system shall be designed to cover a specified floor area beneath the aircraft being protected. The design objective shall be to achieve control of the fire within the protected area within 30 seconds of system actuation and extinguishment of the fire within 60 seconds.

3-3.3

Each supplemental protection system shall be designed, installed, and maintained in accordance with NFPA 11, *Standard for Low-Expansion Foam*, or NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*.

3-3.4 Plans and Specifications.

3-3.4.1* Before systems are installed, complete specifications and working plans shall be drawn to scale showing all essential details, and the plans shall be easily reproducible to provide necessary copies.

3-3.4.2* These plans and specifications shall include:

(a) Accurate and complete layout of the area to be protected, including drainage trench layout;

(b) Information on the primary protection systems installed in the hangar;

(c) Location and spacing of agent distributors, showing the area coverage;

(d) Installation layout of the actuation systems;

(e) Detailed layout of water supply piping, agent storage, pumping and piping, power sources, and location and details of mechanical foam-liquid concentrate injection equipment; and

(f) Make and type of discharge devices and foam concentrate and hydraulic calculations of the systems.

3-3.5 Low-Expansion Foam Systems.

3-3.5.1 Low-expansion foam systems shall employ AFFF, protein, or fluoroprotein foam-liquid concentrates and shall be designed for local application.

3-3.5.2* Coverage of the specified floor area beneath the aircraft shall be by means of a horizontal foam discharge from nozzles located above floor level.

3-3.5.3* Where oscillating nozzles are used, the discharge pattern limits shall be established for the design. Positive securement of the limits of oscillation shall be provided by such devices as set screws, locking pins, or similar methods. When placed in service, the manual override feature, if any, shall be locked out to provide for automatic operation only.

3-3.5.4 Where protein- or fluoroprotein-based concentrates are used, the minimum application density shall be 0.16 gpm of foam solution per sq ft (6.5 L/min/m^2) of floor area beneath the wing and wing center section of the aircraft. Where AFFF concentrate is used, the minimum application density shall be 0.10 gpm of foam solution per sq ft (4.1 L/min/m^2) of floor area beneath the wing and wing center section of the aircraft.

3-3.5.5* The quantity of foam liquid concentrate shall be sufficient for a 10-minute discharge at the water flow rate based on the supply calculation method required in 3-2.2.4.

3-3.5.6 If any nozzles are removed to allow movement of the aircraft, removal of the nozzles shall not reduce the effectiveness of the remaining system.

3-3.5.7 Electric power reliability for concentrate pumps and oscillating nozzles shall be in accordance with electric fire pump requirements of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

3-3.5.8 Where monitor-type nozzles are used, an individual manual control valve shall be provided for each unit. This valve shall be supervised.

3-3.6 High-Expansion Foam Systems.

3-3.6.1 High-expansion foam systems shall utilize surfactants as the foaming ingredient and shall be designed for local application.

3-3.6.2* These systems shall be designed to discharge at a rate to cover the protected area to a depth of at least 3 ft (0.9 m) within 1 minute.

3-3.6.3 Discharge rates shall take into consideration the sprinkler breakdown factor required in 2-3.5.2(b) of NFPA 11A, *Standard for Medium-and High-Expansion Foam Systems*.

3-3.6.4* The quantity of foam concentrate shall be sufficient for a 12-minute discharge at the water flow rate based on the supply calculation method required in 3-2.2.4.

3-3.6.5 The foam generators shall be located at the ceiling or on exterior walls in such a way that only air from outside the aircraft storage and servicing area can be used for foam generation. Roof vents shall be located to avoid recirculation of combustion products into the air inlets of the foam generators.

3-3.6.6* Generators shall be powered by reliable water-driven or electric motors. Electric power reliability for both generators and concentrate pumps shall be in accordance with electric fire pump requirements of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

3-3.7* Water Supply.

Water shall be available in sufficient quantity and pressure to supply the maximum number of agent distributors likely to operate simultaneously, in addition to meeting the demands of overhead hangar protection systems as determined in this chapter, and the requirements for hose stream and other equipment as determined in Section 3-4 of this chapter. Water shall be suitable for the production of foam.

3-3.8* Foam Concentrate.

3-3.8.1 The quantities of foam concentrate shall be sufficient to provide protection specified by the requirements of this chapter.

3-3.8.2* A reserve supply of foam concentrate of compatible type for the system shall be directly connected to the system and readily available. The reserve supply shall be in the same quantity as the main supply.

3-3.8.3 Where foam concentrate is introduced into the water stream by pumping, the total foam concentrate pumping capacity shall be such that the maximum pressures and flows can be met with the largest foam concentrate pump out of service.

3-3.8.4 Control valves, foam concentrate liquid storage tanks, concentrate pumps, controllers, and bypass balancing equipment shall be located outside the aircraft storage and service area.

3-3.9 Acceptance Tests.

3-3.9.1 The following tests shall be performed prior to final acceptance of any supplementary system in an aircraft hangar.

3-3.9.2 All piping shall be subjected to a 2-hour hydrostatic pressure test at 200 psi (1380 kPa) or 50 psi (345 kPa) in excess of the maximum pressure anticipated, whichever is greater, in general conformity with NFPA 13, *Standard for the Installation of Sprinkler Systems*. All normally dry piping shall be checked for leakage, freedom from obstructions, and to determine if proper drainage pitch has been provided.

3-3.9.3 All devices and equipment installed as part of the system shall be tested.

3-3.9.4 Supplementary protection systems shall be subjected to flow tests, with foam flowing simultaneously from the maximum number of primary protection systems expected to operate, in order to ensure that the hazard is protected in conformance with the design specification and to determine whether the flow pressures, agent discharge capacity, foam coverage, percent concentration, and other operating characteristics are satisfactory.

Exception: Where separate proportioning systems are utilized for the primary and supplementary protection systems, water only shall be permitted to be flowed in the primary protection system simultaneously with foam in the supplementary protection system.

3-3.9.5 Supplementary protection systems shall be examined visually to determine that they have been properly installed. Checks shall be made for such items in conformity with installation plans, continuity of piping, tightness of fittings, removal of temporary blank flanges, and accessibility of valves and controls. Devices shall be properly identified and operating instructions prominently posted.

3-3.10 Final Approval.

The installing company shall furnish a written statement to the effect that the work has been completed in accordance with approved plans and specifications, and tested in accordance with 3-3.9 of this section.

3-3.11 Actuation System.

3-3.11.1* Actuation of any primary fire protection system shall simultaneously operate the supplementary extinguishing system.

3-3.11.2 Actuation systems shall be provided with complete circuit supervision and shall be arranged in accordance with Section 3-6 of this chapter.

3-3.11.3 Manual actuation stations shall be provided for each supplemental protection system and shall be located both inside and outside the aircraft maintenance and servicing area. Stations shall be located as close as possible to the aircraft positions to facilitate early system actuation in the event of a fire.

3-4 Hand Hose Systems.

3-4.1*

Hand hose systems shall be installed in every hangar, including sprinklered hangars, to provide for manual fire control.

3-4.2

The hand hose systems shall be arranged to permit application of water or other extinguishing agents on each side and into the interior of the aircraft located in each aircraft storage and servicing area. At least two hose lines shall be considered to be operated simultaneously.

3-4.3 Foam-Water Hand Hose Systems.

3-4.3.1 Foam-water hand hose systems shall be installed in aircraft storage and servicing areas.

Exception: Where aircraft storage and servicing areas house only unfueled aircraft, as defined in 1-3.18, hand hose systems shall be provided in accordance with 3-4.4 of this standard.

3-4.3.2 The systems shall conform with the applicable portions of NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, and NFPA 11, *Standard for Low-Expansion Foam*.

3-4.3.3 These hand hose systems shall be supplied from a connection to the sprinkler system header or from a direct connection to the water source.

3-4.3.4 Each hand hose connection shall be a minimum of $1^1/_2$ in. (38 mm) in size and fitted with a control valve. The hose shall be of suitable length and diameter to provide a minimum flow of 60 gpm (227 L/min) at an adequate nozzle pressure. The stream range shall be calculated based on the volume and pressures available under maximum demand conditions.

3-4.3.5 The hose shall be properly racked or reeled. Hoses shall be fitted with an approved foam-maker nozzle or a combination-type nozzle designed to permit foam application or water spray. Nozzles shall be of the shutoff type or shall have a shutoff valve at the nozzle inlet.

3-4.3.6 Foam-liquid concentrate can be supplied from a central distribution system, separate from or a part of a foam-water sprinkler system, or from stationary foam-liquid concentrate containers fitted with listed proportioning devices.

3-4.3.7 The minimum supply of foam-liquid concentrate shall be sufficient to provide operation of at least two hand hose lines for a period of 20 minutes at a foam solution discharge rate of 60 gpm (227 L/min) each.

3-4.4 Water Hand Hose Systems.

3-4.4.1 Water hand hose and standpipe systems shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, in all shop, office, and nonaircraft storage areas in hangars, except where special hazards that require special protection exist.

3-4.4.2 Hoses shall be fitted with listed adjustable stream pattern nozzles designed to permit straight stream or water spray application.

3-5 Wheeled and Portable Extinguishers.

3-5.1

Wheeled and portable extinguishers shall be provided in accordance with NFPA 10, *Standard* *for Portable Fire Extinguishers*.

3-5.2

In aircraft storage and servicing areas, the distribution of such devices shall be in accordance with the extra hazard classification outlined in NFPA 10, *Standard for Portable Fire Extinguishers*.

3-5.3

The distribution of extinguishers in other areas of aircraft hangars shall be in accordance with light, ordinary, or extra hazard occupancy based on an analysis of each such room or area following the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

3-6* Protection System Alarms.

In addition to local alarm service, alarms shall be transmitted to a constantly attended location.

Chapter 4 Protection of Group II Aircraft Hangars

4-1 General.

4-1.1

The protection of aircraft storage and servicing areas of Group II aircraft hangars, other than those housing unfueled aircraft, shall be in accordance with any one of the following:

(a) The provisions of Chapter 3 of this standard.

Exception: Where foam-water deluge systems utilizing air-aspirating discharge devices are installed for the protection of Group II aircraft hangars, the discharge rate specified in 3-2.2.12 of this standard shall be permitted to be reduced to a minimum of 0.16 gal of foam solution per min per sq ft (6.5 L/min/m^2) of floor area.

(b) A combination of automatic sprinkler protection in accordance with Section 4-2 of this chapter AND an automatic, low-level, low-expansion foam system in accordance with Sections 4-3 and 4-4 of this chapter.

(c) A combination of automatic sprinkler protection in accordance with Section 4-2 of this chapter AND an automatic high expansion foam system in accordance with Sections 4-3 and 4-5 of this chapter.

(d) A closed-head foam-water sprinkler system in accordance with Section 4-6.

4-1.2

Group II aircraft hangar storage and service areas housing unfueled aircraft shall be provided with automatic sprinkler protection specified in Sections 4-2 and 4-8.

4-1.3

Automatic closed-head sprinkler protection shall be provided inside separate shop, office, and storage areas located inside aircraft maintenance and servicing areas. The design shall be in accordance with hazard classifications specified in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-1.4

In addition to the provision for sprinkler and foam extinguishing systems as required by this chapter, protection as required by Sections 3-4, 3-5, and 3-6 of this standard also shall be provided.

4-2 Closed-Head Water Sprinkler System for Aircraft Storage and Servicing Areas.

4-2.1*

Sprinkler systems shall be either wet pipe or preaction, designed and installed in accordance with the applicable sections of NFPA 13, *Standard for the Installation of Sprinkler Systems*, and the provisions of this chapter.

4-2.2

Sprinkler piping shall be hydraulically sized in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-2.3

Sprinkler spacing shall be as specified in 3-2.2.3 of this standard.

4-2.4

Where open hangar doors result in interference with the distribution of water from the hangar sprinkler systems, additional sprinklers shall be provided to ensure effective floor coverage.

4-2.5

The design density from sprinkler systems shall be a minimum of 0.17 gpm of water per sq ft (6.9 L/min/m^2) over any 5,000-ft^2 (464.5-m^2) area, including the hydraulically most demanding area as defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-2.6

Sprinklers shall have a nominal orifice size of $^1/_2$ in. (12.7 mm) or $^{17}/_{32}$ in. (13.5 mm).

4-2.7

Sprinklers shall have a temperature rating of 325°F to 375°F (162°C to 190°C).

4-2.8

Sprinkler systems shall be flushed and tested in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-3* Foam Concentrate — General.

4-3.1

The foam concentrate supplied with the system shall be listed for use with the distribution equipment.

4-3.2

There shall be a reserve of foam concentrate of a compatible type directly connected to the system. The reserve supply shall be in the same quantity as the main supply.

To prevent accidental depletion of this reserve supply, it shall be available to the system only by intentional manual operation.

4-3.3 Foam Concentrate Pumps.

4-3.3.1 Where foam-liquid concentrate is introduced into the water stream by pumping, the total foam concentrate pumping capacity shall be such that the maximum flows and pressures can be met with the largest foam concentrate pump out of service.

4-3.3.2 Power supply for the drivers of foam concentrate pumps shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and NFPA 70, *National Electrical Code.*

Power supplies shall be arranged such that disconnecting power to the protected facility during a fire shall not disconnect the power supply to the foam concentrate pump feeder circuit.

4-3.3.3 Controllers for foam concentrate pumps shall be as follows:

(a) For electric drive foam concentrate pumps greater than 30 horsepower, a listed fire pump controller shall be used.

(b) For electric drive foam concentrate pumps greater than 15 horsepower but not exceeding 30 horsepower, a listed fire pump controller or listed limited service controller shall be used.

(c) For electric drive foam concentrate pumps less than 15 horsepower, a listed limited service controller shall be used.

(d) For diesel engine drive foam concentrate pumps, a listed fire pump controller shall be used.

4-3.3.4 Piping shall be arranged so that maximum foam concentrate demand can be supplied from either primary or reserve foam concentrate tanks.

4-3.4

The control valves, foam-liquid concentrate storage, injection system, and foam concentrate pump shall be located outside aircraft storage and servicing areas. The environmental conditions shall be suitable for the particular agent involved.

4-3.5

Plans and specifications for closed-head foam-water sprinkler systems shall provide the information required by 3-2.1.2 of this standard and NFPA 16A, *Standard for the Installation of Closed-Head Foam-Water Sprinkler Systems*. Plans and specifications for other foam extinguishing systems shall provide the information required by 3-3.4 of this standard.

4-3.6 Acceptance Tests.

4-3.6.1 Acceptance tests for closed-head foam-water sprinkler systems shall be performed in accordance with NFPA 16A, *Standard for the Installation of Closed-Head Foam-Water Sprinkler Systems*.

4-3.6.2 Acceptance tests for foam extinguishing systems shall be performed in accordance with 3-3.9.2, 3-3.9.3, and 3-3.9.5 of this standard.

4-3.6.2.1 The systems shall be subjected to flow tests with foam flowing from the maximum number of foam distributors expected to operate in order to ensure that the hangar is protected in conformance with the design specifications, and to determine if the flow pressures, agent discharge capacity, foam coverage, percentage of concentration, and other operating characteristics are satisfactory.

4-3.6.2.1.1 A flow test shall be performed with only the foam system operating.

4-3.6.2.1.2 A flow test shall be performed with the foam system operating at the design pressure with the sprinkler system and hose demand.

4-3.7

The installing company shall furnish a written statement to the effect that the work has been completed in accordance with approved plans and specifications, and tested in accordance with the provisions of 4-3.6 of this section.

4-4* Low-Expansion Foam System.

4-4.1

Foam systems shall be of the fixed type and shall be designed and installed in accordance with the requirements for fixed-type systems in NFPA 11, *Standard for Low-Expansion Foam*.

4-4.2

The minimum application rate shall be 0.16 gpm of foam solution per sq ft (6.5 L/min/m^2) where protein-based or fluoroprotein-based concentrate is used. Where AFFF concentrate is used, the minimum application rate shall be 0.10 gpm of foam solution per ft^2 (4.1 L/min/m^2).

4-4.3*

The discharge rate of the system shall be based on the rate of application multiplied by the entire aircraft storage and servicing floor area.

4-4.4

The foam system shall use low-level monitor-type discharge nozzles, with individual manual shutoff valves for each nozzle.

The discharge nozzles shall be arranged to achieve initial foam coverage in the expected aircraft parking area.

4-4.5*

The quantity of foam concentrate shall be sufficient for a 10-minute discharge at the water flow rate based on the supply calculation method.

4-5 High-Expansion Foam System.

4-5.1

High-expansion foam systems shall be designed and installed in accordance with NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*, requirements for local application systems.

4-5.2

The high-expansion foam generators shall be arranged to achieve initial foam coverage in the anticipated aircraft parking area.

4-5.3

The effective application rate shall be a minimum of 3 cfm/ft^2 (0.0014 m^3/s).

4-5.4

The discharge rate of the system shall be based on the application rate multiplied by the entire aircraft storage and servicing floor area. The application total discharge rate shall include the sprinkler breakdown factor specified in 2-3.5.2(b) of NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*.

4-5.5

Foam generators shall be supplied with air from outside the aircraft storage and servicing area. Roof vents shall be located to avoid recirculation of combustion products into the air inlets of the foam generators.

4-5.6

Foam generators shall be powered by reliable water-driven or electric motors. Electric power reliability for both foam generators and foam concentrate pumps shall be consistent with electric fire pump requirements specified in Chapters 6 and 7 of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

4-5.7

The quantity of foam concentrate shall be sufficient to operate the system at the required discharge rate as determined in 4-5.4 for a period of at least 12 minutes.

4-6 Closed-Head Foam-Water Sprinkler System.

4-6.1

Closed-head foam-water sprinkler systems shall be designed and installed in accordance with NFPA 16A, *Closed-Head Foam-Water Sprinkler Systems*.

4-6.1.1 AFFF shall be used.

4-6.2

The minimum discharge density shall be 0.16 gpm/ft^2 (6.5 L/min/m^2) of foam solution over the entire storage and service area.

4-6.3

Sprinkler spacing shall not exceed 100 ft^2 (9.3 m^2) as projected on the floor. The maximum distance between sprinklers either on branch lines or between branch lines shall be 12 ft (3.6 m).

4-6.4

In aircraft storage and servicing areas, the maximum projected floor area under an individual sprinkler system shall not exceed 15,000 ft^2 (1393 m^2).

4-6.4.1 Each individual system shall have its own foam concentrate proportioner.

4-6.5

Sprinklers shall have a temperature rating of 175°F to 225°F (79.4°C to 107.2°C).

4-6.6

Foam concentrate supply shall be in accordance with 3-2.3 of this standard.

4-6.7*

Branch lines shall be provided with provisions for periodic flushing.

4-6.7.1 Drains shall be a minimum of 1 in. (2.5 cm) in size.

4-7 Detection and Actuation Systems.

4-7.1

Detectors for actuating high- or low-expansion foam systems and for actuating preaction sprinkler systems shall be rate-of-rise, fixed temperature, or rate compensation type.

4-7.2

These detectors shall be installed in accordance with NFPA 72, *National Fire Alarm Code*.

4-7.3

Detection systems shall be provided with supervision as required by NFPA 72, *National Fire Alarm Code*.

4-7.4

Manual actuation stations shall be located so that each system can be individually operated from both inside and outside the aircraft storage and servicing area. The manual stations shall be installed so that they are unobstructed, readily accessible, and located in the normal paths of exit from the area.

4-8* Water Supply.

4-8.1

The total water supply shall be sufficient to satisfy the combination of systems and hose stations as described in 4-1.1(b), 4-1.1(c), and 4-1.3 of this chapter for durations as specified in this section.

4-8.2

The water supply for closed-head water sprinkler systems in aircraft storage and servicing areas shall meet one of the following:

(a) In aircraft storage and servicing areas housing other than unfueled aircraft, the water supply shall have a minimum duration of 30 minutes at the rate specified in 4-2.5.

(b) In aircraft storage and servicing areas housing unfueled aircraft, the water supply shall have a minimum duration of 60 minutes at the rate specified in 4-2.5.

4-8.3

The water supply for low-expansion foam systems shall be capable of furnishing water at the rate specified in 4-4.2 of this chapter for a period of time at least equal to twice the period of time used to calculate the quantity of foam liquid concentrate in 4-4.5. Water shall be suitable for the production of foam.

4-8.4

The water supply for high-expansion foam systems shall be capable of furnishing water at the rate specified in 4-5.3 of this chapter for a minimum period of 24 minutes. Water shall be suitable for the production of foam.

4-8.5

The water supply for closed-head foam-water sprinkler systems shall have a minimum duration of 30 minutes at the rate specified in 4-6.2.

4-8.6

The water supply for hose stations shall be capable of satisfying the requirements of Section 3-4 of this standard, in addition to those requirements specified in 4-8.2 and either 4-8.3 or 4-8.4 of this section. The demand shall be calculated at the point where supply piping for the hose stations connects to the system piping or fire protection underground.

4-8.7

Where the water supply for the systems also serves as a supply for exterior hose streams, a hose stream allowance of 500 gpm (1893 L/min) shall be included in the water supply hydraulic calculations. Calculations for hose stream shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

4-8.8

Where provided, fire pumps and suction reservoirs shall be designed and installed in accordance with 3-2.5.6 and 3-2.6 of this standard.

Chapter 5 Group III Aircraft Hangars

5-1 Construction.

5-1.1*

Group III hangars shall be constructed of any of the types of construction specified in NFPA 220, *Standard on Types of Building Construction*.

5-1.2

Group III hangars shall be limited to one story. Where a Group III hangar as defined in 1-3.2.3 exceeds one story, the hangar shall be designated as a Group II hangar.

5-1.3

The surface of the grade floor of aircraft storage and servicing areas, regardless of type of hangar construction, shall be noncombustible and above the grade of the approach or apron at the entrance to the hangar.

5-1.4

Hangar aprons shall slope away from the level of the hangar floors to prevent liquid on the apron surfaces from flowing into the hangars.

5-1.5

In freestanding hangars for a single aircraft and in row hangars, a minimum of 6-in. (15-cm) high curbing shall be provided between each aircraft space to prevent the flow of liquid from one space to adjacent spaces.

Open-bay hangars capable of housing multiple aircraft shall be provided with floor drainage in accordance with Section 2-11 of this standard.

5-1.6

Roof coverings shall be listed as Class C, or better, where tested in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.

5-1.7

Exposed interior insulation attached to walls and roofs in aircraft storage and servicing areas shall be noncombustible as defined in NFPA 220, *Standard on Types of Building Construction*.

In an aircraft storage and servicing area of a hangar equipped with an approved sprinkler system designed in accordance with Chapter 4 of this standard, exposed interior insulation attached to walls and roofs shall be permitted to be limited noncombustible as defined in NFPA 220, *Standard Types of Building Construction*.

5-2 Separation and Internal Subdivisions.

5-2.1

For single hangar buildings, the clear space distances specified in Table 5-2.1 shall be maintained on all sides of the single hangar. Where mixed types of construction are involved, the less fire-resistant type of construction shall be used to determine clear space required. Where the minimum clear spaces specified in Table 5-2.1 are not met, the buildings shall be considered a hangar building cluster.

Table 5-2.1

Type of Construction	Minimum Separation Required
Type I (443) and (332)	50 ft (15 m)
Type II (222)	50 ft (15 m)
Type II (111), Type III (211), and Type IV (2HH)	50 ft (15 m)
Type II (000)	50 ft (15 m)
Type III (200)	50 ft (15 m)
Type V (111) and (000)	75 ft (23 m)

Where single hangar buildings adjoin each other and each has fire walls with a minimum rating of at least 2 hours, located so that fire areas shall not exceed the maximum areas specified in Table 1-3.2.3 of this standard, no minimum separation distance shall be required. These buildings shall not be considered a hangar building cluster.

5-2.2

Row hangars shall be divided by solid partitions having a fire resistance equivalent to that of the exterior walls or roof, whichever is greater, so that no more than three aircraft spaces shall be within an enclosed area.

5-2.3

Partitions and ceilings separating aircraft storage and servicing areas from other areas, such as shops, offices, and parts storage areas, shall have at least a 1-hour fire resistance rating with openings protected by listed fire doors having a fire resistance rating of at least $^{3}/_{4}$ hour.

5-3 Hangar Building Clusters.

5-3.1

In hangar building clusters, Group III hangars within that cluster shall be limited in total area for the specific types of construction in accordance with Table 5-3.1. Where mixed types of construction are involved, the less fire-resistant type of construction shall be used to determine the maximum allowable area in accordance with the table.

Table 5-3.1 Maximum Fire Areas for Hangar Building Clusters

Types of Construction	Hangar Building Clusters (Ft^2)	(M^2)
Type I (443) and (332)	60,000	(5,574)
Type II (222)	40,000	(3,716)
Type II (111), Type III (211), and Type IV (2HH)	30,000	(2,787)
Type II (000)	24,000	(2,230)
Type III (200)	24,000	(2,230)
Type V (111)	16,000	(1,486)
Type V (000)	10,000	(929)

5-3.2

Where the total area of all Group III hangars in a cluster exceeds that specified in Table 5-3.1, selected buildings in the hangar cluster shall be considered as Group II hangars and protected in accordance with Chapter 4 of this standard. These buildings shall be selected such that the total area of the unprotected Group III hangar buildings in the hangar cluster is below the maximum area allowed by Table 5-3.1 for the less fire-resistant type of construction.

5-3.3

For hangar building clusters, the clear space distances specified in Table 5-3.3 shall be maintained on all sides of the hangar building clusters. Where mixed types of construction are involved, less fire-resistant type of construction shall be used.

Table 5-3.3

Type of Construction	Minumum Separation Required
Type I (433) and (332)	75 ft (23 m)
Type II (222)	75 ft (23 m)

Type IV (2HH)	75 ft (23 m)
Type II (111) and Type III (211)	100 ft (30 m)
Type II (000)	100 ft (30 m)
Type III (200)	100 ft (30 m)
Type V (111) and (000)	125 ft (38 m)

5-4 Heating and Ventilating.

5-4.1

Heating, ventilation, and air conditioning equipment shall be installed, as applicable, in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; and NFPA 54, *National Fuel Gas Code*, except as hereinafter specifically provided.

5-4.2

No heating, ventilation, and air conditioning equipment employing an open flame or glowing element shall be installed in aircraft storage and servicing areas or sections communicating therewith, except as provided for in 5-4.5 of this section.

5-4.3

Hangar heating plants that are fired with gas, liquid, or solid fuels not covered under 5-4.5 of this section, and that are not located in a detached building, shall be located in a room separated from other parts of the hangar by construction having at least a 1-hour fire resistance rating. This separated room shall not be used for any other hazardous purpose or combustible storage and shall have no direct access from the aircraft storage or servicing area. Openings in the walls of such rooms communicating with other portions of the hangar shall be restricted to those necessary for ducts or pipes. Penetrations of the 1-hour fire resistance rated enclosure shall be firestopped with an approved material properly installed and capable of maintaining the required fire resistance rating for the enclosure. Each such duct shall be protected with a listed automatic fire damper or door. All air for combustion purposes entering such separated rooms shall be drawn from outside the building.

5-4.4*

Heating, ventilating, and air conditioning plants employing recirculation of air within aircraft storage and servicing areas shall have return air openings not less than 10 ft (3 m) above the floor. Supply air openings shall not be installed in the floor and shall be at least 6 in. (152 mm) from the floor measured to the bottom of the opening.

Where automatic fire protection systems are installed in aircraft storage and servicing areas, fans for furnace heating systems shall be arranged to shut down automatically by means of the operations of the interior automatic fire protection system. One or more manual fan shutoff switches shall be provided. Shutoff switches shall be accessible and clearly placarded.

5-4.5 Suspended or Elevated Heaters.

5-4.5.1 Listed electric, gas, or oil heaters shall be permitted to be used if installed as specified in 5-4.5.2, 5-4.5.3, and 5-4.5.4 of this subsection.

5-4.5.2 In aircraft storage and servicing areas, heaters shall be installed at least 10 ft (3 m) above the upper surface of wings or of the engine enclosures of the highest aircraft that can be housed in the hangar. The measurement shall be made from the wing or engine enclosure, whichever is higher from the floor, to the bottom of the heater.

5-4.5.3 In shops, offices, and other sections of aircraft hangars communicating with aircraft storage or servicing areas, the bottom of the heaters shall be installed not less than 8 ft (2.4 m) above the floor.

5-4.5.4 Suspended or elevated heaters shall be located in all spaces of aircraft hangars so that they shall not be subject to injury by aircraft, cranes, movable scaffolding, or other objects. Provision shall be made to ensure accessibility to suspended heaters for recurrent maintenance purposes.

5-4.6

Where a mechanical ventilating system is employed in hangars or shops, the ventilating system shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, and in accordance with the applicable provisions of Section 5-4 of this chapter.

5-4.7

Where blower and exhaust systems are installed for vapor removal, the systems shall be installed in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

5-5 Lighting and Electrical Systems.

5-5.1

Artificial lighting shall be restricted to electric lighting.

5-5.2*

Electrical services shall be installed in compliance with the provisions for aircraft hangars contained in Article 513 of NFPA 70, *National Electrical Code*.

5-6 Lightning Protection.

Where provided, lightning protection shall be installed in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

5-7 Grounding Facilities for Static Electricity.

5-7.1*

Grounding facilities shall be provided for removal and control of static electrical accumulations on aircraft while aircraft are stored or are undergoing servicing in a hangar.

5-7.2

An adequate number of floor-grounding receptacles shall be provided. The receptacles shall be either grounded through individual driven electrodes or electrically bonded together in a grid system and the entire system grounded to underground metal piping or driven electrodes. Where driven electrodes are used, they shall consist of $^5/_8$ in. (15.9 mm) diameter or larger metal rods driven at least 5 ft (1.5 m) into the ground. Floor grounding receptacles shall be designed to minimize the tripping hazard.

5-7.3*

Grounding wires shall be bare and of a gauge that will be satisfactorily durable to withstand mechanical strains and usage.

5-8 Exit and Access Requirements.

5-8.1

Means of egress from the aircraft hangar shall comply with NFPA *101*, *Life Safety Code*.

Egress doors for personnel that do not require the opening of doors accommodating aircraft shall be provided in each partitioned space. Intervals between doors shall not exceed 150 ft (45 m) on all exterior walls or 100 ft (30 m) along interior walls.

5-8.2

Aisles and clear space shall be maintained to ensure access to sprinkler control valves, where provided, standpipe hose, fire extinguishers, and similar equipment.

5-9 Fire Protection for Group III Hangars.

5-9.1

Where hazardous operations including fuel transfer, welding, torch cutting, torch soldering, doping, and spray painting are performed in any Group III hangar, the Group III hangar shall be protected with the fire protection specified in Chapter 4 of this standard and also shall meet the requirements specified in 2-4.2 of this standard.

5-9.2

Portable fire extinguishers shall be provided in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*. Where portable extinguishers are locked up to preclude the possibility of theft, each tenant and aircraft owner shall be provided with a key for the locks.

5-9.2.1 In aircraft storage and servicing areas, the distribution of portable fire extinguishers shall be in accordance with extra hazard classification outlined in NFPA 10, *Standard for Portable Fire Extinguishers*.

5-9.2.2 The distribution of extinguishers in other areas of aircraft hangars shall be in accordance with light, ordinary, or extra hazard occupancy based on an analysis of each room or area following the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

Chapter 6 Periodic Inspection and Testing

6-1 Fire Protection Systems.

6-1.1

Inspection and testing of fire protection systems in aircraft hangars shall be performed in accordance with Table 6-1.1.

Table 6-1.1

System Components	Weekly	Monthly	Semi- Ann.	Ann.	Qtrly.	5 Yrs.
	Type and Frequency of Inspection and Tests					
Sprinkler Heads				V		
Piping				V		D
Pipe Hangers				V		
Sprinkler Alarm Valve		V			01	
Deluge Valve		V		O		D
Shutoff Valves		V		F		
Fire Pumps	F4			D		
Water Reservoirs		V				
Hose Stations		V				D
Strainers				V		
Foam Concentrate				F2		
Conc. Storage Tanks		V				
Conc. Pump	F4			O		D
Conc. Control Valve (Auto)		V		O		D
Conc. Shutoff Valve		V		F

Hangar Floor Drain Sys. & Separators	V			D
Fire Doors	V		F	
Gas Detectors	V	F		
Ventilation System in Pits, Tunnels, & Ducts		F		
Grounding Equipment				F

V = Visual
F = Functional (No flow)
O = Operational (W/Flow - No Discharge)
D = Operational with actual discharge

1 = For the purposes of this test, the inspector's flow valve is acceptable.
2 = A sample should be sent to the manufacturer for analysis.
3 = At this time it is necessary to check that the set points are the same as the original.
4 = Churn test.

6-1.2

All preprimed closed-head AFFF systems shall be drained, flushed, and reprimed annually.

6-1.3

Records of inspections, tests, and test results shall be maintained.

Chapter 7 Referenced Publications

7-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

7-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 780, *Standard for the Installation of Lightning Protection Systems*, 1995 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-2.1

The adequacy and usefulness of aircraft hangars depends to a large extent on the fire resistance of their construction and the fire protection provided within the buildings.

A-1-3 Group III Aircraft Hangars.

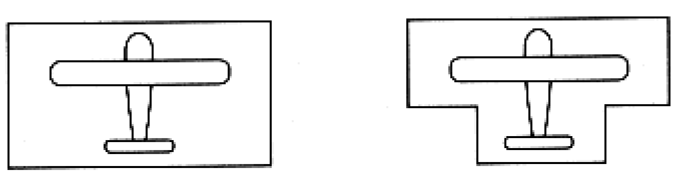

Figure A-1-3(a) Freestanding unit for single aircraft.

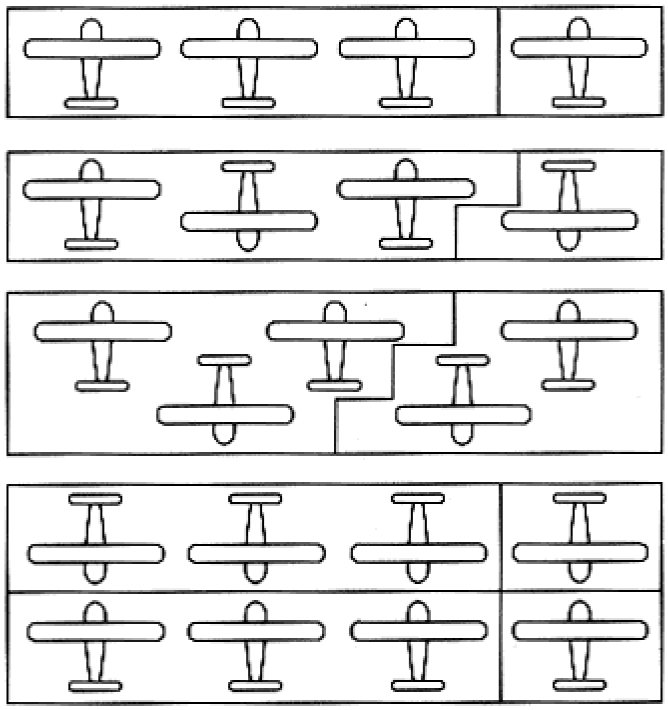

Figure A-1-3(b) Typical configurations of row hangars.

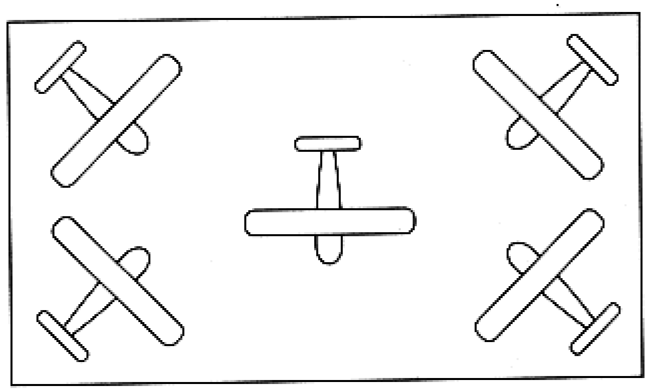

Figure A-1-3(c) Hangar capable of housing multiple aircraft.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-3 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1.1

Building construction types are defined in NFPA 220, *Standard on Types of Building Construction*. The following material is extracted verbatim from the 1992 edition of NFPA 220, and is included here as a convenience for users of this standard. Any requests for Formal Interpretations (FI) or Tentative Interim Amendments (TIA) on the following material must be directed to the Technical Committee on Building Construction.

3-1 Type I (443-332). Type I construction is that type in which the structural members, including walls, columns, beams, floors, and roofs, are of approved noncombustible or limited-combustible materials and have fire resistance ratings not less than those set forth in Table 3.

3-2 Type II (222-111-000). Type II construction is that type not qualifying as Type I construction in which the structural members, including walls, columns, beams, floors, and roofs, are of approved noncombustible or limited-combustible materials and have fire resistance ratings not less than those set forth in Table 3.

3-3 Type III (211-200). Type III construction is that type in which exterior walls and structural members that are portions of exterior walls are of approved noncombustible or limited-combustible materials, and interior structural members, including walls, columns, beams, floors, and roofs, are wholly or partly of wood of smaller dimensions than required for Type IV construction or of approved noncombustible, limited-combustible, or other approved combustible materials. In addition, structural members have fire resistance ratings not less than those set forth in Table 3.

3-4 Type IV (2HH).[1]

1The dimensions used for sawn and glued laminated lumber in this section are nominal dimensions.

3-4.1 Type IV construction is that type in which exterior and interior walls and structural members that are portions of such walls are of approved noncombustible or limited-combustible materials. Other interior structural members, including columns, beams, arches, floors, and roofs, are of solid or laminated wood without concealed spaces and comply with the provisions of 3-4.2 through 3-4.6. In addition, structural members have fire resistance ratings not less than those set forth in Table 3.

Exception No. 1: Interior columns, arches, beams, girders, and trusses of approved materials other than wood shall be permitted provided they are protected to provide a fire resistance rating of not less than 1 hour.

Exception No. 2: Certain concealed spaces shall be permitted by the Exception to 3-4.4.

3-4.2 Wood columns supporting floor loads shall be not less than 8 in. (203 mm) in any dimension; wood columns supporting roof loads only shall be not less than 6 in. (152 mm) in least dimension and not less than 8 in. (203 mm) in depth.

3-4.3 Wood beams and girders supporting floor loads shall be not less than 6 in. (152 mm) in width and not less than 10 in. (254 mm) in depth; wood beams and girders and other roof framing, supporting roof loads only, shall be not less than 4 in. (102 mm) in width and not less than 6 in. (152 mm) in depth.

3-4.4 Framed or glued laminated arches that spring from grade or the floor line and timber trusses that support floor loads shall be not less than 8 in. (203 mm) in width or depth. Framed or glued laminated arches for roof construction that spring from grade or the floor line and do not support floor loads shall have members not less than 6 in. (152 mm) in width and not less than 8 in. (203 mm) in depth for the lower half of the height and not less than 6 in. (152 mm) in depth for the upper half. Framed or glued laminated arches for roof construction that spring from the top of walls or wall abutments and timber trusses that do not support floor loads shall have members not less than 4 in. (102 mm) in width and not less than 6 in. (152 mm) in depth.

Exception: Spaced members shall be permitted to be composed of two or more pieces not less than 3 in. (76 mm) in thickness when blocked solidly throughout their intervening spaces or when such spaces are tightly closed by a continuous wood cover plate not less than 2 in. (51 mm) in thickness, secured to the underside of the members.

Splice plates shall be not less than 3 in. (76 mm) in thickness.

3-4.5 Floors shall be constructed of splined or tongued and grooved plank not less than 3 in. (76 mm) in thickness covered with 1-in. (25-mm) tongue and groove flooring, laid crosswise or diagonally to the plank, or with 1/2-in. (12.7-mm) plywood, or of laminated planks not less than 4 in. (102 mm) in width, set on edge close together, spiked at intervals of 18 in. (457 mm) and covered with 1-in. (25-mm) tongue and groove flooring laid crosswise or diagonally to the plank or with 1/2-in. (12.7-mm) plywood.

3-4.6 Roof decks shall be of splined or tongued and grooved plank not less than 2 in. (51 mm) in thickness; or of laminated planks not less than 3 in. (76 mm) in width, set on edge close together, and laid as required for floors; or of 11/8-in. (28.6-mm) thick interior plywood (exterior glue); or of approved noncombustible or limited-combustible materials of equal fire durability.

3-5 Type V (111-000). Type V construction is that type in which exterior walls, bearing walls, and floors and roofs and their supports are wholly or partly of wood or other approved combustible material smaller than required for Type IV construction. In addition, structural members have fire resistance ratings not less than those set forth in Table 3.

Table 3 Fire Resistance Requirements for Type I through Type V Construction

	Type I		Type II		
	443	332	222	111	000
Exterior Bearing Walls –					
Supporting more than one floor, columns, or other bearing walls......	4	3	2	1	0[1]
Supporting one floor only....................	4	3	2	1	0[1]
Supporting a roof only.........................	4	3	1	1	0[1]
Interior Bearing Walls –					
Supporting more than one floor, columns, or other bearing walls......	4	3	2	1	0
Supporting one floor only....................	3	2	2	1	0
Supporting roofs only..........................	3	2	1	1	0
Columns –					
Supporting more than one floor, columns, or other bearing walls......	4	3	2	1	0
Supporting one floor only....................	3	2	2	1	0
Supporting roofs only..........................	3	2	1	1	0
Beams, Girders, Trusses & Arches –					
Supporting more than one floor, columns, or other bearing walls......	4	3	2	1	0
Supporting one floor only....................	3	2	2	1	0
Supporting roofs only..........................	3	2	1	1	0
Floor Construction	3	2	2	1	0
Roof Construction	2	1 1/2	1	1	0
Exterior Nonbearing Walls	0[1]	0[1]	0[1]	0[1]	0[1]

Those members that shall be permitted to be of approved combustible material.

[1] See NFPA 220, A-3-1 (Table).

[2] "H" indicates heavy timber members; see NFPA 220 for requirements.

A-2-1.2

Preference should be given to the use of noncombustible materials in Type V (111) and (000) hangars. Separate shops, offices, and storage areas should comply with the provisions of 2-2.1.

A-2-2.1

Fire wall construction should be in accordance with a listed construction assembly or the local building code. The construction should be resistant to or protected from mechanical damage and potential damage from discharge of the fixed fire protection system.

Possible reasons to subdivide aircraft storage and service areas into separate fire areas include:

(a) Reducing required water supplies.

(b) Reducing exposed values for insurance or other purposes.

(c) Reducing exposure between occupants.

(d) Modifying the hangar classification.

A-2-2.3

Shops, office, and storage areas should be in separate, detached buildings. Workshops, offices, and storage areas having their own roof coverings and built within aircraft storage or servicing areas should have watertight roof deck coverings.

A-2-3.2.3 See also NFPA 80, *Standard for Fire Doors and Fire Windows*.

A-2-3.3.2 See also NFPA 80, *Standard for Fire Doors and Fire Windows*.

A-2-4.2

These special hazards include, but are not limited to, spray painting or doping areas, flammable liquid storage or mixing rooms, etc.

A-2-5.3

Construction types will dictate the need for sprinkler protection in these spaces.

A-2-6.3

Additional guidance pertaining to fixed water systems can be found in NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*. This information can also be used in the design of foam-water systems. The design of such protection should take into account factors such as the shape of the column, wetting of lower sprinklers, etc.

A-2-7.3

Preplanning should ensure availability of necessary auxiliary equipment such as tractors, cables, grapnels, etc., where manual operation is either impossible or too slow to allow prompt aircraft removal.

A-2-9.1

Landing gear pits, ducts, and tunnels located beneath the hangar floor should be avoided if possible because of the danger of accumulation of flammable liquids or vapors; where their use is essential, the protection measures specified in Section 2-9 must be followed. For floor drainage, see 2-11.2.

A-2-9.7

The venting arrangements will depend on the design of the pits, elevating platforms, and means of access. It might be necessary for part of the platform surface to be grated or perforated to provide adequate explosion venting area. The general principles in NFPA 68, *Guide for Venting of Deflagrations*, should be followed.

A-2-9.8

Consideration should be given to the selection of an extinguishing agent that could also be used as a means of inerting the pit in the event that flammable vapors are present concurrent with the loss of use of the ventilation system due to power failure, maintenance, or other causes.

A-2-11.2.2 Aircraft hangars also might require floor drainage systems to effectively dispose of water used for cleaning aircraft and hangar floor surfaces and water accumulation from possible flooding due to high groundwater tables, and to drain away water discharged from the fire protection equipment provided within the structure. Reference can be made to NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*, for information on drainage systems and the appendix of NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*, for information on drainage equipment and arrangements.

A-2-11.2.4 In general, this will mean that the design must be adequate to ensure that the liquid level at the center of the drain is below the top surface of the drain inlet grating for grated round, rectangular, and long trench-type inlets, or the floor surface in the case of a slit trench.

A-2-12.1

It is recommended that hangar heating, ventilating and air conditioning equipment fired with gas, liquid, or solid fuel be located in a fire-resistive or noncombustible detached building wherever possible.

A-2-12.4

Personnel should be fully instructed that in the event of a serious gasoline or similar flammable liquid spill on the hangar floor, the fans should be shut off.

A-2-13.2

See also 2-7.2 for power supply to doors accommodating aircraft.

A-2-14

All aircraft hangars should be surveyed to determine the need for approved lightning protection. Where installed, such systems should be listed. See NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

A-2-15.1

As low a resistance as possible should be secured and maintained. Ten thousand ohms is a practical recommended maximum where determined by standard procedures. For further details on this subject, see NFPA 407, *Standard for Aircraft Fuel Servicing*, and NFPA 77, *Recommended Practice on Static Electricity*.

A-2-15.3

Speedometer, preformed steel, or equivalent cable will minimize danger of employee hand injury.

A-2-17 Draft Stops.

(a) *Depth.* Draft stops should extend down from the roof or ceiling of aircraft storage and servicing areas not less than one-eighth of the height from the floor to roof or ceiling. Under curved or sloping roofs extending to grade level or close to grade level, draft stops need not be continued below 16 ft (4.8 m) from the floor.

(b) *Installation.* Draft stops should be installed, preferably at right angles to the hangar doors, forming roof pockets that are rectangular in shape. Hangars that are long and narrow, however, might best be subdivided by a "grid" system of draft stops that are both at right angles and parallel to the doors. In arch-type hangars, draft stops can be hung on exposed interior roof supports running parallel to the doors. The method of installation should be based on obtaining maximum operational efficiency from the sprinkler protection, taking into consideration mean wind conditions, floor drains, floor pitch, and details of occupancy usage.

(c) *Roof Sections as Draft Stops.* Structural features of a building that serve the purpose of draft stops (such as roof monitors, sawtooth roofs, etc.) may be permitted in lieu of specially constructed draft stops.

A-3-2.1.1 It is highly important and expedient that all applicable areas of responsibility, such as those that cover adequacy of water supplies, design, testing, flushing, approvals, etc., be clearly defined in the contract documents. This is important where there is shared responsibility for various portions of the fire protection systems.

A-3-2.2.2 The manual control valve for each individual sprinkler system should be located outside aircraft storage and servicing areas.

A-3-2.3 See A-3-3.8.

A-3-2.4.1 Reliability of power supplies for drivers of water pumps, foam concentrate pumps, and foam generators will be a function of all the facilities between the pump driver and the power source. For a diesel engine driven pump and an electric motor driven pump, the independence of the power sources is very clear. This, of course, assumes there is a battery powered starter for the diesel engine. Independence of two diesel engines with separate fuel tanks is also fairly easily seen.

However, the degree of independence of the power sources for two electric motor drivers is much more difficult to establish. A single controller, a single switchgear cabinet, or a single cable route might easily negate the desired reliability.

The considerations of power supply reliability are required in various sections of NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, and NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*. These considerations should demonstrate that the power supply reliability is consistent with that achieved for the mechanical components. There are a number of methods available. Such a method could be a simple inspection and statement of design philosophy or a sophisticated fault tree analysis.

A-3-2.5.1 Actual flow rates are often higher than calculated. This will often result in a reduction in foam supply duration.

Aircraft storage and servicing areas with large doors on both ends can present special draft problems affecting the efficient operation of the sprinkler systems. In such cases, additional systems should be included in the calculation of water supply needed. Draft stops should effectively surround each individual sprinkler system. (*See Section 2-17*.)

A-3-2.5.6 The development of satisfactory water supplies is a matter requiring engineering judgment and careful analysis of local conditions. See NFPA 419, *Guide for Master Planning Airport Water Supply Systems for Fire Protection*; NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*; and NFPA 22, *Standard for Water Tanks for Private Fire Protection*. Acceptable types of water supplies can consist of one or more of the following:

(a) Connections to reliable waterworks systems, including automatic booster pumps where required;

(b) Automatic fire pumps taking suction under a head from storage reservoirs or other suitable supply; and

(c) Gravity tanks.

Combinations of these supplies can be used to advantage. It is desirable to have two independent water supplies. Where reliance is placed on automatic fire pumps, special consideration should be given to the use of multiple pumps rather than single pumps and the use of multiple sources of power in order to increase the reliability of pump drivers. Water supplies should be guarded against entry of foreign material that would clog sprinklers or piping. Waterworks connections, where used as an independent supply, should be capable of delivering water at the specified rate and pressure as determined by flow tests, with due consideration given to any conditions that could have an effect on the design supply and pressure. Investigation should be made to determine the normal and emergency operation of the waterworks system, including domestic consumption and operation of the waterworks pumps at time of test, pressure-reducing valves, or other factors affecting adequacy of a public water supply. Automatic booster fire pumps should be used to provide effective pressure from waterworks connections.

A-3-2.6.4 Supplemental means for automatically starting the fire pumps should also be provided.

A-3-2.7

In connection with the flushing operation, preplanning should be made for means of disposing of the large quantities of water discharged.

A-3-2.11.3 In locating manual actuation stations inside, multiple stations should be considered to provide occupants with a selection of paths of exit from which they can actuate the system.

The location of exterior actuation stations should ensure accessibility once the occupant has exited the hangar through any of the emergency exits. Security fences, adjacent buildings, or other obstructions should be considered when locating exterior actuation stations.

A-3-3.1

Supplementary protection systems for hangars containing several aircraft, each having wing areas less than 3,000 ft^2 (279 m^2), can be warranted. Such systems are recommended where:

(a) Rapid control of a fuel fire exposing a single aircraft is considered essential.

(b) Strategically important military aircraft or multiple high valued aircraft are accommodated.

(c) Arrangement of aircraft within a hangar results in congestion and limited access to individual aircraft.

Table A-3-3.1

Following is a listing of the wing areas of various transport-type aircraft:

Wing Areas of Various Aircraft

		Wing Area	
	Aircraft	**Ft^2**	**(M^2)**
1*	L-500-Galaxy	6,200	(576.0)
2*	Boeing 747	5,500	(511.0)
3*	Concorde	3,856	(358.2)
4*	DC-10-20, 30	3,550	(329.8)
5*	L-1011	3,456	(321.1)
6*	Boeing 767	3,050	(283.4)
7*	Ilyushun IL-62	3,030	(281.5)
8	Boeing 707-320 B/C	2,950	(274.1)
9	DC-10	2,932	(272.4)
10	DC-8-63	2,927	(271.9)
11	DC-8-62	2,926	(271.8)
12	DC-8-61	2,883	(267.8)
13	A-300 Airbus	2,799	(260.0)
14	BAC-3-11	2,450	(227.6)
15	A310 Airbus	2,357	(218.9)
16	Tupolev TU-154	2,169	(201.5)
17	Boeing 757	1,951	(181.2)
18	L-100-20 Hercules	1,745	(162.1)
19	Caravelle	1,579	(146.7)
20	Boeing 727-100	1,560	(144.9)
21	Trident 3B	1,493	(138.7)
22	Trident 1E	1,466	(136.2)
23	Tupolev TU-34	1,370	(127.3)
24	Trident 1C	1,358	(126.2)

25	BAC 1-11-500	1,031	(95.8)
26	NAMC YS-11	1,020	(94.8)
27	BAC 1-11-300,400	1,003	(93.2)
28	DC 9-30	1,001	(93.0)
29	Boeing 737-200, 300	980	(91.0)
30	DC 9-20	934	(86.8)
31	Convair 640	920	(84.5)
32	Herald	886	(82.3)
33	Fokker Fellowship	822	(76.4)
34	Fokker Fellowship	754	(70.0)
35	Nord	592	(55.0)
36	Twin Otter	420	(39.0)
37	Beechcraft Model 99	298	(27.7)

*Aircraft with wing areas in excess of 3,000 ft^2 (279 m^2)

A-3-3.2

In general, the specified floor area would be the area under the wing and wing center sections of the aircraft. Configuration of aircraft and positioning of aircraft and ground equipment within an aircraft storage and servicing area can compromise the effectiveness of any supple mental protection systems. Original design and testing of such systems should anticipate obstructions on the floor (such as those created by working platforms) in providing protection over the specified floor areas. The discharge from overhead hangar protection systems might not protect the aircraft from a fire in the shielded areas beneath the wing and wing center section. The supplementary system is intended to provide protection in these shielded areas by controlling such fires quickly and preventing extensive damage to the aircraft. The area to be protected depends on the configuration and the number of aircraft and their positioning arrangements, as well as the location of permanent service structures within the aircraft maintenance and servicing area. Protection of the entire aircraft maintenance and servicing area could be required because of the variety of possible aircraft positioning arrangements.

The total area to be protected by a single system depends on the number and configuration of aircraft and their proximity to one another and the drainage arrangements. If more than one aircraft is located within any drainage system, the supplementary foam system should preferably be capable of covering the floor area beneath all such aircraft.

A-3-3.4.1 It is highly important and expedient that all applicable areas of responsibility, such as those that cover suitability of agent, application rates used, area covered, approvals, testing, etc., be clearly defined in the contract documents. This is especially important where there might be shared responsibility for the various portions of the fire protection system.

A-3-3.4.2,**A-3-3.5.2** The total area to be protected by a single system depends on the number and configuration of aircraft and their proximity to one another and the drainage arrangements. If more than one aircraft is located within any drainage system, the supplementary foam system should preferably be capable of covering the floor area beneath all such aircraft.

A-3-3.5.3 Experience has shown that the mechanism for manual operation of automatic oscillating monitor nozzles is a major factor in the failure rate of these devices. A large percentage of these failures has been due to operators failing to change the device from the manual to the automatic mode after testing, maintenance, etc. It is considered that the most reliable device is one that is designed for automatic operation only and that has no manual operating mode.

A-3-3.5.5 Actual flow rates are often higher than calculated. This will often result in a reduction in foam supply duration.

A-3-3.6.2 To achieve the design principles, the rate of foam rise should be at least 3 ft/min (0.9 m/min) beneath the aircraft wings and wing center section. With large shielded areas, a higher rate of foam rise could be required. The foam generators should be installed and positioned in such a way that the flow of foam on the floor is directed to areas beneath the aircraft wings and wing center section. If the fire spreads to the aircraft interior, it could seriously damage or destroy the aircraft unless an automatic fire extinguishing system is also provided inside the aircraft cabin. If generators are located on the exterior of the hangar, the possible hazards of freezing water on the generator screens should be considered. The discharge of high-expansion foam in the hangar space can handicap visibility for manual fire fighting.

A-3-3.6.4 Actual flow rates are often higher than calculated. This will often result in a reduction in foam supply duration.

A-3-3.6.6 See A-3-2.4.1.

A-3-3.7

The presence of corrosion inhibitors, antifreeze agents, marine growth, oil, or other contaminants can result in the reduction of foam volume or stability. If the quality of the water used is questionable, the manufacturer of foam equipment should be consulted. In general, the performance of a foam-water extinguishing system depends on the agent composition, the proportioning concentration, and the application technique. Different brands or types of agents should not be mixed without the advice of the equipment manufacturer regarding their interchangeability and compatibility.

A-3-3.8

Experience has shown that different brands of foam might not be compatible and may have varying levels of fire-fighting effectiveness. Care should be utilized in the selection of foam concentrates.

A-3-3.8.2 To prevent accidental use and depletion of this reserve supply, it should be available to the system only by intentional manual operation.

A-3-3.11.1 Detection systems for supplementary systems should be either a radiation (infrared or ultraviolet) or a heat responsive (continuous strip-type or thermistor-type) system. When initially installed, if there is any doubt as to the stability of these actuating devices because of environmental factors, it is recommended that the devices be utilized to actuate only an alarm rather than trigger the extinguishing systems. As soon as operational experience indicates that the devices are stable, they should be arranged to automatically actuate the extinguishing equipment. Spacing of detection devices should be no greater than the maximum recommended by the manufacturer.

A-3-4.1

Section 3-4 provides a means for fire fighting by occupants of the hangar through the use of hand hose supplied from the hangar's fixed fire protection system or from an independent source. The hand hose system in aircraft storage and servicing areas is usually arranged for foam application with water spray or straight water streams used in other areas.

A-3-6

For further information, see NFPA 72, *National Fire Alarm Code*.

A-4-2.1

A preaction standard sprinkler system should be used only if there is a possibility of freezing in an unheated hangar.

A-4-3, A-4-4 See A-3-3.8.

A-4-4.3

This design criteria can be achieved by means of multiple nozzles of the same or different capacities aimed to discharge toward the aircraft parking area. The fluidity of the foam will achieve coverage of the entire floor area.

A-4-4.5

Actual flow rates are often higher than calculated. This will often result in a reduction in foam supply duration.

A-4-6.7

This should be accomplished by providing manifolded drains.

A-4-8

See A-3-3.7.

A-5-1.1

Group III hangars for small aircraft are either prefabricated assemblies or are locally constructed of unprotected steel or aluminum, light wood framing, or cement or cinder blocks. The majority of the prefabricated types are unprotected steel structures with sheet steel or aluminum roof coverings and sidings. Other prefabricated hangars have wood or cement sidings and wood or plywood doors. Except in unusual circumstances, construction types other than Type II (000) and Type V (000) are unlikely because of cost factors. Earth floors are common. Floor drainage is not required for single unit or row hangars, although utility drains are useful and should be provided. The airport operator should have a master key for the Group III hangars on the airport premises so as to provide emergency access in case of fire. (*See A-2-1.1.*)

A-5-4.4

Personnel should be fully instructed that in the event of a serious gasoline or similar flammable liquid spill on the hangar floor, the fans should be shut off.

A-5-5.2

See also 2-7.2 for power supply to doors accommodating aircraft.

A-5-7.1

As low a resistance as possible should be secured and maintained. Ten thousand ohms is a practical recommended maximum where determined by standard procedures. For further details on this subject, see NFPA 407, *Standard for Aircraft Fuel Servicing*, and NFPA 77, *Recommended Practice on Static Electricity*.

A-5-7.3

Speedometer, preformed steel, or equivalent cable should minimize danger of employee hand injury.

1994 Edition

Standard on Aircraft Maintenance

1994 Edition

This edition of NFPA 410, *Standard on Aircraft Maintenance*, was prepared by the Technical Committee on Aircraft Maintenance Operations and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 16 - 18, 1994, in San Francisco, CA. It was issued by the Standards Council on July 14, 1994, with an effective date of August 5, 1994, and supersedes all previous editions.

The 1994 edition of this document has been approved by the American National Standards Institute.

Origin and Development of NFPA 410

Work on an overall project to develop recommendations on fire safety safeguards for aircraft maintenance was launched in 1955. NFPA 410A, *Recommendations on Safeguarding Aircraft Electrical System Maintenance Operations*, was adopted in 1958; NFPA 410B, *Recommendations on Aircraft Breathing Oxygen Systems Maintenance Operations*, was adopted in 1958; NFPA 410C, *Recommendations on Safeguarding Aircraft Fuel System Maintenance*, was adopted in 1962; NFPA 410D, *Recommendations for Safeguarding of Aircraft Cleaning, Painting, and Paint Removal*, was adopted in 1965; NFPA 410E, *Recommended Safe Practice for Aircraft Welding Operations in Hangars*, was adopted in 1963; and NFPA 410F, *Recommendations on Safeguarding Aircraft Cabin Cleaning and Refurbishing Operations*, was adopted in 1963. The 1980 edition was a compilation of the 410 series, compiled as a standard. The 1989 edition of the standard was completely revised. A chapter was added for the fire protection of ramp areas where aircraft can be parked.

This edition is a reconfirmation of the 1989 edition.

Technical Committee on Aircraft Maintenance Operations

John R. Flynn, *Chair*
American Airlines, TX

Nathaniel J. Addleman, Boeing Comm. Airplane, KS

Joseph A. Behnke, Ansul Fire Protection, WI
Rep. Fire Equipment Manufacturer's Assn., Inc.

Jim DeWitt, Int'l Assn. of Machinists & Aerospace Workers, MO

John J. O'Sullivan, British Airways, England

Thomas M. Suehr, Wausau Insurance Co., WI
Rep. The Alliance of American Insurers

Jack A. Treasure, University of Missouri, MO

Alternates

John F. Trinajstich, Kidde-Fenwal Protection Systems, NC (Alt. to J. A. Behnke)

Nonvoting

Jerome Lederer, Laguna Hills, CA
(Member Emeritus)

Mark T. Conroy, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents for fire safe practices during maintenance operations on aircraft including similar operations on aircraft during manufacture. This scope does not include aircraft fuel servicing.

NFPA 410

Standard on Aircraft Maintenance

1994 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 9 and Appendix B.

Chapter 1 Administration

1-1 Scope.

1-1.1

This standard covers the minimum requirements for fire safety to be followed during aircraft maintenance and does not include the health and safety requirements for personnel involved in aircraft maintenance. The operations include maintenance of electrical systems, maintenance of oxygen systems, fuel tank repairing, cleaning, painting and paint removal, welding operations in hangars, interior cleaning, and refurbishing operations.

1-1.2

This standard also covers requirements for fire protection of aircraft ramp areas.

1-2 Purpose.

1-2.1

The purpose of this standard is to provide a reasonable degree of protection for life and property from fire through requirements for aircraft maintenance based upon sound engineering principles, test data, and field experience.

1-3 Definitions.

Air Ventilation. To pass undiluted air (air not containing flammable vapors or inert gases) through an aircraft tank to render the atmosphere of the tank more suitable for human occupancy and to reduce the amount of flammable vapors in the tank to below the lower explosive limit of the fuel vapors involved. It is recognized that, at some time during and possibly after air ventilation, the tank may contain a flammable vapor-air mixture. During such periods, a fire and explosion hazard exists that requires the elimination of ignition sources within the vapor-hazardous areas.

Aircraft Breathing-Oxygen System. A system onboard aircraft to provide breathing oxygen to occupants of aircraft. Such systems do not include equipment used for or with either gaseous or liquid oxygen when used for any purpose other than for breathing. Such systems do not include equipment used for the storage and handling of breathing oxygen and charging equipment outside of operations directly associated with breathing oxygen systems.

Approved. Acceptable to the authority having jurisdiction.

NOTE: The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

NOTE: The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Bladder Tanks. See Fuel Tanks, Bladder.

Cleaning, Exterior. The removal of soil from the complete aircraft exterior or from only localized areas where flammable or combustible solvents are used.

Cleaning, Interior.* The removal of soil from flight deck and cabin areas.

Coating. Application of special-purpose materials such as anticorrosion and walkway paints.

Combustible Liquids. Any liquid having a flash point at or above 100°F (38°C). Classifications are in accordance with NFPA 321, *Standard on Basic Classification of Flammable and Combustible Liquids*.

Electric Converters. Used to convert line voltage alternating current to the voltage and frequency, or direct current, suitable for the aircraft power system. Rectifier units are also used to accomplish this task.

Flammable Liquids. Any liquid having a flash point under 100°F (38°C) closed cup and having a vapor pressure not exceeding 40 psia (2068.6 mm) at 100°F (38°C).

Flight Deck. The area of the aircraft arranged for use by pilot/flight crew in operating the aircraft. Berths, galleys, and lavatory facilities can be associated with the flight crew compartment but are not included in the term “flight deck.”

Fuel Tanks, Bladder. Both collapsible and self-sealing tanks. The bladders themselves are of a special synthetic rubber and fabric material. Normally these cells have a fairly low melting point and change pliability with relatively small changes in temperature. Pliability is a critical quality in the fuel cell material. A plasticizing agent is compounded into the synthetic rubber to keep it pliable. Fuel tends to extract the plasticizing agent; however, this is not detrimental since fuel itself keeps the material pliable.

Fuel Tanks, Integral. Fuel containers whose boundaries are made up of as nearly 100 percent primary structure as possible, primary structure being the elements of the aircraft that carry the major stresses of flight, such as stressed skin spar caps, spar webs, etc. Integral fuel tanks can be part of either the wing or the fuselage. Integral fuel tanks discussed here are confined to the types that are basically without gasket materials installed in the seams, the structural cavities being made fuel-tight by the installation of a sealing material after the completion of fabrication of the unit where the tank is located.

Fuel Tanks, Metal. All types of metal fuel containers, including surge and vent tanks, that can be removed from the aircraft for shop or bench repair, but not including metal fuel containers that are an integral part of the aircraft that, under certain major overhaul conditions, can be removed from the primary portion of the airframe.

Galley. An area of an aircraft used for storing, refrigerating, heating, and dispensing of food and beverages. Such an area typically includes storage areas for plastic trays, plastic dinnerware utensils, and paper napkins.

Hot Work. Work including welding, cutting, soldering, explosive riveting, or any similar process involving an open flame, the application of heat, or a spark-producing tool.

Inert Atmosphere. An atmosphere where combustion cannot occur.

Inert Gas. Any gas that is nonflammable, chemically inactive, noncontaminating for the use intended, and oxygen deficient to the extent required.

Inerting. The use of an inert gas to render the atmosphere of an enclosure nonexplosive or nonflammable. Inerting, in effect, reduces the oxygen content of the air in the tank vapor space below the lowest point at which combustion can occur by replacing the oxygen in air with an inert gas.

Integral Tanks. See Fuel Tanks, Integral.

Listed. Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

NOTE: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Maintenance. Overhaul, repair, and service operations as herein defined.

Major Painting. Complete or virtually complete surface finishing of either the exterior or interior, or both.

May. This term is used to state a permissive use, or an alternative method to a specified requirement.

Metal Fuel Tanks. See Fuel Tanks, Metal.

Overhaul. The major disassembly, inspection, repair, and reassembly of aircraft.

Oxygen, Gaseous. Gaseous oxygen is colorless, tasteless, and nontoxic. It comprises about 21 percent of normal air by volume and is about 10 percent heavier than air. Above its critical temperature of 180.4°F (82.4°C), oxygen can exist only as a gas regardless of the pressure exerted upon it.

Paint Removal. The process of softening existing paint by application of appropriate solvents and spraying or brushing away the residue.

Purging. The removal of flammable vapor atmospheres or any residue capable of producing flammable vapors in the tank and connected distribution lines so that subsequent natural ventilation will not result in the reinstatement of a flammable atmosphere unless or until a flammable liquid is again introduced into the tank or its connected distribution lines.

Ramp. Any outdoor area at an airport, including aprons and hardstands, on which aircraft are normally fueled, defueled, stored, parked, maintained, or serviced.

Refurbishing. The types of refurbishing operations considered herein are the replacement of aircraft interior fabrics, plastic headliners, rugs or synthetic flooring, sound-insulating materials, windows, doors, or paneling.

Repair. The modification of aircraft, rebuilding structural damage, correcting system malfunction, or replacing a major component or subassembly that requires the aircraft to be in "out of flying" status.

Service Operation. Routine service checks, correction of flight crew complaints, and minor repair and maintenance performed while the aircraft is routinely in "out of flying" status.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Tanks. See Fuel Tanks.

Touch-up Painting. The refinishing of only localized areas, exterior or interior, involving no more than 1 qt (1 L) of material by spray or 1 gal (4 L) by brush or roller.

1-4* Units.

In this standard, values for measurement are followed by an equivalent in SI units, but only the first value stated shall be regarded as the requirement. Equivalent values in SI units shall not be considered as the requirement as these values may be approximate.

Chapter 2 Electrical Maintenance Operations

2-1 General.

2-1.1

Electrical system maintenance as used herein and references to NFPA 70, *National Electrical Code*®, shall apply only to aircraft maintenance.

2-1.2

Electrical systems shall be de-energized during maintenance work except in those cases where a live circuit is necessary to accomplish the required maintenance.

2-1.3

Where more than one maintenance operation is being carried out at the same time and an electrical system is energized, steps shall be taken to inform personnel working on the aircraft that the system is energized.

2-1.4

Wherever possible, provision shall be made to effectively tag out or lock out de-energized circuits so that anyone attempting to energize them will be unmistakably alerted to the resulting hazard to other maintenance operations.

2-2 Battery Charging and Equipment.

2-2.1

Whenever possible, aircraft batteries shall be disconnected or removed during maintenance operations in order to de-energize all electrical circuits.

2-2.2

The battery switch on aircraft shall be in the “off” position before removing or installing batteries.

2-2.3*

When moving batteries, including removal and replacement, precautions shall be taken to prevent the terminal prongs from contacting metal structures or objects.

2-2.3.1 During maintenance, extension cable used to provide power to the aircraft from batteries that are not in their normally installed location shall be equipped with standard aircraft battery connectors and integral fusible overload protection. Fuses shall be the instantaneous type and sized no larger than 10 amps above the maximum connected load.

2-2.4

When removing and replacing batteries, precautions shall be taken to prevent the electrolyte from spilling. Similar precautions shall be taken when replacing or adding electrolyte solutions in batteries.

2-2.5*

Batteries in the aircraft shall only be charged where adequate on-the-ground ventilation is provided.

2-2.6

Flexible cords used for charging shall be suitable for the type of service used and approved for extra-hard usage.

2-2.7

Connectors shall have a rating not less than the current-carrying capacity of the cord.

2-2.8

Connectors to the battery terminals shall be of a positive type to prevent them from coming loose due to vibration, causing arcs that might ignite gas from the batteries or other flammables or combustibles.

2-2.9

Tables, racks, trays, and wiring shall conform to the provisions of Article 480 of NFPA 70, *National Electrical Code*, where storage batteries use acid or alkali as the electrolyte and consist of a number of cells connected in series with a nominal voltage in excess of 16 volts.

2-2.10

Mobile chargers shall carry at least one permanently affixed warning sign to read: “Warning—Keep 5 Ft (1.5 M) Horizontally Clear of Aircraft Engines, Fuel Tank Areas, and Vents.”

2-2.11*

Batteries shall be charged at a rate that will not produce a dangerous concentration of gas or excessive heat.

2-2.12

Battery manufacturer’s instructions shall be followed with regard to segregation of nickel-cadmium battery-charging operations from lead-acid battery charging operations to prevent contamination.

2-2.13

Battery chargers and their control equipment, tables, racks, trays, and wiring shall not be located or operated within any of the hazardous areas defined in 513-2(b) of NFPA 70, *National Electrical Code*. They shall preferably be located in a separate building or in an area such as described in 513-2(d) of NFPA 70.

2-2.14

Areas wherein batteries are charged shall be well ventilated to assure that the maximum gas-air mixture that may be generated during charging is held below the lower explosive limits. Where mechanical ventilation is required to accomplish this, it shall be of the type listed for use in Class 1, Group B atmosphere locations as defined in Article 500 of NFPA 70, *National Electrical Code*, and shall be so interlocked as to ensure operation when batteries are on charge. Exhaust ducts shall lead directly to the outside, above roof level, where gases cannot accumulate.

2-2.15

Access to battery rooms shall be limited to qualified personnel only.

2-2.16

Smoking shall be prohibited, and open flames, sparks, arcs, and other sources of ignition shall be kept away from the immediate vicinity of batteries that are being charged. Appropriate warning signs shall be prominently displayed.

2-2.17

Brushes used to clean batteries shall have neither a metal frame nor wire bristles.

2-3 Ground Power Units.

2-3.1

Placement of ground power units in use shall comply with the requirements of Section 513-9 of NFPA 70, *National Electrical Code*, and 2-6.2 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

2-3.2

Ground power units shall be located as far as practical from fueling points, tank vents, tank outlet areas, fuel line drains, and wings. Ground power units shall not be positioned within a 25-ft (8-m) horizontal radius of aircraft fuel system vent openings. They shall not be used in areas wherein adequate ventilation is not available or where they may constitute a fire hazard.

2-3.2.1 If used inside hangars, in addition to the requirements of 2-3.3 of this section, ground power units shall also be so designed and mounted that all electrical equipment, sparking contacts, hot surfaces, and any other possible ignition source shall be at least 18 in. (457 mm) above floor level. At no time shall engine-driven generators be refueled within any aircraft maintenance or storage area within a hangar.

2-3.3

Electrical equipment in hangar floor pits used to store cables shall be of the type approved for Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical*

Code.

2-3.4

A protection system shall be provided to protect against undervoltage and overvoltage.

2-3.5

Ground power units shall always be operated at the prescribed voltage.

2-3.6*

The battery switch in the aircraft shall be turned to the "off" or "ground power" position when the ground power unit is connected to the aircraft.

2-3.7

In the event of extensive fuel spills or whenever similar hazardous conditions exist, ground power units in the vicinity that would constitute a fire hazard shall be withdrawn or left as is until the hazardous condition is corrected. If a portable ground power unit is to be moved under such hazardous conditions, the unit shall be de-energized before disconnecting the cable, and the cable shall be disconnected before the unit is moved.

2-3.8

Cables shall be stowed properly to prevent damage.

2-3.9

Strains on cables and connectors shall be avoided.

2-3.10

The ground power units shall be turned on only after the connector is installed in the aircraft receptacle. When connected, the unit shall be checked to determine that it is operating at the prescribed voltage before supplying power to the aircraft.

2-3.11

The ground power units shall be de-energized before disconnecting, or anti-arcing provisions that interlock the load contactors with the aircraft electrical system shall be provided.

2-3.12

Portable ground power units shall be disconnected before they are moved.

2-4 Repair of Aircraft Electrical Systems.

2-4.1

Consideration shall be given to de-energizing the entire aircraft electrical system by disconnecting or removing the batteries and by disconnecting any outside power source. The use of a "dummy" ground power plug shall be considered.

2-4.2

Whenever the entire aircraft electrical system is not de-energized, all personnel working on the aircraft shall be informed that the aircraft's electrical systems are energized.

2-4.3

Whenever the entire aircraft electrical system is not de-energized due to other work being accomplished, the electrical system being worked on shall be isolated by placing the circuit breaker in an “off” position or pulling the fuse.

2-4.4

When an electrical system is to be isolated in order to work on it, the person who is going to work on the system shall place the circuit breaker in an “off” position or pull the fuse. That person shall not rely on someone else to do this. A positive test on the isolated circuit shall be made.

2-4.5

When two or more people are going to work on the same system, provisions shall be made to make one person responsible for energizing or de-energizing the system.

2-4.6

Circuit breakers shall be in the “off” position and fuses shall be pulled before removing and installing system units.

2-4.7*

The use of a “tag-out” system, covering the switch with masking tape, or some other similar method shall be used to positively indicate that an electrical system is being worked on and that it shall not be energized except on the authorization of the supervisor. (*See Figure A-2-4.7.*)

2-4.8

When working on energized electrical systems in areas containing flammable fluid lines, the following precautions shall be taken:

(a)* Precautions shall be taken whenever working on any part of the aircraft to prevent accidental contact of control cables, tools, or metal parts with energized electrical systems, components, or both. Adjacent terminals, electrical components and wiring, and flammable fluid lines shall be protected to prevent arcing and fire if accidental cross contact is made.

(b) An extinguisher having a rating of not less than 20-B and a minimum capacity of 15 lb (6.8 kg) of agent shall be located within 50 ft (15.2 m) of the work operation.

2-4.9

When troubleshooting, all wires shall be considered “hot” until proven otherwise.

2-4.10

Nonconductive or insulated tools shall be used for working on “hot” circuits.

2-4.11

The aircraft electrical circuit involved shall be de-energized whenever equipment and wiring is removed or installed.

2-4.12

Equipment that is new or repaired shall be thoroughly tested and checked for short circuit before being installed on the aircraft.

2-4.13

Aircraft wiring shall be properly secured to prevent chafing.

2-4.14

All loops provided in electrical cables to prevent flammable fluids from entering electrical connections or components shall be re-formed so that they will perform their intended functions.

2-4.15

When dripshields, cables, sheaths, plug covers, or similar devices have been provided to prevent flammable fluids from contacting electrical components, care shall be taken to see that they are reinstalled so that they effectively perform their intended function.

2-5 Repairs to Communications and Navigation Equipment.

2-5.1

Radar and radio transmitting equipment shall not be operated, tested, or checked on the aircraft whenever fueling, defueling, tank repair operations during the time when flammable vapor-air atmospheres are present, or any other similar hazardous operation is taking place within the distance limits outlined in Section 2-9 of NFPA 407, *Standard for Aircraft Fuel Servicing*, or within the distances of the manufacturer's prescribed limitations.

2-5.2

Such operation, testing, or checking may be made at any time if a dummy load, which prevents the energizing of the antenna, is used. In addition, the precautions outlined in 2-4.10 through 2-4.15 of this chapter shall be followed.

2-6 Cleaning of Electrical Components Installed on the Aircraft.

2-6.1

Electrical components shall not be energized and shall be isolated from other power sources during cleaning operations.

2-6.2

Only nonflammable solvents shall be used for cleaning electrical components.

2-7 Testing of Electrical Equipment During and Following Repair Operations.

2-7.1

Testing of electrical equipment installed on aircraft shall be held to a minimum. Whenever possible, testing shall be done at a bench or in a shop away from the aircraft.

2-7.2

Equipment shall be checked for continuity of circuitry and resistance before power is applied.

2-8 Energizing and De-energizing Electric Circuits During Complete Engine Change.

2-8.1

Standard aircraft static-grounding procedures shall be followed.

2-8.2

Magneto circuits shall be grounded when disconnected at the fire wall.

2-8.3

The electrical systems involved in an engine installation shall be de-energized prior to removal of the engine and remain de-energized until any hazard of flammable vapors in the area has been removed.

2-8.4

Pertinent electrical systems shall be de-energized prior to installation of the engine and remain de-energized until all flammable fluid system connections are completed and no flammable vapors exist in the area.

2-8.5

Personnel performing an engine change shall be advised when the electrical systems are de-energized and re-energized following the principles expressed in 2-1.4 and 2-4.5 of this chapter.

2-8.6

The de-energized circuits shall be tagged out or locked out so that persons attempting to energize them will be definitely aware that others could be endangered by their action.

2-8.7

Electrical disconnects shall be protected against accidental contact, dirt, and moisture during the disconnect period, by tight-fitting blind plugs, tape wrapping, or both.

2-9 Electrical Equipment Mounted on Fixed Work Stands.

2-9.1

Electric wiring, outlets, and equipment, including lamps on or attached to fixed docks and stands that are located or likely to be located in hazardous areas as defined in 513-2 and 513-3 of NFPA 70, *National Electrical Code*, shall conform to the requirements for Class I, Group D, Division 2 locations.

2-9.2

Where docks and workstands are not located or likely to be located in hazardous areas as defined in 2-9.1 of this section, wiring and equipment shall conform to 513-4 and 513-5 of NFPA 70, *National Electrical Code*. Receptacles and attachment plugs shall be of the locking type that will not break apart readily.

2-10 Electrical Equipment Mounted on Movable Stands.

Movable docks and workstands with electrical equipment conforming to 2-9.2 of this chapter shall carry at least one permanently affixed warning sign to read: “Warning—Keep 5 Ft (1.5 M) Horizontally Clear of Aircraft Engines, Fuel Tank Areas, and Vents.”

Chapter 3 Aircraft Breathing-Oxygen Systems

3-1 Oxygen System Charging Operations and Safeguards.

3-1.1*

Because of the possibility of fire or explosion involving quantities of oxygen, the person choosing the site for oxygen charging operations shall consider such items as exposure of other aircraft, vehicles, structures, utilities, and people in the vicinity; and the accessibility of the aircraft to fire fighting equipment.

3-1.2

Where it is necessary to conduct gaseous oxygen system recharging or filling in a hangar or building, it shall be done under controlled conditions.

3-1.3

Liquid oxygen recharging shall not be conducted indoors under any conditions. At least a 50-ft (15.2-m) separation shall be maintained between a filling point and other aircraft, vehicles, and structures. Liquid oxygen charging operations shall not be performed within range of any drainage system elements, such as catch basins, through which a liquid oxygen spill could enter the drainage system since such systems can contain combustible material that could be extremely hazardous in contact with liquid oxygen in the confined space.

3-1.4

Good housekeeping practices, particularly with combustibles such as grease, lubricating oil, and asphalt, shall be maintained in the vicinity of oxygen charging operations.

3-1.5

Open flames, including smoking, shall be prohibited within 50 ft (15.2 m) of charging equipment.

3-1.6

Safeguards shall be taken while performing aircraft servicing or maintenance operations such as fueling, fuel and hydraulic system repairs, use of cleaning fluids or de-icing fluids, or operation of electrical equipment that can inherently or accidentally introduce ignition sources or combustibles concurrent with oxygen charging operations.

3-1.7

Only charging equipment and containers suitable for the specific aircraft breathing-oxygen system shall be used. Each container shall be identified by its marking before connecting it to the aircraft system. Equipment intended or used for other gases shall not be interchanged with oxygen equipment. High-pressure commercial containers, 1,800 psi (12.4 MPa) or higher, shall be connected through a high-pressure regulator specified for oxygen service to service low-pressure aircraft systems. Oxygen charging hoses shall be kept clean, capped when not in use, and clearly marked or tagged, “For Oxygen Use Only.”

3-1.8

Oil, grease, or other readily combustible substances shall not be permitted to come in contact with containers, flasks, valves, regulators, fittings, or any other part of the aircraft oxygen system or charging equipment. Oxygen equipment shall not be handled with oily gloves or tools. Charging operations shall not be performed while wearing oily or greasy clothing. Protective caps shall be kept on equipment as long as possible and replaced as soon as possible. Before charging, all connections shall be inspected for cleanliness. If dust, dirt, grease, or any other contaminant is found, it shall be removed with detergent or solvent approved for oxygen service. A small amount of oxygen shall be bled through hose or valve outlets before connecting to the fill fitting to eliminate foreign material that may escape external inspection.

3-1.8.1 The hose or valve outlet shall be aimed away from the body and equipment and only necessary valves shall be cracked open. A clean, dry container shall be available to collect any liquid oxygen discharge that might accidentally escape.

3-1.9

Only lubricating and thread compounds specifically approved for oxygen service under the pressures and temperatures involved shall be used. Other lubricants shall not be used.

3-1.10

Only valve packing and transfer hose gaskets that are suitable for oxygen service shall be used.

3-1.11

Damage to oxygen containers, hoses, flasks, or converters shall be avoided. Equipment shall be secured so that it cannot fall or roll.

3-1.12

Safety devices, identifying markings, symbols, and nameplates shall not be tampered with.

3-1.13

Valve outlets or controls that become clogged with ice shall be thawed with warm, not boiling, water.

3-1.14

Gaseous oxygen shall not be directed at the body or clothing, and liquid oxygen shall not be allowed to contact the body or clothing because of the possibility of both fire and personal injury.

3-1.15

Desiccant cartridges may be required to ensure that only dry oxygen is introduced and, where required, only fresh desiccant cartridges with filters shall be used.

3-1.16

Threaded fittings on regulators, container valve outlets, and hoses shall properly mate with each other. Connectors that do not fit shall not be forced. Fittings with worn or damaged threads shall be replaced.

3-1.17

After connecting containers or charging hoses to the oxygen system fill fitting, the connection shall be checked for gastightness by audible and visual means. Leak testing shall be done with a solution specifically approved for that particular gaseous, chemical, or liquid oxygen service.

3-1.18

Charging equipment discharge valves shall be closed when charging is completed.

3-2* Specific Cautions Applicable to Gaseous Breathing-Oxygen.

3-2.1

Container charging valves shall be opened slowly to minimize fast discharge of oxygen into the aircraft oxygen system, which can cause dangerous heating and result in a fire or explosion. Container valves shall be fully opened to prevent leakage around the valve stem.

3-2.2

Wrenches, hammers, or other tools shall not be used to force container valves. If a container valve cannot be hand operated, it shall be considered defective and taken out of service.

3-2.3

The aircraft oxygen system shall be charged to the established pressure after properly setting the supply regulating valve to the proper setting.

3-2.4

Where the aircraft oxygen system does not have filler valves and it is necessary to remove the aircraft containers themselves for recharging, the container valve shall be closed and all oxygen in the lines released to atmosphere before attempting container removal. Before removing the container from the aircraft, the container valve outlet shall be disconnected and capped, and all distribution lines shall be plugged.

3-3* Specific Cautions Applicable to Liquid Breathing-Oxygen.

3-3.1

Liquid oxygen shall not be permitted to contact any part of the body or clothes.

3-3.2

Personnel shall wear approved protective clothing and equipment while handling liquid oxygen equipment.

3-3.3

If liquid oxygen is spilled on clothing, the clothing shall be removed immediately and thoroughly aired before reuse.

3-3.4

Personnel who have handled liquid oxygen shall refrain from smoking for at least 15 minutes after leaving the charging area.

3-3.5

If it is necessary to remove moisture from the system, dry, oil-free air, gaseous oxygen, or nitrogen shall be used before introduction of liquid oxygen.

3-3.6

Because of its low temperature, liquid oxygen shall be handled in equipment constructed of materials suitable for the service. Ordinary rubber or plastic hoses, gaskets, or seals shall not be used.

3-3.7

When it is necessary to transfer liquid oxygen from one container to another, splashing shall be avoided. To avoid breakage, the receiving container shall be cooled gradually. Glass containers shall not be reused and containers used shall be clean.

3-3.8

When transferring liquid oxygen, valves shall not be left open all the way. To prevent the valves from freezing in the open position, they shall be opened wide and then immediately closed one-quarter turn.

3-3.9

Pressure relief devices shall be installed on all lines in which liquid oxygen might be trapped between closed valves and on closed containers.

3-3.10

Drip pans shall be used where pavement surfaces may be combustible or contaminated with dirt, oils, or similar materials that could ignite on contact with any spilled liquid oxygen. If a spill does occur, the flow of liquid shall be stopped where possible and the area involving the liquid spill shall be evacuated for the time necessary for liquid oxygen to evaporate. Personnel shall not walk on or move equipment through a liquid oxygen spill.

3-3.11*

The equipment manufacturer's instructions shall be followed when transferring liquid oxygen from the supply tank to the aircraft system.

3-4* Specific Cautions Applicable to Oxygen Generator Systems.

3-4.1

During maintenance operations that require the removal of the generator from its aircraft position, a safety cap shall be installed on the oxygen generator primer, since, when activated, it will generate temperatures up to 500°F (260°C).

3-4.2

If the generator is inadvertently activated, it shall immediately be placed on a noncombustible surface. However, if the generator is inadvertently activated in its aircraft position, it shall be left in its protected location.

3-5 Aircraft Breathing-Oxygen System Test and Repair Operations and Safeguards.

3-5.1*

When flow testing the aircraft system, the minimum amount of oxygen necessary to check the system shall be used.

3-5.2

Distribution lines within the aircraft shall be inspected periodically in accordance with the aircraft manufacturer's recommendations.

3-5.3

Pressure shall be released before attempting to tighten or loosen fittings unless the containers incorporate self-opening and self-venting valves.

3-5.4

When making pressure tests of oxygen distribution lines, the valves isolating the supply containers shall be closed. The system shall be tested in accordance with the specific instructions for the particular application. Oil or grease shall not be permitted to come in contact with escaping oxygen. Only leak testing solutions specifically approved for the purpose shall be used. All solutions shall be carefully cleaned off following the test.

3-5.5

Close check shall be kept on the vacuum available on all vacuum-insulated liquid oxygen tanks, and the manufacturer's instructions shall be closely followed.

3-5.6

When oxygen regulators or other oxygen system components on the pressure side of shutoff valves are removed for repair or replacement, the oxygen in the lines shall be released in the same manner as for container replacement specified in 3-2.4 of this chapter, and all disconnected lines plugged or capped.

3-6 Fire Protection.

3-6.1*

In case of a fire, the oxygen supply to the fire shall be shut off and the fire extinguished in the same manner as a fire in a normal air atmosphere.

3-6.2

An extinguisher having a rating of not less than 20-B and a minimum capacity of 15 lb (6.8 kg) of agent shall be located within 50 ft (15.2 m) of the work operation.

3-7* Breathing-Oxygen Cylinder Storage (DOT Gaseous Oxygen Cylinders and DOT-type 4L Cylinders of Liquid Oxygen).

3-7.1

Cylinders shall be stored in a definitely assigned location and protected against tampering by unauthorized individuals. Oxygen cylinders other than cylinders scheduled to be installed on the aircraft shall not be stored in aircraft servicing and maintenance areas of aircraft hangars.

3-7.2

Storage areas shall be reserved for liquid oxygen storage alone.

3-7.3

Oxygen storage areas shall be clearly placarded “Oxygen — No Smoking — No Open Flames” or equivalent.

3-7.4

Oxygen cylinders shall not be stored near flammable or combustible materials such as petroleum products, other readily combustible substances, or in the same area as compressed combustible gases. Empty and full cylinders shall be stored separately with empty cylinders clearly marked.

3-7.5

Each cylinder of aviator’s breathing oxygen shall be clearly marked to indicate its content. Aviator’s breathing oxygen shall be separately stored from all other oxygen cylinder supplies.

3-7.6

Cylinders shall be stored so that they are never allowed to reach a temperature exceeding 125°F (51.7°C). When stored in the open, they shall be protected against direct rays of the sun in localities where extreme temperatures prevail, from snow and ice where necessary, and from the ground beneath to prevent rusting.

3-7.7

Cylinders shall be protected against abnormal mechanical shock that could damage the cylinder, valve, or safety devices. Valve protection caps shall also be used when cylinders are not connected in use, providing that cylinders are designed for protection caps.

3-7.8

When moving cylinders, care shall be exercised to prevent dropping that might cause injury to the cylinder, valve, or safety devices. Lifting magnets, slings of rope or chain, or any other device in which the cylinders themselves form a part of the carrier shall not be used for hoisting oxygen cylinders. On hand or power trucks or tractors, cylinders shall be secured in an upright position.

3-7.9

DOT regulations regarding hydrostatic testing of DOT Specification 3A or 3AA cylinders shall be followed.

3-8* Liquid Breathing-Oxygen Storage (in Other than DOT-type 4L Cylinders).

3-8.1

Liquid oxygen containers shall be stored outdoors or in a detached, noncombustible structure in accordance with NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites*, if the oxygen quantities fall within the scope of that standard. Smaller quantities shall be located outdoors in a detached noncombustible structure or in a cutoff room provided the cutoff room has effective ventilation and necessary doorways protected by fire doors with ramps or curbs to prevent entrance of flammable liquids and exit of liquid oxygen.

3-8.2

Storage areas shall be reserved for liquid oxygen storage alone and shall be clearly placarded "Oxygen — No Smoking — No Open Flames" or equivalent.

3-8.3

In outdoor areas, valves and safety devices shall be protected from ice and snow accumulations.

3-9* Gaseous Oxygen Equipment.

3-9.1*

Gaseous oxygen cylinders shall conform with DOT regulations; shall be equipped with a shutoff valve; shall be equipped with a frangible disc safety device that meets the requirements of CGA Pressure Relief Device Standards, Part 1 *Cylinders for Compressed Gases*, S-1.1; shall be connected to a common header by suitable pigtails strong enough to safely withstand full cylinder pressure; and shall be securely fastened to the cart.

3-9.2

Manifolds shall be constructed with sufficient strength to safely withstand full cylinder pressure. Manifolds shall be equipped with a valve connection for use in filling the cylinders and a valved outlet connection to which the regulator is attached.

3-9.3

An approved spring-loaded relief valve, preferably equipped with a metal seat, shall be provided to protect the hose and other equipment that may be attached to the outlet of the manifold.

3-9.4

A frangible disc shall be provided in the system, downstream of the manifold outlet, to function in the event that the safety relief valve malfunctions.

3-9.5* Regulators.

3-9.5.1 Regulators and components shall be approved for oxygen service.

3-9.5.2 Seats used in regulators shall be of a material chosen for maximum resistance to ignition in an oxygen atmosphere and that will have the required physical characteristics needed to maintain a gastight seal.

3-9.5.3 Regulators shall be provided with a suitable filter to prevent foreign particles from entering their inlet chambers.

3-9.5.4* Regulators shall be provided with a means for dissipating heat of recompression resulting from admission of high-pressure oxygen to the regulator which might otherwise cause the regulator high-pressure seat to ignite.

3-9.5.5 Regulators shall be equipped with gauges for indicating cylinder and discharge pressures.

3-9.6* Orifice.

3-9.6.1 Where a flow-restricting orifice is used, the orifice plate shall be constructed of approved material and shall be provided with a hole small enough to restrict the flow of oxygen to the equipment being filled to prevent development of excessive temperature in this equipment.

3-9.6.2 A pressure gauge shall be provided downstream of the orifice as a means of indicating the pressure in the aircraft oxygen system being filled.

3-9.7 Dehumidifiers or Dryers.

3-9.7.1 Any drying agent used shall be approved for use with oxygen.

3-9.7.2 The container housing the drying agent shall be constructed of an approved material and shall be strong enough to safely withstand the pressure to which it may be subjected. If steel is used, it shall be protected from corrosion.

3-9.7.3 Gasket materials used shall be approved for use with oxygen.

3-9.8 Hose.

3-9.8.1 Hose shall be approved for use with oxygen. It shall be strong enough to safely withstand any pressure to which it might be subjected.

3-9.8.2 Hose connections shall be secured to prevent loosening.

3-9.8.3 The outlet end of the hose shall be equipped with a shutoff valve.

3-9.8.4 The valve outlet shall be attachable to the system fill receptacle and shall be secured to prevent loosening.

3-9.9 Precautions.

3-9.9.1 No oil, grease, or other such combustible material shall be allowed to come in contact with the equipment.

3-9.9.2 Thread-sealing compounds, when used, shall be approved for use with oxygen.

3-9.9.3 All parts of the equipment shall be thoroughly cleaned of oil or grease before being assembled.

3-9.9.4 The cart manifold outlet valve immediately upstream of the regulator shall be in the closed position before the cylinder valves on the cart are opened.

3-9.9.5 Oxygen valves shall be opened slowly to avoid rapid pressure rise.

3-9.9.6 After opening cylinder valves on the cart, the manifold outlet valve shall not be opened for 60 sec in order to permit heat of recompression to dissipate.

3-9.9.7 The regulator shall be relieved of pressure (if the regulator is not the self-relieving type) before the manifold outlet valve to the regulator is opened.

3-9.9.8 Before disconnecting, the valve at the end of the fill hose shall be closed to avoid whipping.

3-10 Miscellaneous Requirements.

3-10.1

Oxygen shall not be used as a substitute for compressed air to operate pneumatic tools, or for pressurizing containers, paint spraying, or blowing out pipelines.

3-10.2

Gases shall not be mixed in an oxygen container.

Chapter 4 Aircraft Fuel System Maintenance

4-1 Fuel Transfer Equipment and Operations.

4-1.1*

The requirements of this section shall apply to aircraft fuel transfer operations during aircraft maintenance and overhaul operations. The fuel transfer operations shall include:

(a) Transferring fuel from one tank to another within an aircraft while on the ground preparatory to maintenance;

(b) Transferring fuel from a tank in an aircraft to a tank in ground equipment or vice versa in order to achieve a maintenance objective;

(c) Transferring fuel for the purpose of performing tank repairs, replacement of tank accessories, or balancing of fuel loads.

4-1.2

Aircraft fuel transfer operations shall use one of the systems as required by 4-1.4. Where fuels used have a flash point under 100°F (37.8°C), fuel transfer operations shall be conducted only out of doors.

4-1.3

Fuel transfer operations shall be conducted only out of doors if the aircraft tanks contained gasoline or JET B fuels during the preceding 20 flying hours.

4-1.4

A fixed fuel transfer piping system shall be used where fuel transfer operations are conducted on a routine basis.

4-1.4.1 A limited capacity self-contained trailer having a closed liquid transfer system shall be permitted to be used.

4-1.4.2 Self-propelled fuel servicing vehicles shall be permitted to be used.

4-1.5

Where a fixed fuel transfer piping system specified in 4-1.4 is used, it shall meet the requirements of Chapter 5 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-1.5.1* Where fuel transfer piping extends into a hangar for aircraft fuel servicing operations, the portion of the piping located inside the hangar shall meet the requirements of Section 5-6 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-1.6

Where self-propelled fuel servicing vehicles specified in 4-1.4.2 of this section are used, the fuel servicing vehicles shall meet the requirements of Chapter 4 of NFPA 407, *Standard for Aircraft Fuel Servicing*. In addition, the fuel servicing vehicles shall not be permitted inside the hangar and shall be so positioned outside the hangar as to be readily movable.

4-1.7*

All hangars used for these fuel transfer operations shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

4-1.8

Each fuel transfer operation shall be tailored to the fuel system design features of each type of aircraft and shall be performed only after the detailed procedures have been approved by the authority having jurisdiction.

4-1.9

Where multiple aircraft occupy one aircraft storage and servicing area, the location used for fuel transfer operations shall be identified.

4-1.10

During each fuel transfer operation, a trained and qualified person shall be assigned to specifically oversee the fire safety of the procedures used, including the handling of the fire protection equipment provided, spill emergency precautions, and ventilation techniques.

4-1.11

Any fueling hose used shall be continuous, without intermediate couplings, and shall conform to and be maintained in accordance with the requirements of Chapter 3 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-1.12

Nozzles shall comply with the requirements of 4-9.3 or 4-9.4 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-1.13

Only one aircraft shall undergo fuel transfer operations at any one time in a single aircraft storage and servicing area.

4-1.14

Any other simultaneous maintenance operation on that aircraft or within 25 ft (7.6 m) of the aircraft fuel system vents, fuel tank openings, or fuel servicing vehicle, if used, that can constitute a source of ignition of vapors that might be released during an operation shall not be permitted.

4-1.15

Personnel selected for fuel transfer operations shall have a thorough knowledge of the fuel system of the aircraft involved and the handling of flammable and combustible liquids, and shall be familiar with the operation and limitations of the fire extinguishing equipment available.

4-1.16

At least two extinguishers, each with a minimum rating of at least 80-B:C and a minimum capacity of 125 lb (57 kg) of agent, shall be located within a 50-ft (15-m) distance, one on each side of the aircraft undergoing maintenance.

4-1.17

All open flame and spark-producing equipment or devices within the vapor hazard area shall be shut down and not operated during the fuel transfer operations.

4-1.18

Electrical equipment used in the vapor hazard area shall be listed for use in Class I, Group D, Division 1, hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-1.19

Procedures to guard against the accumulation of static electrical charges on the aircraft wing section or tank, the procedures of Section 2-3 of NFPA 407, *Standard for Aircraft Fuel Servicing*, shall be followed, and the equipment as specified in Section 2-15 of NFPA 409, *Standard on Aircraft Hangars*, shall be utilized. Apparel worn by personnel shall be made of material that will not accumulate static charges.

4-1.20

Internal combustion engine-powered equipment shall not be operated within 25 ft (7.6 m) of the aircraft fuel system vents or fuel tank openings prior to the start of fuel transfer operations.

4-1.21

When transferring fuel from an aircraft tank by suction using an external pump or fuel servicing truck, sufficient personnel shall be assigned to accomplish the operation, to prevent overfilling, and to guard against hose slippage and any flammable or combustible liquid spillage.

4-1.22

Aircraft radio, radar, strobe lights, and electronic transmitting equipment shall not be operated during fuel transfer operations.

4-1.23

Any fuel transfer hose nozzle used during these operations shall be electrically bonded to the aircraft. These bonding connections shall be made prior to the start of operations and maintained until after the fuel transfer operations have been completed.

4-1.24

When removing fuel from an aircraft tank by gravity, free fall of the fuel shall be avoided and a positive electrical bond shall be provided between the fuel tank and the receiving container.

4-1.25

Any spillage of fuel shall be handled in accordance with the requirements of Section 2-2 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-1.26

When transferring aircraft fuels by hose into a tank or drum, the hose shall be extended and fixed below the liquid level of the receiving tank to reduce the hazard of liquid surface electrostatic generation.

4-2* Air Ventilation.

4-2.1

Air mover equipment used to secure air ventilation shall not create fire hazards.

4-2.2

Air movers designed to operate by expansion of compressed air or steam shall be used.

4-2.3

Compressed air shall not be introduced directly into aircraft fuel tanks for air ventilation purposes.

4-2.4

Where electrical equipment is used, the appliances shall conform to the types specified by Article 513 of NFPA 70, *National Electrical Code*.

4-2.5

A safety factor shall be included where the lower flammable limit is the criterion and 20 percent of the limits shown in Table 4-2.5 shall be considered the maximum allowable concentration of fuel vapor.

Table 4-2.5 Lower Flammable Limits of Aviation Fuels

	Lower Flammability Limit	
Fuel	**Percent by Volume**	**Parts per Million**
Aviation Gasoline (all grades)	1.4	14,000
Type A (kerosene) Turbine Fuel	0.6	6,000
Type B (gasoline-kerosene blend)	0.8	8,000

4-2.6

Instruments used to measure the lower flammable limit shall only be used by qualified personnel and shall be calibrated accurately for the type of vapors present and checked periodically against standard samples to assure maintenance of calibration. Sampling tubes shall be of a type that will be impervious to absorption of the vapors. Instruments depending upon electrical power, if not designed for use in Class I, Group D, Division 1 atmospheres as defined in NFPA 70, *National Electrical Code*, or certified as intrinsically safe because of their low energy design, shall be operated only in nonhazardous locations.

4-2.7

Personnel selected to conduct air ventilation work shall have considerable knowledge of and experience in handling flammable liquids and a thorough knowledge of the aircraft fuel system.

4-2.8

Aircraft shall be defueled in accordance with Section 4-1 of this chapter.

4-2.9*

Aircraft undergoing fuel tank ventilation procedures shall be segregated or isolated from other aircraft when the flash point of the fuel is less than 100°F (37.8°C) or until a flammable vapor concentration of 20 percent of the lower flammable limit is maintained.

4-2.10

When air ventilation is done in an enclosed hangar and where a closed ventilating system to discharge vapors from tanks to outside the hangar is not used and tank vapors are discharged into the hangar, tests shall be conducted to determine that the presence of such fuel vapor-laden air in the enclosed hangar does not constitute a hazard under the worst conditions that can normally be anticipated. Any flammable vapor concentration over 20 percent of the lower flammable limit downwind from any discharge point of a tank shall result in emergency revisions of procedures.

4-2.11

All open flame and spark-producing equipment or devices within the vapor hazard area shall be shut down and not operated during the ventilation procedures.

4-2.12

Electrical equipment used in the vapor hazard areas shall be listed for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-2.13

Procedures to guard against the accumulation of static electrical charges on the aircraft wing section or tank shall utilize equipment as specified in Section 2-15 of NFPA 409, *Standard on Aircraft Hangars*. Exhaust equipment and the aircraft to be ventilated shall be electrically bonded and grounded. If ducting is used, a static bonding wire from each exhaust hose nozzle shall be connected to the aircraft before opening the fuel tank(s).

4-2.14

Aircraft electrical circuits that are in vapor-hazardous areas shall be de-energized.

4-2.15

Aircraft radar operations shall be controlled as required in Section 2-9 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-2.16

Suitable warning signs shall be placed in conspicuous locations around the aircraft to indicate that tank ventilation is in progress until a flammable vapor concentration less than 20 percent of the lower flammable limit is maintained.

4-2.17*

Aircraft hangars in which this work is conducted shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

4-2.18

At least one extinguisher having a rating of not less than 20-B and a minimum capacity of 15 lb (6.8 kg) of agent shall be located within 50 ft (15.2 m) of the aircraft undergoing air ventilation.

4-2.19

When air exhaust only is used, precautions shall be taken to prevent building up a negative pressure, which might result in tank collapse. Where a blower is used, the volume and pressure of air introduced and discharged shall be so balanced that no pressure differential arises that might have an adverse effect on the tank structure.

4-2.20

The following equipment shall be required to accomplish air ventilation of aircraft fuel tanks:

(a) An air mover (exhaust) and, if circumstances dictate, a blower.

(b) When air ventilation is conducted in an enclosed hangar and conditions warrant, an exhaust system designed to discharge the vapors to the outside of the hangar.

(c)* Properly calibrated instruments designed to take readings of fuel and solvent vapor and oxygen concentrations within the tank volume being treated and appropriate gas sampling tubing.

4-3 Repair of Fuel Tanks.

4-3.1

Prior to conducting work on tanks, if it is necessary to defuel the tank or tanks to be repaired or inspected, such defueling operation shall be done in accordance with the requirements contained in Section 4-1 of this standard.

4-3.2

Residual fuel that cannot be withdrawn by normal defueling procedures shall be drained from the tanks by removal of tank access plates. With the opening of the tanks, air ventilation procedures shall be immediately instituted. Residual fuel shall be retrieved in the safest possible manner and the fuel prevented from excessively wetting the undersurface of the wing or dripping to the ground or ramp to form pools. The residual fuel shall be siphoned out of the tank or be manually sponged or mopped up from tank low points or where trapped by baffles or other internal structural members.

4-3.3

Prior to entry into the tank or the start of any repairs, tests shall be conducted to determine that a flammable vapor concentration less than 20 percent of the lower flammable limit exists.

4-3.4

When repairs are to be made to integral tanks that are interconnected to other integral or bladder tanks that do not require work, steps shall be taken to prevent vapors from entering the tank or the section undergoing repairs by plugging or taping interconnector openings, vent openings, or vent manifolds.

4-3.5

Personnel selected to perform fuel tank repair shall be trained in the hazardous characteristics of the work environment and the materials present.

4-3.6

The supervisor in charge of the operation shall have a thorough knowledge of the operation.

4-3.7

Aircraft hangars in which tank repair work is being conducted shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

4-3.8

When tank repair work is done in an enclosed hangar and tank vapors are discharged into the hangar, tests shall be conducted to determine that the presence of such fuel vapor-laden air does not constitute a hazard under the worst conditions that can normally be anticipated. Any flammable vapor concentration over 20 percent of the lower flammable limit anywhere within the hangar shall result in emergency revision of procedures.

4-3.9

All open flame and spark-producing equipment or devices within the vapor hazard area shall be shut down and not operated during the repair operations.

4-3.10

Electrical equipment used in the vapor hazard area shall be listed for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-3.11

Procedures to guard against the accumulation of static electrical charges on the aircraft wing section or tank, the procedures of Section 2-3 of NFPA 407, *Standard for Aircraft Fuel Servicing*, shall be followed and the equipment as specified in Section 2-15 of NFPA 409, *Standard on Aircraft Hangars*, shall be utilized. Apparel worn by personnel shall be made of material that will not accumulate static charges.

4-3.12

When tank repairs are in progress, steps shall be taken to prevent all electrical and manual controls to the affected tank from being activated or energized.

4-3.13

Aircraft electrical circuits that are in vapor hazardous areas shall not be energized.

4-3.14

At least one extinguisher having a rating not less than 20-B and a minimum capacity of 15 lb (6.8 kg) of agent shall be located within 50 ft (15.2 m) of the aircraft.

4-3.15

Portable electrical lights used in tank repair operations shall be listed for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-3.16

If flashlights are used within integral fuel cells, they shall be listed for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-3.17

Containers used to transport flammable solvents used in effecting compound removal within the fuel tanks shall be equipped with positive closing or antispill lids to prevent spills while entering the fuel tank.

4-3.18

Electrical heating units used in tank repair operations shall be approved for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-3.19

Blowers having electrical components used to accelerate cure time of sealant or to warm tank interiors shall be listed for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-3.20* Additional Requirements for Repair of Integral Fuel Tanks.

4-3.20.1* Removal of existing sealant shall be accomplished with nonsparking metallic or hardwood scrapers. Plastic scrapers that tend to accumulate a static electric charge shall not be used.

4-3.20.2 Repairs necessitating structural rework shall be accomplished with compressed air-driven tools.

4-3.20.3* During top coating of fuel tank sealant base materials, extreme caution shall be taken to eliminate all possible ignition sources.

4-3.21* Additional Requirements for Repair of Bladder Tanks.

4-3.21.1* Fuel cell repair areas shall be well ventilated and segregated from other maintenance or assembly areas.

4-3.21.2 During application of coats of solvent and sealer over and under the patch, extreme caution shall be taken to eliminate all possible ignition sources.

4-3.21.3 Upon reinstallation of the cell, air ventilation procedures shall be started again and maintained until the fuel cell is closed.

4-3.22* Additional Requirements for Repair of Metal Tanks.

4-3.22.1 Required procedures for the safe removal of flammable vapors from metal tanks shall be as specified in NFPA 327, *Standard Procedures for Cleaning or Safeguarding Small Tanks and Containers.*

4-3.22.2 In addition to the precautions contained in NFPA 327, *Standard Procedures for Cleaning or Safeguarding Small Tanks and Containers Without Entry*, the following special precautions shall also be followed:

(a) Each compartment in a container having two or more compartments shall be treated in the same manner, regardless of which compartment is to be repaired.

(b) All tanks that have been cleaned and tested shall be stenciled and tagged. The stencil or tag shall include a phrase such as “Safe for Welding or Cutting,” the signature of the person so certifying, and the date.

4-4 Pressure Testing of Aircraft Fuel Systems.

4-4.1

The requirements of this section shall apply to aircraft fuel system pressure testing using a test fluid or fuel to assure integrity of the fuel system.

4-4.2

Where fuels used have a flash point under 100°F (37.8°C), fuel system pressure testing shall be conducted out of doors.

4-4.3

Aircraft fuel system pressure testing shall only be conducted out of doors if the aircraft tanks contained gasoline or JET B fuels during the preceding 20 flying hours.

4-4.4

Dump-valve tests involving fuel discharge shall also be done out of doors.

4-4.5

Fuel transfer operations done in conjunction with aircraft fuel system pressure testing shall comply with the requirements specified in Section 4-1 of this chapter.

4-4.6*

All hangars used for these operations shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

4-4.7

Each fuel system pressure testing operation shall be tailored to the fuel system design features of each type of aircraft and shall be performed only after the detailed procedures have been approved by the authority having jurisdiction.

4-4.8

An aircraft undergoing fuel system pressure testing shall be located in the hangar so that it or adjacent aircraft, unless on jacks or otherwise immobilized, can be rapidly withdrawn from the hangar in an emergency. Provisions shall be made to tow aircraft using preplanned techniques so that emergency fire control procedures can be undertaken.

4-4.9

Hangar doors shall be open when weather conditions permit and, if closed, unlatched and in such condition so that in an emergency the doors can be opened.

4-4.10

The amount of test fluid or fuel transferred shall be the minimum considered essential to each pressure testing operation.

4-4.11

The area used for fuel system pressure testing operations shall be placarded with suitably worded warning signs.

4-4.12

During each fuel system pressure testing operation, a trained and qualified person shall be assigned to specifically oversee the fire safety of the procedures used, including the handling of the fire protection equipment provided, spill emergency precautions, and ventilation techniques.

4-4.13

Any fueling hose used shall be continuous, without intermediate couplings, and shall conform and be maintained in accordance with Chapter 3 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

4-4.14

Nozzles shall comply with the requirements of 4-9.3 or 4-9.4 of NFPA 407*, Standard for Aircraft Fuel Servicing*.

4-4.15

Only one aircraft shall undergo fuel system pressure testing at any one time in a single aircraft storage and servicing area.

4-4.16

Any other simultaneous maintenance operation on that aircraft or within 25 ft (7.6 m) of the aircraft fuel system vents, fuel tank openings, or fuel servicing vehicle (if used) that can constitute a source of ignition of vapors that might be released during an operation shall not be permitted.

4-4.17

Personnel selected for fuel system pressure testing operations shall have a thorough knowledge of the fuel system of the aircraft involved and the handling of flammable and combustible liquids, and shall be familiar with the operation and limitations of the fire extinguishing equipment available.

4-4.18

At least two extinguishers, each with a minimum rating of at least 80-B:C and a minimum capacity of 125 lb (57 kg) of agent, shall be located within a 50-ft (15.2-m) distance, one on each side of the aircraft undergoing maintenance.

4-4.19

All open flame and spark-producing equipment or devices within the vapor hazard area shall be shut down and not operated during the ventilation procedure.

4-4.20

Electrical equipment used in the vapor hazard area shall be approved for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

4-4.21

Procedures to guard against the accumulation of static electrical charges on the aircraft wing section or tank shall utilize equipment as specified in Section 2-15 of NFPA 409, *Standard on Aircraft Hangars*. Apparel worn by personnel shall be made of material that will not accumulate static charges.

4-4.22

Internal combustion engine-powered equipment shall not be operated within 25 ft (8 m) of the aircraft fuel system vents or fuel tank openings prior to the start of fuel system pressure testing.

4-4.23

Ground power units, which are essential when employing the aircraft fuel booster pump for the fuel system pressure testing work, shall not be located within 25 ft (8 m) of the aircraft fuel system vents or fuel tank openings.

4-4.24

When transferring fuel from one aircraft tank to another by means of an aircraft fuel booster pump, sufficient personnel shall be assigned to accomplish the operation, to prevent overfilling and overpressurizing, and to detect possible leakage. Where such fuel transfer operations cannot be done utilizing the internal aircraft fuel system plumbing, there shall be sufficient personnel to perform the functions outlined in the previous sentence with particular attention given to the integrity of the external plumbing arrangement.

4-4.25

Aircraft radio, radar, strobe lights, and electronic transmitting equipment shall not be operated during fuel system pressure testing.

4-4.26

Caution shall be exercised to prevent intermixing of test fluids or different grades of fuel.

4-4.27

Any spillage of fuel shall be handled in accordance with the requirements given in Section 2-2 of NFPA 407, *Standard for Aircraft Fuel Servicing*.

Chapter 5 Aircraft External Cleaning, Painting, and Paint Removal

5-1 General.

5-1.1

Cleaning, painting, or paint removal operations using flammable or combustible materials shall be conducted in accordance with the requirements of this chapter.

5-1.2

Cleaning, painting, and paint removal of components and subassemblies that are small enough to be removed from the aircraft for work and that require a total application rate of more than 1 qt (1 L) of material in one hour, or the cumulative use of more than 1 gal (4 L) of material in eight hours shall be conducted in accordance with NFPA 33, *Standard for Spray Application Using Flammable and Combustible Materials*, and will not be discussed in this chapter.

5-1.3*

In selecting materials for cleaning, painting, and paint removal purposes, material with the highest flash point available shall be used.

5-2 Operational Sites and Precautions.

5-2.1*

When conducting cleaning, painting, or paint removal operations, the major consideration in choosing a location shall be that of good general ventilation and ease of cleanup.

5-2.2

When cleaning, painting, or paint removal operations of aircraft, major aircraft assemblies, or aircraft subassemblies that are not removable as specified in 5-1.2 are conducted in a hangar, that hangar shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

5-2.2.1 Where the hangars house only aircraft with drained and purged fuel tanks as defined in 1-3.7 of NFPA 409, *Standard on Aircraft Hangars*, the hangar shall be protected with at least an automatic sprinkler system that meets the requirements specified in Section 4-2 of NFPA 409.

5-2.3*

Ramp areas used for these maintenance procedures shall be servicing ramps not subject to public access. Sufficient clearance shall be maintained to avoid creating a hazard to adjacent aircraft or structures and to assure access by fire-fighting equipment, and the aircraft being worked on shall not be in the path of other normal aircraft movements on the ramp.

5-2.4

Where cleaning, painting, or paint removal operations are being conducted, no concurrent, potentially hazardous operations shall be conducted within 50 ft (15.2 m) of the working area. Even for touch-up operations, the area shall be inspected prior to the start of operations for any ignition sources within the working area and these sources shall be eliminated. Such conditions shall be maintained hazard-free during the entire work period.

5-2.5

Sufficient air movement to prevent flammable vapor concentrations at floor level, in floor pits and drains, and in aircraft compartments from reaching 20 percent of the lower explosive limit during these operations shall be provided by general ventilation, by opening of hangar doors, or by forced ventilation.

5-2.6

Fixed electrical equipment shall conform to Article 513 of NFPA 70, *National Electrical Code*. Temporary lighting used for general illumination during these operations shall be located so as not to be in direct range of any flammable sprays or liquids or in any “overspray” areas. Such equipment, if not listed for use in Class I, Group D hazardous locations, shall be of the enclosed and gasketed type to minimize the danger of breakage and reduce entrance of hazardous vapors within the fixtures.

5-2.7

The use of heat lamps to accelerate the drying of painted surfaces shall be prohibited unless used as part of an approved drying booth or enclosure in accordance with the requirements of NFPA 33, *Standard for Spray Application Using Flammable and Combustible Materials*, and NFPA 86, *Standard for Ovens and Furnaces*.

5-2.8

When cleaning or paint removal agents are applied through spray nozzles under pressure, the nozzle shall be of the self-closing type so that, when the hand of the operator is removed, the nozzle will automatically close.

5-2.9

Aircraft electrical systems shall be de-energized during cleaning, painting, and paint removal operations.

5-2.9.1 When aircraft power is required for concurrent operations in accordance with 5-2.4 of this chapter, the electrical equipment exposed to flammable or combustible liquids or vapors shall be de-energized.

5-3 Control of Flammable and Combustible Materials for Painting of Aircraft.

5-3.1

Supply stores of paints and flammable thinners and solvents shall be located in a separate building or segregated from the aircraft maintenance and servicing areas of hangars by a fire partition with openings that shall be protected by an approved and listed fire door. Storage shall conform to the requirements of NFPA 30, *Flammable and Combustible Liquids Code*.

5-3.2

Only an operational supply of paints and flammable solvents, limited to not more than one day's needs, shall be maintained in a hangar. These shall be in approved, marked containers located remotely from other operations. Dispensing drums, when essential to the operation, shall be equipped with positive acting pumps and pressure relief fittings and shall be provided with drip pans and static bonding clamps and cables. No pneumatic devices that pressurize the drum shall be used for dispensing the liquids.

5-3.3

Flammable and combustible liquids on the job shall be kept in approved containers, marked with the product name. Premixed paints shall be kept in their original metal containers, covered when not in use. Maximum solvent or paint container size on the job shall be 5 gal (20 L).

5-3.4

Epoxy or polyester resins shall not be stored close to ketone-type thinners.

5-3.5

Petroleum distillate suitable for use as a dry-cleaning solvent and other solvent cleaners such as mineral spirits, aliphatic naphtha, aromatic naphtha, trichlorethylene, xylene, methyl ethyl ketone, and other ketone-type thinners shall not be used in areas of aircraft oxygen systems.

5-4 Fire Extinguishing Equipment Requirements.

Regardless of how small, all aircraft on which cleaning, paint removal, or painting operations are performed shall have a minimum of one hand-portable fire extinguisher having at least a 20-B:C rating with a minimum capacity of 15 lb (6.8 kg) of agent and one nonsparking wheeled fire extinguisher having at least an 80-B:C rating with a minimum capacity of 125 lb (58 kg) of agent, located within 50 ft (15.2 m) of the operation, available for immediate use.

5-5 Housekeeping and General Safeguards.

5-5.1

Upon completion of each cleaning, paint removal, or painting operation, and at least once each day during the progress of the operation, all waste solvents, wiping waste, used masking tape, and waste paper shall be collected and safely disposed of. Under no circumstances shall flammable liquids or painting materials be dumped into sanitary or storm drains. Industrial waste disposal shall be made. Particular attention shall be paid to removing waste regularly from floor pits and trenches and from aircraft holds and recesses. Until properly disposed of, waste shall be kept in covered metal containers. Rags contaminated with finishing materials shall be kept in a separate container and not in those used to keep other waste materials.

5-5.2

The aircraft, unless immobilized, shall be parked in the painting area so that it can be readily removed in an emergency, with no obstacles between the aircraft and the doors.

5-5.3*

To reduce the hazards associated with static electricity, aircraft shall be electrically grounded when parked in aircraft hangars. The aircraft manufacturer's description and maintenance instructions shall be consulted regarding the location of grounding points on the aircraft and the number of grounding cables required.

5-5.4*

Spills shall be cleaned up as they occur.

5-5.5*

Other than designated safe smoking areas, smoking shall be prohibited in hangars or aircraft servicing ramps used for cleaning, paint removal, or painting operations.

5-5.6

Footwear with metal cleats or tacks shall not be permitted to be worn as they can cause sparks when scuffed along the floor.

5-5.7

No open flame shall be permitted in the vicinity of the working area.

5-6 Inspection and Preventive Maintenance.

5-6.1

Electrical equipment shall be inspected to ensure that it is being properly maintained in first-class condition and that it will not cause short circuits.

5-6.2

Grounding or bonding equipment shall be regularly inspected, properly maintained, and properly used.

5-6.3

Pumps, faucets, and pressure relief vents of containers used for flammable liquids or solvents shall be kept leak-free and functioning.

5-6.4

Any damage to containers, structure, seals, or flame arrestors shall be promptly and properly repaired.

5-6.5

Cleaning solution spray equipment, paint removal equipment, paint spray equipment, and other applicators shall be maintained in a safe condition.

5-6.6

Stands, docks, floors, filters, scaffolds, staging, and drop curtains shall be maintained on a regular basis to keep them sound and free from combustible accumulations.

5-6.7

Floors, roof trusses, light fixtures, and overhead equipment shall be regularly inspected for paint overspray and dust accumulation and cleaned when necessary.

Chapter 6 Aircraft Welding Operations

6-1 General Requirements.

6-1.1*

Aircraft welding operations shall conform to the requirements of this chapter.

6-1.2

Only gas-shielded arc-welding shall be performed on aircraft.

6-1.3

Only qualified welders, trained in the technique and familiar with the hazards involved, shall be permitted to do this work.

6-1.4*

A written, special welding permit shall be obtained for each welding operation conducted on an aircraft from an individual designated by management as responsible for authorizing welding operations. A welding fire safety check list shall also be tailor-made and used to cover the individual hazards of each type of operation. If a hazard is encountered that is not covered on the check list, work shall be stopped until the individual designated by management as responsible for authorizing welding operations provides any needed additional guidance.

6-1.5

No welding shall be conducted, or welding equipment brought to the work area, until a permit has been issued.

6-1.6

No other work shall be permitted within a 25-ft (7.6-m) radius of the location of any gas-shielded arc-welding operation.

6-1.7

If other aircraft are located adjacent to the welding operation, the person responsible for each aircraft shall be notified in advance that welding is to be conducted.

6-2 Flammable Vapors.

6-2.1

Welding shall not be done on an aircraft while work is in progress on any system or component of that aircraft which contains, or did contain, fuel or other flammable or combustible liquids.

6-2.2

Welding shall not be done on an aircraft while work is in progress on the fuel systems on any other aircraft within 50 ft (15.2 m) from the point of welding.

6-2.3

Fuel tank access plates and any fuel tank openings shall be closed on all aircraft within 50 ft (15 m) from the point of any welding. All fuel lines, valves, manifolds, and other fuel components on the aircraft on which welding is being done shall be in place, secured, or capped prior to the start of welding operations and during such welding operations.

6-2.4*

All fuel tank vents on the aircraft being worked on and the vents of other aircraft within a 50-ft (15-m) radius of the welding operation shall be plugged or covered prior to the start of welding operations and during such welding operations.

6-2.5

Prior to the start of welding and at least every 15 minutes during the welding operation, a qualified person shall check with a combustible gas analyzer to assure that flammable vapors do not reach 20 percent of the lower explosive limit whenever welding is being done in the vicinity of sources of flammable vapors. Floor drains in the area of a welding operation, when conducted in a hangar, shall be checked in the same manner.

6-3 Equipment.

6-3.1

Welding generating equipment shall be placarded as follows: “Warning—Keep 5 Ft (1.5 M) Horizontally Clear of Aircraft Engines, Fuel Tank Areas, and Vents.”

6-3.2

Welding equipment shall have no electrical components other than flexible lead cables within 18 in. (457 mm) of the floor. The ground leads shall be as close to the area to be welded as possible, and clamps used on such ground leads shall be of the “C” clamp type, not the clip type. Components that could produce arcs, sparks, or hot metal under any condition of operation shall be of the totally enclosed type or shall have suitable guards or spacing in compliance with the requirements of Article 500, Hazardous (Classified) Locations, of NFPA 70, *National Electrical Code*. The inert gas cylinder shall be securely fastened to prevent tipping and the regulator and gage shall be in proper working condition.

6-4 Fire Protection.

6-4.1

When welding operations are performed in an aircraft hangar, that hangar shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

6-4.1.1 Where the hangars house only aircraft with drained and purged fuel tanks as defined in 1-3.7 of NFPA 409, *Standard on Aircraft Hangars*, the hangar shall be protected with at least an automatic sprinkler system that meets the requirements specified in Section 4-2 of NFPA 409.

6-4.2

Any welding performed shall take into consideration the type of automatic fire detection equipment installed in the hangar to avoid false alarms or accidental actuation of the fire protection equipment provided.

6-4.3

The specific location where the welding is being done shall be roped off or otherwise segregated by physical barrier to prevent unintended entry into the welding area. A placard reading "Welding Operations in Progress" shall be prominently displayed.

6-4.4

Good housekeeping shall prevail in the welding area.

6-4.5

At least one hand-portable fire extinguisher having a minimum rating of 20-B with a minimum capacity of 15 lb (6.8 kg) of agent shall be positioned in the immediate area of the welding operation ready for instant use, and one wheeled extinguisher having a minimum rating of 80-B with a minimum capacity of 125 lb (58 kg) of agent shall be readily available.

6-4.6

A qualified fire watcher shall be assigned to operate this equipment and shall monitor the entire welding operation. In the event a hazardous condition develops, the fire watcher shall have the authority to stop the welding operation.

Chapter 7 Interior Cleaning and Refurbishing Operations

7-1 General Requirements.

7-1.1*

Flammable liquid cleaning agents shall not be used. Combustible liquid cleaning agents shall be permitted to be used.

7-1.2*

Aircraft cleaning or refurbishing operations using combustible liquids shall be conducted in accordance with this chapter.

7-2 Precautions for Combustible Liquid Cleaning Agents.

7-2.1

Combustible liquids shall be stored and controlled in accordance with the provisions of NFPA 30, *Flammable and Combustible Liquids Code*. Container storage areas shall be segregated from the aircraft maintenance and servicing area of hangars by a fire partition with openings protected by an approved fire door or located in a separate building.

7-2.2

Combustible liquids shall be handled only in approved containers appropriately marked.

7-2.3

Aircraft interiors shall be provided with ventilation sufficient at all times to prevent the accumulation of flammable or combustible vapors. To accomplish this, doors to interiors shall be open to secure maximum advantage of natural ventilation. Where such natural ventilation is insufficient, approved mechanical ventilation equipment shall be provided and used to prevent the accumulation of flammable or combustible vapors from reaching 20 percent of the lower flammability limit of the particular vapor being used.

7-2.4

All open flame and spark-producing equipment or devices that might be brought within the vapor hazard area shall be shut down and not operated during the period when flammable or combustible vapors might exist.

7-2.5

Electrical equipment of a hand-portable nature used within a vapor hazard area shall be of the type approved for use in Class I, Group D, Division 1 hazardous locations as defined by NFPA 70, *National Electrical Code*.

7-2.6

Temporary lighting used outside the hazard area for general illumination within an interior during cleaning and refurbishing operations, that is not listed for use in Class I, Group D hazardous locations, shall be enclosed and gasketed to reduce entrance of hazardous vapors within the fixtures, attached and located so as to minimize danger of breakage, and installed so as not to be in direct contact with any combustible liquids or “overspray.”

7-2.7

Switches to aircraft interior lighting and to the aircraft electrical system components within the interior area shall not be worked on or switched on or off during cleaning operations where flammable vapors might exist.

7-3 Fire Protection Requirements.

7-3.1*

During such cleaning or refurbishing operations in an aircraft outside of the hangar, portable fire extinguishers having a minimum rating of 4-A:20-B with a minimum capacity of 15 lb (6.8 kg) of agent shall be provided at cabin entrances.

7-3.2

When such cleaning or refurbishing operations are performed in an aircraft hangar, that hangar shall meet the requirements of NFPA 409, *Standard on Aircraft Hangars*.

7-3.2.1 Where the hangars house only aircraft with drained and purged fuel tanks as defined in 1-3.7 of NFPA 409, *Standard on Aircraft Hangars*, the hangar shall be protected with at least an automatic sprinkler system that meets the requirements specified in Section 4-2 of NFPA 409.

7-3.2.2 In all cases, aircraft undergoing such operations in any hangar shall also have the portable fire extinguishers required in 7-3.1 of this section.

7-3.2.3 In all cases, aircraft undergoing such operations in a Group I or II hangar shall also have at least one hose line available with an adjustable spray nozzle and a discharge of not less than 50 gpm (189.25 L/min). This hose line shall be capable of reaching into the cabin area.

Chapter 8 Aircraft Ramp Fire Protection

8-1 General Requirements.

8-1.1

This chapter shall apply to the minimum requirements for fire safety on aircraft ramps.

8-1.2

The requirements of NFPA 407, *Standard on Aircraft Fuel Servicing*, shall be met during aircraft fuel servicing operations.

8-1.3

Smoking shall be prohibited on the ramp.

8-1.4

Open flames shall not be allowed within a 50-ft (15-m) radius of aircraft.

8-1.5

A Permit to Work shall be obtained before commencement of any open flame or hot work on the ramp. The permit shall be issued on a daily basis by the authority having jurisdiction.

8-1.6

Aircraft shall be kept under observation when connected to ground power.

8-1.7

Rubbish shall not be allowed to accumulate on the ramp and shall be disposed of in approved containers.

8-1.8

All waste flammable liquids shall be placed in approved containers prior to disposal.

8-1.9

Flammable liquids shall not be placed in trash cans or poured down storm drains.

8-2 Fire Extinguishers.

8-2.1*

At least one wheeled extinguisher having a rating of not less than 80-B and a minimum capacity of not less than 125 lb (55 kg) shall be provided at each gate or stand, or at intervals of 200 ft (61 m) along the length of aircraft ramps.

8-2.2

All portable extinguishers shall meet the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

8-3 Fire Incidents.

8-3.1*

In the event of a fire on or adjacent to an aircraft, the captain, crew, or personnel on board shall be alerted immediately so that an evacuation can be initiated.

8-3.2*

The fire shall be reported immediately to the fire department and the exact location and aircraft registration given by one or more of the following methods:

(a) Telephone;

(b) Mobile or portable radio;

(c) Aircraft radio;

(d) Fire alarm.

8-3.3*

All personnel employed on aircraft ramps shall be given training on action to take in case of fire. This shall include hands-on training in the use of portable and wheeled extinguishers.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-3 Cleaning, Interior.

The principal areas of aircraft interiors that may need periodic cleaning are:

(a) Aircraft passenger interior areas (seats, carpets, side panels, headliners, overhead racks, curtains, ashtrays, windows, doors, and decorative panels of plastic, wood, or similar materials).

(b) Aircraft flight station areas (similar materials to those found in passenger interior areas plus instrument panels, control pedestals, glare shields, flooring materials, metallic surfaces of instruments and flight control equipment, electrical cables and contacts, etc.).

(c) Lavatories and buffets (similar materials to those found in passenger cabin areas plus toilet facilities, metal fixtures and trim, trash containers, cabinets, wash and sink basins, mirrors, ovens, etc.).

A-1-4

Metric units of measurement in this standard are in accordance with the modernized metric system known as the International System of Units (SI). One unit (liter), outside of but recognized by SI, is commonly used in international fire protection. For additional information, see ASTM E380, *Standard for Metric Practice*.

The conversion procedure for the SI units is to multiply the quantity by the conversion factor and then round the result to the appropriate number of significant digits.

A-2-2.3

A short across these terminals can burn or weld metal, and resultant arcs can cause an explosion if the short circuit occurs in the presence of a flammable vapor.

Wrenches and other hand tools should be used carefully to avoid short circuits. Finger rings, wrist watches, wrist chains, etc., should not be worn while working near battery terminals because a short circuit could cause an arc or result in a severe burn.

A-2-2.5

Most aircraft have battery compartments designed for in-flight ventilation only, and if batteries are charged in such compartments while the aircraft is on the ground, an explosive gas-air mixture can be trapped in the battery compartment.

A-2-2.11

Lead-acid batteries can release hydrogen gas during charging, and any sulfuric acid vapors released are corrosive. Vented nickel-cadmium batteries can release oxygen and hydrogen if overcharged. Sealed nickel-cadmium batteries can swell, vent, or rupture if charged at a greater than recommended rate or if excessively overcharged.

A-2-3.6

This is extremely important, because in some aircraft the battery switch has a midposition, and, if the switch is in this position and the batteries have not been removed or disconnected, the batteries will be charged in the aircraft battery compartment, giving off excessive heat and hydrogen gas.

A-2-4.7

See Figure A-2-4.7.

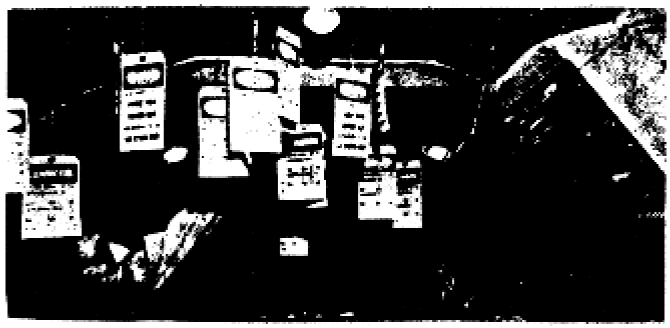

Figure A-2-4.7 Typical illustration of the use of a "tag-out" system.
(Courtesy of American Airlines, Inc.)

A-2-4.8(a) No fewer than two persons should work on energized electrical systems in areas containing flammable fluid lines.

A-3-1.1

For information on bulk storage of oxygen, see NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites*, and NFPA 53, *Guide on Fire Hazards in Oxygen-Enriched Atmospheres*.

Description of Gaseous and Liquid Oxygen.

Current aircraft breathing-oxygen systems can utilize either gaseous or liquid oxygen or a chemical-oxygen generator.

Gaseous oxygen is colorless, odorless, tasteless, and nontoxic. It comprises about 21 percent of normal air by volume and is about 10 percent heavier than air. Above its critical temperature of 180.4°F (82.4°C), oxygen can exist only as a gas regardless of the pressure exerted upon it.

Liquid oxygen is a light blue, transparent liquid that flows like water. It boils at –297°F (-147.2°C) at standard atmospheric pressure. The gaseous oxygen formed at room temperature [70°F (21°C)] and standard atmospheric pressure [29.92 in. (760 mm) of mercury] by vaporization of liquid oxygen will occupy a volume about 862 times that occupied by the original liquid. If a volume of liquid oxygen is confined and allowed to warm to room temperature, the attempt of the vaporizing oxygen to expand will result in the attaining of extremely high pressures [in the order of 40,000 psi (276 MPa)]. For this reason, liquid oxygen containers must be fitted with safety relief devices or vented to the atmosphere.

Hazards.

Both gaseous and liquid oxygen are stable materials and are nonflammable. Combustible materials ignite more readily in an oxygen-enriched atmosphere. The intensity of a fire increases in the presence of oxygen. This makes it very important to keep concentrations of oxygen separated from combustibles and from any source of ignition. Therefore, the highest standards of housekeeping are essential in areas where oxygen is stored or serviced. Physical damage to or failure of oxygen containers, valves, or plumbing can result in an explosive rupture in oxygen system components with resultant danger to life, limb, and property.

Combustible materials, particularly easily ignitible flammable liquids and lubricating oil, are especially hazardous when present inside the aircraft breathing-oxygen systems where the oxygen concentrations are high. There have been several incidents where explosive rupture of system components has resulted under these circumstances.

In addition to aggravating the fire hazard, liquid oxygen will cause severe “burns” (frostbite) in contact with the skin because of its low temperature.

Since oxygen-enriched atmospheres accelerate the corrosion process, only materials approved for oxygen service should be used.

A-3-2

Low-Pressure Breathing-Oxygen Systems.

These fixed systems utilize compressed gaseous oxygen stored in containers having a maximum service pressure of about 400 to 450 psi (2.76 to 3.10 MPa). A typical system consists of one or more containers manifolded to suitable oxygen distribution piping, check valves to isolate individual containers, relief devices to prevent container overpressure from overcharging or heating, a pressure gauge to indicate quantity of oxygen available, a manual shutoff valve, valves to isolate portions of the system, a fill fitting to permit charging the system, and one or more of the types of regulators previously described.

High-Pressure Breathing-Oxygen Systems.

These fixed systems utilize compressed gaseous oxygen stored in containers having a maximum service pressure of about 1800 to 2200 psi (12.4 to 15.2 MPa). A typical system is quite similar to the low-pressure systems except that fill fittings may sometimes not be provided. (In such systems, the entire container is replaced with a full container as needed.)

Portable Equipment.

Portable equipment (“walk-around bottles”) utilize compressed gaseous oxygen in either the low- or high-pressure containers. A typical system is comprised of either a demand or continuous flow regulator, a pressure reducer, a quick disconnect fill fitting equipped with a check valve for charging, a container pressure gauge, and a snap-in connection for mask fittings.

A-3-3 Liquid Breathing-Oxygen Converter Systems.

These fixed systems utilize liquid oxygen stored in highly insulated containers that can be vented to the atmosphere or operated under low or moderate pressure. A typical system utilizes demand or continuous flow regulators and the liquid oxygen is passed through tubing where it vaporizes and then through a warm-up coil (heat exchanger) to raise the temperature of the gaseous oxygen to a comfortable breathing level. A pressure-operated control valve maintains the desired delivery pressure and volume. Overpressure relief devices vent excessive pressures overboard. Other components include a cockpit oxygen quantity indicator, a fill fitting, and the necessary distribution piping and check valves. Some liquid oxygen containers are spherical in shape and are surrounded by integral vaporizer tubing. Others have the vaporizer tubing separate from the container. Liquid breathing-oxygen charging operations are not regarded as more hazardous than gaseous breathing-oxygen charging operations; however, a spill of liquid oxygen introduces a new hazard that should be specifically safeguarded.

A-3-3.11

The following recommendations outline procedures considered typical; however, variances in design between aircraft systems and charging equipment might require deviations. Always observe the equipment manufacturer's instructions.

(a) Before transferring liquid oxygen from the supply tank to the aircraft system, be sure that the pressure relief valve on the supply tank is operating.

(b) To develop the desired pressure to effect transfer, close the vent valve and open the pressure buildup valve slowly. Allow the pressure to reach the desired level and then close the pressure buildup valve.

(c) Attach the transfer hose to the tank and open the fill-drain valve. Purge the transfer hose in accordance with the specific instructions of the manufacturer and then close the fill-drain valve.

(d) After purging, attach the hose to the fill fitting in the aircraft oxygen system and open the fill-drain valve slowly.

(e) Fill the aircraft converter until a steady flow of liquid (caught in a clean, dry container specifically reserved for this purpose) comes from the converter vent line, decreasing the built-up pressure in the supply tank as the converter approaches the full condition by opening the supply tank vent valve.

(f) When the aircraft converter is full, close the fill-drain valve on the tank and release pressure in the transfer hose by opening the pressure relief valve. It might be necessary to operate the pressure relief valve several times until there is no further pressure rise. Disconnect the transfer hose from the aircraft fill fitting.

(g) Replace the cap on the aircraft fill fitting and set the buildup and vent valves in accordance with the manufacturer's instructions.

Liquid oxygen might contain trace quantities of dissolved hydrocarbon impurities. Repeated recharging of containers from which oxygen is withdrawn as a gas, without periodically warming such containers sufficiently to volatilize and clean out the impurities, can concentrate these impurities to an objectionable degree. Normally this will not be a problem if the system is warmed and purged at each major overhaul period.

A-3-4 Oxygen Generator Systems.

These systems utilize a generator with a chemical core. Chemical reaction is initiated by an electrically fired squib or a firing pin. Upon initiation, the generator supplies oxygen to the masks. The generator systems are installed on some turbine aircraft to supply emergency oxygen to the passengers and interior attendants in the event of loss of interior pressure.

A-3-5.1

If available, breathing air, rather than oxygen, can be used for this purpose.

A-3-6.1

If liquid oxygen is involved in a fire, it is normally desirable to allow the fire to burn until the liquid oxygen present in the fire area has evaporated. The combustible materials ignited should be attacked with the appropriate agent. Oxygen can combine with a number of combustible materials and cause an explosion. Liquid oxygen, as a vigorous oxidizing agent, cannot be effectively blanketed by extinguishing agents.

A-3-7 Breathing-Oxygen Cylinder Storage.

(a) Gaseous breathing oxygen is generally received in high-pressure [1800 to 3000 psi (12.4 to 20.7 MPa)] containers. The containers can be conventional commercial cylinders, in which case they are stored and transported to the charging site where they are used to charge the aircraft system storage containers. In some instances the aircraft system storage containers themselves might be received, in which case they are stored and transported to the charging site and interchanged with the empty containers in the aircraft system.

(b) Liquid breathing oxygen is generally received in a tank car or truck and is transferred to a storage vessel. It is then transferred as needed to a mobile charging vehicle and transported to the charging site where it is used to charge the converter in the aircraft system.

(c) In general, the applicable provisions of NFPA 51, *Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes*, and NFPA 50, *Standard for Bulk Oxygen Systems at Consumer Sites*, should be followed. NFPA 51 is applicable to cylinder storage in smaller quantities. NFPA 50 is applicable to larger systems of both gaseous and liquid oxygen.

A-3-8 Liquid Oxygen Storage Equipment.

In the United States, liquid oxygen storage containers are fabricated from materials meeting the impact test requirements of Paragraph UG-84 of the ANSI B31.1 *Boiler and Pressure Vessel Code*, Section VIII — Unfired Pressure Vessels, or meet the specifications of DOT for 4L cylinders. Vessels (other than DOT 4L cylinders) operating at pressures above 15 psig (103 kPa gauge) are designed in accordance with the further appropriate provisions of the ASME code. A gastight, carbon steel jacket generally encloses the liquid-holding container, the annular space is filled with noncombustible insulation, and a high vacuum is maintained in the space. Containers used for this purpose should be painted and legibly marked “Aviator’s Breathing Oxygen” in a manner similar to that described in A-3-9(e).

A-3-9 Gaseous Oxygen Equipment.

(*See also A-3-8*.)

(a) In the United States, regulations of the Department of Transportation (DOT) govern the type and capacity of containers in which commercial oxygen as a nonflammable compressed gas can be transported and stored. In Canada, specifications issued by the Board of Transport Commissioners apply. In other countries, similar rules are generally issued by the appropriate governmental agencies. In the United States, commercial oxygen at a pressure in excess of 40 psi (276 kPa) absolute [25 psig (272 kPa gauge) approximate] at 70°F (21.1°C) is most commonly packed and shipped in seamless steel cylinders constructed to DOT Specification 3A or 3AA.

(b) Commercial oxygen container valve outlet and inlet connections should conform to standards prepared by the Compressed Gas Association, Inc., that have been adopted by both the American and Canadian standards associations.

(c) Most oxygen cylinders are required by DOT to be equipped with safety devices. Usually, this is accomplished by using a frangible disc, a fusible metal core, or a combination thereof on the cylinder valve, designed to release the gas in the event the cylinder is subjected to an abnormally high temperature, as in a fire.

(d) Each DOT 3A and 3AA cylinder is marked with a service pressure, and filling of the cylinder at 70°F (21.1°C) must not exceed 110 percent of the service pressure if the cylinder is marked with a plus sign following the last test date and if the cylinder valve is fitted with a frangible disc (without fusible metal) safety device; if not so marked and fitted, the filling must not exceed the marked service pressure.

(e) DOT cylinders are required to have the DOT specification number followed by the service pressure (e.g., DOT3A2015); a serial number and identifying symbol (registered with the Bureau of Explosives) of the purchaser, user, or maker; the inspector's official mark and the date of the test to which the cylinder was subjected in manufacture; and the word "Spun" or "Plug" when an end enclosure is made by the spinning process or effected by plugging. In addition, cylinders used in this service should be painted and legibly marked "Aviator's Breathing Oxygen" as recommended by CGA C-4, *Method for Marking Portable Compressed Gas Cylinders to Identify the Material Contained*.

A-3-9.1

The conventional equipment consists of a wheeled cart on which is mounted a number of high-pressure cylinders with an attached manifold. A pressure-reducing device, such as a regulator, installed on the manifold is provided with an outlet connection to which the hose used to fill the aircraft oxygen system is attached. A dehumidifier, used to dry the oxygen, is sometimes interposed between the regulator outlet and the filling hose.

A-3-9.5 Types of Aircraft Breathing-Oxygen Regulators.

The three basic types of aircraft breathing-oxygen regulators are supplied from fixed or portable oxygen systems as described in A-3-2, A-3-3, and A-3-4.

(a) A continuous flow-type regulator, automatic or manual, is a means for increasing the flow with altitude. With this regulator, the breathing-oxygen flow is fixed for any given adjustment and does not vary automatically to suit work or rest conditions.

(b) A demand-type regulator allows breathing oxygen to flow only when a suction is applied, as by inhaling through a mask or tube. This regulator might feed only pure breathing oxygen, or the diluter demand-type may have automatic means for mixing air with the pure breathing oxygen to maintain the partial pressure of oxygen in the lungs at a preset, low-altitude condition up to some predetermined altitude. An emergency valve for eliminating the dilution of pure breathing oxygen is normally provided.

(c) A pressure breathing demand-type regulator, when used with the proper mask, imposes a predetermined pressure upon the lungs at certain altitudes [usually above 30,000 ft (9000 m)]. Below that altitude, the regulator functions as an ordinary diluter demand-type.

A-3-9.5.4 This can be a dead-end chamber directly connected to the inlet passage of the regulator or some other heat-absorbing device.

A-3-9.6 Pressure reduction can also be achieved through the use of a flow-restricting orifice installed at the manifold outlet valve or in the line between the outer valve and the cylinder to be filled. This arrangement, unlike the one employing a regulator, requires the presence of an operator to shut off the gas supply from the manifold when the aircraft oxygen system comes up to specified pressure.

A-4-1.1

See NFPA 407, *Standard for Aircraft Fuel Servicing*, for aircraft fuel transfer operations not associated with aircraft maintenance or overhaul operations.

A-4-1.5.1 While Chapter 5 of NFPA 407 does not allow fuel transfer piping to be located in a building, NFPA 407 does not apply to aircraft fuel system maintenance operations. (*See Section 1-1 of NFPA 407, Standard for Aircraft Fuel Servicing*.) This document, NFPA 410, covers aircraft fuel system maintenance, and the provisions of 4-1.5.1 allow the fuel transfer piping to extend into a hangar for aircraft fuel system maintenance operations provided that it is protected as stated.

A-4-1.7

Aircraft that are brought into a heated hangar from a cold outdoor atmosphere should be carefully watched for fuel expansion, because normalization to ambient temperature can take several hours.

A-4-2

Air ventilation of aircraft fuel tanks is recommended for the sole purpose of rendering the atmosphere in an aircraft fuel tank more suitable for personnel to enter the tank area for inspection or work purposes. This basically requires reducing the fuel tank vapors to below a predetermined toxic threshold (unless respiratory protection is provided) and below the predetermined lower flammability limits of the flammable vapors and, then, maintaining this condition throughout the period of inspection or work. Air ventilation is not a method of inerting an aircraft fuel tank, and this distinction must be clearly understood.

Air ventilation should be accomplished by exhausting the fuel tank atmosphere of toxic and flammable concentrations of fuel vapors through a specified vapor exhaust system with or without a blower designed to augment the sweeping of the fuel vapors from the tank. The design of the air ventilation system used on any particular aircraft must be tailor-engineered to satisfy the requirements of the aircraft in question, and detailed specifications will be required for each fuel tank configuration to properly achieve these objectives.

When using air ventilation procedures, there might be times when the fuel vapor-air mixture in the tank will be within the flammability range. During such periods, a fire and explosion hazard exists. It is thus vitally important that there be no ignition sources within the tank or within reach of the vapors being discharged from the tank.

Successful use of air ventilation depends heavily on three basic factors:

(a) Complete drainage of the fuel tank to be treated, including siphoning, sponging, or mopping up of fuel residues that might be trapped in the tank. During the latter operations, extreme caution is necessary to prevent accidental ignition of the vapors that will be present.

Fuel vapor concentrations must be maintained below 20 percent of lower flammable limit.

(b) Establishment of adequate air circulation through the tank to assure that the air movement rids the entire tank volume of hazardous quantities of fuel vapors. This requires tests on each tank configuration to establish the correct tank openings required, the rate of air movement, and the time needed. Such tests should include combustible vapor measurements of the entire tank volume to assure that no hazardous vapor pockets remain, especially in tank corners that might not be properly air ventilated if the air currents established by the exhaust and/or blower systems are ineffective.

(c) Continuation of air ventilation during the entire period that the tanks are open and any work is being done.

Under some conditions (particularly in integral-type fuel tanks having sealing compounds at tank joints and in baffled tanks where drainage through baffles might not be efficient), it is possible to reinstate a flammable fuel vapor-air concentration after initial ventilation has secured a satisfactory condition. Where flammable solvents are used to remove or replace sealant or where fuel vapors are released by the breaking of sealing compound blisters, a localized toxic or flammable vapor atmosphere can be created. To minimize this type of hazard, nonflammable solvents should be used wherever possible. Periodic checks should be made with a combustibles detector or other appropriate instrument in the area of work to assure the maintenance of a safe tank atmosphere.

The periodic checks are to check any unusual conditions that might develop and to help maintain a fire safety consciousness among the employees involved in fuel tank maintenance work.

Example Procedure, Air Ventilation (Enclosed Aircraft Hangar). This example procedure is illustrative of one method only and can be altered as required for different situations and conditions. However, these principles should be followed.

(a) Place the aircraft in the proper position in the hangar with fuel tanks drained, residual fuel mopped up, and the proper underwing tank plates removed; where possible, air ventilation should have been started outdoors and a satisfactory combustible instrument reading indicating a nonhazardous tank atmosphere secured.

(b) Guard against static spark hazards by electrically bonding and grounding exhaust equipment and the aircraft to be ventilated. If ducting is used, connect a static bonding wire from each exhaust hose nozzle to the aircraft before opening the fuel tank(s).

(c) When a closed ventilating system (*see 4-2.10*) is used, connect the prearranged exhaust system to an explosionproof exhaust fan designed to extract air at a specific rate. (Airflow must be calibrated for each tank volume and configuration to assure effective fuel vapor removal.)

NOTE: It cannot be assumed that a high rate of airflow through a tank will be more efficient than a moderate rate. Complete sweeping of the tank volume is desired without bypassing corners or creating excessive turbulence.

(d) When portable air movers or blowers are used, place this equipment in position, secure the equipment, and, for exhaust systems, seal around tank attachment. When ducting is used with air-moving equipment to help sweep vapors from the tank, bond the ducting (if conductive) to the aircraft and pressurize the ducting before making a tight connection around attachment openings. Having a positive pressure in the ducting should prevent any flammable vapors from entering the ducting that might ignite by a source of ignition in the air-moving equipment. The air introduced into the tank through the ducting should be clean and should not contain any entrained dust, moisture, or flammable vapors. When exhaust ducts are used, the air should be exhausted to a location not containing any ignition source and to a point outside the hangar or building.

(e) Maintain the ventilation for the time prescribed to achieve a safe atmosphere within the tank (*see 4-2.5*) and during all tank maintenance work. Check the actual conditions periodically with the combustibles detector.

(f) Halt tank maintenance operations when any unsafe condition develops, and do not resume operations until a safe condition is restored. (*See 4-2.10.*)

(g) When work has been completed, remove ventilating equipment. When ducts are used, remove the exhaust nozzles from the tank(s) leaving the exhaust fan operating and static bonding wire(s) attached. Replace tank caps or plates. Allow the exhaust fan to run for three or four minutes to permit removal of all vapors from the ducts. Disconnect the static bond wires from the aircraft and turn off the exhaust fan.

A-4-2.9

Where such facilities are available and practical, hangar docks (open-faced structures) are preferable to enclosed hangars for the balance of the air ventilation procedure.

A-4-2.17

See A-4-1.7.

A-4-2.20

(c) **Warning!** The reliance placed on combustible vapor detectors requires great care in the selection of the proper instrument and thorough knowledge of its capabilities and limitations. Expert maintenance is normally required. Only persons specially trained in the use of the instruments selected and in interpreting the measurements secured should be relied on to perform the required tests.

A-4-3.20

The designation integral fuel tank is confined to fuel containers whose boundaries are made up of as nearly 100 percent primary structure as possible, primary structure being the elements of the aircraft that carry the major stresses of flight, such as stressed skin, spar caps, spar webs, etc. Integral fuel tanks can be either part of the wing or the fuselage. Integral fuel tanks discussed here are confined to the types that are basically without gasket materials installed in the seams, the structural cavities being made fuel-tight by the installation of a sealing material after the completion of fabrication of the unit where the tank is located.

Example Procedure. The example procedure detailed herein might have to be altered under certain conditions depending on aircraft design factors and the fuel tank configuration.

(a) Place the aircraft in the proper position in the hangar dock or hangar building with fuel tanks, fuel lines, and cross-feed system drained as required. Consideration should be given to cross-feed and selector valve positions to obtain the desired isolation of fuel within the system.

(b) Suitable warning signs should be placed in conspicuous locations around the aircraft to indicate that tank repairs and air ventilation are in progress.

(c) Guard against static spark hazards by electrically grounding the aircraft to be repaired.

(d) Attach air movers or blowers to the exhaust system, seal around tank attachments, and electrically bond to the aircraft. For blower system, remove the necessary tank door and insert the exhaust hose nozzle, bond, and ground as necessary to guard against static spark hazards.

(e) Maintain ventilation for the time prescribed to achieve a safe atmosphere within the tank and during all tank repair work. Check the actual conditions periodically with the combustible gas detector and maintain frequent verbal contact with personnel within tanks. (*See 4-2*.)

(f) Remove additional tank access doors when necessary to effect repairs. Such removal can expose additional quantities of trapped or residual fuel. When such is the case, applicable precautions, as outlined in the text, should be followed.

A-4-3.20.1 Removal of sealant and cleanup of the area to be resealed often requires considerable agitation of the solvent or stripper. When flammable solvents or strippers are used for this operation, it becomes imperative that extreme caution be exercised to eliminate all possible ignition sources. To minimize this type of hazard, nonflammable solvents should be used whenever possible, recognizing, however, that nonflammable solvents might be more toxic.

A-4-3.20.3 Application of top coating by spray method is not recommended.

A-4-3.21

The designation "bladder tank" includes both collapsible and self-sealing tanks. The bladders themselves are of a special synthetic rubber and fabric material. Normally these cells have a fairly low melting point and change pliability with relatively small changes in temperature. Pliability is a critical quality in the fuel cell material. A plasticizing agent is compounded into the synthetic rubber to keep it pliable. Fuel tends to extract the plasticizing agent; however, this is not detrimental since fuel itself keeps the material pliable.

Example Procedure. The example procedure detailed herein might have to be altered under certain conditions depending on aircraft design factors and the type of bladders being repaired.

(a) Place the aircraft in the proper position in the hangar dock or hangar building with fuel tanks, fuel lines, and cross-feed system drained. Consideration should be given to cross-feed and selector valve positions to obtain the desired isolation of fuel within the system.

(b) Suitable warning signs should be placed in conspicuous locations around the aircraft to indicate that fuel system repairs and air ventilation are in progress.

(c) Guard against static spark hazards by grounding the aircraft.

(d) Remove the access doors and open the fuel cells.

(e) Attach the ventilation system and maintain for the time prescribed to achieve a safe atmosphere within the tank and until the cell is ready for removal. Check the actual conditions periodically with a combustible gas detector. (*See 4-2*.)

NOTE: Turbine-powered aircraft are most frequently fueled with Type A (kerosene) fuel. The use of a combustible vapor detector can be recommended only to detect the possible mixtures of lower flash point Type

B turbine fuels or aviation gasoline.

(f) Remove all of the equipment, lines, etc., and detach the cell from the fuel cell cavity. Prior to the removal of the cell, all equipment, pumps, lines, etc., should be removed, and any residual fuel remaining in the cell should be siphoned out or manually sponged or mopped up from cell low points.

(g) Collapse the cell and remove from the aircraft.

(h) After removal of the cell, the cell cavity should be checked with a combustible gas detector to be certain that a safe condition exists.

(i) Transport the cell to the repair area and preserve in accordance with the manufacturer's recommendations.

A-4-3.21.1 It is recommended that aircraft be segregated or isolated during the time fuel cells are being removed.

A-4-3.22

The term "metal tanks" applies to all types of metal fuel containers, including surge and vent tanks that can be removed from the aircraft for shop or bench repair, but does not include metal fuel containers that are an integral part of the aircraft that can, under certain major overhaul conditions, be removed from the primary portion of the airframe.

A-4-4.6

See A-4-1.7.

A-5-1.3 Paint Removal.

(a) Polyurethane paint systems consisting of an epoxy coat and a polyurethane topcoat have been widely used in the aerospace industry. One phase of the aircraft surface conditioning requires solvent wipe-down just before applying the epoxy primer. This solvent could be methyl ethyl ketone or aliphatic naphta, both of which have low flash points and require safeguards of proper ventilation and control of ignition sources to reduce the incidence of fire.

(b) Walkway coatings are applied to internal and external areas of aircraft that are normally walked upon frequently by personnel. It is used to protect the metal surface and to provide a safe footing for personnel. This paint system is suitable for brush or roller application, but the thinner most used is xylene with a flash point less than 100°F (38°C), which requires the appropriate fire hazard safeguards.

(c) In the aerospace industry the low flash point paint removers have largely been replaced by self-extinguishing water-rinsable type with a low fire hazard.

A-5-2.1

All areas used for paint finishing should be provided with mechanical ventilation discharging to the outside atmosphere of such capacity to permit between 20 to 30 air changes per hour by volume. Exhaust from spray booths should be of such capacity as to provide an airflow of not less than 250 linear ft per min (76.2 m/min). Air exhausted from spraying operations should not be circulated. Exhaust ducts should pass directly through the nearest outside wall or through the roof. Ducts should not pass through fire walls or the floor. Air intake should be from the outside atmosphere (through steam blast coils where necessary). Air intake should be from other areas provided the atmosphere does not contain flammable vapor or residue. Air intake openings should be protected with automatic dampers that close in the event of a fire. Hangar ventilation will reduce human respiratory hazard, but dermatic hazard, eye hazard, and other protective health measures should also be considered. See also NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, and NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

A-5-2.3

See NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*, for applicable data.

A-5-5.3

When aircraft maintenance platforms are used in the painting operation, they should be bonded to the aircraft. Cables used for grounding painting equipment such as metal tables, racks, tanks, maintenance stands, etc., should be attached in such a manner that they cannot be disconnected or broken if the equipment is accidentally moved.

A-5-5.4

Hangar and shop floors should be protected from fuel, oil, and other spillage through the use of drip trays or collection containers.

A-5-5.5

Cigarette lighters and matches should not be carried by personnel.

A-6-1.1

The chapter covers the welding of aircraft by the gas-shielded arc method. Welding operations other than those on aircraft should conform to NFPA 51, *Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes*; NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*; and ANSI Z49.1, *Safety in Welding and Cutting*.

Occasionally it is necessary to stress-relieve certain portions of the aircraft engines or structures by normalizing through the use of an oxyacetylene flame. Silver soldering is also required on certain electrical connections and fluid lines. The same basic precautions outlined herein should apply to these operations.

NFPA 51B, *Standard for Fire Protection in Use of Cutting and Welding Processes*, gives the basic rules for cutting and welding processes using electric arcs or oxy-fuel flames.

NFPA 51, *Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes*, applies to the installation and operation of all gas welding and cutting systems. Structural welding in hangars should follow the procedures outlined in NFPA 51 and NFPA 51B. It is recommended that any contract to perform structural or general welding in a hangar take special note of the hazard to the contents. Aircraft should be removed wherever possible and the precautions herein applied as applicable.

A-6-1.4

A-6-2.4

Streamers should be attached to covered vents and promptly removed after completion of the welding operation.

A-7-1.1 Nonflammable Agents and Solvents.

(a) In selecting nonflammable agents, care should be exercised to assure that a toxicity hazard is not introduced that cannot be effectively controlled by practical protective means under normal working conditions. While health hazards are outside the scope of this standard, a number of effective nonflammable cleaning agents (e.g., carbon tetrachloride) do present a serious toxicity problem. Industrial hygienists and safety professionals as well as fire protection engineers should be consulted before selecting any cleaning agent or solvent for this use.

(b) Types of Nonflammable Agents and Solvents.

1. *Detergents and Soaps*. These have widespread application for most aircraft cleaning operations involving fabrics, headliners, rugs, windows, and similar surfaces that are not easily damaged by water solutions because they are colorfast and nonshrinkable. Care should be taken to prevent leaching of water-soluble fire-retardant salts that might have been used to treat such materials in order to reduce their flame spread characteristics.

2. *Alkaline Cleaners*. Most of these agents are water soluble and thus have no fire hazard properties. They can be used on fabrics, headliners, rugs, and similar surfaces in the same manner as detergent and soap solutions with only minor added limitations resulting from their inherent caustic characteristics that might increase their efficiency as cleaning agents but result in somewhat greater deteriorating effects on certain fabrics and plastics.

3. *Acid Solutions*. A number of proprietary acid solutions are available for use as cleaning agents. They are normally mild solutions designed primarily to remove carbon smut or corrosive stains. As water-based solutions, they have no flash point but should require more careful and judicious use, not only to prevent damage to fabrics, plastics, or other surfaces, but also to protect the skin and clothing of those using the materials.

4. *Deodorizing or Disinfecting Agents*. A number of proprietary agents useful for aircraft interior deodorizing or disinfecting are nonflammable. Most of these are designed for spray application (aerosol type) and have a nonflammable pressurizing agent, but check this carefully as some might contain a flammable compressed gas for pressurization.

5. *Abrasives*. Some proprietary nonflammable mild abrasive materials are available for rejuvenating painted or polished surfaces. They present no fire hazard.

6. *Dry-Cleaning Agents*. Perchlorethylene and trichlorethylene, as used at ambient temperatures, are examples of nonflammable dry-cleaning agents. These materials do have a toxicity hazard requiring care in their use. Fire-retardant-treated materials might be adversely affected by the application of these agents as can water-soluble agents.

A-7-1.2

The Underwriters Laboratories Inc. Gas and Oil Equipment List contains a listing of liquid products classified by fire hazard. *Flash Point Index of Trade Name Liquids* gives important details on the fire hazard properties of some 8,800 trade name liquids (including cleaning agents) commonly used in the United States and Canada. See NFPA 325, *Fire Hazard Properties of Flammable Liquids, Gases, and Volatile Solids*, for a complete listing.

A-7-3.1

All-purpose (ABC) dry chemical-type extinguishers should not be used in situations where aluminum corrosion is a problem.

A-8-2.1

At least one portable extinguisher having a rating of not less than 20-B and a minimum capacity of not less than 15 lb (6.8 kg) should be provided on mobile service equipment including:

(a) Air conditioning units;

(b) Aircraft tractors;

(c) Air starter units;

(d) Cabin service trucks;

(e) Catering trucks;

(f) Container loaders;

(g) De-icer trucks;

(h) Engine driven passenger loading steps;

(i) Ground power units;

(j) Mobile lounges.

In those vehicles classified in (d), (e), (g), (h), and (j), consideration should be given to placing an extinguisher on both the chassis and the elevated section of the vehicle.

At least one portable extinguisher having a rating of not less than 5-B and a minimum capacity of 3 lb (1.5 kg) should be provided on other miscellaneous motorized vehicles that operate within 25-ft (8-m) radius of any part of the aircraft.

A-8-3.1

When an aircraft lands with a suspected fire or smoke warning in a cargo hold, the fire department should be informed immediately and a full passenger evacuation of the aircraft should be carried out before any hold door is opened. Hold doors should not be opened until the fire department is in attendance at the aircraft.

Failure to observe this recommendation could result in an in-rush of air into the hold, which could cause the fire to erupt, creating danger if passengers or crew are still onboard the aircraft.

A-8-3.2

When a fire is discovered in an aircraft, immediate action should be taken to extinguish it, with either the fire extinguishers available in the aircraft or those situated on the ramp. The fire department should be informed immediately.

In some instances, it might not be possible to extinguish the fire, or alternatively, the fire might have developed to a point where the readily available fire extinguishers are inadequate. If so, the progress of the fire and the damage caused can be reduced by vacating the aircraft and closing all doors, hatches, etc.

A-8-3.3

When dealing with aircraft wheel fires, approach should be made from a fore or aft direction and never from the side. The heating of aircraft wheels and tires presents a potential explosion hazard, greatly emphasized when fire is present. It is important not to mistake hot brakes for brake fires. Hot brakes will normally cool by themselves, or with the assistance of an air cooling appliance, without the use of an extinguishing agent.

Since the heat is transferred to the wheel from the brake, it is essential that the extinguishing agent be applied to the brake area. Once the fire has been extinguished, further extinguishing agent should not be discharged for cooling purposes.

Too rapid cooling of a hot wheel, especially if localized, can cause explosive failure of the wheel. Solid streams of water or carbon dioxide should not be used. Halon 1211 is an effective extinguishing agent for wheel fires. Dry chemical has a limited cooling effect, but is an effective extinguishing agent.

NFPA 412

1993 Edition

Standard for Evaluating Aircraft Rescue and Fire Fighting

Foam Equipment

1993 Edition

This edition of NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc. at its Annual Meeting held May 24-27, 1993, in Orlando, FL. It was issued by the Standards Council on July 23, 1993, with an effective date of August 20, 1993, and supersedes all previous editions.

The 1993 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 412

Work on this material started in 1955 when the NFPA Subcommittee on Aircraft Rescue and Fire Fighting (as then constituted) initiated a study on methods of evaluating aircraft rescue and fire fighting vehicles. A tentative text was adopted by the Association in 1957 and a revised text officially adopted in 1959. Revisions were made in 1960, 1964, 1965, 1969, 1973, and 1974. With the introduction of new types of foam liquid concentrates over the years for this specialized service, the text has been broadened to cover these concentrates.

In 1987 the standard was completely revised to bring it into conformance with the *Manual of Style* and to refine the test methods.

The 1993 edition of the standard establishes a single test method for expansion and drainage for all foams (previously there were two). Additionally, information on using the conductivity meter for determining foam solution concentration was added.

The following task group was appointed to assist in the 1993 revision of this standard:

Task Group on Evaluating Foam Fire Fighting Equipment on Aircraft Rescue and Fire Fighting Vehicles

Joseph L. Scheffey, Chair, Hughes Associates Inc., MD; William M. Carey, Underwriters Laboratories Inc., IL; Robert L. Darwin, Dept. of the Navy — Fire Protection Div., DC; James F. O'Regan, Westboro, MA; John M. Schuster, 3M Company, MN

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for the criteria for aircraft rescue and fire fighting services and equipment, procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. The Committee also shall have responsibility for developing aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 412
Standard for
Evaluating Aircraft Rescue and
Fire Fighting Foam Equipment

1993 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.

Information on referenced publications can be found in Chapter 5.

Chapter 1 Administration

1-1 Scope.

1-1.1

This standard establishes test procedures for evaluating the foam fire fighting equipment installed on rescue and fire fighting vehicles designed in accordance with the applicable portions of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*.

1-2 Purpose.

1-2.1

The tests specified in this standard provide procedures for the evaluation of foam fire fighting equipment in the field to determine compliance with NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, and NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*.

1-3 Definitions.

Foam. An aggregation of small bubbles used to form an air-excluding, vapor-suppressing blanket over the surface of a flammable liquid fuel.

Foam, Alcohol-Resistant. Used for fighting fires involving water soluble materials or fuels that are destructive to other types of foams. Some alcohol-resistant foams may be capable of forming a vapor-suppressing aqueous film on the surface of hydrocarbon fuels.

Foam, Aqueous Film Forming (AFFF). A concentrated aqueous solution of one or more hydrocarbon or fluorochemical surfactants that forms a foam capable of producing a vapor-suppressing aqueous film on the surface of hydrocarbon fuels. The foam produced from AFFF concentrates is dry-chemical compatible and is therefore suitable for use in combination with that agent.

Foam Concentrate. A concentrated liquid foaming agent that is mixed with water and air in designated proportions to form foam.

Foam Drainage Time (Quarter Life). The time in minutes that it takes for 25 percent of the total liquid contained in the foam sample to drain out from the foam.

Foam Expansion. The ratio between the volume of foam produced and the volume of solution used in its production.

Foam, Film Forming Fluoroprotein (FFFP). A protein-based foam concentrate incorporating fluorinated surfactants that forms a foam capable of producing a vapor-suppressing aqueous film on the surface of hydrocarbon fuels. This foam may show an acceptable level of compatibility with dry chemicals, and may be suitable for use with those agents.

Foam, Fluoroprotein (FP). A protein-based foam concentrate, with added fluorochemical surfactants, that forms a foam showing a measurable degree of compatibility with dry chemical extinguishing agents and an increase in tolerance to contamination by fuel.

Foam Pattern. The ground area over which foam is distributed during the discharge of a foam-making device.

Foam, Protein (P). A protein-based foam concentrate that is stabilized with metal salts to make a fire-resistant foam blanket.

Foam Solution. The solution that results when foam concentrate and water are mixed in designated proportions prior to aerating to form foam.

Foam Stability. The degree to which a foam resists spontaneous collapse or degradation caused by external influences such as heat or chemical action.

Foam Weep. That portion of foam that is separated from the principal foam stream during discharge and falls at short range.

Heat Resistance. The property of a foam to withstand exposure to high heat fluxes without loss of stability.

Shall. Indicates a mandatory requirement.

Should. This term, as used in the Appendix, indicates a recommendation or that which is advised but not required.

Chapter 2 Rescue and Fire Fighting Vehicle Foam Production Performance Testing

2-1 Foam and Foam System Tests.

2-1.1

The expansion and 25 percent drainage time are the foam characteristics that shall be determined. Additionally, the foam concentration shall be determined, both as a test of the vehicle proportioning system, and to establish the legitimacy of the expansion and drainage data obtained. Foam distribution patterns shall be determined for use in calculating the area of fire that the vehicle is capable of controlling.

2-2 Turret Nozzles.

2-2.1

The foam distribution patterns shall meet the requirements of 2-15.6.3 for major RFF vehicles, 3-13.9.3 for rapid intervention vehicles, and 4-13.9.3 for combined agent vehicles of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, when tested as specified in Section 4-1 of this standard.

2-2.2

Foam samples shall be obtained by the methods given in 4-3.1.2 of this standard.

2-2.3

Foam samples shall be analyzed for expansion and drainage time using the method specified in Section 3-1 of this standard.

2-2.4

Foam samples shall be analyzed for concentration as specified in Section 3-2 of this standard.

2-3 Ground Sweep Nozzles.

2-3.1

The foam distribution patterns shall meet the requirements of 2-15.8.1 of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, when tested as specified in Section 4-2 of this standard.

2-3.2

Foam samples shall be obtained by the methods given in 4-3.1.2 of this standard.

2-3.3

Foam samples shall be analyzed for expansion and drainage time using the method specified in Section 3-1 of this standard.

2-3.4

Foam samples shall be analyzed for concentration as specified in Section 3-2 of this standard.

2-4 Hand Line Nozzles.

2-4.1

The foam distribution patterns shall meet the requirements of 2-15.7.3.3 for major RFF vehicles, 3-13.10.2.3 for rapid intervention vehicles, and 4-13.10.2.3 for combined agent vehicles of NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, when tested as specified in Section 4-2 of this standard.

2-4.2

Foam samples shall be obtained by the methods given in 4-3.1.2 of this standard.

2-4.3

Foam samples shall be analyzed for expansion and drainage time using the method specified in Section 3-1 of this standard.

2-4.4

Foam samples shall be analyzed for concentration as specified in Section 3-2 of this standard.

2-5 Undertruck Nozzles.

2-5.1

The foam distribution pattern shall provide protection for the area beneath the vehicle.

2-5.2

Foam samples shall be collected and analyzed for concentration as specified in Section 3-2 of this standard.

Chapter 3 Performance Criteria

3-1 Expansion Ratio and Drainage Time Requirements.

Foams shall be tested as specified in 4-3.2 of this standard and shall meet at least the performance requirements specified in Table 3-1 of this chapter.

Table 3-1 Foam Quality Requirements

Foam Agents	Minimum Expansion Ratio	Minimum Solution 25% Drainage Time in Minutes
AFFF Air-Aspirated	5:1	2.25
FFFP Air-Aspirated	5:1	2.25
AFFF Non- Air-Aspirated	3:1	0.75
FFFP Non- Air-Aspirated	3:1	0.75
Protein	8:1	10
Fluoroprotein	6:1	10

3-2 Foam Solution Concentration.

3-2.1

Foam solution concentration shall be tested in accordance with Section 4-4 of this standard.

3-2.2*

For nominal 6 percent concentrates, the concentration shall be between 5.5 and 7.0 percent for turret and ground sweep nozzles, and between 5.5 and 8.0 percent for hand line and undertruck nozzles.

3-2.3

For nominal 3 percent concentrates, the concentration shall be between 2.8 and 3.5 percent for turret and ground sweep nozzles, and between 2.8 and 4.0 percent for hand line and undertruck nozzles.

Chapter 4 Test Methods and Calculations

4-1 Turret Ground Pattern Test.

4-1.1

Prior to the start of the tests, the water tank shall be full, the foam concentrate tank shall be full with the type of foam concentrate to be used during the actual emergencies, and the proportioner shall be set for normal fire fighting operation. For premixed systems, the tank shall be full with the premixed solution in the correct proportion for normal fire fighting operations.

4-1.2*

Discharge tests shall be conducted to establish the fire fighting foam discharge patterns produced and the maximum range attainable by the turret nozzle. The test shall be conducted under wind conditions of 5 mph or less. To determine maximum discharge range, the turret nozzles shall be tilted upward to form a 30-degree angle with the horizontal.

4-1.3

Foam shall be discharged onto a paved surface for a period of 30 seconds at the specified pressure, in both the straight stream and fully dispersed nozzle settings. Immediately after foam discharge has stopped, markers shall be placed around the outside perimeter to preserve the identity of the foam pattern as it fell on the ground. For purposes of defining the edge of the pattern, any foam of less than $^{1}/_{2}$ inch in depth shall be disregarded. Distances between markers shall be plotted on graph paper. The vertical axis shall show the reach, and the horizontal axis shall show the pattern width for each nozzle setting. The distance from the nozzle to the end of the effective foam pattern shall be measured and plotted on the graph paper.

4-2 Ground Sweep and Hand Line Nozzle Tests.

4-2.1

Ground sweep nozzles and hand line foam nozzles shall be discharged onto a paved surface for a period of 30 seconds.

4-2.2

Ground sweep nozzles shall be discharged from their fixed positions.

4-2.3

Hand line nozzles shall be held at their normal working height and tilted upward to form a 30-degree angle with the horizontal.

4-2.4

Markers shall be set out to denote the outline of the effective foam pattern and plotted, as described under the turret test in 4-1.3.

4-2.5

Patterns from both the straight stream and the fully dispersed nozzle settings shall be established, measured, and recorded.

4-3 Foam Tests.

4-3.1 General Requirements for All Test Methods.

4-3.1.1 The tests shall be conducted with the temperature of the water or foam solution in the range of 60°–80°F (16°–27°C).

4-3.1.2 The following corrections shall be applied to protective foams:

Expansion: If the solution temperature is higher than 70°F, no correction shall apply. If the temperature is lower than 70°F, 0.1 unit of expansion shall be added for each 3°F below 70°F.

Drainage Time: If the solution temperature is higher than 70°F, 0.1 minute shall be added for each 3°F above 70°F. If the solution temperature is lower than 70°F, 0.1 minute shall be subtracted for each 3°F lower than 70°F.

4-3.1.3 Foam samples selected for analysis shall be representative of the foam produced by the nozzle as it would be applied onto the fire hazard. This shall be accomplished by placing a foam sample collector in the center of the ground pattern as determined in the nozzle pattern test.

4-3.2 Test Method.

4-3.2.1 Foam Sampling Apparatus.

4-3.2.1.1 The object is to obtain a sample of foam that is typical of that to be applied to the burning fuel surface under anticipated fire conditions. The foam collector shall be constructed as specified in Figure 4-3.2.1.1.

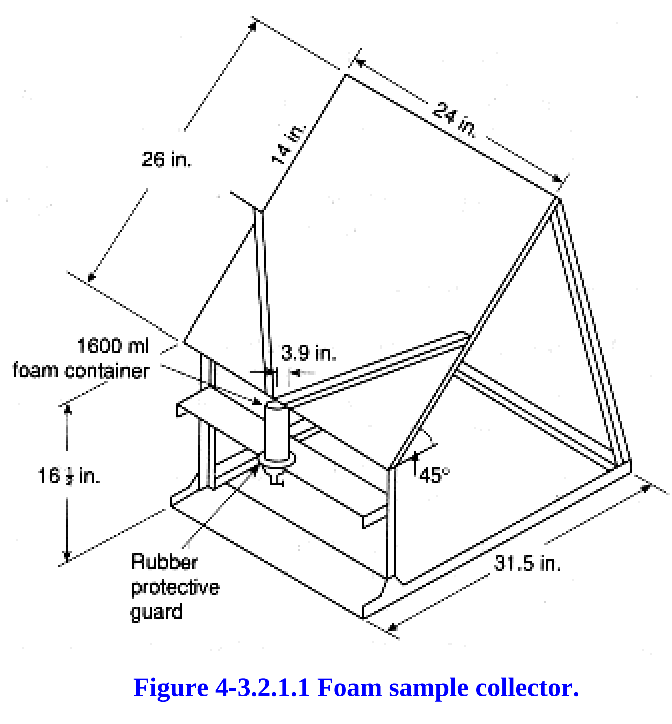

Figure 4-3.2.1.1 Foam sample collector.

4-3.2.1.2 The foam sample shall be collected in a cylindrical 1600-ml container. The foam sample container shall be constructed as specified in Figure 4-3.2.1.2.

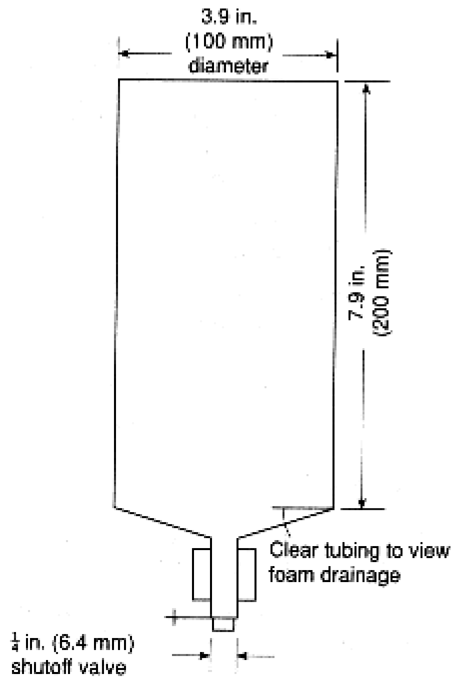

Figure 4-3.2.1.2 1600-ml foam sample container.

4-3.2.2 Test Procedure.

4-3.2.2.1 The empty weight of the foam sample container shall be recorded to the nearest gram on a balance having a maximum capacity sufficient to weigh the foam sample container, on a suitable support, and the foam sample. The foam sample collector shall then be located in the center of the discharge pattern determined in Section 4-1 of this standard. The foam sample container shall be positioned at the bottom of the foam collector so that the foam hitting the collector will flow into the container. The foam nozzle shall be aimed off the side of the foam collector, adjusted to its normal operating pressure, and then moved so as to discharge foam onto the foam sample collector. As soon as the foam sample container has been completely filled with foam, the discharge nozzle shall be shut off and the timing of the 25 percent drainage started.

4-3.2.2.2 The foam sample container shall be removed from the base of the foam collector, excess foam struck off the top of the foam container using a straight edge, and any remaining foam wiped from the outside surface of the container. The container shall then be placed on the balance. The total weight of the foam sample and container shall be determined to the nearest gram. The weight of the foam sample in the container shall be determined by subtracting the weight of the empty container from the weight of the container filled with the foam. The weight of the foam sample in grams shall be divided by four to obtain the equivalent 25 percent drainage volume in milliliters.

4-3.2.2.3 The foam sample container shall then be placed on a suitable support and a graduated cylinder placed below the drain spout. At 30-second intervals, the accumulated solution in the bottom of the foam sample container shall be drawn off into a graduated cylinder and the amount recorded. If the expected expansion ratio is more than 5:1, then a 100-ml graduated cylinder shall be used to collect the drainage, and if the expected expansion ratio is 5:1 or less, then a 250-ml graduated cylinder shall be used.

4-3.2.2.4* Foam samples shall be weighed to the nearest gram. The expansion of the foam shall be calculated by the following equation:

$$\text{Expansion: } = \frac{1600 \text{ ml}}{\text{full weight minus empty weight in grams}}$$

4-4 Foam Solution Concentration Determination.

4-4.1*

A hand-held refractometer or conductivity meter shall be used to measure the refractive index or conductivity of the solution, from which the solution concentration may be calculated. Special care shall be taken when determining the concentration of AFFFs by means of refractive index due to the very low refractive index exhibited by these products.

4-4.2

A calibration curve shall be prepared using the following apparatus:

(a) three 100-ml graduates

(b) one measuring pipette (10-ml capacity)

(c) one 100-ml beaker

(d) one 500-ml beaker.

(e)* one hand-held refractometer — American Optical Co. Model No. 10430 or equivalent; or one hand-held conductivity meter — Omega Model CDH-70 or equivalent.

4-4.3*

Using water and foam concentrate from the tanks of the vehicle to be tested, three standard solutions shall be made up by pipetting into three 100-ml graduated cylinders, volumes of foam concentrate in milliliters equal to:

(a) the nominal concentration of the foam concentrate

(b) $^{1}/_{3}$ more than the nominal concentration

(c) $^{1}/_{3}$ less than the nominal concentration.

The graduated cylinders shall then be filled to the 100-ml mark with the water. After thoroughly mixing, a refractive index reading shall be taken of each standard by placing a few drops of the solution on the refractometer prism, closing the cover plate, and observing the scale reading at the dark field intersection. Or, if using conductivity, the probe shall be dipped into the solution and the digital scale read. A plot shall be made on graph paper of the scale reading against the known foam solution concentrates and shall serve as a calibration curve for this particular series of foam tests.

4-4.4*

Portions of solution drained out during the previously described drainage test shall be used as a source of test sample for the concentration determination. Refractive index or conductivity readings of the unknown shall be compared to the calibration curve and the corresponding foam solution concentration read from the graph.

4-5 Report of Results of Tests.

4-5.1*

All test reports shall include a statement of the operating conditions, such as pressures, temperatures, wind velocities and direction in relation to vehicle position, and a full description of the materials and equipment used.

Chapter 5 Referenced Publications

5-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

5-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, 1993 edition.

NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, 1990 edition.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

A-3-2.2

The amount of foam concentrate in the solution fed to the foam maker plays an important part, not only in the making of foam with the proper expansion and drainage rate, but also in making a fire-resistant foam. Therefore, it is essential that correct proportioning is maintained and that the concentration meets the required level even if the foam meets the minimum expansion and drainage time values at other levels of concentration.

A-4-1.2

See Figure A-4-1.2 on the following page.

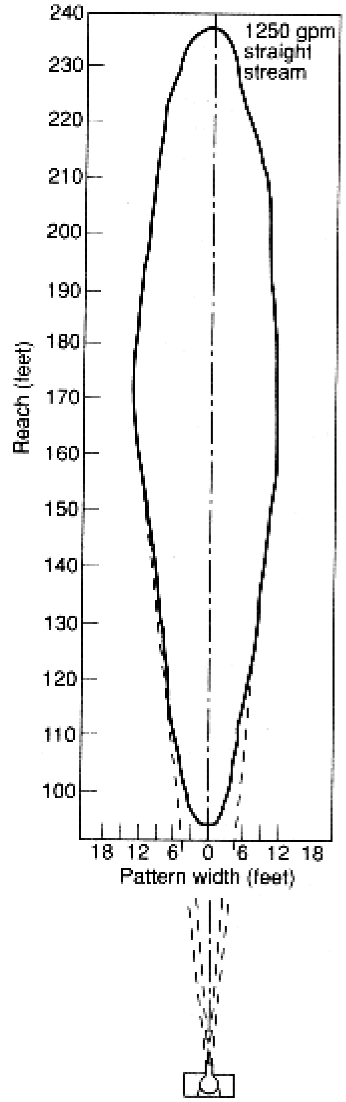

Figure A-4-1.2 Typical foam discharge pattern.

A-4-3.2.2.4 The following shows the calculation of expansion. The net weight of the foam sample (see drainage example) is assumed to be 200 g; therefore, the volume of foam solution contained in the 1600 ml foam sample is 200 ml.

$$\text{Expansion:} = \frac{\text{volume of foam}}{\text{volume of solution}} = \frac{1600\ \text{ml}}{200\ \text{ml}} = 8$$

A-4-4.1

The conductivity method is not recommended where seawater is used for making foam solution.

When the conductivity method is used and samples are to be stored and analyzed at some time other than during testing, clean glass containers should be used to store the samples.

Storage of solution in other types of containers (metal, low density polyethylene) may affect the conductivity reading over a period of time.

Care should be taken that conductivity measurements are made when the water and foam solution are at the same temperature. Small differences in temperature may substantially change conductivity measurements.

The recommended meter automatically compensates for different temperatures. If other meters are used, the instructions for the conductivity meter calibration and temperature compensation should be carefully followed.

A-4-4.2 (e) ATAGO Co. Ltd. Model No. N10, AO Model No. 10441, or equivalent showing 0-10 on the BRIX scale is recommended to enable low readings given by AFFF solutions to be read easily.

A-4-4.3

See Figures A-4-4.3(a), A-4-4.3(b), and A-4-4.3(c).

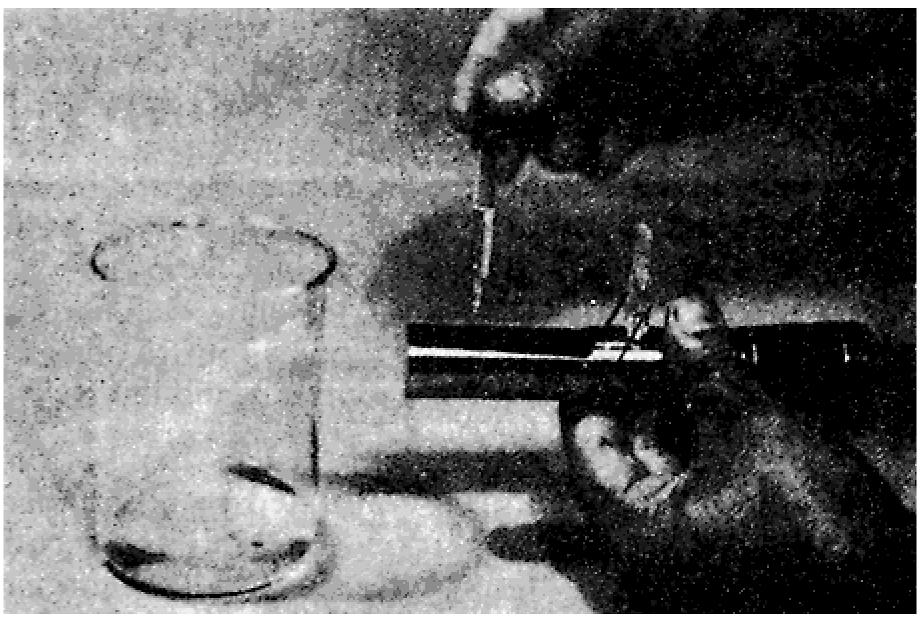

Figure A-4-4.3(a) The index of refraction is measured by placing a few drops of the solution to be tested on the prism of a refractometer and closing the cover plate. This is a typical refractometer suitable for this purpose.

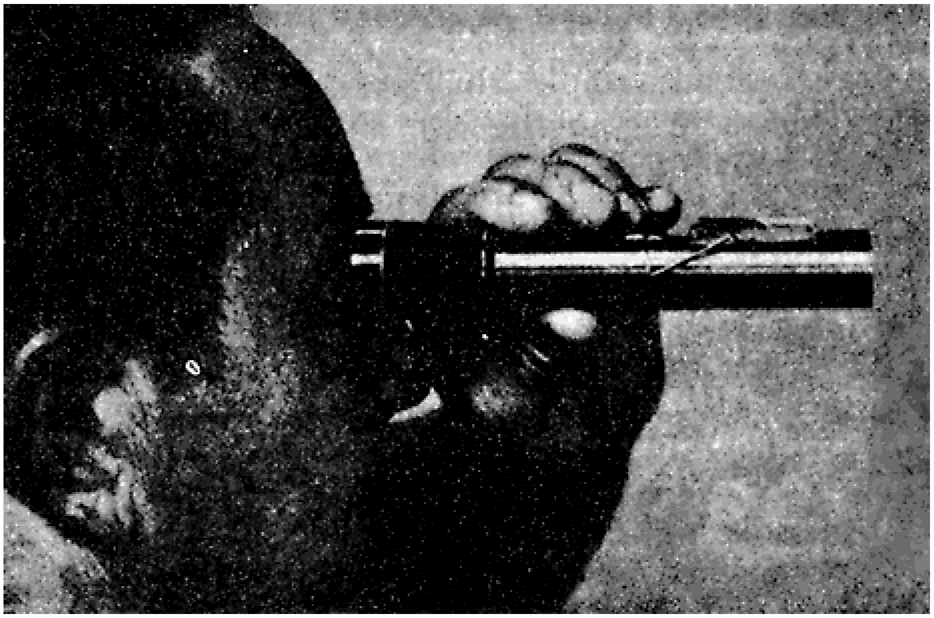

Figure A-4-4.3(b) When this type refractometer is held up to a light source, a reading is taken where the dark field intersects the numbered scale.

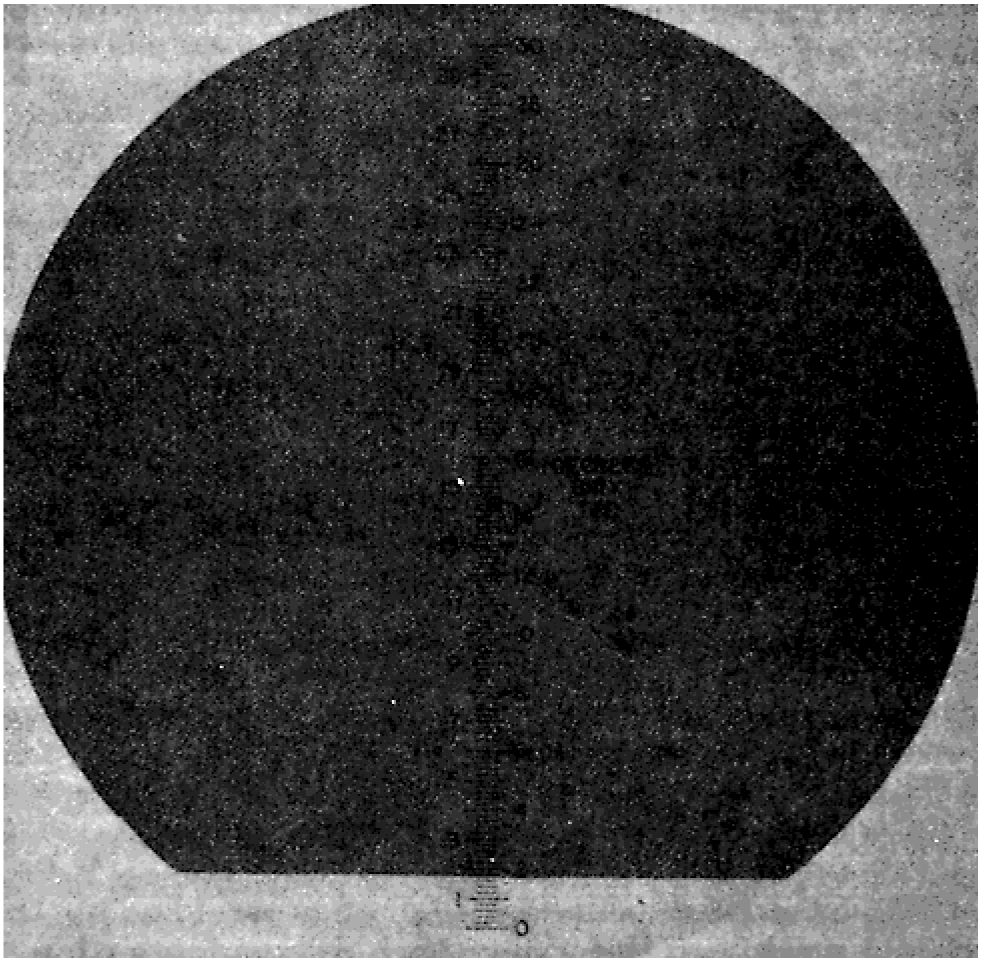

Figure A-4-4.3(c) This illustrates the field of view looking into the refractometer illustrated in Figures A-4-4.3 (a) and A-4-4.3 (b) containing a 6 percent AFFF solution. The dark intersects the scale at 1.7 and this value is recorded as the reading for a 6 percent concentration

A-4-4.4

Because of the high sensitivity of the conductivity meter, it is necessary to collect a larger sample of drainage before making the determination. This will allow for the variation in conductivity of the drained liquid caused by small changes in the chemical composition of AFFF solution as it drains out over a period of time.

Appendix B

This Appendix is not a part of the requirements of this NFPA document, but is included for information purposes only.

B-1 Foam Extinguishing System Capability.

B-1.1

The following is a suggested method for evaluating the basic extinguishing capability of the foam fire fighting system.

B-1.2 Basic Extinguishing Capability.

B-1.2.1 Foam performance is judged on two criteria: (1) ability for quick knockdown of flames, and (2) ability to keep fuel area secure against re-ignition. To obtain meaningful information, it is necessary that the foam be applied at low rates per square foot of fuel surface. This will represent the performance to be expected when the system is pushed to its ultimate capability on a large fire. High application rates will overwhelm the fire and obscure any possible shortcomings. Fire tests sufficiently large to challenge the foam equipment are very costly and difficult to conduct without creating undue environmental problems. Therefore, an attempt is made in this standard to devise a restricted but still significant procedure.

B-1.2.2 A foam vehicle user might utilize the basic test procedure in several ways. For example, it might be desired to establish the minimum rate of foam application at which a fire can be extinguished. By using this rate and the time for extinguishment, the volume of water required to extinguish one unit fire area (square foot or square meter), and the maximum fire area the vehicle is capable of extinguishing, can be calculated. It should be kept in mind, however, that the most efficient use of water lends to long extinguishing times. In practice, a high application rate is required because it gives the most rapid knockdown of flame, although it will be less efficient in terms of agent consumed. Operation of the turret to achieve complete extinguishment also wastes water. Generally, after the fire has been 90 percent extinguished, it is better to shut down the turret and complete the extinguishment by application of foam from handlines or by the application of one of the complementary agents.

B-1.2.3 A user might desire to compare the system used on two different fuels or under several different weather conditions such as high winds, heavy rain, or extreme low temperatures, or with obstacles within the fire area. In this type of testing, care must be taken to change only one variable at a time. All other conditions must remain the same.

B-1.2.4 A user might desire to check the foam used against its “as purchased” condition. Here the tests must be conducted under the same conditions as those prevailing during the original tests.

B-1.3 Turret or Hand Line Extinguishing Tests.

B-1.3.1 The exact size of the fire to be used is not critical; however, it should be not less than 100 ft^2 (10 ft × 10 ft) in area. Large-scale testing has shown that larger fire areas do not necessarily require higher application rates or greater quantities of agent (foam) per unit area.

B-1.3.2 The choice of fuel is optional depending on the data desired. Gasolines are normally the most difficult fuels to extinguish, a Jet A (JP-5) the easiest. Jet B (JP-4) is a variable fuel without a definitive flash point.

B-1.3.3 Water may be used to level a large pit to ensure a level fuel area, and bare ground should be presoaked to prevent the loss of fuel. The amount of fuel to be used is partially dependent on the length of preburn to be allowed. With preburn times of 1 min, at least 1 gal of fuel for each 2 ft^2 of area should be used.

B-1.3.4 Local clean air regulations might dictate the length of preburn as this is the period of greatest smoke generation.

B-1.3.5 Establishing and maintaining the desired rate of foam application will require some work and practice prior to the conducting of the fire test. The object is to sweep the turret or nozzle back and forth over the fire area at an even rate in order to apply the foam at the desired gallons per minute (gpm) per square foot.

B-1.3.6 The actual rate is checked by placing 1 ft^2 (or other known convenient size of known area) shallow pans near the edges of the fire area. After the foam discharge pattern has been swept back and forth over the fire area and pans for a measured period of time, the stream is shut off, the weight of the contents of each pan determined, and the application rate calculated. If the rate was too high, a faster rate and wider angle of sweep will be required and vice versa. Once the proper technique has been worked out, the fire is extinguished in the same manner. The pans can be used during the fire test to verify the application rate. NFPA 403 requires a rate of 0.13 gpm per square foot for AFFF, 0.20 gpm per square foot for protein foam, and 0.18 gpm per square foot for fluoroprotein foam.

B-1.3.7 The following calculations are typical of those used in the determination of the basic extinguishing capability of an aircraft rescue and fire fighting vehicle of 1000 gal water capacity:

Gross weight of pan with collected foam	412 oz
Empty weight of pan	350

Net weight of foam sample	62 oz

$$\text{Water collected} = \frac{\text{foam wt. oz}}{133.3} = \frac{62}{133.3} = 0.465 \text{ gallons}$$

$$\text{Total water applied} = \frac{\text{water collected, gal}}{\text{area of pan, ft}^2} = \frac{0.465}{3.5}$$

$$= 0.133 \text{ gal/ft}^2$$

$$\text{Basic extinguishing capability} = \frac{1000 \text{ gal}}{0.133 \text{ gal/ft}^2}$$

$$= 7600 \text{ ft}^2\text{/1000 gal water}$$

B-1.4 Burnback Test.

B-1.4.1 The resistance of the foam blanket to the fire is important. Wind plays a big role in the determination of this property and repeat results are difficult to obtain with an outdoor test. Another factor, but one easier to control, is the size of the fire area at the start of re-ignition. To standardize this, a short section of stovepipe 12 in. in diameter is dropped into the foam blanket like a cookie cutter. The foam is removed from the inside, and the fuel surface is ignited and allowed to burn for one minute before the stovepipe is removed. The rate of enlargement of the fire is then observed. A long period of confinement is desired. The delay period after end of foam application and start of re-ignition may be varied, but for comparative tests, it must be kept constant.

B-1.4.2 Burnback resistance is related to the amount of foam that has been applied to the fire. A burnback test on a fire area that has been extinguished with a minimum application of foam will not afford a high level of protection.

B-1.4.3 To compare the degree of burnback protection of different agents and depths of foam, and to familiarize crew with the degree of protection afforded, repeated tests using varied delays between end of foam application and start of re-ignition are suggested.

Appendix C Referenced Publications

C-1

The following documents or portions thereof are referenced within this standard for informational purposes only and thus are not considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

C-1.1 NFPA Publication.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, 1993 edition.

NFPA 414

1995 Edition

Standard for Aircraft Rescue and Fire-Fighting Vehicles

1995 Edition

This edition of NFPA 414, *Standard for Aircraft Rescue and Fire-Fighting Vehicles*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 414 was approved as an American National Standard on August 11, 1995.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 414

In 1960, a tentative edition of this standard was adopted by the Association. The original document was further revised in 1962, 1963, 1964, 1965, 1967, 1968, 1969, 1970, 1975, and 1978.

In 1984, the standard was revised completely to identify three types of vehicles and to make the document easier to use. The text also was rewritten to conform with the NFPA *Manual of Style*.

The standard was revised again in 1990, and a chapter was added to provide a test method to verify the design requirements.

Notable revisions to the 1995 edition include the removal of requirements for a separate category of rapid intervention vehicle.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on aircraft rescue and fire-fighting services and equipment, for procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports, with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. This Committee also shall have responsibility for documents on aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

Standard for
Aircraft Rescue and Fire-Fighting Vehicles

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 5 and Appendix E.

Chapter 1 Administration

1-1 Scope.

1-1.1*

This standard specifies the optimum design, performance, and acceptance criteria for aircraft rescue and fire-fighting vehicles intended to carry rescue and fire-fighting equipment for rescuing occupants and combating fires in aircraft on, or in the vicinity of, an airport.

1-1.2

This standard shall cover three types of vehicles as follows:

(a) Major vehicles;

(b) Rapid intervention vehicles; and

(c) Combined agent vehicles.

1-1.3

Vehicles without wheels, such as track, amphibious, or air-cushion types, are not covered by this standard.

1-1.4

The design criteria for the standard vehicles described by this document shall consider temperature extremes ranging from 32°F to 110°F (0°C to 43.3°C). For cold weather operation where temperatures periodically range from -40°F to 32°F (-40°C to 0°C) or lower, some type of winterization system shall be specified by the purchaser.

1-2 Purpose.

1-2.1

The purpose of this standard is to specify features and components that, when assembled, produce an efficient and capable fire-fighting vehicle for both on-pavement and off-pavement performance. Off-pavement capability is important to ensure timely and effective response of these vehicles to aircraft accident sites located off paved surfaces. Fire-fighting capabilities are considered to be optimum for the proper performance of these vehicles.

1-2.2

It is not the purpose of this standard to serve as a detailed purchase specification. Drafting of complete specifications for bidding purposes is the responsibility of the purchaser.

1-3* Definitions.

AFFF. See Aqueous Film-Forming Foam Concentrate.

Aggressive Tire Tread. Tread designed to provide maximum traction for all types of surfaces. These include sand, mud, snow, ice, and hard surfaces, wet or dry.

Air-Cooled Engine. An engine in which the heat produced by the cylinder walls is absorbed directly by the atmosphere rather than by being absorbed by a liquid coolant that acts only as a vehicle for transferring the heat from the engine to a radiator.

Air-Mechanical Brakes. Brakes in which the force from an individual air chamber is applied directly to the friction surfaces through a mechanical linkage.

Air-Over-Hydraulic Brakes. Brakes in which the force of a master air cylinder is applied to the friction surfaces through an intervening hydraulic system.

All-Wheel Drive. A vehicle that drives on all wheels such as described in (b), (d), and (e) under the definition of Vehicle Types.

Ambient Temperature. The average temperature of the environment surrounding a vehicle.

Angle of Approach. The measure of the steepest ramp that a fully loaded vehicle can approach. It is determined by the horizontal ground line and the line tangent to the loaded radius of the front tire extended forward to that fixed point on the vehicle that forms the smallest angle.

Angle of Departure. The measure of the steepest ramp from which the fully loaded vehicle can depart. It is determined by the horizontal ground line and the line tangent to the loaded radius of the rear tire extended rearward to that fixed point on the vehicle that forms the smallest angle.

Approved.* Acceptable to the authority having jurisdiction.

Aqueous Film-Forming Foam (AFFF) Concentrate. A concentrated aqueous solution of fluorinated surfactant(s) and foam stabilizers that is capable of producing an aqueous fluorocarbon film on the surface of hydrocarbon fuels to suppress vaporization.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Automatic Locking Differential. A type of nonslip differential that operates automatically.

Axle Tread. The distance between the center of two tires or wheels on one axle. Where dual tires and wheels are used at each end of an axle, the tread is measured as the distance between centers of the pairs of tires or wheels.

Bogie. A combination of two axles used to support the end of a vehicle; therefore, in a 6 × 6 vehicle, there are two axles at the rear of the vehicle to support the weight on the rear. This two-axle combination is called a “rear bogie.” With an 8 × 8 vehicle, there are two axles in the front and two axles in the rear; therefore, there is a front bogie and a rear bogie.

Center of Gravity. The point within a vehicle at which all of its weight can be considered to be concentrated. Where a vehicle is tipped to such a degree that a vertical line passing through the center of gravity falls on the ground outside the tire track, it is unstable and can turn over.

Chassis. The assembled frame, engine, drive train, and tires of a vehicle.

Component Manufacturer’s Certification. A signed application approval furnished by the component manufacturer that certifies the following:

(a) The component is approved as being properly installed or applied, or both, in the vehicle for its intended use; or

(b) The component complies with the respective construction criteria required by the standard.

Cooling Preheater Device. A device for heating the engine coolant so that the engine is maintained at a constant temperature. It usually consists of a coolant jacket and an electric heating element. The engine coolant flows through the preheater jacket and is heated by the heating element, which obtains its power from an outside source, thereby maintaining the engine coolant at a constant temperature for fast starting.

Dry Nitrogen, Dry Air. Nitrogen or air that has a dew point of -60°F (-51°C) or lower.

Extendable Turret. A device, permanently mounted with a power-operated boom or booms, designed to supply a large-capacity, mobile, elevatable water stream or other fire-extinguishing agents, or both. The operator, while at the scene of the fire, has the ability to reposition the primary turret and attachments to a location that enhances the visibility of and access to hard to reach areas, thus providing the opportunity to utilize fire-fighting agents most effectively.

Fluid Coupling. A turbine-like device that transmits power solely through the action of a fluid in a closed circuit without direct mechanical connection between input and output shafts and without producing torque multiplication.

Fluoroprotein Foam Concentrate. A protein foam concentrate incorporating one or more fluorochemical surfactants to enhance its tolerance to fuel contamination.

Foam Expansion. The ratio between the volume of foam produced and the volume of solution used in its production.

Foam-Liquid Concentrate Percentage. The percentage of foam-liquid concentrate in solution with water.

Fully Loaded Vehicle. A fully loaded vehicle shall consist of the fully assembled vehicle, complete with a full compliment of crew, fuel, and fire-fighting agents. The crew allowance shall be 175 lb (79.3 kg) per seating position. Unless otherwise specified, the equipment allowance shall be 250 lb (113.3 kg) per storage compartment up to a maximum of 1000 lb (453.6 kg). Where the customer specifications require that more equipment shall be carried, the actual weight of the equipment shall be included.

In-Service Condition. A state or condition of readiness for intended duty; usually an emergency vehicle properly serviced with all equipment properly loaded and ready for immediate response.

Intended Airport Service.* All aspects of aircraft rescue and fire-fighting services as provided by this standard.

Interaxle Clearance Angle (Ramp Angle). The measure of the ability of a fully loaded vehicle to negotiate a ramp without encountering interference between the vehicle and the ramp between any two axles. It shall be determined by the horizontal ground line and whichever of the following lines forms the smaller angle:

(a) The line tangent to the loaded radius of the front tire extended rearward to that fixed point on the vehicle, ahead of a vertical line midway between the two axles, that determines the smallest angle;

(b) The line tangent to the loaded radius of the rear tire extended forward to that fixed point on the vehicle, behind a vertical line midway between the two axles, that determines the smallest angle.

Interaxle Differential. A differential in the line of drive between any two axles.

Lightweight Construction. The use of nonferrous metals or plastics or a reduction in weight by the use of advanced engineering practices resulting in a weight saving without sacrifice of strength or efficiency.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

May. This term is used to state a permissive use or an alternative method to a specified requirement.

No-Load Condition. The status of an engine with standard accessories operating without an imposed load, with the vehicle drive clutches and any special accessory clutches in a disengaged or neutral condition.

Off-Pavement Performance. A vehicle's ability to perform or operate on other than paved surfaces. "Other than paved surfaces" includes dirt roads and trails and open cross-country of all kinds. This ability sometimes is referred to as off-road mobility or cross-country mobility. All of these terms are synonymous.

Operational Tests. An all-vehicle test conducted by the manufacturer to ensure that each vehicle is fully operational when it is delivered and to ensure that the original level of performance of the prototype vehicle has been maintained.

Overall Height, Length, and Width. The dimensions determined with the vehicle fully loaded and equipped, unless otherwise specified. These dimensions shall include all fixed protrusions that could in any way hinder the passage of the vehicle. Dimensions that include a movable protrusion shall be determined with the protrusion in its normally stored position.

Percent Grade. The ratio of the change in elevation to the horizontal distance traveled multiplied by 100. A change in elevation of 50 ft (15.2 m) over a horizontal distance of 50 ft (15.2 m) is equivalent to a grade of 100 percent.

Power-Assist Steering. A system using hydraulic or air power to aid in the steering assist. This system is supplementary to the mechanical system in order to maintain steering ability in the event of power failure.

Protein Foam Concentrate. A concentrate consisting primarily of products from a protein hydrolysate, plus stabilizing additives and inhibitors to protect against freezing, to prevent corrosion of equipment and containers, to resist bacterial decomposition, to control viscosity, and otherwise to ensure readiness for use under emergency conditions.

Prototype Vehicle. The first vehicle of a unique vehicle configuration built to establish its performance capability and the performance capability of all subsequent vehicles manufactured from its drawings and parts list. A given chassis, body, and fire-fighting system and fully loaded weight condition shall constitute a vehicle configuration. Product improvements and customer options shall negate previously conducted prototype tests only if they substantially affect a performance factor.

Radio Suppression. Suppression of the ignition and electrical system noises that normally interfere with radio transmission and reception.

Reserve Capacity Rating. The number of minutes a new, fully charged battery at 80°F (26.7°C) can be discharged at 25 amperes while maintaining 1.75 volts per cell or higher.

Rubber-Gasketed Fitting. A device for providing a leakproof connection between two pieces of pipe while allowing moderate movement of one pipe relative to the other. It incorporates a rubber seal held in place by a two-piece clamp that also engages annular grooves near the end of each pipe to prevent pullout under pressure.

Seat Belt. A two-point lap belt, a three-point lap/shoulder belt, or a four-point lap/shoulder harness for vehicle occupants designed to limit their movement in the event of an accident, rapid acceleration, or rapid deceleration by safely securing the individual to a vehicle while in a seated position.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Steering Drive Ends. Steering drive ends or stub shafts are in the front wheel spindle in a driving steering axle as used at the front of an all-wheel drive vehicle. The universal joint that allows steering while transmitting power is supported by the steering drive end at its inner end, and the outer end is connected to the wheel hub through a driving flange.

Ton. Weight equivalent to 2000 lb (906 kg).

Torque Converter. A device that is similar to a fluid coupling but that produces, by means of additional turbine blades, variable torque multiplication.

Twenty-Five (25) Percent Drainage Time. The time in minutes that it takes for 25 percent of the total liquid contained in the foam collected in a specified manner to drain. A method of measuring drainage time is provided in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

Underbody Clearance Dimensions. The dimensions determined with the vehicle fully loaded and fully equipped, unless otherwise specified. These dimensions shall include all components of the vehicle, except those that are part of the axle assemblies, that could hinder the passage of the vehicle.

Unitized Rigid Body and Frame Structure. A structure in which parts that generally comprise a separate body are integrated with the chassis frame to form a single, rigid, load-carrying structure.

Unsprung Weight. The total weight of all vehicle components that are not supported completely by the suspension system.

Vehicle Types. Vehicle types are designed as 4 × 2, 4 × 4, 6 × 4, 6 × 6, and 8 × 8. These designations are used to indicate the number of wheels on the vehicle and the number of wheels that propel or drive the vehicle. The term “wheel” in this designation is interpreted to mean either a single tire or a set of dual tires operating as one tire. The first number is the number of wheels, the second number is the number of driving wheels, therefore:

(a) A 4 × 2 vehicle has four wheels and drives on two wheels.

(b) A 4 × 4 vehicle has four wheels and drives on all four wheels.

(c) A 6 × 4 vehicle has six wheels and drives on four wheels.

(d) A 6 × 6 vehicle has six wheels and drives on all six wheels.

(e) An 8 × 8 vehicle has eight wheels and drives on all eight wheels.

Wall-to-Wall Turning Diameter. A measurement of the space that completely contains a vehicle as it is being turned. It is, therefore, the diameter of the smallest circle that can be described by the outermost point on the vehicle as it negotiates a 360-degree turn to the right or left.

Weatherproof. Sufficiently protected to prevent the penetration of rain, snow, and wind-driven sand, dirt, or dust under all operating conditions. This term is not intended to describe items that are watertight or submersible.

Weathertight. Having sufficient compartment closure to prevent the penetration of rain, snow, and wind-driven sand, dirt, or dust under all operating conditions. This term is not intended to describe items that are watertight or submersible.

Weight Scale Measurement. The accurate measurement of vehicle weight by means of a scale to verify or check a stated or estimated weight.

1-4 Requirements for All Aircraft Rescue and Fire-Fighting Vehicles — Responsibility of Contractors/Suppliers.

1-4.1*

The aircraft rescue and fire-fighting vehicle manufacturer shall assume responsibility for the design, construction, and performance of all component parts of the complete vehicle, even if major portions are subcontracted, and shall certify that the completed vehicle meets the requirements of this standard.

1-4.2

The manufacturer shall supply at time of delivery at least two complete copies of the following manuals:

(a) Operator’s manual;

(b) Service manual;

(c) Parts manual.

These manuals shall cover the entire vehicle and shall be in accordance with 1-4.2.1 through 1-4.2.3.2.

1-4.2.1 Operator's Manual. Operating instructions shall include all information required for operation of the vehicle, vehicle components, fire-fighting systems, and integral vehicular options. The location and function of all controls and instruments shall be covered by illustrations and descriptions. These instructions, as a minimum, also shall include the following:

(a) A complete description of the vehicle and special equipment;

(b) Preparation for use of the vehicle upon receipt;

(c) Daily maintenance and mission readiness checks to be performed by the operator;

(d) Periodic operator inspection.

1-4.2.2 Service Manual. The repair and overhaul instructions shall be factual, specific, concise, and clearly worded. The instructions shall cover such typical maintenance and repair operations as troubleshooting, adjustment procedures, minor and major repairs and overhaul, removal and replacement of units, assemblies and subassemblies, and complete instructions for disassembly and reassembly of components. The instructions also shall include data that include tolerances, specifications, and capacities. Illustrations, wiring diagrams, and exploded views shall be used to clarify text and shall appear as close to the related text as possible. Special tools needed for the repair and overhaul of the equipment shall be specified and illustrated. The service manual shall contain a suitable index.

1-4.2.3 Parts Manual. The parts list shall include illustrations and exploded views necessary for the proper identification of all parts, assemblies, and subassemblies. Assemblies or components shall be shown in illustrations and shall be identified by reference numbers that correspond to the reference numbers in the parts list. The size, thread dimensions, and special characteristics shall be given on all nonstandard nuts, bolts, washers, grease fittings, and similar items. The parts identification manual shall provide the description and quantity of each item used per vehicle. The parts identification manual shall contain a numerical index.

1-4.2.3.1 The vehicle manufacturer shall ensure the purchaser that parts critical to the mission of the vehicle are shipped within 48 hours. The original equipment manufacturers shall be disclosed to the owner if the vendor is unable to supply the necessary parts within this time frame to allow local purchase of an equivalent part.

1-4.2.3.2 A qualified and responsible representative of the contractor shall instruct personnel specified by the purchaser in the operation, care, and maintenance of the vehicle delivered. The purchasers shall specify provisions for training, including the location and duration, and shall agree on suitable training aids such as video tapes and training manuals.

1-4.3 Metal Finish.

1-4.3.1 All exposed ferrous metal surfaces that are not plated or of stainless steel or that are not otherwise treated to resist corrosion shall be cleaned thoroughly and prepared and shall be painted in the color(s) specified by the purchaser. If nonferrous body components are furnished, the purchaser shall specify which surfaces are to be painted. The paint, including the primer, shall be applied in accordance with the paint manufacturer's recommendation.

1-4.3.1.1 Paint finish shall be selected for maximum visibility and shall be resistant to damage from fire-fighting agents.

1-4.3.1.2 Dissimilar metals shall not be in contact with each other. Metal plating or metal spraying of metals of dissimilar base to provide electromotively compatible abutting surfaces shall be permitted. The use of dissimilar metals separated by suitable insulating material shall be permitted.

Exception: In systems where bridging of insulation materials by an electrically conductive fluid can occur, dissimilar metals shall not be permitted.

1-4.3.1.3 Materials that deteriorate when exposed to sunlight, weather, or operational conditions normally encountered during service shall not be used or shall have a means of protection against such deterioration that does not prevent compliance with performance requirements.

1-4.3.1.4 Protective coatings that chip, crack, or scale with age or extremes of climatic conditions or when exposed to heat shall not be used.

1-4.3.1.5 The use of proven, nonmetallic materials in lieu of metal shall be permitted, provided such use contributes to reduced weight, lower cost, or less maintenance and there is no degradation in performance or increase in long-term operations and maintenance costs.

1-4.4 Lettering, Numbering, and Striping.

1-4.4.1 Vehicle numbering, lettering, and minimum 8-in. (0.2-m) wide reflective striping shall be provided in accordance with ASTM D4956, *Standard Specification for Retroreflective Sheeting for Traffic Control*. Striping shall be placed horizontally on the sides of the vehicle below the body centerline. Vehicles shall display an identification number on each side and roof. Side numbers shall be a minimum of 16 in. (0.4 m) in height. Roof numbers shall be a minimum of 24 in. (0.6 m) in height and affixed with their base toward the front of the vehicle. Numbering, lettering, and striping shall be in sharp contrast to the vehicle color.

Chapter 2 Major Fire-Fighting Vehicles

2-1 General.

2-1.1

The category of major vehicles shall encompass a range of water capacity commencing at 1000 gal (3785 L) and extending to over 6000 gal (22 710 L). Because the same performance cannot be expected of all vehicles within this range, vehicles shall be classified into water capacity ranges within which a similar level of performance is practical.

2-1.2

Table 2-1.2 provides vehicles rated in gallons that shall be used to establish the class of vehicle.

Table 2-1.2 Vehicle Water Capacities

Minimum Rated Water Capacity

Class	(gal)	(L)
1	1000	3785
2	1500	5677.5
3	2500	9462.5
4	3000	11,355
5	4000	15,140
6	5000	18,925
7	6000	22,710

2-2 Weights and Dimensions.

2-2.1 Weights.

2-2.1.1 The actual gross vehicle weight of a fully staffed, loaded, and equipped vehicle ready for service shall not exceed the manufacturer's gross vehicle weight rating.

2-2.1.2* The weight shall be distributed as equally as practical over the axles and tires of the fully loaded vehicle. The difference in weight between tires on any axle shall not exceed 5 percent of the average tire weight for that axle. The difference in weight between any two axles shall not exceed 10 percent of the weight of the heaviest axle if the heavy axle is a rear axle. If the heavy axle is a front axle, the weight difference between that axle and any other axle shall not exceed 5 percent of the heavy axle weight. Under no circumstances shall the axle and tire manufacturers' ratings be exceeded.

2-2.1.3 The center of gravity of the vehicle shall be kept as low as possible under all conditions of loading. Vehicles in Classes 1, 2, 3, and 4 through 7 shall be able to stand on sideways slopes of 30 degrees, 28 degrees, 26.5 degrees, and 24 degrees (58 percent, 53 percent, 50 percent, and 45 percent, respectively).

2-2.1.4 The vehicle also shall be driven on a steering pad around a circle with a radius of 100 ft (30.5 m). The steering wheel rotation shall increase with acceleration of speed to ensure the vehicle does not exhibit oversteer characteristics. A speed in excess of 22 mph (35.4 km/h) shall be obtained with vehicles in Classes 1 and 2, and a speed in excess of 18.5 mph (29.8 km/h) shall be obtained with Classes 3 through 7 vehicles.

2-2.2 Dimensions.

2-2.2.1 The vehicle clearance shall allow mobility in soft soils and rough terrain with the vehicle tires inflated to highway inflation pressures. The minimum dimensions shall be as follows:

(a) Angle of approach — 30 degrees;

(b) Angle of departure — 30 degrees;

(c) Interaxle clearance angle — 12 degrees;

(d) Underaxle clearance — 13-in. (33.0-cm) underaxle differential housing bowl;

(e) Underbody clearance — 18 in. (45.7 cm).

2-2.2.2* The overall height, length, and width of the vehicle shall be held to a minimum consistent with the best operational performance of the vehicle and the design concepts needed to achieve this performance and to provide optimum maneuverability and facilitate movement on public highways.

2-2.2.3 The vehicle shall be constructed so that a seated driver, having an eye reference point of $31^3/_4$ in. (806.5 mm) above the seat cushion and 12 in. (30.5 cm) forward from the seat back, shall be able to see the ground 20 ft (6.1 m) ahead of the vehicle and shall have a field of vision of at least 5 degrees above the horizontal plane. The field of vision in the horizontal plane shall be at least 90 degrees on each side from the straight ahead position.

2-2.2.4 Adjustable rear view mirrors with a glass area of not less than 60 in.^{2} (387.1 cm^2) shall be provided on each side of the vehicle. Each side shall be provided with a minimum 7-in.^{2} (45.2-cm^2) wide-angle (convex) mirror.

Exception: In lieu of mirrors, audiovisual devices that meet or exceed the field of vision provided by the wide-angle mirrors shall be permitted.

2-3 Engine.

2-3.1 Performance Requirements.

2-3.1.1 The vehicle engines shall have sufficient horsepower, torque, and speed characteristics to meet and maintain all vehicular performance characteristics specified in this standard. The engine manufacturer shall certify that the installed engine is approved for this application.

2-3.1.2* The fully loaded vehicle shall be able to accelerate consistently from 0 mph to 50 mph (0 km/h to 80.5 km/h) on dry, level concrete pavement at the operational airport within the times specified in Table 2-3.1.2. The maximum speed shall not be less than 65 mph (104.6 km/h). If any vehicle accelerates from 0 mph to 50 mph (0 km/h to 80.5 km/h) in less than 20 seconds, it shall meet the tilt-table parameters of 35 degrees side slope as a minimum for all classes.

The acceleration times provided in Table 2-3.1.2 shall be achieved with the engine and transmission at their normal operating temperatures at any ambient temperature from 0°F to 110°F (-17.8°C to 43.3°C) and at elevations up to 2000 ft (609.6 m) above sea level unless a higher elevation is specified.

For airports above 2000 ft (609.6 m), the elevation at which the vehicle shall operate in order to ensure the necessary performance shall be specified.

Table 2-3.1.2 Vehicle Acceleration Requirements

Class	Minimum Water Capacity		Maximum Acceleration Time 0 mph to 50 mph (0 km/h to 80 km/h)
	U.S. (gal)	(L)	(sec)
1	1000	4000	23

2	1500	6000	26
3	2500	9000	35
4	3000	11,000	40
5	4000	15,140	45
6	5000	18,925	50
7	6000	22,710	50

2-3.1.3 The vehicle also shall be capable of ascending, stopping, starting, and continuing ascent on a 40-percent grade on dry pavement at a speed up to at least 1 mph (1.6 km/h) with extinguishing agents being discharged from the primary turret nozzle(s).

2-3.2 Engine Cooling Systems.

2-3.2.1 Liquid-Cooled Engines. An engine coolant preheating device shall be provided as an aid to rapid starting and high initial engine performance. This device shall be fitted with a thermostat.

2-3.2.1.1 The cooling system shall be designed so that the stabilized engine coolant temperature remains within the engine manufacturer's prescribed limits under all operational conditions and at all ambient temperatures encountered at the operational airport. The cooling system shall be provided with an automatic thermostat for rapid engine warming.

2-3.2.1.2 Where specified, radiator shutters, where furnished for cold climates, shall be of the automatic type and shall be designed to open automatically upon failure.

2-3.2.2 Air-Cooled Engines. Air-cooled engines shall be designed so that the stabilized cylinder head and oil temperatures remain within the engine manufacturer's prescribed limits under all operational conditions and at all ambient temperatures encountered at the operational airport.

2-3.3 Fuel System.

2-3.3.1 A complete fuel system installed with the engine manufacturer's approval shall include a fuel pump, fuel filtration, and flexible fuel lines, where necessary, that shall be protected from damage, exhaust heat, and exposure to ground fires.

2-3.3.2 Accessible filtration shall be provided for each fuel supply line, and a drain shall be provided at the bottom of the fuel tank.

2-3.3.3 Fuel tanks shall not be installed in a manner that allows gravity feed.

2-3.3.4 The fuel tank shall have sufficient capacity to provide for a minimum of 30 mi (48.3 km) of highway travel at 55 mph (88.5 km/h) plus 2 hours of pumping at the full rated discharge. Additional fuel capacity shall be provided for a minimum of 4 hours of operation of each accessory item (such as a generator or fuel-fired heaters) that uses the common fuel tank as a source.

2-3.4 Exhaust System.

2-3.4.1 The exhaust system shall be of a size that avoids undue back pressure and shall be located and constructed in such a manner that entrance of exhaust gases into the cab is minimized under all conditions of operation. The exhaust system shall be of high-grade, rust-resistant materials. The exhaust system shall include a muffler to reduce engine noise.

2-3.4.2 The exhaust system shall be protected from damage that could result from traversing rough terrain. The tail pipe shall be designed to discharge upward or to the rear and shall not be directed toward the ground.

2-4 Vehicle Electrical System.

2-4.1

The vehicle shall be provided with one of the following electrical systems:

(a) A 12-volt electrical and starting system;

(b) A 24-volt electrical and starting system;

(c) A 12-volt electrical/24-volt starting system.

2-4.2

The electrical system shall have a negative ground including a transistorized alternator and a fully transistorized voltage regulator. The alternator shall be rated at 100 percent of the anticipated load at 50 percent of the engine-governed speed and, if belt driven, it shall be driven by dual belts.

2-4.2.1 For 12-volt electrical and starting systems and for 12-volt electrical/24-volt starting systems, the curb idle minimum charging rate of the alternator shall be 50 amperes.

2-4.2.2 For 24-volt electrical and starting systems, the curb idle minimum charging rate of the alternator shall be 30 amperes.

2-4.3

Batteries shall be mounted securely and adequately protected against physical injury and vibration, water spray, and engine and exhaust heat. Where an enclosed battery compartment is provided, it shall be ventilated adequately, and the batteries shall be readily accessible for examination, test, and maintenance.

2-4.3.1 For 12-volt starting systems, the batteries shall be connected so that their capacity meets the cold-cranking performance amperes at 0°F (-17.8°C) to comply with the engine manufacturer's recommendations. In addition to the cold-cranking performance ampere requirements, a minimum reserve capacity of 600 minutes at 80°F (26.7°C) shall be provided.

2-4.3.2 For 24-volt starting systems, the batteries shall be connected so that their capacity meets the cold-cranking performance amperes at 0°F (-17.8°C) to comply with the engine manufacturer's recommendations.

2-4.4 Battery Capacity.

2-4.4.1 Battery capacity and wiring circuits, including the starter switch and circuit and the starter to battery connections, shall meet or exceed the manufacturer's recommendations. A master power disconnect system shall isolate power from all of the electrical system except the primary power circuits to the alternator and starter. Exceptions shall apply only to systems that are required to operate when the vehicle is not attended. The control device shall be accessible from the driver's seated position.

2-4.4.2 For 12-volt electrical/24-volt starting systems, the batteries shall be connected in a series parallel through a solid-state series parallel circuit to accomplish 24-volt starting. The batteries shall be connected so that their capacity meets the cold-cranking performance amperes at 0°F (-17.8°C) to comply with the engine manufacturer's recommendations. In addition to the cold-cranking ampere requirements, a minimum reserve capacity of 600 minutes at 80°F (26.7°C) shall be provided.

2-4.5 Battery Chargers.

2-4.5.1 A built-in battery charger shall be provided on the vehicle to maintain full charge on all batteries. A grounded AC receptacle shall be provided to allow a pull-away connection from the local electric power supply to the battery charger.

2-4.5.2 Where specified, an on-board battery charger/conditioner shall be provided on the vehicle and shall have a minimum output rating of one-half percent of the cold-cranking ampere rating at 32°F (0°C) of the engine-starting battery system. The battery charger shall be supplied from an external power source of 115 volts or 220 volts AC. This battery charger/conditioner shall be the type that can be connected to the batteries at all times and yet maintain a charge to the batteries without causing any damage. The unit shall reduce its charging output level to a point where a small amount of charge is allowed to the batteries continuously or it shall shut off completely. The charger/conditioner shall have protection built into it to protect it from damage during high current demands such as those caused by starting the engine. The unit shall be provided with a grounded AC receptacle to allow a pull-away connection from the local electrical power supply to the battery charger/conditioner.

2-4.6

The electrical system and its components shall be weatherproof, insulated, and protected from chafing, damage from road debris, and exposure to ground fires. All wiring shall be coded to correspond with the wiring diagram provided with the vehicle. Circuit protection shall be provided to protect the vehicle in the event of electrical overload.

2-4.7

Radio suppression of the electrical system shall be in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000 MHz)*, or an equivalent radio suppression standard.

2-5 Vehicle Drive.

Transmission of power from the engine to the wheels of the vehicle shall be through a torque converter and an automatic or a semiautomatic gearbox. The entire drive train shall be designed and rated by the component manufacturer as having sufficient capacity to slip the wheels of the static-loaded vehicle on a surface having a coefficient of friction of 0.8. A range of gears providing the specified top speed and a grade ability of 50 percent shall be provided with sufficient intermediate gears to achieve the specified acceleration. The transmission shall be matched to the engine properly and shall be approved for the application by the transmission manufacturer.

2-5.1

A transmission cooling system shall be provided and designed so that the stabilized transmission oil temperature remains within the transmission manufacturer's prescribed limits under all operational conditions and at all ambient temperatures encountered at the operational airport.

2-5.2

A positive drive shall be provided to each wheel by means of a fully locked driveline in order to maximize traction on low-friction surfaces. Positive drive shall be permitted to be achieved either by the use of automatic locking and torque proportioning differentials or shall be permitted to be selected manually by the seated driver by use of a single control while the vehicle is in motion.

2-5.3

All-wheel drive on these vehicles shall incorporate a drive to the front and rear axles that is engaged at all times during the intended airport service. An interaxle differential shall be installed with automatic means or driver-selected means of differential locking.

2-5.4

All traction-increasing devices shall be operated by a single control for driving simplicity.

2-5.5

Front and rear axles shall have adequate capacity to carry the maximum imposed load under all intended operating conditions. The variations in axle tread shall not exceed 20 percent of the tire sectional width at rated load.

2-6 Suspension.

The suspension system shall be designed to allow the loaded vehicle to perform as follows:

(a) Travel at the specified speeds over improved surface;

(b) Travel at moderate speeds over unimproved surface;

(c) Provide diagonally opposite wheel motion 14 in. (355.6 mm) above ground obstacles without raising the remaining wheels from the ground;

(d) Prevent damage to the vehicle caused by wheel movement; and

(e) Provide a good environment for the crew when traveling over all surfaces.

2-7 Rims, Tires, and Wheels.

2-7.1

Vehicles shall be required to have off-highway mobility while meeting the specified paved surface performance.

2-7.2

Tires shall be selected to maximize the acceleration, speed, braking, and maneuvering capabilities of the vehicle on paved surfaces without sacrificing performance on all reasonable terrains found within the airport boundary.

2-7.3*

The purchaser shall provide a tire description that reflects the off-road performance requirements necessitated by the soil conditions encountered at the operational airport. Soil conditions that vary from an extremely fine grain soil or clay to an extremely coarse grain soil, sand, or gravel in a dry, saturated, or frozen condition shall be considered.

To optimize floatation under soft ground conditions, tires of larger diameter or width, or both, than is needed for bearing weight only shall be specified. Similarly, the lowest tire pressure compatible with the high speed performance requirements also shall be specified.

2-7.4

Vehicle and tire manufacturers shall be consulted for the tread design most suitable for the specific soil composition at individual airports.

2-7.5

All wheels on the vehicle shall be of the single-wheel type with all rims, tires, and wheels of an identical size and the same tire tread design.

2-7.6

Rims, tires, wheels, and inflation pressures shall be approved by their respective manufacturers as having sufficient capacity to meet the specified performance and shall be certified for not less than 5 mi (8 km) of continuous operation at 65 mph (104.6 km/h) at normal operational pressure.

2-8* Towing Connections.

At least two large tow eyes or tow hooks (one at the front and one at the rear), capable of towing the vehicle on level ground without damage, shall be mounted on the truck and attached directly to the frame structure or where recommended by the vehicle manufacturer.

2-9 Brakes.

2-9.1*

The braking system shall feature service, emergency, and parking brake systems. Service brakes shall be of the power-actuation air, hydraulic, or air-over-hydraulic type. Expanding shoe and drum brakes or caliper disc brakes shall be furnished. A brake chamber shall be provided for each wheel and shall be mounted so that no part of the brake chamber projects below the axle bowl.

2-9.2*

Service brakes shall be of the all-wheel type with split circuits so that failure of one circuit shall not cause total service brake failure.

2-9.2.1 The service brakes shall be capable of holding the fully loaded vehicle on a 50 percent grade.

2-9.2.2 For Classes 1, 2, and 3 vehicles, the service brakes shall stop the vehicle within 35 ft (10.7 m) at 20 mph (32.2 km/h), and within 131 ft (39.9 m) at 40 mph (64.4 km/h).

2-9.2.3 For Classes 4 through 7 vehicles, the service brakes shall stop the vehicle within 40 ft (12.2 m) at 20 mph (32.2 km/h) and within 160 ft (48.8 m) at 40 mph (64.4 km/h).

2-9.2.4 Stopping distances shall be accomplished on a dry, hard, approximately level roadway that is free from loose material and that has a roadway width equal to the vehicle width plus 4 ft (1.2 m) without any part of the vehicle leaving the roadway.

2-9.2.5 For each vehicle class, the service brakes shall provide one power-assisted stop while the vehicle engine is inoperative for the stopping distances specified in 2-9.2.2 through 2-9.2.4.

2-9.3

An emergency brake system shall be provided that is applied and released by the driver from the cab and is capable of modulation by means of the service brake control. When a single failure in the service brake system of a part designed to contain compressed air or brake fluid occurs, other than failure of a common valve, manifold, brake fluid housing, or brake chamber housing, the vehicle shall stop within no more than 288 ft (87.8 m) at 40 mph (64.4 km/h) without any part of the vehicle leaving a dry, hard, approximately level roadway that has a width equal to the vehicle width plus 4 ft (1.2 m).

2-9.4

The parking brake shall be capable of holding the fully loaded vehicle on a 20-percent grade without air or hydraulic assistance.

2-9.5 Brakes — Air System.

2-9.5.1 Where the vehicle is supplied with air brakes, the air compressor shall meet the following criteria:

(a) The compressor shall be engine driven;

(b) The compressor shall have sufficient capacity to increase air pressure in the supply and service reservoirs from 85 psi to 100 psi (586.1 kPa to 689.5 kPa) when the engine is operating at the vehicle manufacturer's maximum recommended revolutions per minute (rpm) in a maximum of 25 seconds;

(c) The compressor shall have the capacity for quick buildup of tank pressure from 0 psi (0 kPa) to the pressure to release spring brakes, and this buildup in pressure shall be accomplished within 15 seconds; and

(d) The compressor shall incorporate an automatic air-drying system immediately downstream from the compressor to prevent condensation buildup in all pneumatic lines.

2-9.5.2 Service reservoirs shall be provided. The calculated reservoir capacity shall include reservoirs, supply lines, and air dryer volumes. The total of the service reservoir volume shall be at least twelve times the total combined brake chamber volume at full stroke. If the reservoir volume is greater than the minimum required, a proportionately longer buildup time shall be allowed using the following formula:

$$\frac{\text{Actual reservoir capacity} \times 25}{\text{Required reservoir capacity}}$$

2-9.5.3 Reservoirs shall be equipped with drain valves and safety valves.

2-9.5.4 Provision shall be made for charging of air tanks with either a pull-away electrical connection used to power a vehicle-mounted auxiliary compressor or a pull-away air connection for charging of air tanks from an external air source.

2-9.5.5 Visual and audible low air pressure warning devices shall be provided. The low pressure warning device shall be visual and audible from the inside of the vehicle and shall be audible from the outside of the vehicle.

2-10 Steering.

2-10.1

The chassis shall be equipped with power-assisted steering with direct mechanical linkage from the steering wheel to the steered axle(s) to allow manual control in the event of power-assist failure.

2-10.2

The power steering system shall have sufficient capacity so that no more than 15 lbf (66.7 N) pull is needed on the steering wheel rim in order to turn the steering linkage from stop to stop with the fully loaded vehicle stationary on a dry, level, paved surface with the engine at idle.

2-10.3

The wall-to-wall turning diameter of the fully loaded vehicle shall be less than three times the vehicle length.

2-11 Cab.

2-11.1

The cab shall be fully enclosed (i.e., floor, roof, and four sides) and mounted on the forward part of the vehicle. Seating for the crew shall be restricted to the cab. The maximum number of crew seat positions provided in the cab shall be designated by the manufacturer and so labeled in the cab. As a minimum, two designated seat positions shall be provided, one for the driver and one for an additional crew member. Seat belts approved by the authority having jurisdiction shall be provided for each of the designated seating positions. Space shall be provided for all instrument controls and equipment specified without hindering the crew. Doors that open to as wide a position as possible shall be provided on each side of the cab with the necessary steps and handrails to allow rapid and safe entrance and exit from the cab. The cab design shall take into consideration the provision of ample space for the crew to enter and exit the cab and carry out normal operations while wearing full protective equipment.

2-11.2

The cab shall meet the visibility requirements of 2-2.2.3. Interior cab reflections from exterior and interior lighting shall be minimized. The windshield shall be shatterproof safety glass, and all other windows shall be constructed of approved safety glass. The cab shall be provided with wide gutters to prevent foam and water from dripping on the windshield and side windows. Where equipped with a roof turret having manual controls above the cab roof, the cab shall be designed with a quick-access passage to the roof turret(s).

2-11.3

The cab shall be weatherproof and shall be fully insulated thermally and acoustically with a fire-resistant material. The cab interior noise level at any seated position shall not exceed 85 dBA while traveling at 50 mph (80.5 km/h) on a level, hard surface without warning devices operating. With warning devices operating, the maximum limit shall be 90 dBA. The cab shall be permitted to be of the unitized rigid body and frame structure type, or it shall be permitted to be a separate unit flexibly mounted on the main vehicle frame. The cab shall be constructed from materials of adequate strength to ensure a high degree of safety for the crew under all operating conditions, including excess heat exposure and vehicle roll-over accidents.

2-11.4 Instruments, Warning Lights, and Controls.

2-11.4.1 The minimum number of instruments, warning lights, and controls consistent with the safe and efficient operation of the vehicle, chassis, and fire-fighting system shall be provided. All chassis instruments and warning lights shall be grouped together on a panel in front of the driver. All fire-fighting system instruments, warning lights, and controls shall be grouped together by function to provide ready accessibility and high visibility for the driver as well as crew members.

2-11.4.2 All instruments and controls shall be illuminated, and backlighting shall be used where practical.

2-11.4.3 Groupings of both the chassis and fire-fighting system instruments, warning lights, and controls shall be easily removable as a unit or shall be on a panel hinged for back access by the use of quick-disconnect fittings for all electrical, air, and hydraulic circuits.

2-11.4.4 The following instruments or warning lights, or both, shall be provided as a minimum:

(a) Speedometer/odometer;

(b) Engine(s) tachometer;

(c) Fuel level;

(d) Air pressure;

(e) Engine(s) temperature;

(f) Engine(s) oil pressure;

(g) Voltmeter(s);

(h) Transmission(s) oil temperature;

(i) Pump(s) pressure;

(j) Water tank level;

(k) Foam tank level;

(l) Low air pressure warning;

(m) Headlight beam indicator;

(n) Engine hour meter.

2-11.4.5 The cab shall have all the necessary controls within easy reach of the driver for the full operation of the vehicle and the pumping system. The following cab controls shall be provided:

(a) Accelerator pedal;

(b) Brake pedal;

(c) Parking brake control;

(d) Steering wheel, with directional signal control and horn;

(e) Transmission range selector;

(f) Pump control or selector;

(g) Foam control;

(h) Siren switch(es);

(i) Bumper turret controls or ground sweep valve control;

(j) Where specified, undertruck valve control;

(k) Remote turret controls, where remote turret is provided;

(l) Light switches;

(m) Windshield wipers with delayed and multispeed capability and washer controls;

(n) Heater/defroster controls;

(o) Master electrical switch;

(p) Means of starting and stopping engine;

(q) Auxiliary agent pressurization control, where specified;

(r) Windshield deluge system switch, where specified.

2-11.4.6 Where specified, a windshield deluge system shall be included to cool the windshield and to provide operator visibility during fire-fighting operations. It shall be designed to flood the windshield with clear water when activated. Clear water shall be discharged under sufficient pressure and in a pattern that ensures the driver/operator's field of vision can be kept clear of foam solution where used in conjunction with the windshield wiper. The windshield wipers shall be energized automatically whenever the deluge system is operated.

2-11.5 Equipment.

All interior crew and driving compartment door handles shall be designed and installed to protect against accidental or inadvertent opening.

2-11.5.1 The following equipment shall be provided in or on the cab, as applicable:

(a) Heater/defroster;

(b) Driver's suspension seat with vertical, fore, and aft adjustment, with seat belt;

Exception: The use of a nonsuspension driver's seat shall be permitted where recommended by the manufacturer.

(c) Crew seats with individual retractable seat belts;

(d) Windshield washers appropriate for removing foam;

(e) Windshield wipers appropriate for removing foam;

(f) Siren;

(g) Horn;

(h) Sun visors, interior transparent;

(i) Outside rear view mirrors, as specified in 2-2.2.4;

(j) Interior lighting;

(k) Provisions for mounting SCBA of the type specified by the purchaser at each crew seat position.

2-11.5.2 Where tools, equipment, or SCBA are carried within enclosed seating areas of fire department vehicles, such items shall be secured by either a positive mechanical means of holding the item in its stored position or in a compartment with a positive latching door. The means for holding the item in place or in the compartment shall be designed to minimize injury to persons in the enclosed area of the vehicle caused by loose equipment during travel and, in the event of an accident, a rapid deceleration or a rapid acceleration.

2-11.6

Signs that state "Occupants must be seated and wearing a seat belt when apparatus is in motion" shall be provided. Such signs shall be visible from each seated position. An accident prevention sign shall be located at the rear step area of the vehicle, if it exists. It shall warn personnel that standing on the step while the vehicle is in motion is prohibited.

2-12 Body.

2-12.1

The body shall be constructed of materials that are of the lightest weight consistent with the strength necessary for off-pavement operation over rough terrain and where exposed to excess heat. The body shall be permitted to be of the unitized-with-chassis-rigid-structure type or it shall be permitted to be flexibly mounted on the vehicle chassis. It also shall include front and rear fenders or wheel wells. Body panels shall be removable where necessary to provide access to the interior of the vehicle.

2-12.2

Access doors shall be provided for those areas of the interior of the vehicle that are inspected frequently. In particular, access doors of sufficient size and number shall be provided for access to the following:

(a) Engine;

(b) Pump;

(c) Foam proportioning system;

(d) Battery storage;

(e) Fluid reservoirs.

Other areas that need to be accessible for inspection or maintenance shall be open or shall have removable panels.

2-12.3

Suitable, lighted compartments shall be provided for convenient storage of equipment and tools to be carried on the vehicle. Compartments shall be weathertight and self-draining.

2-12.4

A working deck shall be provided and shall be reinforced adequately to allow the crew to perform its duties in the roof turret area, cab hatch area, water tank top fill area, foam-liquid top fill area, and in other areas where access to auxiliary or installed equipment is necessary.

2-12.5

Handrails or bulwarks shall be provided where necessary for the safety and convenience of the crew. Rails and stanchions shall be braced strongly and constructed of a material that is durable and resists corrosion. Handrails shall be constructed of, or covered with, a slip-resistant material.

2-12.6

Steps or ladders shall be provided for access to the top fill area. The lowermost step(s) shall be permitted to extend below the angle of approach or departure or ground clearance limits if it is designed to swing clear. All other steps shall be rigidly constructed. All steps shall have a nonskid surface. The lowermost step(s) shall be no more than 22 in. (558.8 mm) above level ground when the vehicle is fully loaded. Adequate lighting shall be provided to illuminate steps and walkways.

2-12.7

A heavy-duty front bumper shall be mounted on the vehicle and secured to the frame structure.

2-12.8

Vehicle numbering, lettering, and minimum 8-in. (20.3-cm) wide reflective striping shall be provided in accordance with ASTM D4956, *Standard Specification for Retroreflective Sheeting for Traffic Control*. Striping shall be placed on at least 60 percent of the perimeter length of each side, width, and rear. At least 40 percent of the perimeter width of the front of the vehicle shall have the reflective stripe.

Exception: A graphic design meeting the reflectivity requirements of this paragraph shall be permitted to replace all or part of the required striping, provided the design or combination thereof covers a minimum of the same perimeter length required above.

2-12.9

Attachments shall be provided for all tools, equipment, and other items that the purchaser specifies to be furnished on the vehicle. Equipment holders shall be attached firmly and designed so that equipment remains in place under all operating conditions, but the equipment shall be quickly removable for use.

2-13 Fire-Fighting Systems and Agents.

2-13.1 General.

2-13.1.1 For aircraft rescue and fire-fighting purposes, the primary and auxiliary extinguishing agents used shall be tested in accordance with NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*.

2-13.1.2 Vehicles designed to discharge auxiliary agents shall require the use of auxiliary agents that are compatible with the primary agent.

2-13.1.3 All components of the agent systems, including such items as the tanks, piping, fill troughs, and screens, shall be made of materials resistant to corrosion by the primary agent, primary agent/water solution, water, and, where specified, the auxiliary agent.

2-14 Agent Pump(s) and Pump Drive.

2-14.1 Agent Pump(s).

2-14.1.1 The water pump(s) shall be constructed of corrosion-resistant metals and shall be of the single-stage or multiple-stage centrifugal type and shall be designed for dependable emergency service. Pumps shall be designed carefully and built in accordance with good modern practice. Pumps shall be gravity primed from the vehicle tank. The pump and piping system shall be designed to eliminate the entrapment of air.

2-14.1.2 All proportioning system components shall be made of materials resistant to corrosion by all primary agents.

2-14.1.3 Where discharging foam solution, the pumping system shall be capable of discharging at a rate equal to or exceeding the total requirements of the roof or extendable turret(s), bumper turret or ground sweep nozzles, preconnected hand line nozzles, and undertruck nozzles, where specified, discharging simultaneously at designed pressures.

2-14.2 Pump Drive.

2-14.2.1 The pump(s) drive shall allow operation of the pump(s) and simultaneous operation of the vehicle. The pump(s) shall not be affected by changes in transmission ratios or the actuation of clutches in the vehicle drive. The design of the drive system and controls shall prevent damage to the drive or shall minimize lurching of the vehicle when the vehicle drive is engaged during pumping operations. The pump(s) drive system shall be capable of absorbing the maximum torque delivered by the engine to the pump(s) and withstanding the engagement of the pump(s) at all engine and vehicle speeds and under all operating conditions. The operation of the pump(s) shall not, under any conditions, cause the engine to stall or cause more than a slight and momentary reduction in engine speed and consequent drop in pump pressure.

2-14.2.2 While pumping at rated capacity, the drive shall allow controlled vehicle operation at speeds from 1 mph to 5 mph (1.6 km/h to 8 km/h). The pump(s) drive shall have sufficient power capacity to provide the pump(s) discharge requirements of 2-14.1.3 while the vehicle is being propelled under all operating conditions where a fire-fighting capability is needed.

2-14.2.3 If an independent engine is used to drive the pump(s), it shall have the same fuel and electrical system as the chassis engine and shall be equipped with an air cleaner, a replaceable element oil filter, a full pressure lubricating system, and an overspeed governing device to prevent engine damage. The engine also shall be provided with a cooling system that meets the requirements of 2-3.2.1 or 2-3.2.2.

2-14.3 Suction Connections.

2-14.3.1 The suction system shall be designed for efficient flow at the pumping rates required by 2-14.1.3. The pump suction line(s) shall be of large diameter and of the shortest length consistent with the most suitable pump location. There shall be a drain at the lowest point with a valve for draining all of the liquid from the pumping system where desired. Suction lines and valves shall be constructed of corrosion-resistant materials.

2-14.3.2 Where two pumps are used, they shall be arranged in parallel with manifolding so that either or both can supply any discharge outlet at the required operating pressure. During single pump operation, the total capacity shall be permitted to be reduced.

2-14.4 Discharge Connections.

All discharge outlets shall have National (American) Standard fire hose coupling thread. Adapter couplings, securely attached, shall be provided on each outlet if local couplings are not National (American) Standard as specified in NFPA 1963, *Standard for Fire Hose Connections*. No outlet or outlet with adapters shall add width to the vehicle.

2-14.5 Piping, Couplings, and Valves.

2-14.5.1 All piping, couplings, and valves shall be sized for necessary flow with minimum restriction and pressure loss. Material for all piping, couplings, and valves shall be selected to avoid corrosive or galvanic action.

2-14.5.2 Piping shall be mounted securely and provided with flexible couplings to minimize stress. Union or rubber-gasketed fittings shall be provided where necessary to facilitate removal of piping.

2-14.5.3 All valves shall be of the quarter-turn type and shall be selected for ease of operation and freedom from leakage.

2-14.5.4 All water system piping shall be tested on the suction side of the pump to detect possible leakage. All water and foam solution discharge piping, together with the agent pump(s), shall be tested at 50 percent above the system operating pressure.

2-14.6 Overheat Protection.

A system line shall be provided from the water pump discharge and, if applicable, from the foam pump discharge to prevent overheating of the pumps while engaged and operating at zero (0) discharge. The line shall be automatic.

2-14.7 Pressure Relief Valves.

A pressure relief valve shall be fitted both to protect and ensure optimum performance of the system.

2-14.8 Drains.

A drainage system with collector tubing from the low points on the pump(s) and piping shall be provided. The drain shall be provided with a quarter-turn valve.

2-15 Water Tank.

2-15.1 Capacity.

2-15.1.1 A water tank shall have a usable capacity as specified in 2-1.2.

2-15.1.2 The rated capacity of the tank shall be equal to the usable capacity that can be pumped from the tank while the vehicle is parked on level ground. The tank outlets shall be arranged to allow the use of at least 75 percent of the rated capacity with the vehicle positioned as follows:

(a) On a 20-percent side slope;

(b) On a 30-percent ascending grade;

(c) On a 30-percent descending grade.

2-15.2 Construction.

2-15.2.1 The tank shall be constructed to resist all forms of deterioration that could be caused by the water and foam concentrate while affording the structural integrity necessary for off-road operation. The tank shall have longitudinal and transverse baffles. The construction and connections shall be made to prevent the possibility of galvanic corrosion of dissimilar metals.

2-15.2.2 The tank shall be equipped with easily removable manhole covers over the tank discharge. Where specified, the tank shall be designed to allow access within each baffled compartment of the tank for internal and external inspection and service. The tank shall have a drain valve(s).

2-15.2.3 Provisions shall be made for necessary overflow and venting. Venting shall be sized to allow agent discharge at the maximum design flow rate without danger of tank collapse and shall be sized to allow rapid and complete filling without exceeding the internal pressure design limit of the tank. Additionally, overflows shall be designed to prevent loss of water from the tank during normal maneuvering and to direct the discharge of overflow water directly to the ground.

2-15.2.4 The water tank shall be mounted in a manner that limits the transfer of the torsional strains from the chassis frame to the tank during off-pavement driving. The tank shall be separate and distinct from the crew compartment, engine compartment, and chassis and shall be easily removable as a unit. Water tanks used as an integral part of unitized rigid body construction shall be permitted.

2-15.2.5 The water tank shall be equipped with at least one top fill opening of not less than 8 in. (20.3 cm) internal diameter. The top fill shall be equipped with an easily removable strainer of $^{1}/_{4}$-in. (6.4-mm) mesh construction. The top fill opening shall be equipped with a cap designed to prevent spillage.

2-15.3 Tank Fill Connection(s).

2-15.3.1 A tank fill connection(s) shall be provided in a position where it can be reached easily from the ground.

2-15.3.2 All connections shall have National (American) Standard fire hose coupling threads. Securely attached adapters shall be provided on each connection if local couplings are not National (American) Standard. Connections and adapter threads shall be as specified in NFPA 1963, *Standard for Fire Hose Connections*. Connections and connections with adapters attached shall not protrude beyond the normal body metalwork of the vehicle.

2-15.3.3 The connection(s) shall be provided with strainers of $^{1}/_{4}$-in. (6.4-mm) mesh and shall have check valves or shall be constructed so that water is not lost from the tank when connection or disconnection is made.

2-15.3.4 The tank fill connection(s) shall be sized to allow filling of the water tank in 2 minutes at a pressure of 80 psi (551.6 kPa) at the tank intake connection.

2-16 Foam System.

2-16.1 Foam-Liquid Concentrate Tank(s).

2-16.1.1 The purchaser shall specify the percent concentrate foam system to be provided. The foam-liquid concentrate tank(s) shall have a working capacity sufficient for two tanks of water at the maximum tolerance specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

2-16.1.2 Foam-liquid concentrate tanks shall be permitted to be of either the rigid or flexible type. Where specified, the tank(s) shall be designed for compatibility with the foam concentrate being used and shall resist all forms of deterioration that could be caused by the foam concentrate or water.

2-16.1.3 Tanks shall be designed to allow access within each baffled compartment of the tank for internal and external inspection and service. A large capacity drain connection shall be installed flush with the bottom of the sump.

2-16.1.4 The tank outlets shall be located above the bottom of the sump and shall provide continuous foam-liquid concentrate to the foam proportioning system, with that system operating as specified in 2-16.4 and with the vehicle discharging two tank loads of usable water as specified in 2-15.1.

2-16.1.5 If separate from the water tank, the foam-liquid tank shall be mounted in a manner that limits the transfer of the torsional strains from the chassis frame to the tank during off-pavement driving. The tank shall be separate and distinct from the crew compartment, engine compartment, and chassis and shall be easily removable as a unit. Foam liquid tanks used as an integral part of unitized rigid body construction shall be permitted.

A flexible tank shall be structurally supported to resist tearing. The structural support shall not be dependent on the fluid level in either the water or foam tanks.

2-16.1.6 A top fill trough shall be provided and shall be equipped with a stainless steel No. 10 mesh screen and container openers to allow emptying 5-gal (18.9-L) foam-liquid concentrate containers into the storage tank(s) at a rapid rate regardless of water tank level. The trough shall be connected to the foam-liquid storage tank(s) with a fill line designed to introduce foam-liquid concentrate near the bottom of the tank(s) to minimize foaming within the storage tank.

2-16.1.7 The tank fill connection(s) shall be provided in a position where it can be reached easily from the ground to allow the pumping of foam-liquid concentrate into the storage tank(s). The connection(s) shall be provided with strainers of $^1/_4$-in. (6.4-mm) mesh and shall have check valves or shall be constructed so that foam is not lost from the tank when connection or disconnection is made.

Where flexible tanks are used, the supply system shall be designed so that the flexible tanks are not subject to excess pressure. The supply system shall be capable of delivering foam-liquid at a rate at least equal to or greater than the maximum discharge rate of the foam system.

2-16.1.8 The tank(s) shall be vented adequately to allow rapid and complete filling without the buildup of excessive pressure and to allow emptying of the tank at the maximum design flow rate without danger of collapse. The vent outlets shall be directed to the ground to prevent spillage of foam-liquid concentrate on vehicle components.

2-16.2 Foam-Liquid Concentrate Pump.

2-16.2.1 The foam-liquid concentrate system shall be arranged so that the entire piping system, including the foam-liquid concentrate pump or pumps, can be flushed readily with clear water.

2-16.2.2 The foam-liquid concentrate pump or pumps shall be capable of delivering the necessary quantity of foam-liquid at a pressure in excess of the water pump operating pressure, regardless of the water flow rate or variations in engine speed.

2-16.3 Foam-Liquid Concentrate Piping.

2-16.3.1* The foam-liquid concentrate piping shall be of material resistant to corrosion by foam-liquid concentrates addressed in this standard. Care shall be taken that combinations of dissimilar metals that produce galvanic corrosion are not selected or that such dissimilar metals are electrically insulated. Where plastic piping is used, it shall be fabricated from unplasticized resins, unless it has been demonstrated that the stipulated plasticizer does not adversely affect the performance characteristics of the foam-liquid concentrates addressed in this standard. The plastic pipe shall be permitted to be reinforced with glass fibers.

2-16.3.2 The foam-liquid concentrate piping shall be adequately sized to allow the maximum required flow rate and shall be arranged to prevent water from entering the foam tank.

2-16.4 Foam-Liquid Proportioning Systems.

2-16.4.1 The foam concentrate proportioning system shall provide a preset or adjustable means of controlling the ratio of foam concentrate to the quantity of water in the foam solution being discharged from all orifices normally used for aircraft fire-fighting operations.

2-16.4.2 The proportioning system shall be sufficiently accurate to provide for the discharge of finished foam within the range specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

2-16.5 Turret Nozzles.

2-16.5.1 Major aircraft rescue and fire-fighting vehicles shall have one or two primary turret nozzles. The primary turret nozzle(s) shall meet the requirements of 2-16.5.2 and 2-16.5.3.

2-16.5.2 The total foam solution discharge rate from the primary turret, or pair of primary turrets, shall be as specified in Table 2-16.5.2. The primary turret nozzles shall include roof turret(s), extendable turret nozzles, and bumper turrets.

Table 2-16.5.2 Turret Flow Rates

Vehicle Class	Rated Tank Capacity		Minimum Turret(s) Capacity Required		Roof Turret with Bumper Turret Flow Rates				Roof Turret without Bumper Turret	
					Roof		Bumper			
	(gal)	(L)	(gpm)	(lpm)	(gpm)	(lpm)	(gpm)	(lpm)	(gpm)	(lpm)
1	1000	3785	750	2838.8	500	1892.5	250	946.3	500	1892.5
2	1500	5677.5	750	2838.8	500	1892.5	250	946.3	750	2838.8
3	2500	9462.5	1250	4731.3	1000	3785	250	946.3	1250	4731.3
4	3000	11,355	1250	4731.3	1000	3785	250	946.3	1250	4731.3
5	4000	15,140	1250	4731.3	1000	3785	250	946.3	1250	4731.3
6	5000	18,925	1250	4731.3	1000	3785	250	946.3	1250	4731.3

7	6000	22,710	1250	4731.3	1000	3785	250	946.3	1250	4731.3

For Classes 3 through 7 vehicles, the minimum combined rated turret discharge capacity shall be at least 1250 gpm (4731 lpm).

2-16.5.3 A turret(s) shall be capable of discharging foam as specified in Table 2-16.5.3 in still air in a continuously variable pattern with the turret(s) elevated to the maximum stream reach position.

Table 2-16.5.3 Turret Requirements

Vehicle Class	Straight Stream Minimum Range Far Point		Dispersed Stream Minimum Width		Dispersed Stream Minimum Range Far Point	
	(ft	m)	(ft	m)	(ft	m)
1	160	49	35	10	60	18
2	190	58	35	10	65	20
3	230	70	35	10	70	21
4	250	76	35	10	75	23
5	250	76	35	10	75	23
6	250	76	35	10	75	23
7	250	76	35	10	75	23

2-16.5.4 Turret nozzles with liquid flow rates of 750 gpm (2839 lpm) or more shall be of the dual discharge type and arranged to allow selection of either 50 percent or 100 percent of the turret capacity. The roof turret discharge rates shall have a tolerance of +10 percent/–0 percent.

2-16.5.5 Turrets shall be permitted to be operated manually or to be power controlled. Where turret remote control is provided in the cab, operation shall be less than 30 lbf (13.6 kgf), and cab indication of turret elevation and azimuth shall be provided. Manual override of all fixed, mounted, roof turret controls shall be provided inside the cab for all power controlled turrets, and manual override operation shall be less than 30 lbf (13.6 kgf). Where turret control is at the platform, operation shall be less than 50 lbf (22.7 kgf). All power-assisted controls shall have identical operating characteristics.

2-16.5.6 Turrets shall be capable of being elevated at least 45 degrees above the horizontal and shall be depressed to discharge agent within 30 ft (9.1 m) in front of the vehicle at full output using a dispersed stream. Where a single turret is used on a vehicle, it shall be capable of being rotated not less than 105 degrees to either side, with total traverse not less than 210 degrees. Where two turrets are used on a vehicle, suitable stops shall be provided so that neither turret can interfere with the other turret.

2-16.5.7* If the primary turret is of the extendable type, it shall meet the following design and functional requirements:

(a) It shall comply with NFPA 1901, *Standard for Pumper Fire Apparatus*, Section 8-5, 8-5.2, and 8-5.3, and shall meet the requirements of 2-2.1.3 and 2-2.1.4 of this standard while in the stowed position. It shall achieve a 20-percent side slope with the extendable turret fully elevated and the nozzle rotated uphill at maximum horizontal rotation while discharging at maximum flow rate. The vehicle shall be provided with an interlock or warning system and placards in full view of the driver/operator to provide the operational limitations during all phases of operation.

Exception: Flow rates shall be in accordance with Table 2-16.5.2 for major vehicles.

(b) The extendable turret shall function without the use of outriggers or other ground contact stabilizers.

(c) The primary turret shall achieve the elevation and reach needed to service the highest tail-mounted engine for the aircraft being protected.

(d) The extendable turret shall function as a conventional roof turret in accordance with 2-16.5.2 for major vehicles.

(e) The extendable turret shall be capable of applying agent to the interior of the aircraft through cargo bay openings, passenger doorways, and emergency exits on the type of aircraft being protected while the aircraft is in either the gear up or gear down landing position.

2-16.6 Preconnected Hand Lines.

Preconnected hand lines shall be those hand lines for discharging foam streams that are specified by the purchaser as intended for use as primary crash/fire/rescue attack equipment. All other hand lines that are installed on the vehicle for discharging either water or foam, or both, shall be considered as additional hand lines and not preconnected hand lines.

Each preconnected hand line compartment shall be located so that the distance between the hand line nozzle and the ground, step, or deck plate upon which the operator stands to initiate the pulling of the hand line from the reel or the top lay of the woven jacket hose is not more than 6 ft (1.8 m) above that surface.

2-16.6.1 Major aircraft rescue and fire-fighting vehicles shall have a minimum of two preconnected hand lines that meet the requirements of either 2-16.6.3 or 2-16.6.4. The two preconnected hand lines shall not be located on the same side of the vehicle.

2-16.6.2 The purchaser shall specify either two reeled hand lines as specified in 2-16.6.3 or two woven jacket hand lines as specified in 2-16.6.4 or one of each.

2-16.6.3 Reeled Hand Lines.

2-16.6.3.1 Hand lines for reels shall have a minimum internal diameter of 1 in. (25.4 mm), shall have a minimum burst pressure rating three times the nominal working pressure of the system, and shall be able to discharge the flow required in 2-16.6.3.3 without unreeling the hose.

2-16.6.3.2 At least 100 ft (30.5 m) of hose shall be provided for each reel.

2-16.6.3.3 Each hand line shall be equipped with a shutoff-type nozzle designed to discharge both foam and water at a nominal discharge rate of 60 gpm (227.1 lpm), +10 percent/–0 percent.

Each nozzle shall have minimum foam discharge patterns from a dispersed stream of 15 ft (4.6 m) in width and 20 ft (6.1 m) in range to a straight foam stream with a 50-ft (15.2-m) range.

2-16.6.3.4 Each hose reel shall have capacity for at least 100 ft (30.5 m) of 1-in. (25.4-mm) hose or more if specified by the purchaser.

2-16.6.3.5 Each hose reel shall be designed and positioned to allow hose reel removal by a single person from any position in a 120-degree horizontal sector. Each hose reel shall be equipped with a friction brake to prevent the hose from unreeling when not desired. A power rewind with manual override shall be provided. The nozzle holder, friction brake, rewind controls, and manual valve control shall be accessible from the ground.

2-16.6.3.6 The discharge control to each hand line shall be adjacent to the hand line and accessible to the person using the hand line.

2-16.6.4 Woven Jacket Hand Lines.

2-16.6.4.1 Woven jacket hand lines shall have a minimum diameter of $1^1/_2$ in. (38.1 mm) and shall meet the requirements of NFPA 1961, *Standard for Fire Hose*.

2-16.6.4.2 At least 150 ft (45.7 m) of hose shall be provided for each hand line.

2-16.6.4.3 Each hand line shall be equipped with a shutoff-type nozzle designed to discharge both foam and water at a nominal discharge rate of 95 gpm (359.6 lpm), ±5 percent. Each nozzle shall have minimum foam discharge patterns from a dispersed stream of 15 ft (4.6 m) in width and 20 ft (6.1 m) in range to a straight foam stream with a 65-ft (19.8-m) range.

2-16.6.4.4 Each hand line shall be stored in a hose compartment and shall be preconnected. Each hose compartment shall have a capacity for a minimum of 150 ft (45.7 m) of $1^1/_2$-in. (38.1-mm) multiple jacket hose or more if specified by the purchaser.

2-16.6.4.5 Hose compartments shall be fabricated from noncorrosive material and shall be designed to drain effectively. The compartment shall be smooth and free from all projections that might damage the hose. No other equipment shall be mounted or located where it can obstruct the removal of the hose.

2-16.6.4.6 The discharge control to each hand line shall be adjacent to the hand line and accessible to the person using the hand line.

2-16.7 Bumper Turret, Ground Sweep, and Undertruck Nozzles.

2-16.7.1 Vehicles shall have a remote-controlled bumper turret or ground sweep nozzle(s) mounted on the front of the vehicle. Controls for the bumper turret or ground sweep nozzle(s) shall be mounted inside the cab within easy reach of the driver and a crew person.

2-16.7.1.1 The bumper turret shall have a horizontal rotation of 180 degrees, +10 percent/-0 percent, and vertical travel of +45 degrees/-20 degrees. The flow rate shall be 250 gpm (946.3 lpm), +10 percent/–0 percent.

2-16.7.1.2 The ground sweep nozzle(s) shall have a total discharge rate of 100 gpm (378.5 lpm), +10 percent/–0 percent. The minimum reach requirements are as follows:

Minimum reach	30 ft (9.1 m)
Minimum pattern width	12 ft (3.7 m)

2-16.7.2 Where specified, two or more undertruck nozzles shall be mounted under the truck and controlled from the cab. A sufficient number shall be provided to protect the bottom of the vehicle and the inner sides of the wheels and tires with foam solution discharged in a spray pattern.

2-16.8 Foam Quality.

Turrets, hand lines, and ground sweeps shall discharge foam having the quality specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

Measurement of the expansion ratio and 25-percent drainage times shall be in accordance with the procedures outlined in NFPA 412.

2-17 Auxiliary Agent System.

Where specified, the vehicle shall be equipped with an auxiliary agent system using either dry chemical (potassium bicarbonate) or Halon 1211. The minimum capacity of the auxiliary agent system shall be 450 lb (204.3 kg) of potassium bicarbonate for all classes of vehicles.

2-17.1 Dry Chemical Container.

The dry chemical container shall be constructed in accordance with the ASME *Boiler and Pressure Vessel Code*, Section 8, and shall be so stamped.

2-17.1.1 All piping and fittings shall conform to the appropriate ASME code and shall be designed to withstand the working pressure of the system. The design of the piping and valving shall provide the desired flow of gas into the system and the minimum amount of restriction from the chemical container(s) to the hose connection. Where more than one hose line is provided, piping and fittings shall be sized and designed so that there is equal flow to each line, regardless of the number of lines placed in operation.

2-17.1.2 Provisions shall be made for purging all piping and hose of dry chemical after use without discharging the dry chemical remaining in the dry chemical container(s). Provisions also shall be made for the depressurization of the dry chemical container(s) without the loss of the remainder of the dry chemical. A pressure gauge shall be provided that indicates the internal pressure of the agent storage container(s) at all times.

2-17.1.3 The system shall be designed to ensure fluidization of the dry chemical at the time of operation. Where any design includes the movement of the chemical container(s) to fluidize the contents, such design also shall include a manual operating feature.

2-17.1.4 A check valve shall be provided in the gas piping to prevent the extinguishing agent from being forced back into the propellant gas line.

2-17.1.5 A means of pressure relief conforming to appropriate ASME codes shall be provided for the dry chemical container and piping to prevent overpressurization in the event of a malfunction in the propellant gas regulator system or in the event the container is involved in a severe fire exposure.

2-17.1.6 The fill opening in the dry chemical container shall be located so that it is easily accessible for recharging and necessitates a minimum amount of time and effort to open and close. Filling shall be accomplished without the removal of any of the extinguisher piping or any major component.

2-17.1.7 A quick-acting control to be operated by the driver to pressurize the dry chemical agent system from the cab of the vehicle shall be provided, with a similar control at the hand line.

2-17.2 Propellants.

2-17.2.1 The propelling agent shall be dry nitrogen or dry air.

2-17.2.2 All propellant gas cylinders and valves shall be in accordance with U.S. Department of Transportation (DOT) requirements or regulations. Cylinders shall bear the DOT marking.

2-17.2.3 The method of adequately pressurizing and propelling the dry chemical in the system shall provide a sufficient quantity of gas to expel the agent, as well as allowing the complete purging of all piping and hose lines after each use.

2-17.2.4 The design of the propellant source shall provide for quick and easy replacement after each use.

2-17.2.5 A pressure gauge shall be provided and shall indicate the pressure on the propellant gas source at all times.

2-17.2.6 Cylinder valves, gauges, and piping shall be arranged to preclude accidental mechanical damage.

2-17.3 Pressure Regulation.

2-17.3.1 Pressure regulation shall be designed to reduce the normal cylinder pressure automatically and to hold the propellant gas pressure at the designed operating pressure of the dry chemical container(s).

2-17.3.2 All pressure regulating devices shall be sealed or pinned at the designed operating pressures after final adjustment by the system manufacturer.

2-17.3.3 Pressure regulating devices shall be equipped with a spring-loaded relief valve that relieves any excess pressure that develops in the regulator.

2-17.3.4 The pressure regulator shall be permitted to be of a type without pressure indicating gauges.

2-18 Halon 1211 System.

2-18.1 Halon Container.

2-18.1.1 The storage container shall be designed for pressurization and shall be constructed in accordance with the ASME *Boiler and Pressure Vessel Code* and shall be so marked.

2-18.1.2 The material of construction shall be resistant to corrosion by the halon agent to be stored.

2-18.1.3 A readily accessible charge coupling of sufficient size to allow ease in filling shall be provided. Filling shall be accomplished without the removal of any of the extinguisher piping or any major component. A pressure gauge shall be provided that indicates the internal pressure of the agent storage containers at all times.

2-18.1.4 A means shall be provided to determine the contents of the container as a guide in recharging partial loads and to prevent overfilling of the tank.

2-18.2 Propellant Gas.

2-18.2.1 The propellant gas shall be dry nitrogen or dry compressed air and shall be provided in sufficient quantity to expel the halon agent as well as to purge all piping and hose lines after use.

2-18.2.2 All propellant gas cylinders and valves shall be in accordance with U.S. Department of Transportation (DOT) requirements or regulations. Cylinders shall bear the DOT marking.

2-18.2.3 Pipes and valves connected to the halon container shall conform to the appropriate ASME code and shall be designed to withstand the working pressure of the system.

2-18.2.4 The design of the propellant source shall provide for quick and easy replacement after each use.

2-18.2.5 A pressure gauge shall be provided and shall indicate the pressure of the propellant gas source at all times.

2-18.2.6 Cylinder valves, gauges, and piping shall be arranged to preclude accidental mechanical damage.

2-18.2.7 A check valve shall be provided in the gas piping to prevent the liquid agent from being forced back into the propellant gas line.

2-18.3 Pressure Regulation.

2-18.3.1 An ASME-approved pressure relief valve of adequate capacity shall be provided on the container and shall be set to prevent pressures in excess of the maximum design working pressure.

2-18.3.2 Pressure regulation shall be designed to reduce the normal cylinder pressure automatically and to hold the propellant gas pressure at the designed operating pressure of the halon container(s).

2-18.3.3 All pressure regulating devices shall be sealed or pinned at the designed operating pressures after final adjustment by the system manufacturer.

2-18.3.4 Pressure regulating devices shall be equipped with a spring-loaded relief valve that relieves any excess pressure that develops in the regulator.

2-18.3.5 The pressure regulator shall be permitted to be of a type without pressure indicating gauges.

2-18.4 Halon Delivery Piping and Valves.

2-18.4.1 All piping, couplings, and valves shall be sized for necessary flow with minimum restriction and pressure loss. Material for all piping, couplings, and valves shall be selected to avoid corrosive and galvanic action. Piping shall be mounted securely and provided with flexible couplings to minimize stress.

2-18.4.2 All valves shall be of the quarter-turn type and shall be selected for ease of operation and freedom from leakage.

2-18.4.3 All discharge piping shall be tested at 50 percent above the system operating pressure.

2-18.4.4 Where more than one hose line is provided, piping and fittings shall be sized and designed so that there is equal flow to each line, regardless of the number of lines placed in operation.

2-18.4.5 Provisions shall be made for purging all piping and hose of the halon after use without discharging the halon remaining in the container(s). Provisions also shall be made for venting of the halon container without loss of the remainder of the liquid agent.

2-18.4.6 A quick-acting control to be operated by the driver to pressurize the halon system from the cab of the vehicle shall be provided, with a similar control at the hand line.

2-19 Dry Chemical Turret.

2-19.1 Auxiliary Agent Discharge.

Where specified, a primary turret shall have an auxiliary agent discharge mounted parallel to the primary agent discharge so that the auxiliary agent discharge is controlled the same way, and with the same travel requirements, as the primary turret.

2-19.1.1 The dry chemical minimum discharge rate from the turret shall be ≥ 16 lb/sec to ≤ 22 lb/sec (≥ 7.3 kg/sec to ≤ 10 kg/sec). The minimum far point reach for dry chemical shall be 100 ft (30.5 m), and the minimum width shall be 17 ft (5.2 m).

2-19.1.2 The dry chemical system shall be designed so that the operator can select to discharge both the primary and the auxiliary agent systems separately or simultaneously.

2-19.2 Auxiliary Agent Hand Lines.

2-19.2.1 Hand lines for auxiliary agents shall have a minimum burst pressure rating three times the nominal working pressure of the system and meet the requirements specified below. The auxiliary agent hand line shall be equipped with a nozzle that allows a fully opened to a fully closed position in a single, simple movement and shall be designed to discharge agent at a minimum rate of ≥ 5 lb/sec to ≤ 7 lb/sec (≥ 2.3 kg/sec to ≤ 3.3 kg/sec) at a minimum range of 20 ft (6.1 m). Nozzle construction shall be of nonferrous metal or stainless steel.

2-19.2.2 Twinned hand lines and nozzles shall be designed so that each agent can be discharged separately or simultaneously. The barrels shall be linked together to provide coordinated application by one operator.

2-19.2.2.1 Each reel shall have capacity for at least 100 ft (30.5 m) of 1-in. (25.4-mm) hose or more if specified by the purchaser.

2-19.2.2.2 Each reel shall be designed and positioned to allow hose line removal by a single person from any position in a 120-degree horizontal sector. Each reel shall be equipped with a friction brake to prevent the hose from unreeling when not desired. A power rewind with manual override shall be provided. The nozzle holder, friction brake, rewind controls, and manual valve control shall be accessible from the ground.

2-20 Lighting and Electrical Equipment.

2-20.1

Lighting equipment shall be installed in conformity with local road regulations, where practicable, and shall include the following:

(a) Headlights with upper and lower driving beams. A control switch that is readily accessible to the driver shall be provided for beam selection.

(b) Dual taillights and stoplights.

(c) Self-canceling turn signals, front and rear, with a steering column-mounted control and a visual and audible indicator. A four-way flasher switch shall be provided.

(d) Where specified, a minimum 6-in. (152.4-mm) spotlight on both left and right sides of the windshield, hand-adjustable type, with controls for beam adjustment inside the truck cab.

(e) Where specified, a minimum 6-in. (152.4-mm) spotlight mounted on a turret nozzle with a control switch that is readily accessible to the driver.

(f) Adequate reflectors and marker and clearance lights furnished to describe the overall length and width of the vehicle.

(g) Engine compartment lights, nonglare type, arranged to illuminate both sides of the engine, with individual switches located in the engine compartment. Service lighting shall be provided for all areas described in 2-12.2(a), (b), and (c), as well as for the engine compartment.

(h) Lighting provided for all top deck working areas.

(i) At least one back-up light and an audible alarm with a minimum of 97 dBA meeting SAE J994, *Standard on Alarm-Backup-Electric Laboratory Performance Testing*, installed in the rear of the body.

(j) A flashing red beacon or alternate red and white flashing lights mounted on the top deck and visible for 360 degrees in the horizontal plane. The mounting of the beacon also shall provide good visibility from the air. A control switch shall be provided on the instrument panel in the cab for control of the beacon.

2-20.2*

A warning siren shall be provided that has a sound output of not less than 95 dBA at 100 ft (30.5 m) when measured directly ahead of the siren and not less than 90 dBA at 100 ft (30.5 m), measured at 45 degrees on either side. The siren shall be mounted to allow maximum forward sound projection but shall be protected from foam dripping from the turret or water splashed up by the tires.

2-20.3

A horn shall be provided and shall be mounted at the front part of the vehicle with the control positioned so that it is readily accessible to the driver.

2-20.4

A master switch for all emergency lights shall be provided.

2-20.5 Radios.

2-20.5.1 Provision shall be made for mounting radios. Operation of the radios shall be from the cab. Radios shall be mounted to allow quick servicing or replacement.

2-20.5.2 The purchaser shall specify all necessary radios and frequencies that are to be provided.

2-20.6

Where furnished, air horns, an electric siren(s), and an electronic siren speaker(s) shall be mounted as low and as far forward on the apparatus as practical. Audible warning equipment shall not be mounted on the roof of the apparatus.

2-20.7

The purchaser shall specify whether a manually operated or a power-assisted turret shall be provided. Where a manually operated turret is specified, controls shall be in the cab, operation force shall be less than 30 lbf (13.6 kgf), and an indication of turret elevation and azimuth shall be provided. Where a power-assisted turret is specified, controls shall be in the cab, operation forces shall be less than 30 lbf (13.6 kgf), an indication of turret elevation and azimuth shall be provided, and a manual override of all roof turret functions shall be provided in the cab. The manual override operation force shall be less than 30 lbf (13.6 kgf). Where turret control is at the platform, operation forces shall be less than 50 lbf (22.7 kgf).

2-21* Tools.

Provision shall be made for mounting tools and equipment, as specified by the purchaser, on the truck. Special tools for servicing the vehicle, fire suppression system, and any of the auxiliary equipment shall be furnished as necessary by the vehicle manufacturer.

Chapter 3 Combined Agent Vehicles

3-1 General.

3-1.1

The category of combined agent vehicles shall encompass the range of water capacity commencing at 100 gal (378.5 L) and extending to 500 gal (1892.5 L). In addition to carrying foam as a primary agent, either dry chemical or Halon 1211 extinguishing agent also shall be carried as an auxiliary agent.

3-1.2

The following quantities of water and auxiliary agent shall establish the class of vehicle:

Table 3-1.2 Combined Agent Vehicle Classes

	Minimum Water Capacity		Minimum Auxiliary Agent	
Class	(gal)	(L)	(lb)	(kg)
1	100	400	450	204.3
2	200	800	450	204.3
3	300	1200	450	204.3
4	500	2000	450	204.3

3-2 Weights and Dimensions.

3-2.1 Weights.

3-2.1.1 The gross vehicle weight rating of the chassis as furnished shall equal or exceed the actual gross weight of the fully loaded and equipped vehicle.

3-2.1.2 The weight shall be distributed as equally as practical over the axles and tires of the fully loaded vehicle. The difference in weight between tires on any axle shall not exceed 5 percent of that axle weight, and the difference in weight between axles shall not exceed 15 percent of the weight of the heaviest axle. The front axle shall not be the heaviest axle. Under no circumstances shall the axle and tire manufacturers' ratings be exceeded.

3-2.1.3 The vehicle's center of gravity shall be kept as low as possible under all conditions of loading. The vehicle shall be capable of operations on a 20-percent side slope in both directions and shall be capable of ascending and descending a 50-percent grade in forward gear. Classes 1, 2, and 3 vehicles shall stand on a 30-degree side slope, and Class 4 vehicles shall stand on a 28-degree side slope. They shall be capable of ascending and descending at grades of 58 percent and 53 percent, respectively.

3-2.1.4 The vehicle also shall be driven on a steering pad around a circle with a radius of 100 ft (30.5 m). The steering wheel rotation shall increase with accelerating speed to ensure that the vehicle does not exhibit oversteer characteristics. A speed of 25 mph (40.2 km/h) shall be obtained for all classes of vehicles.

3-2.2 Dimensions.

3-2.2.1 Underchassis clearance of the vehicle shall allow mobility in soft soils and rough terrain. The minimum dimensions shall be as follows:

(a) Angle of approach — 30 degrees;

(b) Angle of departure — 30 degrees;

(c) Interaxle clearance angle — 12 degrees;

(d) Underaxle clearance — 8-in. (20.3-cm) underaxle differential housing bowl;

(e) Underbody clearance, Classes 1, 2, and 3 – 13 in. (33.0 cm);

(f) Underaxle clearance, Class 4 – $10^1/_2$ in. (26.7 cm);

(g) Underbody clearance, Class 4 – 18 in. (45.7 cm).

3-2.2.2* The overall height, length, and width of the vehicle shall be held to a minimum consistent with the best operational performance of the vehicle and the design concepts needed to achieve this performance and to provide optimum maneuverability and facilitate movement on public highways.

3-2.2.3 The vehicle shall be constructed so that a seated driver, having an eye reference point of $31^3/_4$ in. (80.7 cm) above the seat cushion and 12 in. (30.5 cm) forward from the seat back, shall be able to see the ground 20 ft (6.1 m) ahead of the vehicle and shall have a field of vision of at least 5 degrees above the horizontal plane. The field of vision in the horizontal plane shall be at least 90 degrees on each side from the straight ahead position.

3-2.2.4 Adjustable rear view mirrors with a glass area of not less than 60 in.^{2} (387 cm^2) shall be provided on each side of the vehicle. Each side shall be provided with a minimum 7-in.^{2} (45.2-cm^2) wide angle (convex) mirror.

Exception: In lieu of mirrors, audiovisual devices that meet or exceed the field of vision provided by the wide angle mirrors shall be permitted.

3-3 Engine.

3-3.1 Performance Requirements.

3-3.1.1 The vehicle engines shall have sufficient horsepower, torque, and speed characteristics to meet and maintain all vehicular performance characteristics specified in this standard. The engine manufacturer shall certify that the installed engine is approved for this application.

3-3.1.2* The fully loaded vehicle shall be able to accelerate consistently from 0 mph to 50 mph (0 km/h to 80.5 km/h) on dry, level concrete pavement at the operational airport within the times specified in Table 3-3.1.2. The maximum speed shall not be less than 65 mph (104.6 km/h). If any vehicle accelerates from 0 mph to 50 mph (0 km/h to 80.5 km/h) in less than 20 seconds, it shall meet the tilt table parameters of 35 degrees side slope as a minimum for all classes.

The acceleration times provided in Table 3-3.1.2 shall be achieved with the engine and transmission at their normal operating temperature at any ambient temperature from 0°F to 110°F (-17.8°C to 43.3°C) and at elevations up to 2000 ft (609.6 m) above sea level unless a higher elevation is specified.

For airports above 2000 ft (609.6 m), the elevation at which the vehicle shall operate in order to ensure the necessary performance shall be specified.

Table 3-3.1.2 Acceleration Times for Combined Agent Vehicles

Vehicle Class	Maximum Acceleration Time 0 mph to 50 mph (0 km/h to 80 km/h) (sec)
1	25
2	30
3	30
4	30

3-3.1.3 Where the engine is used to power both the vehicle and a fire-fighting pump, provision shall be made to ensure that the operation of the pump does not cause the following:

(a) Stalling of the engine;

(b) Pump speed in excess of that recommended.

3-3.2 Engine Cooling Systems.

3-3.2.1 Liquid-Cooled Engines. An engine coolant preheating device shall be provided as an aid to rapid starting and high initial engine performance. This device shall be fitted with a thermostat.

3-3.2.1.1 The cooling system shall be designed so that the stabilized engine coolant temperature remains within the engine manufacturer's prescribed limits under all operational conditions and at all ambient temperatures encountered at the operational airport. The cooling system shall be provided with automatic thermostat for rapid engine warming.

3-3.2.1.2 Where specified, radiator shutters, where furnished for cold climates, shall be of the automatic type and shall be designed to open automatically upon failure.

3-3.2.2 Air-Cooled Engines. Air-cooled engines shall be designed so that the stabilized cylinder head and oil temperatures remain within the engine manufacturer's prescribed limits under all operational conditions and at all ambient temperatures encountered at the operational airport.

3-3.3 Fuel System.

3-3.3.1 A complete fuel system installed with the engine manufacturer's approval shall include a fuel pump, fuel filtration, and flexible fuel lines, where necessary, that shall be protected from damage, exhaust heat, and exposure to ground fires. Gasoline engines shall have an electric fuel pump located near the fuel tank to prevent vapor lock.

3-3.3.2 Accessible filtration shall be provided for each fuel supply line, and a drain shall be provided at the bottom of the fuel tank.

3-3.3.3 Fuel tanks shall not be installed in a manner that allows gravity feed.

3-3.3.4 Fuel tanks shall have a minimum capacity of 18 gal (68.1 L).

3-3.4 Exhaust System.

3-3.4.1 The exhaust system shall be of a size that avoids undue back pressure and shall be located and constructed in such a manner that entrance of exhaust gases into the cab is minimized under all conditions of operation. The exhaust system shall be of high-grade, rust-resistant materials.

3-3.4.2 The tail pipe and muffler shall be protected from damage that could result from traversing rough terrain. The tail pipe shall be designed to discharge upward or to the rear and shall not be directed toward the ground.

3-4 Vehicle Electrical System.

3-4.1

The engine shall be equipped with a complete battery starting system.

3-4.2

A complete 12-volt, negative electrical system including transistorized alternator and fully transistorized voltage regulator shall be furnished. The idle minimum charging rate shall be 30 amperes. The alternator shall be driven by dual belts.

3-4.2.1 For 12-volt systems, the batteries shall be connected so that their capacity meets the cold-cranking performance amperes at 0°F (–17.8°C) to comply with the engine manufacturer's recommendations. In addition to the cold-cranking performance ampere requirements, a minimum reserve capacity of 600 minutes at 80°F (26.7°C) shall be provided.

3-4.2.2 For 24-volt systems, the batteries shall be connected so that their capacity meets the cold-cranking performance amperes at 0°F (–17.8°C) to comply with the engine manufacturer's recommendations.

3-4.3

Batteries shall be mounted securely and adequately protected against physical injury and vibration, water spray, and engine and exhaust heat. Where an enclosed battery compartment is provided, it shall be ventilated adequately, and the batteries shall be readily accessible for examination, test, and maintenance.

3-4.4 Battery Capacity.

3-4.4.1 Battery capacity shall be commensurate with the size of the engine and the anticipated electrical load. The capacity shall be not less than a rating of 120 ampere-hours at a 20-hour discharge rate (520 cold-cranking amperes) for gasoline engines and a rating of 200 ampere-hours at a 20-hour discharge rate (900 cold-cranking amperes) for diesel engines using 12-volt starting systems. One or more polarized receptacles shall be provided for charging all batteries.

3-4.4.2 Battery capacity and wiring circuits, including the starter switch and circuit and the starter to battery connections, shall meet or exceed the manufacturer's recommendations. A master power disconnect system shall isolate power from all of the electrical system except the primary power circuits to the alternator and starter. Exceptions apply only to systems that are required to operate when the vehicle is not attended. The control device shall be accessible from the driver's seated position.

3-4.4.3 Where specified, an on-board battery charger/conditioner shall be provided on the vehicle and shall have a minimum output rating of one-half percent of the cold-cranking ampere rating at 32°F (0°C) of the engine-starting battery system. The battery charger shall be supplied from an external power source of 115 volts or 220 volts AC. This battery charger/conditioner shall be the type that can be connected to the batteries at all times and yet maintain a charge to the batteries without causing any damage. The unit shall reduce its charging output level to a point where a small amount of charge is allowed to the batteries continuously or it shall shut off completely. The charger/conditioner shall have protection built into it to protect it from damage during high current demands such as those caused by starting the engine. The unit shall be provided with a grounded AC receptacle to allow a pull-away connection from the local electrical power supply to the battery charger/conditioner.

3-4.5

The electrical system and its components shall be weatherproof, insulated, and protected from chafing, damage from road debris, and exposure to ground fires. All wiring shall be coded to correspond with the wiring diagram provided with the vehicle. Circuit protection shall be provided to protect the vehicle in the event of electrical overload.

3-4.6

Radio suppression of the electrical system shall be in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000 MHz)*, or an equivalent radio suppression standard.

3-5 Vehicle Drive.

3-5.1

Transmission of power from the engine to the wheels of the vehicle shall be through a torque converter and an automatic or a semiautomatic gearbox. The entire drive train shall be designed and rated by the component manufacturer as having sufficient capacity to slip the wheels of the static-loaded vehicle on a surface having a coefficient of friction of 0.8. A range of gears providing the specified top speed and a grade ability of 50 percent shall be provided with sufficient intermediate gears to achieve the specified acceleration.

3-5.2

A positive drive shall be provided to each wheel by means of a fully locked driveline in order to maximize traction on low-friction surfaces. Positive drive shall be permitted to be achieved either by the use of automatic locking and torque proportioning differentials or shall be permitted to be selected manually by the seated driver by use of a single control while the vehicle is in motion.

3-5.3

All-wheel drive on these vehicles shall incorporate a drive to the front and rear axles that is engaged at all times during the intended airport service. An interaxle differential shall be installed with automatic means or driver-selected means of differential locking.

3-5.4

All traction-increasing devices shall be operated by a single control for driving simplicity.

3-5.5

Front and rear axles shall have adequate capacity to carry the maximum imposed load under all intended operating conditions. The variations in axle tread shall not exceed 20 percent of the tire sectional width at rated load.

3-6 Suspension.

The suspension system shall be designed to allow the loaded vehicle to perform as follows:

(a) Travel at the specified speeds over improved surface;

(b) Travel at moderate speeds over unimproved surface;

(c) Provide diagonally opposite wheel motion 10 in. (25.4 cm) above ground obstacles without raising the remaining wheels from the ground;

(d) Prevent damage to the vehicle caused by wheel movement; and

(e) Provide a good environment for the crew when traveling over all surfaces.

3-7 Wheels, Tires, and Rims.

3-7.1

Vehicles shall be required to have off-highway mobility while meeting the specified paved surface performance.

3-7.2

Tires shall be selected to maximize the acceleration, speed, braking, and maneuvering capabilities of the vehicle on paved surfaces without sacrificing performance on all reasonable terrains found within the airport boundary.

3-7.3*

The purchaser shall provide a tire description that reflects the off-road performance requirements necessitated by the soil conditions encountered at the operational airport. Soil conditions that vary from an extremely fine grain soil or clay to an extremely coarse grain soil, sand, or gravel in a dry, saturated, or frozen condition shall be considered.

To optimize flotation under soft ground conditions, tires of larger diameter or width, or both, than is needed for bearing weight only shall be specified. Similarly, the lowest tire pressure compatible with the high speed performance requirements also shall be specified.

3-7.4

Vehicle and tire manufacturers shall be consulted for the tread design most suitable for the specific soil composition at individual airports.

3-7.5

All wheels on the vehicle shall be of the single-wheel type with all rims, tires, and wheels of an identical size and the same tire tread design.

3-7.6

Rims, tires, wheels, and inflation pressures shall be approved by their respective manufacturers as having sufficient capacity to meet the specified performance and shall be certified for not less than 5 mi (8 km) of continuous operation at 65 mph (104.6 km/h) at normal operational pressure.

3-8 Towing Connections.

At least two large tow eyes or tow hooks (one at the front and one at the rear), capable of towing the vehicle on level ground without damage, shall be mounted on the truck and attached directly to the frame structure or where recommended by the vehicle manufacturer.

3-9 Brakes.

3-9.1*

Service brakes shall be of the all-wheel type. Service brakes shall be permitted to be of the hydraulic type with power booster or of the air-mechanical type.

3-9.2

If air-mechanical brakes are furnished, a brake chamber shall be provided for each wheel and shall be mounted so that no part of the brake chamber projects below the axle bowl.

3-9.3

Air brake systems shall include a compressor, an automatic air-drying system immediately downstream from the compressor to prevent condensation buildup in all pneumatic lines, a release valve, a brake control valve, a treadle-type actuating pedal, an air pressure gauge, enclosed-type brake adjusters, low pressure warning, and all necessary connections.

3-9.4

The compressor shall have the capacity for quick buildup of tank pressure from 0 psi (0 kPa) to the pressure to release spring brakes, and this buildup in pressure shall be accomplished within 15 seconds.

3-9.5 Compressed Air Reservoirs.

3-9.5.1 Compressed air reservoirs shall have a minimum capacity of 2000 $in.^3$ (3 277 400 cm^3) and shall be equipped with drain and safety valves.

3-9.5.2 Provision shall be made for charging of air tanks with either a pull-away electrical connection used to power a vehicle-mounted auxiliary compressor or a pull-away air connection for charging of air tanks from an external air source.

3-9.6

The service brakes shall be capable of holding the fully loaded vehicle on a 50-percent grade and shall be capable of bringing the fully loaded vehicle to five complete successive stops within 35 ft (10.7 m) at a speed of 20 mph (32.2 km/h) on dry, hard, approximately level road that is free from loose material.

3-9.7*

The parking brake system shall be an entirely independent mechanical system or shall be permitted to be connected to the same brake shoes as the service brakes but through entirely separate mechanical means.

3-9.8

The parking brake shall be capable of holding the fully loaded vehicle on a 20-percent grade.

3-9.9

An emergency brake system shall be provided that is applied and released by the driver from the cab and is capable of modulation by means of the service brake control. When a single failure in the service brake system of a part designed to contain compressed air or brake fluid occurs, other than failure of a common valve, manifold, brake fluid housing, or brake chamber housing, the vehicle shall stop within no more than 288 ft (87.8 m) at 40 mph (64.4 km/h) without any part of the vehicle leaving a dry, hard, approximately level roadway that has a width equal to the vehicle width plus 4 ft (1.2 m).

3-10 Steering.

3-10.1

The chassis shall be equipped with power-assisted steering with direct mechanical linkage from the steering wheel to the steered axle(s) to allow manual control in the event of power-assist failure.

3-10.2

The power steering system shall have sufficient capacity so that no more than 15 lbf (66.7 N) pull is needed on the steering wheel rim in order to turn the steering linkage from stop to stop with the fully loaded vehicle stationary on a dry, level, paved surface with the engine at idle.

3-10.3

The wall-to-wall turning diameter of the fully loaded vehicle shall be less than three times the vehicle length.

3-11 Cab.

3-11.1

The cab shall be fully enclosed (i.e., floor, roof, and four sides) and mounted on the forward part of the vehicle. Seating for the crew shall be restricted to the cab. The maximum number of crew seat positions provided in the cab shall be designated by the manufacturer and so labeled in the cab. As a minimum, two designated seat positions shall be provided, one for the driver and one for an additional crew member. Seat belts approved by the authority having jurisdiction shall be provided for each of the designated seating positions. Space shall be provided for all instrument controls and equipment specified without hindering the crew. Doors that open to as wide a position as possible shall be provided on each side of the cab with the necessary steps and handrails to allow rapid and safe entrance and exit from the cab. The cab design shall take into consideration the provision of ample space for the crew to enter and exit the cab and carry out normal operations while wearing full protective equipment.

3-11.2

The cab shall meet the visibility requirements of 3-2.2.3. Interior cab reflections from exterior and interior lighting shall be minimized. The windshield shall be shatterproof safety glass, and all other windows shall be constructed of approved safety glass. The cab shall be provided with wide gutters to prevent foam and water from dripping on the windshield and side windows. Where equipped with a roof turret having manual controls above the cab roof, the cab shall be designed with a quick-access passage to the roof turret(s).

3-11.3

The cab shall be weatherproof and shall be fully insulated thermally and acoustically with a fire-resistant material. The cab interior noise level at any seated position shall not exceed 85 dBA while traveling at 50 mph (80.5 km/h) on a level, hard surface without warning devices operating. With warning devices operating, the maximum limit shall be 90 dBA. The cab shall be permitted to be of the unitized rigid body and frame structure type, or it shall be permitted to be a separate unit flexibly mounted on the main vehicle frame. The cab shall be constructed from materials of adequate strength to ensure a high degree of safety for the crew under all operating conditions, including excess heat exposure and vehicle roll-over accidents.

3-11.4 Instruments, Warning Lights, and Controls.

3-11.4.1 The minimum number of instruments, warning lights, and controls consistent with the safe and efficient operation of the vehicle chassis and fire-fighting system shall be provided. All chassis instruments and warning lights shall be grouped together on a panel immediately in front of the driver. All fire-fighting system instruments, warning lights, and controls shall be grouped together by function to provide ready accessibility as well as high visibility for the driver as well as crew members.

3-11.4.2 All instruments and controls shall be illuminated, and backlighting shall be used where practical.

3-11.4.3 Groupings of both the chassis and fire-fighting system instruments, warning lights, and controls shall be easily removable as a unit or shall be on a panel hinged for back access by the use of quick-disconnect fittings for all electrical, air, and hydraulic circuits.

3-11.4.4 The following instruments or warning lights, or both, shall be provided as a minimum:

(a) Speedometer/odometer;

(b) Engine tachometer(s), where specified;

(c) Fuel level;

(d) Air pressure, where specified;

(e) Engine(s) temperature;

(f) Pump pressure, where specified;

(g) Water tank level, where specified;

(h) Foam-liquid tank level, where specified;

(i) Low air pressure warning, where specified;

(j) Headlight beam indicator;

(k) Engine(s) oil pressure;

(l) Voltmeter(s);

(m) Transmission oil temperature.

3-11.4.5 The cab shall have all the necessary controls within easy reach of the driver for the full operation of the vehicle and for activating the fire-fighting system. The following cab controls shall be provided, as applicable:

(a) Accelerator pedal;

(b) Brake pedal;

(c) Parking brake control;

(d) Steering wheel, with self-canceling directional control signal and horn;

(e) Transmission range selector;

(f) Pump control or liquid agent pressurization control;

(g) Liquid agent tank valve control;

(h) Siren switch(es);

(i) Ignition switch(es);

(j) Auxiliary agent pressurization control;

(k) Remote turret, only where remote turret is furnished;

(l) Starter switch(es);

(m) Light switches;

(n) Windshield wiper and washer controls;

(o) Heater/defroster controls.

3-11.5 Equipment.

3-11.5.1 The following equipment shall be provided in or on the cab, as applicable:

(a) Heater/defroster;

(b) Driver's seat with fore and aft adjustment, with seat belt;

(c) Crew seats with individual retractable seat belts;

(d) Windshield washers appropriate for removing foam;

(e) Windshield wipers appropriate for removing foam;

(f) Siren;

(g) Horn;

(h) Sun visors;

(i) Outside rear view mirrors, as specified in 3-2.2.4;

(j) Interior lighting;

(k) Provisions for mounting SCBA of the type specified by the purchaser at each crew seat position.

3-11.5.2 The minimum number of instruments, warning lights, and controls consistent with the safe and efficient operation of the vehicle, chassis, and fire-fighting system shall be provided. All chassis instruments and warning lights shall be grouped together on a panel in front of the driver. All fire-fighting system instruments, warning lights, and controls shall be grouped together by function to provide ready accessibility and high visibility for the driver as well as crew members.

3-11.6

Signs that state "Occupants must be seated and wearing a seat belt when apparatus is in motion" shall be provided. Such signs shall be visible from each seated position. An accident prevention sign shall be located at the rear step area of the vehicle, if it exists. It shall warn personnel that standing on the step while the vehicle is in motion is prohibited.

3-12 Body.

3-12.1

The body shall be constructed of materials that are of the lightest weight consistent with the strength necessary for off-pavement operation over rough terrain and where exposed to excess heat. The body shall be permitted to be of the unitized-with-chassis-rigid-structure type or it shall be permitted to be flexibly mounted on the vehicle chassis. It also shall include front and rear fenders or wheel wells. Body panels shall be removable where necessary to provide access to the interior of the vehicle.

3-12.2

Access doors shall be provided for those areas of the interior of the vehicle that are inspected frequently. In particular, access doors of sufficient size and number shall be provided for access to the following:

(a) Engine;

(b) Pump;

(c) Battery storage;

(d) Fluid reservoirs;

(e) Foam system.

Other areas that need to be accessible for inspection or maintenance shall be open or shall have removable panels.

3-12.3

Suitable, lighted compartments shall be provided for convenient storage of equipment and tools to be carried on the vehicle. Compartment doors shall be operable for hands covered with bulky gloves. Compartments shall be weathertight and self-draining.

3-12.4

The working deck of the vehicle shall be reinforced adequately to allow the crew to perform its duties in all areas where access to auxiliary or installed equipment is necessary.

3-12.5

Handrails or bulwarks shall be provided where necessary for the safety and convenience of the crew. Rails and stanchions shall be braced strongly and constructed of a material that is durable and resists corrosion. Handrails shall be constructed of, or covered with, a slip-resistant material.

3-12.6

Steps or ladders shall be provided for access to the top fill area. The lowermost step(s) shall be permitted to extend below the angle of approach or departure or ground clearance limits if it is designed to swing clear. All other steps shall be rigidly constructed. All steps shall have a nonskid surface. The lowermost step(s) shall be no more than 22 in. (558.8 mm) above level ground when the vehicle is fully loaded. Adequate lighting shall be provided to illuminate steps and walkways.

3-12.7

A heavy-duty front bumper shall be mounted on the vehicle and secured to the frame structure.

3-12.8

Attachments shall be provided for all tools, equipment, and other items that the purchaser specifies to be furnished on the vehicle. Equipment holders shall be attached firmly and designed so that equipment remains in place under all operating conditions, but the equipment shall be quickly removable for use.

3-13 Fire-Fighting Systems and Agents.

3-13.1 General.

3-13.1.1 For aircraft rescue and fire-fighting purposes, primary and auxiliary extinguishing agents shall be tested in accordance with NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*.

3-13.1.2 Vehicles designed to discharge auxiliary agents shall require the use of auxiliary agents that are compatible with the primary agent.

3-13.1.3 All components of the agent systems, including such items as the tanks, piping, fill troughs, and screens, shall be made of materials resistant to corrosion by the primary agent, primary agent/water solution, water, and, where specified, the auxiliary agent.

3-13.2 Pump(s) and Pump Drive.

3-13.2.1 Water Pump(s).

3-13.2.1.1 The water pump(s) shall be constructed of corrosion-resistant metals and shall be of the single-stage or multiple-stage centrifugal type and shall be designed for dependable emergency service. It shall be designed carefully and built in accordance with good modern practice. Pumps shall be gravity primed from the vehicle tank. The pump and piping system shall be designed to eliminate the entrapment of air.

3-13.2.1.2 Where discharging foam solution, the pump shall be capable of discharging at a rate equal to or exceeding the total requirements of turrets and hand line nozzles discharging simultaneously at designed pressures.

3-13.2.2 Pump Drive.

3-13.2.2.1 The pump(s) drive shall allow operation of the pump(s) and simultaneous operation of the vehicle. The pump(s) shall not be affected by changes in transmission ratios or the actuation of clutches in the vehicle drive. The design of the drive system and controls shall prevent damage to the drive or minimize lurching of the vehicle when the vehicle drive is engaged during pumping operations. The pump(s) drive system shall be capable of absorbing the maximum torque delivered by the engine to the pump(s) and withstanding the engagement of the pump(s) at all engine speeds and under all operating conditions. The operation of the pump(s) shall not, under any conditions, cause the engine to stall or cause more than a slight and momentary reduction in engine speed and consequent drop in pump pressure.

3-13.2.2.2 While pumping at rated capacity, the drive shall allow controlled vehicle operation at speeds from 1 mph to 5 mph (1.6 km/h to 8 km/h). The pump(s) drive shall have sufficient power capacity to provide the pump discharge requirements of 3-13.2.1.2 while the vehicle is being propelled under all operating conditions where a fire-fighting capability is needed.

3-13.2.2.3 If an independent engine is used to drive the pump(s), it shall have the same fuel and electrical system as the chassis engine and shall be equipped with an air cleaner, replaceable element oil filter, a full pressure lubricating system, and an overspeed governing device to prevent engine damage. The engine also shall be provided with a cooling system that meets the requirements of 3-3.2.1 or 3-3.2.2.

3-13.2.3 Suction Connections. The suction system shall be designed for efficient flow at the pumping rates required by 3-13.2.1.2. The pump suction line(s) shall be of large diameter and of the shortest length consistent with the most suitable pump location. There shall be a drain at the lowest point with a valve for draining all of the liquid from the pumping system where desired. Suction lines and valves shall be constructed of corrosion-resistant materials.

3-13.2.4 Discharge Connections. All discharge outlets shall have National (American) Standard fire hose coupling thread. Adapter couplings, securely attached, shall be provided on each outlet if local couplings are not National (American) Standard as specified in NFPA 1963, *Standard for Fire Hose Connections*.

3-13.2.5 Piping, Couplings, and Valves.

3-13.2.5.1 All piping, couplings, and valves shall be sized for necessary flow with minimum restriction and pressure loss. Material for all piping, couplings, and valves shall be selected to avoid corrosive and galvanic action.

3-13.2.5.2 Piping shall be mounted securely and provided with flexible couplings to minimize stress. Union or rubber-gasketed fittings shall be provided where necessary to facilitate removal of piping.

3-13.2.5.3 All valves shall be of the quarter-turn type and shall be selected for ease of operation and freedom from leakage.

3-13.2.5.4 All water system piping shall be tested on the suction side of the pump to detect possible leakage. All water and foam solution discharge piping, together with the agent pump(s), shall be tested at 50 percent above the system operating pressure.

3-13.2.6 Overheat Protection. A system line shall be provided from the water pump discharge and, if applicable, from the foam pump discharge to prevent overheating of the pumps while engaged and operating at zero (0) discharge. The line shall be automatic.

3-13.2.7 Pressure Relief Valves. A pressure relief valve shall be fitted both to protect and ensure optimum performance of the system.

3-13.3 Water Tank for Nonpressurized Systems.

3-13.3.1 Capacity.

3-13.3.1.1 A water tank shall have a usable capacity as specified in 3-1.2.

3-13.3.1.2 The rated capacity of the tank shall be equal to the usable capacity that can be pumped from the tank while the vehicle is parked on level ground. The tank outlets shall be arranged to allow use of at least 85 percent of the rated capacity with the vehicle positioned as follows:

(a) On a 20-percent side slope;

(b) On a 30-percent ascending grade;

(c) On a 30-percent descending grade.

3-13.3.2 Construction.

3-13.3.2.1 The tank shall be constructed to resist all forms of deterioration that could be caused by the water and foam concentrate while affording the structural integrity necessary for off-road operation. The tank shall have longitudinal and transverse baffles. The construction and connections shall be made to prevent the possibility of galvanic corrosion of dissimilar metals.

3-13.3.2.2 The tank shall be equipped with easily removable manhole covers over the tank discharge. Where specified, the tank shall be designed to allow access within each baffled compartment of the tank for internal and external inspection and service. The tank shall have a drain valve(s).

3-13.3.2.3 Provisions shall be made for necessary overflow and venting. Venting shall be sized to allow agent discharge at the maximum design flow rate without danger of tank collapse and shall be sized to allow rapid and complete filling without exceeding the internal pressure design limit of the tank. Additionally, overflows shall be designed to prevent the loss of water from the tank during normal maneuvering and to direct the discharge of overflow water directly to the ground.

3-13.3.2.4 The water tank shall be mounted in a manner that limits the transfer of the torsional strains from the chassis frame to the tank during off-pavement driving. The tank shall be separate and distinct from the crew compartment, engine compartment, and chassis and shall be easily removable as a unit.

3-13.3.2.5 The water tank shall be equipped with at least one top fill opening of not less than 5 in. (127 mm) internal diameter. The top fill shall be equipped with an easily removable strainer of $^1/_4$-in. (6.4-mm) mesh construction. The top fill opening shall be equipped with a cap designed to prevent spillage.

3-13.3.3 Tank Fill Connection(s).

3-13.3.3.1 A tank fill connection(s) shall be provided in a position where it can be reached easily from the ground.

3-13.3.3.2 All connections shall have National (American) Standard fire hose coupling threads. Securely attached adapters shall be provided on each connection if local couplings are not National (American) Standard. Connections and adapter threads shall be as specified in NFPA 1963, *Standard for Fire Hose Connections*. Connections and connections with adapters attached shall not protrude beyond the normal body metalwork of the vehicle.

3-13.3.3.3 The connection(s) shall be provided with strainers of $^1/_4$-in. (6.4-mm) mesh and shall have check valves or shall be constructed so that water is not lost from the tank when connection or disconnection is made.

3-13.3.3.4 The tank fill connection(s) shall be sized to allow filling of the water tank in 2 minutes at a pressure of 80 psi (551.6 kPa) at the tank intake connection.

3-13.4 Foam Proportioning System.

3-13.4.1 Foam-Liquid Concentrate Tank(s).

3-13.4.1.1 The purchaser shall specify the percent concentrate foam system to be provided. The foam-liquid concentrate tank(s) shall have a working capacity sufficient for two tanks of water at the maximum tolerance specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

3-13.4.1.2 Foam-liquid concentrate tanks shall be permitted to be of either the rigid or flexible type. The tank(s) shall be designed for compatibility with the foam concentrate being used and shall resist all forms of deterioration that could be caused by the foam concentrate or water.

3-13.4.1.3 Tanks shall be designed to provide ready access for internal and external inspection and service. A large capacity drain connection shall be installed flush with the bottom of the sump.

3-13.4.1.4 The tank outlets shall be located above the bottom of the sump and shall provide continuous foam-liquid concentrate to the foam proportioning system, with that system operating as specified in 3-13.4.3 and with the vehicle discharging two tank loads of usable water as specified in 3-13.3.1.

3-13.4.1.5 If separate from the water tank, the foam-liquid tank shall be mounted in a manner that limits the transfer of the torsional strains from the chassis frame to the tank during off-pavement driving. The tank shall be separate and distinct from the crew compartment, engine compartment, and chassis and shall be easily removable as a unit.

A flexible tank shall be structurally supported to resist tearing. The structural support shall not be dependent on the fluid level in either the water or foam tanks.

3-13.4.1.6 A top fill trough shall be provided and shall be equipped with a stainless steel No. 10 mesh screen and container openers to allow emptying 5-gal (18.9-L) foam-liquid concentrate containers into the storage tank(s) at a rapid rate regardless of water tank level. The trough shall be connected to the foam-liquid storage tank(s) with a fill line designed to introduce foam-liquid concentrate near the bottom of the tank(s) to minimize foaming within the storage tank.

3-13.4.1.7 The tank fill connection(s) shall be provided in a position where it can be reached easily from the ground to allow the pumping of foam-liquid concentrate into the storage tank(s). The connection(s) shall be provided with strainers of $^{1}/_{4}$-in. (6.4-mm) mesh and shall have check valves or be constructed so that foam is not lost from the tank when connection or disconnection is made.

Where flexible tanks are used, the supply system shall be designed so that the flexible tanks are not subject to excess pressure. The supply system shall be capable of delivering foam-liquid at a rate at least equal to or greater than the maximum discharge rate of the foam system.

3-13.4.1.8 The tank(s) shall be vented adequately to allow rapid and complete filling without the buildup of excessive pressure and to allow emptying the tank at the maximum design flow rate without danger of collapse. The vent outlets shall be directed to the ground to prevent spillage of foam-liquid concentrate on vehicle components.

3-13.4.2 Foam-Liquid Concentrate Piping.

3-13.4.2.1* The foam-liquid concentrate piping shall be of material resistant to corrosion by foam-liquid concentrate. Care shall be taken that combinations of dissimilar metals that produce galvanic corrosion are not selected or that such dissimilar metals are electrically insulated. Where plastic piping is used, it shall be fabricated from unplasticized resins, unless it has been demonstrated that the stipulated plasticizer does not adversely affect the performance characteristics of the foam-liquid concentrate. The plastic pipe shall be permitted to be reinforced with glass fibers.

3-13.4.2.2 The foam-liquid concentrate piping shall be adequately sized to allow the maximum required flow rate and shall be arranged to prevent water from entering the foam tank.

3-13.4.3 Foam-Liquid Proportioning System.

3-13.4.3.1 The foam concentrate proportioning system shall provide a means of controlling the ratio of foam concentrate to the quantity of water in the foam solution being discharged from all orifices normally used for aircraft fire-fighting operations.

3-13.4.3.2 The proportioning system shall be sufficiently accurate to provide for the discharge of finished foam within the range specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam*.

3-13.5 Premixed — Pump System.

Where premix solution in the main water tank is selected as the means of proportioning foam to water, the foam solution used shall be AFFF only. Care shall be exercised that the premixed solution is mixed to exact proportions. Where premix solution is used, operation of the vehicle fire-fighting system shall conform to the requirements of 3-13.2 and 3-13.3.

3-13.6 Premixed — Pressurized System.

3-13.6.1 Liquid Agent Container(s).

3-13.6.1.1 The storage container(s) and liquid agent(s) shall be designed for pressurization and shall be constructed in accordance with the ASME *Boiler and Pressure Vessel Code* and shall be so marked.

3-13.6.1.2 The material of construction shall be resistant to corrosion by the AFFF agent to be stored, or a suitable lining material shall be provided.

3-13.6.1.3 An ASME-approved pressure relief valve of adequate capacity shall be provided on the container and set to prevent pressures in excess of the maximum design working pressure. A pressure gauge shall be provided that indicates the internal pressure of the agent storage container at all times.

3-13.6.1.4 A readily accessible fill opening of sufficient size to allow ease in filling, and stirring if necessary, shall be provided. It shall be in compliance with ASME or local codes and in no case shall be less than 3 in. (76.2 mm) in diameter. Filling shall be accomplished without the removal of any of the extinguisher piping or any major component.

3-13.6.1.5 A means shall be provided to determine the contents of the container as a guide in recharging partial loads.

3-13.6.2 Propellant Gas.

3-13.6.2.1 The propellant gas shall be dry nitrogen or dry compressed air and provided in sufficient quantity to expel the fire-fighting agent as well as to purge all piping and hose lines after use.

3-13.6.2.2 All propellant gas cylinders and valves shall be in accordance with U.S. Department of Transportation (DOT) requirements or regulations. Cylinders shall bear the DOT marking.

3-13.6.2.3 The design of the propellant source shall provide for quick and easy replacement after each use.

3-13.6.2.4 A pressure gauge shall be provided and shall indicate the pressure of the propellant gas source at all times.

3-13.6.2.5 Cylinder valves, gauges, and piping shall be arranged to preclude accidental mechanical damage.

3-13.6.2.6 The cylinder valve shall be capable of being opened by quick-acting control and also shall be suitable for remote operation.

3-13.6.3 Pressure Regulation.

3-13.6.3.1 Pressure regulation shall be designed to reducethe normal cylinder pressure automatically and to hold the propellant gas pressure at the designed operating pressure of the liquid agent container(s).

3-13.6.3.2 All pressure regulating devices shall be sealed or pinned at the designed operating pressures after final adjustment by the system manufacturer.

3-13.6.3.3 Pressure regulating devices shall be equipped with a spring-loaded relief valve that relieves any excess pressure that develops in the regulator.

3-13.6.3.4 The pressure regulator shall be permitted to be of a type without pressure indicating gauges.

3-13.6.4 Piping and Valves.

3-13.6.4.1 All propellant piping and fittings shall conform to the appropriate ASME code and shall be designed to withstand the working pressure of the system. The design of the piping and valving shall provide the desired flow of gas into the system and the minimum amount of restriction from the liquid agent container(s) to the hose connection. Where more than one hose line is provided, piping and fittings shall be sized and designed so that there is equal flow to each line, regardless of the number of lines placed in operation.

3-13.6.4.2 Provisions shall be made for purging all piping and hose of the liquid after use without discharging the liquid agent remaining in the container(s). Provisions also shall be made for the depressurization of the liquid agent container(s) without the loss of the remainder of the liquid agent.

3-13.6.4.3 Drains shall be provided to allow complete draining of the system.

3-13.6.4.4 All valves shall be of the quarter-turn, quick-opening, ball type. A maximum of two operations, exclusive of the nozzle, shall be provided to charge the system. Controls shall be arranged for simultaneous charging of the liquid agent and dry chemical systems.

Exception: Valves on the gas cylinder specified in 3-13.6.2.2 shall not be required to be of the quarter-turn, quick-opening ball type.

3-13.6.4.5 A quick-acting control to be operated by the driver to pressurize the liquid agent system from the cab of the vehicle shall be provided, with a similar control at the unit.

3-13.6.4.6 All valves and piping shall be resistant to corrosion by the foam-liquid concentrate.

3-13.6.4.7 A check valve shall be provided in the gas piping to prevent the liquid agent from being forced back into the propellant gas line.

3-13.7 Dry Chemical System.

3-13.7.1 General.

3-13.7.1.1 The dry chemical container(s) shall be constructed in accordance with the ASME *Boiler and Pressure Vessel Code*, Section 8, and shall be so stamped.

3-13.7.1.2 All piping and fittings shall conform to the appropriate ASME code and shall be designed to withstand the working pressure of the system. The design of the piping and valving shall provide the desired flow of gas into the system and the minimum amount of restriction from the chemical container(s) to the hose connection. Where more than one hose line is provided, piping and fittings shall be sized and designed so that there is equal flow to each line, regardless of the number of lines placed in operation.

3-13.7.1.3 Provisions shall be made for purging all piping and hose of dry chemical after use without discharging the dry chemical remaining in the dry chemical container(s). Provisions also shall be made for the depressurization of the dry chemical container(s) without the loss of the remainder of the dry chemical. A pressure gauge shall be provided that indicates the internal pressure of the agent storage container(s) at all times.

3-13.7.1.4 The system shall be designed to ensure fluidization of the dry chemical at the time of operation. Where any design includes the movement of the chemical container(s) to fluidize the contents, such design also shall include a manual operating feature.

3-13.7.1.5 A check valve shall be provided in the gas piping to prevent the extinguishing agent from being forced back into the propellant gas line.

3-13.7.1.6 A means of pressure relief conforming to appropriate ASME codes shall be provided for the dry chemical container(s) and piping to prevent overpressurization in the event of a malfunction in the propellant gas regulator system or in the event the container is involved in a severe fire exposure.

3-13.7.1.7 The fill opening in the dry chemical container shall be located so that it is easily accessible for recharging and necessitates a minimum amount of time and effort to open and close. Filling shall be accomplished without the removal of any of the extinguisher piping or any major component.

3-13.7.1.8 A quick-acting control to be operated by the driver to pressurize the dry chemical agent system from the cab of the vehicle shall be provided, with a similar control at the hand line.

3-13.7.2 Propellants.

3-13.7.2.1 The propelling agent shall be dry nitrogen or dry air.

3-13.7.2.2 All propellant gas cylinders and valves shall be in accordance with U.S. Department of Transportation (DOT) requirements or regulations. Cylinders shall bear the DOT marking.

3-13.7.2.3 The method of adequately pressurizing and propelling the dry chemical in the system shall provide a sufficient quantity of gas to expel the agent, as well as allowing the complete purging of all piping and hose lines after each use.

3-13.7.2.4 The design of the propellant source shall provide for quick and easy replacement after each use.

3-13.7.2.5 A pressure gauge shall be provided and shall indicate the pressure on the propellant gas source at all times.

3-13.7.2.6 Cylinder valves, gauges, and piping shall be arranged to preclude accidental mechanical damage.

3-13.7.3 Pressure Regulation.

3-13.7.3.1 Pressure regulation shall be designed to reduce the normal cylinder pressure automatically and to hold the propellant gas pressure at the designed operating pressure of the dry chemical container(s).

3-13.7.3.2 All pressure regulating devices shall be sealed or pinned at the designed operating pressures after final adjustment by the system manufacturer.

3-13.7.3.3 Pressure regulating devices shall be equipped with a spring-loaded relief valve that relieves any excess pressure that develops in the regulator.

3-13.7.3.4 The pressure regulator shall be permitted to be of a type without pressure indicating gauges.

3-13.8 Halon 1211 System.

3-13.8.1 Halon Container.

3-13.8.1.1 The storage container shall be designed for pressurization and shall be constructed in accordance with the ASME *Boiler and Pressure Vessel Code* and shall be so marked.

3-13.8.1.2 The material of construction shall be resistant to corrosion by the halon agent to be stored.

3-13.8.1.3 A readily accessible charge coupling of sufficient size to allow ease in filling shall be provided. Filling shall be accomplished without the removal of any of the extinguisher piping or any major component. A pressure gauge shall be provided that indicates the internal pressure of the agent storage container at all times.

3-13.8.1.4 A means shall be provided to determine the contents of the container as a guide in recharging partial loads and to prevent overfilling of the tank.

3-13.8.2 Propellant Gas.

3-13.8.2.1 The propellant gas shall be dry nitrogen or dry compressed air and provided in sufficient quantity to expel the halon agent as well as purge all piping and hose lines after use.

3-13.8.2.2 All propellant gas cylinders and valves shall be in accordance with U.S. Department of Transportation (DOT) requirements or regulations. Cylinders shall bear the DOT marking.

3-13.8.2.3 Pipes and valves connected to the halon container shall conform to the appropriate ASME code and shall be designed to withstand the working pressure of the system.

3-13.8.2.4 The design of the propellant source shall provide for quick and easy replacement after each use.

3-13.8.2.5 A pressure gauge shall be provided and shall indicate the pressure of the propellant gas source at all times.

3-13.8.2.6 Cylinder valves, gauges, and piping shall be arranged to preclude accidental mechanical damage.

3-13.8.2.7 A check valve shall be provided in the gas piping to prevent the liquid agent from being forced back into the propellant gas line.

3-13.8.3 Pressure Regulation.

3-13.8.3.1 An ASME-approved pressure relief valve of adequate capacity shall be provided on the container and shall be set to prevent pressures in excess of the maximum design working pressure.

3-13.8.3.2 Pressure regulation shall be designed to reduce the normal cylinder pressure automatically and to hold the propellant gas pressure at the designed operating pressure of the halon container.

3-13.8.3.3 All pressure regulating devices shall be sealed or pinned at the designed operating pressures after final adjustment by the system manufacturer.

3-13.8.3.4 Pressure regulating devices shall be equipped with a spring-loaded relief valve that relieves any excess pressure that develops in the regulator.

3-13.8.3.5 The pressure regulator shall be permitted to be of a type without pressure indicating gauges.

3-13.8.4 Halon Delivery Piping and Valves.

3-13.8.4.1 All piping, couplings, and valves shall be sized for necessary flow with minimum restriction and pressure loss. Material for all piping, couplings, and valves shall be selected to avoid corrosive and galvanic action. Piping shall be mounted securely and provided with flexible couplings to minimize stress.

3-13.8.4.2 All valves shall be of the quarter-turn type and shall be selected for ease of operation and freedom from leakage.

3-13.8.4.3 All discharge piping shall be tested at 50 percent above the system operating pressure.

3-13.8.4.4 Where more than one hose line is provided, piping and fittings shall be sized and designed so that there is equal flow to each line, regardless of the number of lines placed in operation.

3-13.8.4.5 Provisions shall be made for purging all piping and hose of the halon after use without discharging the halon remaining in the container(s). Provisions also shall be made for venting of the halon container without loss of the remainder of the liquid agent.

3-13.8.4.6 A quick-acting control to be operated by the driver to pressurize the halon system from the cab of the vehicle shall be provided, with a similar control at the hand line.

3-13.9 Primary Turret Nozzles.

3-13.9.1 Classes 2, 3, and 4 vehicles shall have a foam turret or a twin (dry chemical and foam) turret. Where Halon 1211 is utilized, a twin turret shall not be required.

3-13.9.2 The nominal foam solution discharge rate from the foam turret shall be 150 gpm (567.8 lpm) for Class 2 vehicles, 200 gpm (757 lpm) for Class 3 vehicles, and 250 gpm (946.3 lpm) for Class 4 vehicles. The roof turret discharge rate shall have a tolerance of +10 percent/-0 percent.

3-13.9.3 Both single foam turrets and the foam barrel of a twin turret for simultaneous agent discharge shall be capable of discharging foam, as specified in Table 3-13.9.3, in still air in a variable pattern with the turret elevated to the maximum stream reach position.

Table 3-13.9.3 Foam Turret Barrel Pattern

Vehicle Class	Straight Stream	Dispersed Stream	
	Far Point (ft) (m)	Full Width (ft) (m)	Full Width Far point (ft) (m)
2	125 38	20 6	25 7.6
3	125 38	25 7.6	25 7.6
4	125 38	25 7.6	25 7.6

3-13.9.4 The dry chemical barrel of a twin turret for simultaneous agent discharge shall be designed to dispense the dry chemical agent at a minimum discharge rate of ≥ 16 lb/sec to ≤ 22 lb/sec (≥ 7.3 kg/sec to ≤ 10.0 kg/sec) and with a minimum far point range of not less than 100 ft (30.5 m), with a pattern width not less than 17 ft (5.2 m) with the turret stationary.

3-13.9.5 The foam barrel of a twin turret for simultaneous agent discharge shall be positioned so that the foam stream pattern falls to the ground 10 ft (3 m) behind the dry chemical stream pattern.

3-13.9.6 Turret controls for both foam and dry chemical turrets shall be accessible both to the driver and the crew member.

3-13.9.7 Both single and twin turrets shall be capable of being elevated at least 45 degrees above the horizontal and depressed to discharge agent within 20 ft (6.1 m) in front of the vehicle at full output using a dispersed stream. The turret shall be capable of being rotated not less than 90 degrees to either side, with total traverse not less than 180 degrees. Where two turrets are used on a vehicle, suitable stops shall be provided so that neither turret can interfere with the other turret.

3-13.9.8 The dry chemical agent system shall be designed so that the operator can discharge both the primary and the auxiliary agent system separately or simultaneously.

3-13.10 Preconnected Hand Lines, Reels, and Nozzles.

3-13.10.1 Combined agent vehicles shall have at least one preconnected hand line and nozzle for each agent. Hand lines and nozzles shall be permitted to be separate or twinned together for simultaneous agent discharge. Hand lines shall be permitted to be reeled hand lines as specified in 3-13.10.2 or woven jacket hand lines as specified in 3-13.10.3.

3-13.10.2 Preconnected Hand Lines.

3-13.10.2.1 Preconnected hand lines for reels shall have a minimum internal diameter of 1 in. (25.4 mm), shall have a minimum burst pressure rating three times the nominal working pressure of the system, and shall discharge the gpm (lpm) required in 3-13.10.2.3 without unreeling the hose.

3-13.10.2.2 At least 100 ft (30.5 m) of hose shall be provided for each reel.

3-13.10.2.3 Each hand line shall be equipped with a shutoff-type nozzle designed to discharge both foam and water at a nominal discharge rate of 60 gpm (227.1 lpm), +10 percent/–0 percent. Each nozzle shall have minimum foam discharge patterns from a dispersed stream of 15 ft (4.6 m) in width and 20 ft (6.1 m) in range to a straight foam stream with a 50-ft (15.2-m) range.

3-13.10.2.4 Each reel shall have capacity for at least 100 ft (30.5 m) of 1-in. (25.4-mm) hose or more if specified by the purchaser.

3-13.10.2.5 Each reel shall be designed and positioned to allow hose line removal by a single person from any position in a 120-degree horizontal sector. Each reel shall be equipped with a friction brake to prevent the hose from unreeling when not desired. A power rewind with manual override shall be provided. The nozzle holder, friction brake, rewind controls, and manual valve control shall be accessible from the ground.

3-13.10.2.6 The discharge control to each hand line shall be adjacent to the hand line and accessible to the person using the hand line.

3-13.10.3 Woven Jacket Hand Lines.

3-13.10.3.1 Woven jacket hand lines shall have a minimum diameter of $1^1/_2$ in. (38.1 mm) and shall meet the requirements of NFPA 1961, *Standard for Fire Hose*.

3-13.10.3.2 At least 150 ft (45.7 m) of hose shall be provided for each hand line.

3-13.10.3.3 Each hand line shall be equipped with a shutoff-type nozzle designed to discharge both foam and water at a nominal discharge rate of 95 gpm (359.6 lpm), +10 percent/–0 percent.

Each nozzle shall have minimum foam discharge patterns from a dispersed stream of 15 ft (4.6 m) in width and 20 ft (6.1 m) in range to a straight foam stream with a 65-ft (19.8-m) range.

3-13.10.3.4 Each hand line shall be stored, flat loaded, in a hose compartment and shall be preconnected. Each hose compartment shall have a capacity for a minimum of 150 ft (45.7 m) of $1^{1}/_{2}$-in. (38.1-mm) multiple jacket hose or more if specified by the purchaser.

3-13.10.3.5 Hose compartments shall be fabricated from noncorrosive material and shall be designed to drain effectively. The compartment shall be smooth and free from all projections that might damage the hose. No other equipment shall be mounted or located where it can obstruct the removal of the hose. Each preconnected hand line compartment shall be located so that the distance between the hand line nozzle and the ground, step, or deck plate upon which the operator stands to initiate the pulling of the hand line from the reel or the top lay of the woven jacket hose is not more than 6 ft (1.8 m) above that surface.

3-13.10.3.6 The discharge control to each hand line shall be adjacent to the hand line and accessible to the person using the hand line.

3-13.10.4 Auxiliary Agent Hand Lines.

3-13.10.4.1 Hand lines for auxiliary agents shall have a minimum burst pressure rating three times the nominal working pressure of the system and meet the requirements specified below. The auxiliary agent hand line shall be equipped with a nozzle that allows a fully opened to a fully closed position in a single, simple movement and shall be designed to discharge agent at a minimum rate of ≥5 lb/sec to ≤7 lb/sec (≥2.3 kg/sec to ≤3.3 kg/sec) at a minimum range of 20 ft (6.1 m). Nozzle construction shall be of nonferrous metal or stainless steel.

3-13.10.4.2 Twinned hand lines and nozzles shall be designed so that each agent can be discharged separately or simultaneously. The barrels shall be linked together to provide coordinated application by one operator.

3-13.10.4.2.1 Each reel shall have capacity for at least 100 ft (30.5 m) of 1-in. (25.4-mm) hose or more if specified by the purchaser.

3-13.10.4.2.2 Each reel shall be designed and positioned to allow hose line removal by a single person from any position in a 120-degree horizontal sector. Each reel shall be equipped with a friction brake to prevent the hose from unreeling when not desired. A power rewind with manual override shall be provided. The nozzle holder, friction brake, rewind controls, and manual valve control shall be accessible from the ground.

3-13.10.4.2.3 The discharge control to each hand line shall be adjacent to the hand line and accessible to the person using the hand line.

3-13.11 Foam Quality.

Turrets and hand lines shall discharge foam having the quality specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*.

Measurement of the expansion ratio and 25-percent drainage times shall be in accordance with the procedures outlined in NFPA 412.

3-14 Lighting and Electrical Equipment.

3-14.1

Lighting equipment shall be installed in conformity with local road regulations, where practicable, and shall include the following:

(a) Headlights with upper and lower driving beams. A control switch that is readily accessible to the driver shall be provided for beam selection.

(b) Dual taillights and stoplights.

(c) Self-canceling turn signals, front and rear, with a steering column-mounted control and a visual and audible indicator. A four-way flasher switch shall be provided.

(d) Where specified, a minimum 6-in. (152.4-mm) spotlight on both left and right sides of the windshield, hand-adjustable type, with controls for beam adjustments inside the truck cab.

(e) Adequate reflectors, and marker and clearance light, shall be furnished to describe the overall length and width of the vehicle.

(f) Engine compartment lights, nonglare type, arranged to illuminate both sides of the engine, with individual switches located in the engine compartment. Service lighting shall be provided for all areas described in 2-12.2(a), (b), and (c), as well as for the engine compartment.

(g) Two swivel-mounted lights, 6 in. (152.4 mm) minimum, with clear lens and individual switches, mounted on the top deck for equipment lighting.

(h) Lighting provided for all top deck working areas.

(i) At least one back-up light and an audible alarm with a minimum of 97 dBA meeting SAE J994, *Standard on Alarm-Backup-Electric Laboratory Performance Testing*, installed in the rear of the body.

(j) A flashing red beacon or alternate red and white flashing lights mounted on the top deck and visible for 360 degrees in the horizontal plane. The mounting of the beacon also shall provide good visibility from the air. A control switch shall be provided on the instrument panel in the cab for control of the beacon.

3-14.2*

A warning system shall be provided that has a sound output of not less than 95 dBA at 100 ft (30.5 m), when measured directly ahead of the siren and not less than 90 dBA at 100 ft (30.5 m), measured at 45 degrees on either side. The siren shall be mounted to allow maximum forward sound projection but shall be protected from foam dripping from the turret or water splashed up by the tires.

3-14.3

A master switch for all emergency lights shall be provided.

3-14.4

An electric or air horn shall be provided and shall be mounted at the front part of the vehicle with the control positioned so that it is readily accessible to the driver.

3-14.5

Where furnished, air horns, an electric siren(s), and an electronic siren speaker(s) shall be mounted as low and as far forward on the apparatus as practical. Audible warning equipment shall not be mounted on the roof of the apparatus.

3-14.6 Radios.

3-14.6.1 Provision shall be made for mounting radios. Operation of the radios shall be from the cab. Radios shall be mounted to allow quick servicing or replacement.

3-14.6.2 The purchaser shall specify all necessary radios and frequencies that are to be provided.

3-15* Tools.

Provision shall be made for mounting tools and equipment, as specified by the purchaser, on the truck. Special tools for servicing the vehicle, fire suppression system, and any of the auxiliary equipment shall be furnished as necessary by the vehicle manufacturer.

Chapter 4 Acceptance Criteria

4-1 General.

4-1.1

Compliance with the requirements of this standard shall be verified by one of the following methods:

(a) The component manufacturer's certification;

(b) Prototype vehicle tests;

(c) Operational tests.

4-1.2

The component manufacturer's certification shall be provided where specified in Section 4-2. The manufacturer shall certify that the component is approved for use in the RFF application.

4-1.3

Prototype vehicle tests shall be conducted by the manufacturer in accordance with the standardized procedures found in Section 4-3 to ensure that the performance requirements have been achieved with the design. Calculated performance capability shall not be substituted for an actual prototype test.

4-1.4

Operational tests shall be performed either at the airport or the manufacturer's facility as specified in Section 4-4. The test shall be conducted by the manufacturer on every vehicle built.

4-1.5

The manufacturer of the vehicle shall demonstrate to the purchasing authority or its designee the care and maintenance and operational capability of the vehicle.

4-2 Component Manufacturer's Certification.

4-2.1

A copy of the manufacturer's signed application for approval shall be provided with the vehicle documents for the following components:

(a) Engine;

(b) Transmission;

(c) Axles;

(d) Transfer case;

(e) Wheels;

(f) Tires;

(g) Hand line hose with couplings attached;

(h) Premixed storage container;

(i) Premixed system pressure relief valve;

(j) Propellant gas cylinder;

(k) Propellant gas cylinder regulating device;

(l) Complementary agent storage container;

(m) Complementary agent pressure relief device.

4-2.2

The cooling system shall be certified by the vehicle manufacturer to satisfy all operational conditions at all ambient temperatures encountered at the operational airport for both the engine and the transmission.

4-2.3

The brake system shall be certified by the vehicle manufacturer to satisfy the service brake, emergency brake, and grade-holding performance requirements for the corresponding class of vehicle.

4-2.4

Where the vehicle is equipped with an air brake system, the vehicle manufacturer shall provide itemized, certified data relative to the air system as follows:

(a) Total reservoir capacity;

(b) Total required volume (twelve times the total combined brake chamber volume at full stoke);

(c) Quick buildup system capacity;

(d) Quick buildup system pressure needed to release the spring brakes.

4-3 Prototype Vehicle Tests.

Where the vehicle is fitted with an extendable turret (*see definition in Section 1-3*), the test shall be conducted with the extendable turret in the stowed position.

4-3.1 Rated Water/Foam Tank Capacity Test.

4-3.1.1 Test facilities shall consist of an open site suitable for discharging agent that includes both level ground and measured grades of at least 20 percent and 30 percent. Access to a refill water supply shall be required.

4-3.1.2 Test equipment shall consist of the following:

(a) A calibrated sight gauge;

(b) A liquid volume measuring device accurate to within ± 1.0 percent;

(c) *Alternative:* A stopwatch and a scale capable of measuring the total vehicle weight accurate to within ± 1.0 percent.

4-3.1.3 The vehicle shall have had its primary turret(s) discharge rate verified prior to beginning this test to ensure that the turret(s) discharges at or above the minimum rate specified, and the accuracy of the foam metering system shall have been verified.

4-3.1.4 The rated water and foam tank capacity shall be determined as follows:

(a) Park the vehicle on level ground.

(b) If necessary, attach a calibrated site gauge to both the water tank and the foam tank.

(c) Fill the water piping up to a level even with the bottom of the tank. Do not record the water quantity used.

(d) *Alternative:* After completion of 4-3.1.4(c), record the weight of the vehicle. Fill the water tank and foam tank and record the weight of the vehicle.

(e) While filling both tanks with a liquid volume measuring device, correlate and record the amount of water added to each tank with the site gauge calibrations. When the tanks are filled to the top, record the total liquid capacity for each tank.

(f) Add dye to the foam tank.

(g) Set the agent system to discharge at the specified foam solution rate, and adjust the system discharge pressure to the recommended pressure.

(h) Starting with tanks that are completely full, discharge at maximum rate through the primary turret(s) until the agent pump(s) shows a drop in discharge pressure, and then stop immediately. Verify that dye is apparent in the discharge stream throughout the test. Record the discharge time if using the weight measurement method.

(i) *Alternative:* Record the weight of the vehicle after discharging. Calculate the pump-out capacity of the water tank using the weight of the water plus the foam discharged, the foam proportioning rate as verified in 4-3.1.3, and the discharge time.

(j) Measure the amount of liquid remaining in both tanks and convert to gallons using the conversion established in 4-3.1.4(e). Subtract the amount remaining from the total capacity to determine the amount pumped out. Record the total amount of liquid pumped out of the tanks.

(k) Refill the water tank only (not the foam tank). Discharge the water tank as in 4-3.1.4(h). Verify that dye is apparent throughout the test. Measure and record the additional amount of liquid discharged from the foam tank. Fill the water tank and discharge as many times as necessary to eliminate all usable liquid from the foam tank.

(l) Total and record the amount of liquid discharged from the foam tank from the time of initial fill.

(m) Refill both tanks and repeat 4-3.1.4(f) through (k) with the vehicle parked in the following attitudes:

After pumping on a slope, with the vehicle in the following slope conditions, return the vehicle to level ground to measure the water volume discharged:

1. A 20-percent side slope, left side up;
2. A 20-percent side slope, right side up;
3. A 30-percent slope, ascending;
4. A 30-percent slope, descending;

(n) Divide the volume of liquid discharged from each tank on the four slope conditions by 0.75 and record.

4-3.1.5 The rated or usable water tank capacity shall be the lesser of the volumes calculated in 4-3.1.4(j) or 4-3.1.4(n). The rated or usable foam tank capacity shall be the lesser of the volumes calculated in 4-3.1.4(l) or 4-3.1.4(n).

4-3.2 Side Slope.

4-3.2.1 Test facilities shall consist of either a measured fixed grade equal to or in excess of the slope requirement for the class of vehicle being tested or a surface on which the tires of the vehicle can be placed that is capable of being tilted. Means to restrain the vehicle at the balance point shall be required.

4-3.2.2 Test equipment shall consist of a suitable inclinometer capable of measuring the slope of the support surface with an accuracy of ± 1 degree.

4-3.2.3 Vehicle Testing.

4-3.2.3.1 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended operating pressure. A suitable ballast shall be used in place of the crew for safety.

4-3.2.3.2 Where the vehicle is fitted with an extendable turret, an additional test shall be performed as follows:

Tilt the vehicle on a table, or position the vehicle on a 20-percent grade. Elevate the extendable turret to the highest elevation. Position the turret nozzle uphill at maximum horizontal rotation, and discharge the agent at maximum flow rate for the class of vehicle being tested.

4-3.2.4 The side slope capability of the vehicle shall be determined as follows:

(a) Tilt the vehicle on a table, or position the vehicle on a grade having an angle above the horizon at least equal to the side slope angle specified for the vehicle being tested.

(b) Once the vehicle is positioned at the required angle, check the vehicle restraints to ensure that no tension is applied.

4-3.2.5 The vehicle shall be considered to meet its side slope requirement if the vehicle can stand by itself on the grade without the use of the safety restraints.

4-3.3 Cornering Stability.

4-3.3.1 Test facilities shall consist of a level site having a dry, paved surface at least 250 ft (76.2 m) in diameter that is free from loose material upon which a circle with a radius of 100 ft (30.5 m) shall be marked in a manner that can be followed easily by a driver.

4-3.3.2 A calibrated speedometer and a means of indicating steering wheel angle shall be required.

4-3.3.3 The vehicle shall be tested in its fully loaded condition. (*See definition of Fully Loaded Vehicle in Section 1-3.*)

4-3.3.4 The vehicle shall be tested as follows:

(a) Slowly drive the vehicle around the 100-ft (30.5-m) radius circle while keeping the centerline of the front of the vehicle directly over the marked line.

(b) Establish a reference position on the steering wheel position indicator at a slow speed.

(c) Gradually increase the speed until the maximum safe speed, as judged by the driver, is reached.

(d) Record the maximum speed and the corresponding position of the steering wheel.

(e) Repeat 4-3.3.4(a) through (d) while driving the vehicle in the opposite direction.

4-3.3.5 The speed achieved shall equal or exceed the requirement for the corresponding class of vehicle, and the steering angle shall not decrease with increasing speed.

4-3.4 Vehicle Dimensions.

4-3.4.1 Test facilities shall consist of a flat measurement pad that is large enough to accommodate the entire vehicle.

4-3.4.2 Test equipment shall consist of a tape measure and a protractor.

4-3.4.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended operating pressure.

4-3.4.4 The following vehicle dimensions shall be measured in accordance with their definitions with the vehicle positioned on the flat pad:

(a) Angle of approach;

(b) Angle of departure;

(c) Interaxle clearance angle;

(d) Underbody clearance;

(e) Underaxle clearance.

4-3.4.5 Linear dimensions shall be rounded down to the nearest $^1/_2$ in. (1.3 cm), and angular dimensions shall be rounded down to the nearest $^1/_2$ degree and compared against the vehicle specifications.

4-3.5 Driver Vision Measurement.

4-3.5.1 Test facilities shall consist of a level site at least 20 ft (6.1 m) longer than the vehicle.

4-3.5.2 Test equipment shall consist of a plumb bob, tape measure, and a protractor or an inclinometer.

4-3.5.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended operating pressure.

4-3.5.4 The driver's vision shall be determined as follows:

(a) Adjust the driver's seat to its mid position with respect to height, weight, and fore and aft adjustments.

(b) Place a suitable structure on the seat cushion for locating an eye height of $31^3/_4$ in. (806.5 mm) and a position 12 in. (30.5 cm) forward from the seat back. Place the seat back in a vertical position.

(c) Establish the features that limit the upward and downward line of vision that are located directly in front of the driver's seat.

(d) Measure and record the angle above the horizon at which upward vision is obstructed from the eye height point established in 4-3.5.4(b).

(e) Establish the lowest possible line of vision below the horizon directly in front of the eye height point and project this line forward of the cab until it intersects with the ground. Project this line of vision by using a light beam, or, if the windshield is removed, use a string line. Measure and record the distance from this intersection with the ground and the front face of the bumper at the front of the truck.

(f) Stretch a line from the eye height point laterally across the cab in order to establish and record the 90-degree line of vision to the left and right of the straight ahead position. Note obstructions within these angles.

4-3.5.5 The recorded values for the distance at which the line of vision meets the ground in front of the truck and the angle of vision above the horizon shall equal or exceed the vehicle's specification. Obstacles within the 90-degree horizontal line of vision to the right or left shall not create an obstruction of more than 5 degrees per obstruction.

4-3.6 Pump and Roll on a 40-Percent Grade.

4-3.6.1 Test facilities shall consist of a site suitable for discharging agent that includes a measured grade of 40 percent that is at least twice the vehicle's length or a level, paved test pad adequate for an extended draw bar pull.

4-3.6.2 Test equipment shall consist of the following:

(a) A calibrated speedometer;

(b) A vehicle equipped pump pressure gauge;

(c) A load cell accurate to within ± 500 lb (± 227 kg) (applicable only to the alternate draw bar method);

(d) A variable load dynamometer sled (applicable only to the alternate draw bar method).

4-3.6.3 The vehicle shall have had its primary turret(s) discharge rate and pressure verified prior to beginning this test to ensure that the turret(s) discharges at or above the minimum rate specified. The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded*

Vehicle in Section 1-3) with tires inflated to their recommended operating pressure.

4-3.6.4 The capability of the vehicle to ascend, stop, start, and continue ascent on a 40-percent grade without interruption in the discharge rate shall be demonstrated either on an actual grade or by means of an equivalent draw bar test as follows:

(a) Fill both the water and foam tanks with water, and add dye to the foam tank.

(b) Set the agent system to discharge in the foam mode, and set the system discharge pressure for optimum performance.

(c) Position the vehicle at the bottom of a 40-percent grade and initiate discharge at full output through the primary turret nozzles. Verify that dye is apparent in the discharge stream throughout the test.

(d) Initiate the vehicle's ascent of the grade and achieve a speed of at least 1 mph (1.6 km/h). During the ascent, bring the vehicle to a stop and resume the ascent at a speed of at least 1 mph (1.6 km/h) without interruption in the discharge stream. Record the vehicle speed and any variation in discharge pressure.

(e) If an actual 40-percent grade is not available, repeat 4-3.6.4(a) through (d) with the vehicle coupled to a 40-percent grade equivalent draw bar load determined as follows:

1. A 40-percent grade — 21.8-degree angle.

2. The loaded vehicle weight × sin 21.8 degrees (0.371) equals the necessary draw bar pull to simulate ascending a 40-percent grade.

3. The area of the load cell shall be determined at the time of the test.

4. The load cell reading, in psi (kPa), that simulates a 40-percent grade shall be calculated by the following:

$$\frac{\sin 21.8 \text{ degrees} \times \text{vehicle weight}}{\text{area of load cell}}$$

4-3.6.5 The vehicle shall negotiate the grade or draw bar pull smoothly while maintaining an operating pressure of at least 50 percent of the specified design pressure for the primary turret(s) at speeds of at least 1 mph (1.6 km/h).

4-3.7 Electrical Charging System.

4-3.7.1 Test facilities shall consist of an area suitable for running the engine while the electric loads and charging rates are being measured.

4-3.7.2 Test instrumentation shall consist of the following:

(a) A laboratory quality voltmeter with a scale range compatible with the design voltage of the vehicle's electrical system. The scale on the voltmeter shall be graduated to allow reading voltages with a ± 0.1-volt accuracy.

(b) A laboratory quality ammeter with a scale range compatible with the anticipated electrical load present on the vehicle. The ammeter shall be graduated to allow reading current flow within a ± 3-percent accuracy.

(c) The tachometer installed in the vehicle.

4-3.7.3 The test vehicle shall have a fully charged set of batteries, and the vehicle's electric and charging systems shall be fully operational. The test shall be conducted in ambient conditions of 50°F to 90°F (10°C to 32.2°C).

4-3.7.4 The test shall be conducted as follows:

(a) Check each battery cell to verify that voltage and specific gravity are at the battery manufacturer's specifications.

(b) Install a voltmeter to monitor the battery charge continuously during the test.

(c) Install an ammeter/shunt system at the battery to measure the full current demand of the electrical system. Install another ammeter/shunt system at the alternator to measure the total current output of the alternator.

(d) Record voltage and ampere readings under the following conditions:

1. Battery (engine off, no load).

2. Engine at idle and all electrical devices shut off. The engine shall be allowed to run long enough after starting to recharge the batteries prior to making these measurements.

3. Engine at idle and all electrical loads that normally run simultaneously turned on.

4. Engine at 50 percent of governed speed with all electrical loads that normally run simultaneously turned on.

5. Engine at governed speed with all electrical loads that normally run simultaneously turned on.

4-3.7.5 The electrical system performance shall be compared against the specification at engine idle and at 50 percent of engine rpm. The measured voltage of the batteries shall remain above 13 volts (for a 12-volt system) and 26 volts (for a 24-volt system) at all times while the alternator is running.

4-3.8 Radio Suppression.

4-3.8.1 Test facilities shall be in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000 MH_z)*, or the equivalent standard being used.

4-3.8.2 Test equipment shall be in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000 MH_z)*, or the equivalent standard being used.

4-3.8.3 The vehicle shall be configured with all standard electrical features mounted and operational. During the tests, all vehicle engines shall be operated at idle, and all vehicle-mounted electrical devices normally functioning at the crash site shall be turned on with the following stipulations:

(a) All vehicle lighting shall be on.

(b) All heating, defrosting, and air conditioning systems shall be on with their respective fans adjusted to the maximum speed setting.

(c) Auxiliary power generating devices (where applicable) shall be running.

(d) Intermittent warning devices, such as hazard flashers, warning buzzers, and horns, shall be turned off.

4-3.8.4 The vehicle shall be tested in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000* MH_z*)*, or the equivalent standard being used.

4-3.8.5 The results of the test shall be evaluated in accordance with SAE J551, *Standard on Performance Levels and Methods of Measurement of Electromagnetic Radiation from Vehicles and Devices (30-1000* MH_z*)*, or the equivalent standard being used.

4-3.9 Gradability Test.

4-3.9.1 Test facilities shall consist of a site that includes a measured grade of 50 percent at least equal to the vehicle in length or a level, paved test pad adequate for an extended draw bar pull.

4-3.9.2 Test equipment shall consist of the following:

(a) A load cell accurate to within ± 500 lb (± 227 kg) (applicable only to the alternate draw bar method).

(b) A variable load dynamometer sled (applicable only to the alternate draw bar method).

4-3.9.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended operating pressure.

4-3.9.4 The capability of the fully loaded vehicle (*see definition of Fully Loaded Vehicle in Section 1-3*) to ascend a 50-percent grade shall be demonstrated either on an actual grade or by means of an equivalent draw bar pull test. If an actual 50-percent grade is not available, then the vehicle shall be coupled to a 50-percent equivalent draw bar load determined as follows:

(a) A 50-percent grade — 26.57-degree angle.

(b) The loaded vehicle weight × sin 26.57 degrees (0.447) equals the necessary draw bar pull to simulate ascending a 50-percent grade.

(c) The area of the load cell shall be determined at the time of the test.

(d) The load cell reading, in psi (kPa), that simulates a 50-percent grade shall be calculated by the following:

$$\frac{\text{sin 26.57 degrees} \times \text{vehicle weight}}{\text{area of load cell}}$$

4-3.9.5 The vehicle shall negotiate the grade or draw pull smoothly and safely.

4-3.10 Body and Chassis Flexibility Test.

4-3.10.1 Test facilities shall consist of a flat test pad suitable for discharging agent and securing portable ramps under the vehicle.

4-3.10.2 Test equipment shall consist of two to four 14-in. (35.6-cm) ramps with flat tops large enough for the tire footprint and graduated on both sides to allow the vehicle to ascend and descend safely.

4-3.10.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended operating pressure.

4-3.10.4 The vehicle shall be tested as follows:

(a) For a 4 × 4, drive the fully loaded vehicle onto 14-in. (35.6-cm) blocks positioned under the diagonally opposite front and rear wheels. For a 6 × 6, these correspond to axle 1 and axle 3. For an 8 × 8, these correspond to axle 1 and axle 4.

(b) With the vehicle in this position:

1. Inspect the vehicle thoroughly to ensure that there are no sheet metal interferences and that all moving parts are free to function.

2. Demonstrate all systems to ensure that they function normally, including discharge from all orifices.

(c) For a 6 × 6 and an 8 × 8, add a block under the second wheel of the bogie axle(s) so that both wheels on one side of the tandem axle are elevated simultaneously and diagonally opposite front and rear, and then repeat 4-3.10.4(b)1.

(d) Switch the blocks to the opposite sides of the truck and repeat 4-3.10.4(a) through (c).

4-3.10.5 No moving part shall interfere with another. If component contact should occur, it shall in no way damage the component or detract from the vehicle's ability to carry out its mission. No clearance shall be permitted between any tire and its supporting surface.

4-3.11 Service/Emergency Brake Test.

4-3.11.1 Test facilities shall consist of any dry, smooth, level, paved surface adequate in length to reach the respective test speeds and stop safely. The test area shall be marked so that a lane equivalent in width to that of the vehicle plus 4 ft (1.2 m) is established.

4-3.11.2 Instrumentation shall consist of the following:

(a) A calibrated fifth-wheel-type speed measuring device that is accurate to within ± 0.5 mph (± 0.8 km/h) or ± 0.5 percent of the actual vehicle speed;

(b) A ground speed readout device controlled by the fifth wheel;

(c) A trigger device that detects brake pedal movement;

(d) A strip chart recorder suitable for recording distance traveled, vehicle speed, and the point at which actuation of the brake system occurs.

4-3.11.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with the brakes adjusted and the tires inflated to the vehicle manufacturer's recommended specifications. The brakes shall have been adequately burnished to ensure repeatable results.

4-3.11.4 The service and emergency brake stopping distances shall be determined in the following manner:

(a) While traveling down the center of the lane established by the width of the vehicle plus 4 ft (1.2 m), attain a speed slightly above the desired test speed and release the throttle.

(b) With the strip chart recorder running, at the instant that the vehicle reaches the desired test speed, actuate the brake pedal as if in a panic stop and continue applying the brakes until the vehicle comes to a complete stop. While stopped, modulate the brake pedal, as necessary, to maintain vehicle control. Record the distance traveled from the time that the brake pedal is applied to the time that the vehicle comes to rest.

(c) Observe whether or not the vehicle leaves the established lane during the brake stop.

(d) Repeat 4-3.11.4(a) through (c) for a total of five stops from each test speed.

(e) Repeat 4-3.11.4(a) through (d) to obtain results at speeds of 20 mph (32.2 km/h) and 40 mph (64.4 km/h).

(f) Disable the front service brakes and repeat 4-3.11.4(a) through (d) at a test speed of 40 mph (64.4 km/h).

(g) Reconnect the front service brakes and disable the rear service brakes and repeat 4-3.11.4(a) through (d) at a test speed of 40 mph (64.4 km/h).

4-3.11.5 Each of the recorded stops shall be within the specified distance without any part of the vehicle leaving the established test lane.

4-3.12 Service/Parking Brake Grade Holding Test.

4-3.12.1 Test facilities shall consist of dry, smooth, measured grades of 20 percent and 50 percent that are at least equal to the vehicle in length.

4-3.12.2 No instrumentation shall be required.

4-3.12.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with the brakes adjusted and the tires inflated to the vehicle manufacturer’s recommended specifications. The brakes shall have been adequately burnished to ensure repeatable results.

4-3.12.4 The tests shall be conducted in the following manner:

(a) Drive the vehicle in a forward direction onto the 20-percent grade, stop, and set the parking brake.

(b) Shift the transmission to neutral and release the service brakes and verify that there is no wheel rotation.

(c) Repeat 4-3.12.4(a) and (b) with the vehicle facing the opposite direction.

(d) Drive the vehicle in a forward direction onto the 50-percent grade, apply the service brakes, and shift the transmission to neutral.

(e) Verify that there is no wheel rotation.

(f) Repeat 4-3.12.4(d) and (e) with the vehicle facing the opposite direction.

4-3.12.5 The brakes shall lock the wheels and hold the vehicle stationary on both the 20-percent and 50-percent grades with the vehicle pointed either uphill or downhill.

4-3.13 Steering Control Test.

4-3.13.1 Test facilities shall consist of any dry, level, paved surface that is free from loose material.

4-3.13.2 Test equipment shall consist of a steering wheel and a torque meter or a spring scale.

4-3.13.3 The vehicle shall be tested in a fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their normal operating pressure.

4-3.13.4 The vehicle shall be tested as follows:

(a) Set the road wheels in the straight ahead position, engage neutral, and release the brakes, ensuring that there is no vehicle movement.

(b) With the engine at idle speed, measure and record the force applied to the steering rim that is necessary to turn the steering linkage from stop to stop.

4-3.13.5 The measured force shall not exceed the design specifications.

4-3.14 Vehicle Clearance Circle Test.

4-3.14.1 Test facilities shall consist of a level site having a dry, paved surface greater than three times the vehicle's length in diameter and shall be free from loose material.

4-3.14.2 A tape measure, markers or a marking device, and a calculator shall be required.

4-3.14.3 The vehicle's steering system shall be fully operational, and the steering linkage stops shall be adjusted within the manufacturer's specified production tolerance limits.

4-3.14.4 The vehicle shall be tested as follows:

(a) Drive the vehicle in a full cramp, making a left or right turn as necessary, in at least one complete circle to fully "settle" the wheels into their steady-state condition.

(b) Slowly drive the vehicle in the full cramp turn.

(c) Stop the vehicle in three locations around the turning circle, applying the brake smoothly and gradually.

(d) At each stop, mark the outermost projected point of the vehicle on the ground.

(e) Measure and record the straight line distances between the marks for each of the stop locations (length 1, length 2, and length 3).

(f) Calculate the vehicle clearance circle radius (R) as follows:

S = length 1 + length 2 + length 3

$$R = \frac{(\text{length } 1)(\text{length } 2)(\text{length } 3)}{4\,[S(S - \text{length } 1)(S - \text{length } 2)(S - \text{length } 3)]^{1/2}}$$

(g) Repeat 4-3.14.4(a) through (f) while turning the vehicle in the opposite direction.

4-3.14.5 The vehicle's clearance circle diameter (2R) shall be less than three times the maximum overall length of the vehicle.

4-3.15 Agent Pump(s)/Tank Vent Discharge Test.

4-3.15.1 Test facilities shall consist of a level, open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.15.2 Test equipment shall consist of a liquid level measuring device accurate to with ± 1.0 percent.

4-3.15.3 Each discharge nozzle on the vehicle shall have been individually verified as discharging at a flow rate at or above the minimum rate specified when the agent system is operated at the recommended pressure.

4-3.15.4 The test shall be conducted as follows:

(a) Fill the water and the foam tank to the top.

(b) Set the foam proportioning system to proportion foams at the concentration specified, and set the agent selector for the foam mode.

(c) Set the agent system pressure relief to the recommended pressure.

(d) Engage the agent pumps and operate them at maximum pumping speed with all discharge outlets closed.

(e) Simultaneously initiate discharge of the primary roof turret(s), primary hand lines, ground sweeps/bumper turret, and undertruck nozzles. After approximately 75 percent of the contents from the water tank has been discharged, simultaneously stop discharge through all nozzle outlets. Record the time of discharge.

(f) Measure and then add together the total amount of liquid discharged from the water tank and the foam tank. Calculate the average discharge rate using the discharge time from 4-3.15.4(e).

(g) Calculate the quantity of liquid used from the foam tank as a percentage of the total liquid discharged.

4-3.15.5 The measured total discharge rate shall be equal to at least the sum of the minimum specified discharge rates of the nozzles used during the test. A calculated average foam concentration within the tolerance permitted for the respective foam type confirms the adequacy of the foam-liquid concentrate piping to supply foam at a rate compatible with the maximum discharge requirements of the vehicle.

4-3.16 Water Tank Fill and Overflow Test.

4-3.16.1 Test facilities shall consist of a level site with pumping or hydrant capacity, or both, sufficient to provide the water delivery rate needed to fill the water tank in 2 minutes at an inlet pressure of 80 psi (551.6 kPa).

4-3.16.2 Instrumentation shall consist of calibrated mechanical or electronic pressure measuring devices with an accuracy of ± 3 percent and a stopwatch.

4-3.16.3 The water tank shall be empty, and the water tank fill and vent system shall be fully operational for this test.

4-3.16.4 The water tank fill and vent system shall be tested as follows to verify that the tank can be filled in 2 minutes or less:

(a) Park the vehicle on level ground.

(b) Attach one pressure measuring device at the inlet to the tank fill piping, and attach the other pressure measuring device to the tank body or an extension of the tank body.

(c) Simultaneously initiate flow to the tank and start the stopwatch. The water supply pressure shall be maintained at 80 psi (551.6 kPa) throughout the test.

(d) At the moment water begins to flow from the overflow piping, stop the watch and record the elapsed time.

(e) While maintaining an 80 psi (551.6 kPa) supply pressure and an overflow condition, record the internal tank pressure. After recording this pressure, shut off the water supply.

4-3.16.5 The results of this test shall be evaluated as follows:

(a) The time to fill the tank to the overflow condition shall be 2 minutes or less.

(b) The internal tank pressure shall not exceed the tank design pressure.

4-3.17 Flushing System Test.

4-3.17.1 Test facilities shall consist of an open site suitable for discharging agent and draining the vehicle. Access to a refill water supply shall be required.

4-3.17.2 No special instrumentation shall be required for this test.

4-3.17.3 The vehicle's agent system and flushing system shall be fully operational for this test.

4-3.17.4 The vehicle's flushing system shall be tested as follows:

(a) Fill the water tank and foam tank with clean water and add dye to the foam tank.

(b) Discharge agent through each discharge orifice on the vehicle while operating in the foam mode until dye is present in the discharge stream.

(c) Mark the liquid level in the foam tank.

(d) Set the agent system in the flush mode and discharge through each discharge orifice until clear water is present in the discharge stream.

(e) Shut the agent system down and drain the piping.

(f) Recheck the foam tank level.

4-3.17.5 Failure to develop a clear water stream through each nozzle shall be considered evidence that the flushing system is inadequate. There shall be no evidence of feedback of clear water into the foam tank.

4-3.18 Roof Turret Flow Rate Test.

4-3.18.1 Test facilities shall consist of a level, open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.18.2 Test equipment shall consist of the following:

(a) A calibrated sight gauge;

(b) A liquid volume measuring device accurate to within ± 1.0 percent;

(c) A calibrated pressure gauge, if not already provided on the truck;

(d) *Alternative:* A stopwatch and a scale capable of measuring total vehicle weight accurate to within ± 1.0 percent.

4-3.18.3 It shall have been verified that the vehicle's pumping system is capable of operating at full rate.

4-3.18.4 The roof turret discharge rate shall be determined as follows:

(a) Set the roof turret pattern for straight stream operation.

(b) Fill the water tank completely.

(c) Engage the pump and operate it at design speed.

(d) Open the turret flow control valve.

(e) The following procedures also shall be performed, as necessary:

1. If flow meters are used, read and record the flow rate once the discharge pressure stabilizes.

2. If a sight gauge is used, read and record the tank volume in gallons while simultaneously starting a stopwatch after the discharge pressure stabilizes. Read and record the tank volume in gallons when the watch is stopped after allowing flow for at least 1 minute. Determine the flow rate in gpm by dividing the difference in gallons by the time of discharge.

3. If a scale is used, record the vehicle weight prior to discharge. Start a stopwatch and discharge water at stabilized pressure for 1 minute. Record the vehicle weight after discharge and calculate the flow rate.

(f) Reset the roof turret pattern to the dispersed setting and repeat 4-3.18.4(b) through (e).

(g) Reset the roof turret to the half flow rate setting (if applicable) and repeat 4-3.18.4(a) through (f).

4-3.18.5 The measured turret flow rates shall equal the specified flow rate within a tolerance of +10 percent/ –0 percent.

4-3.19 Roof Turret Pattern Test.

The roof turret pattern test shall be conducted in accordance with the requirements of NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, and the results shall be evaluated in accordance with the vehicle specifications.

4-3.20 Roof Turret Control Force Measurement.

4-3.20.1 Test facilities shall consist of a level, open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.20.2 Test equipment shall consist of a spring scale that can be attached to the end of the turret control handle or a torque measuring device that can be attached to the rotational axis of the turret.

4-3.20.3 The water tank shall be filled prior to starting the test, and it shall have been verified that the vehicle pump system is capable of operating at design flow and pressure. The test shall be conducted with the roof turret at the full flow rate setting. The turret power-assist system, if applicable, shall be fully operational.

4-3.20.4 The test shall be conducted as follows:

(a) Set the turret pattern control for straight stream and, where applicable, engage the power assist.

(b) Engage the pump and operate it at design speed.

(c) Open the turret flow control valve.

(d) Using a spring scale attached to the end of the turret aiming handle, rotate the turret to the right and to the left, recording the needed force for each direction. Again, using the spring scale attached to the end of the turret aiming handle, elevate and depress the turret and record the force needed to elevate and depress.

(e) Repeat 4-3.20.4(b) through (d) with the pattern control set at the maximum dispersed position after refilling the water tank as necessary.

4-3.20.5 The forces recorded shall not exceed the forces specified.

4-3.21 Roof Turret Articulation Test.

4-3.21.1 Test facilities shall consist of a level, open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.21.2 The test equipment shall consist of a tape measure, a level, and a protractor.

4-3.21.3 The water tank shall be filled prior to the test, and the turret power-assist system, if applicable, shall be fully operational.

4-3.21.4 The test shall be conducted as follows:

(a) With the turret pointed ahead, raise the turret barrel to the maximum elevated position. With a level held horizontal at the vertical rotation axis, measure the angle between the level and the turret barrel with the protractor and record.

(b) Rotate the roof turret barrel to the right and left to the angle needed.

(c) Place a marker 30 ft (9.1 m) in front of the vehicle. Aim the turret straight ahead with the rate control at full flow, with the pattern control in the maximum dispersed position, and with the turret in the maximum depressed position. When water discharges, observe whether water strikes the marker or strikes closer to the vehicle.

4-3.21.5 Turret articulation shall be considered acceptable if the measurements meet or exceed the specifications.

4-3.22 Hand Line Nozzle Flow Rate Test.

4-3.22.1 Test facilities shall consist of a level, open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.22.2 Test equipment shall consist of the following:

(a) A calibrated sight gauge;

(b) A liquid volume measuring device accurate to within ± 1.0 percent;

(c) A calibrated pressure gauge, if not already provided on the truck;

(d) *Alternative:* A stopwatch and a scale capable of measuring total vehicle weight accurate to within ± 1.0 percent.

4-3.22.3 It shall have been verified that the vehicle's pumping system is capable of operating at full rate.

4-3.22.4 The hand line nozzle flow rate shall be determined as follows:

(a) Set the hand line nozzle pattern for straight stream operation.

(b) Fill the water tank completely.

(c) Engage the pump and operate it at design speed.

(d) Open the hand line nozzle flow control valve.

(e) The following procedures also shall be performed, as necessary:

1. If flow meters are used, read and record the flow rate once the discharge pressure stabilizes.

2. If a sight gauge is used, read and record the tank volume in gallons while simultaneously starting a stopwatch after the discharge pressure stabilizes. Read and record the tank volume in gallons when the watch is stopped after allowing flow for at least 5 minutes. Determine the flow rate in gpm by dividing the difference in gallons by the time of discharge.

3. If an open top calibrated tank is used, discharge through the nozzle until the pressure stabilizes, and then simultaneously direct the stream into the tank while starting the stopwatch. Stop the stopwatch when the tank is full and remove or shut off the nozzle. Determine the flow rate by dividing the tank volume in gallons by the fill time in minutes.

4. If a scale is used, record the vehicle weight prior to discharge. Start a stopwatch and discharge water at stabilized pressure for 1 minute. Record the vehicle weight after discharge and calculate flow rate.

(f) If the nozzle is the nonair-aspirated type, repeat 4-3.22.4(b) through (e) with the nozzle pattern setting in the fully dispersed position.

4-3.22.5 The measured hand line nozzle flow rates shall equal the specified flow rate within a tolerance of +10 percent/–0 percent.

4-3.23 Hand Line Nozzle Pattern Test.

The hand line nozzle pattern test shall be conducted in accordance with the requirements of NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, and the results shall be evaluated in accordance with the vehicle specifications.

4-3.24 Ground Sweep/Bumper Turret Flow Rate Test.

4-3.24.1 Test facilities shall consist of an open site suitable for discharging agent. Access to a refill water supply shall be required.

4-3.24.2 Test equipment shall consist of the following:

(a) A calibrated sight gauge;

(b) A liquid volume measuring device accurate to within ± 1.0 percent;

(c) A calibrated pressure gauge, if not already provided on the truck;

(d) *Alternative:* A stopwatch and a scale capable of measuring total vehicle weight accurate to within ± 1.0 percent.

4-3.24.3 It shall have been verified that the vehicle's pumping system is capable of operating at full rate.

4-3.24.4 The ground sweep/bumper turret discharge rate shall be determined as follows:

(a) Set the ground sweep/bumper turret pattern for straight stream operation.

(b) Fill the water tank completely.

(c) Engage the pump and operate it at design speed.

(d) Open the ground sweep/bumper turret flow control valve.

(e) The following procedures also shall be performed, as necessary:

1. If flow meters are used, read and record the flow rate once the discharge pressure stabilizes.

2. If a sight gauge is used, read and record the tank volume in gallons while simultaneously starting a stopwatch after the discharge pressure stabilizes. Read and record the tank volume in gallons when the watch is stopped after allowing flow for at least 1 minute. Determine the flow rate in gpm by dividing the difference in gallons by the time of discharge.

3. If a scale is used, record the vehicle weight prior to discharge. Start a stopwatch and discharge water at stabilized pressure for 1 minute. Record the vehicle weight after discharge and calculate the flow rate.

(f) If the ground sweep/bumper turret is the nonair-aspirated type, repeat 4-3.24.4(b) through (e) with the nozzle pattern setting in the fully dispersed position.

4-3.24.5 The measured flow rates shall equal the specified flow rate within a tolerance of +10 percent/–0 percent.

4-3.25 Ground Sweep/Bumper Turret Pattern Test.

The ground sweep/bumper turret pattern test shall be conducted in accordance with the requirements of NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, and the results shall be evaluated in accordance with the vehicle specifications.

4-3.26 Undertruck Nozzle Test.

4-3.26.1 Test facilities shall consist of an open site suitable for discharging agent.

4-3.26.2 Markers shall be available for use in defining the pattern boundaries.

4-3.26.3 It shall have been verified that the vehicle's pump system is capable of operating at full rate, and the agent tanks shall be filled with water and foam, respectively.

4-3.26.4 The test shall be conducted as follows:

(a) Set the agent system to operate in the foam mode.

(b) Engage the agent pump and operate it at design speed.

(c) Open the undertruck nozzles to discharge simultaneously, and continue to discharge until a definite pattern outline is apparent.

(d) Close the discharge and mark and record the boundaries of the pattern.

4-3.26.5 The pattern shall be considered acceptable if the foam spray covers the outline created by the vehicle on the ground and wets the inside of all tires.

4-3.27 Foam Concentration/Foam Quality Test.

4-3.27.1 Test facilities shall consist of an open site suitable for discharging agent. Access to a refill water supply and a foam concentrate supply shall be required.

4-3.27.2 The test equipment described in NFPA 412, *Standard for Aircraft Rescue and Fire Fighting Foam Equipment*, shall be used for this test.

4-3.27.3 Each discharge nozzle on the vehicle shall have been individually verified as discharging at a flow rate within the tolerance specified. The agent system shall have been verified as capable of operating at full rate.

4-3.27.4 The test shall be conducted as follows:

(a) Fill the water tank and the foam tank to the top and refill as necessary throughout the test.

(b) Set the foam proportioning system to proportion foams at the concentration specified, and set the agent selector for the foam mode.

(c) Set the agent system pressure relief to the recommended pressure.

(d) Engage the agent pumps and operate them at maximum pumping speed with all discharge outlets closed.

(e) Each foam delivery system shall be tested first for the individual nozzle/flow rate specified in the following list and then for a total combined simultaneous discharge in accordance with NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*:

1. Roof turret(s) full rate;
2. Roof turret(s) half rate;
3. Ground sweep/bumper turret;
4. Hand line nozzles;
5. Undertruck nozzles.

4-3.27.5 The foam concentrations measured shall fall within the permitted tolerances specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, for each nozzle and for the combined simultaneous discharge. The foam expansion and drainage time measurements shall equal or exceed those specified in NFPA 412 for each nozzle.

4-3.28 Warning Siren Test.

4-3.28.1 Test facilities shall consist of a flat, open area that is free from any large reflecting surfaces (such as other vehicles, signboards, or hills) within a 200-ft (61-m) radius of the vehicle.

4-3.28.2 Test equipment shall consist of the following:

(a) A sound level meter that meets the requirements of ANSI S1.4, *Specification for Sound Level Meters*, for Type 1 or S1A meters. The sound level meter shall have been calibrated by a certified testing laboratory within the previous 12 months.

(b) A tape measure.

4-3.28.3 The vehicle's siren speaker shall be mounted in its proper location and shall be in working order.

4-3.28.4 The capability of the warning siren on the vehicle to project sound forward and to the sides shall be determined as follows:

(a) Set the sound level meter to the A-weighing network, "fast" meter response, and position the meter directly ahead of the vehicle at a distance of 100 ft (30.5 m) from the front bumper. The microphone shall be at ear level.

(b) Energize the siren and record the meter reading.

(c) Repeat 4-3.28.4(a) and (b) with the sound level meter 100 ft (30.5 m) from the vehicle, first at a position 45 degrees to the right and then at 45 degrees to the left of the longitudinal centerline of the vehicle.

4-3.28.5 The recorded noise level shall equal or exceed the specifications.

4-3.29 Propellant Gas.

4-3.29.1 Test facilities shall consist of an open site suitable for discharging AFFF, dry chemical, or halon agent.

4-3.29.2 Test equipment shall consist of a calibrated scale or load cell with an accuracy of ± 1.0 percent.

4-3.29.3 The vehicle extinguishing agent piping system shall be operational, and the agent tank(s) shall be empty. The propellant gas tank(s) shall be fully charged and within proper pressure. A means of lifting the agent tanks for weighing without loss of agent shall be provided. Alternatively, the extinguishing agent tank(s) shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the agent tank(s) and related piping, fittings, valves, hose, and nozzle(s) in the same configurations in which they are installed on the vehicle.

4-3.29.4 The test for each of the extinguishing agents shall be conducted in the following manner:

(a) Weigh the empty tank(s) and record as tare weight.

(b) Using the manufacturer's recommended filling procedure, charge the tank(s) with the manufacturer's recommended extinguishing agent to the upper fill weight/volume tolerance. Reweigh and record this as gross filled weight.

(c) Ensure that all fill caps are tightened securely, all propellant gas lines are connected, the discharge nozzle(s) is in the closed position, and all fittings and connections are tight.

(d) Pressurize the agent tank(s) using the manufacturer's recommended procedure.

(e) Simultaneously, fully open all discharge nozzles and keep open until only the pressurizing gas is expelled.

(f) Shut down the propellant gas supply.

(g) Reweigh the agent tank(s) and record this as post-discharge weight.

(h) Calculate and record the total agent discharged as follows:

Gross filled weight – post-discharge weight = total agent discharge.

4-3.29.5 There shall be a sufficient supply of propellant gas to purge all discharge lines as evidenced by the emission from each nozzle of gas only. The total agent discharged shall equal or exceed the design capacity.

4-3.30 Pressure Regulation.

4-3.30.1 Test facilities shall consist of an open site suitable for discharging the AFFF, dry chemical, or halon agent.

4-3.30.2 Test equipment shall consist of a calibrated pressure gauge or transducer capable of reading the recommended tank top discharge pressure and possessing an accuracy of ± 5.0 psi (± 34.5 kPa).

4-3.30.3 The vehicle extinguishing agent system shall be piped to all discharge outlets with the tank(s) empty. The propellant gas tank(s) shall be fully charged and at proper pressure. A means for mounting a pressure gauge or transducer somewhere between the downstream (low pressure) side of the regulator and the agent tank top shall be provided. Alternatively, the extinguishing agent tank(s) shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the agent tank(s) and related piping, fittings, valves, hose, and nozzle(s) in the same configuration in which they are installed on the vehicle.

4-3.30.4 The test for each of the extinguishing agents shall be conducted in the following manner:

(a) Using the manufacturer's recommended filling procedure, charge the tank(s) with the manufacturer's recommended extinguishing agent to the upper fill weight/volume tolerance.

(b) Install a pressure gauge or transducer between the downstream (low pressure) side of the regulator and the agent tank top.

(c) Ensure that all fill caps are tightened securely, all propellant gas lines are connected, the discharge nozzle(s) is in the closed position, and all fittings are tight.

(d) Pressurize the agent tank(s) using the manufacturer's recommended procedure. Record the agent tank pressure.

(e) Simultaneously, fully open all discharge nozzles and keep open until only the pressurizing gas is expelled.

(f) During agent discharge, monitor agent tank pressure and record at 5-second or shorter intervals.

(g) Once the gas point has been reached for all discharge nozzles, shut down the gas supply.

4-3.30.5 The pressure regulation system shall be capable of maintaining pressure throughout the discharge. At no time shall pressure fall below or exceed the design range specified by the manufacturer.

4-3.31 AFFF Premix Piping and Valves.

4-3.31.1 Test facilities shall consist of a level, open site suitable for discharging the agent and measuring ranges.

4-3.31.2 Test equipment shall consist of the following:

(a) A calibrated scale or load cell with an accuracy of ± 1.0 percent;

(b) A stopwatch.

4-3.31.3 All vehicle foam discharge piping shall be operational, and the premix tank shall be empty. The propellant gas tank(s) shall be fully charged and within proper pressure. A means of lifting the agent tank(s) for weighing without loss of agent shall be provided. Alternatively, the system shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the premix tank and related piping, fittings, valves, hose, and nozzle(s) in the same configuration in which they are installed on the vehicle.

4-3.31.4 The test shall be conducted in the following manner:

(a) Weigh the empty premix tank and record as tare weight.

(b) Using the manufacturer's recommended filling procedure, charge the tank with water or premix solution. Reweigh and record as gross filled weight.

(c) Ensure that all fill caps are tightened securely, all propellant gas lines are connected, the discharge nozzle(s) is in the closed position, and all fittings and connections are tight.

(d) Pull all hand line hose from the reel(s) or hose compartment(s).

(e) Pressurize the system using the manufacturer's recommended procedure.

(f) Simultaneously, start the stopwatch and fully open the turret(s), undertruck nozzles, and hand line(s).

(g) After discharging for at least 30 seconds, simultaneously stop the stopwatch and close the turret(s), undertruck nozzles, and hand line(s). Record the elapsed time on the stopwatch as discharge time.

(h) Following the manufacturer's instructions, shut off the propellant gas supply and blow down the system.

(i) Reweigh the premix tank and record this as post-discharge weight.

(j) Add the recommended flow rates from each discharge nozzle and record this sum as the designed total flow rate.

(k) Calculate the actual total flow rate as follows:

$$\frac{\text{gross filled weight} - \text{post-discharge weight}}{(\text{density}) \times \frac{(\text{elapsed time in seconds})}{60}} = \text{actual total flow rate}$$

4-3.31.5 The actual total flow rate shall equal the specified designed total flow rate within a tolerance of + 10 percent/ –0 percent.

4-3.32 Pressurized Agent Purging and Venting.

4-3.32.1 Test facilities shall consist of an open site suitable for discharging AFFF, dry chemical, or halon agent.

4-3.32.2 No special test equipment or instrumentation shall be required to conduct the test(s).

4-3.32.3 The vehicle extinguishing agent system(s) shall be fully operational, and the agent tank(s) shall be fully charged with the manufacturer's recommended agent. The propellant gas tank(s) shall be fully charged and within proper pressure. Alternatively, the extinguishing agent tank(s) shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the fully charged agent tank(s) and related piping, fittings, valves, hose, and nozzle(s) in the same configuration in which they are installed on the vehicle.

4-3.32.4 The test for each of the pressurized extinguishing agent systems shall be conducted in the following manner:

(a) Pressurize the agent tank(s) using the manufacturer's recommended procedure.

(b) Pull all hose from the reel(s) or compartment(s).

(c) Fully open all discharge devices.

(d) After approximately 5 seconds to 20 seconds, close all discharge devices.

(e) Purge all discharge lines and vent the agent tank(s) using the manufacturer's recommended procedure.

4-3.32.5 Any agent beyond the tank outlet shall be purged from the discharge piping and hose as evidenced by the discharge from each nozzle of gas only. The depressurization or venting of the agent tank shall allow only minimal quantities of agent to escape.

4-3.33 Auxiliary Agent Hand Line Flow Rate and Range.

4-3.33.1 Test facilities shall consist of a level, open site suitable for discharging the dry chemical or halon agent and measuring ranges. Wind conditions shall be calm [less than 5 mph (8 km/h)].

4-3.33.2 Test equipment shall consist of the following:

(a) A calibrated scale or load cell with an accuracy of ± 1.0 percent;

(b) A stopwatch;

(c) A tape measure or other device for measuring distance;

(d) A calibrated anemometer;

(e) A pan containing at least 1 ft^2 (0.09 m^2) of motor or aviation gasoline.

4-3.33.3 All vehicle agent piping shall be operational, and the agent tank shall be empty. The propellant gas tank(s) shall be fully charged and within proper pressure. A means of lifting the agent tank(s) for weighing without loss of agent shall be provided. Alternatively, the system shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the agent tank and related piping, fittings, valves, hose, and nozzle(s) in the same configuration in which they are installed on the vehicle.

4-3.33.4 The test shall be conducted in the following manner:

(a) Using the manufacturer's recommended agent and filling procedure, charge the agent tank.

(b) Ensure that all fill caps are tightened securely, all propellant gas lines are connected, the discharge nozzle(s) is in the closed position, and all fittings and connections are tight.

(c) Pull all hand line hose from the reel(s).

(d) Pressurize the system using the manufacturer's recommended procedure and open all hand line nozzles until agent flow is observed. Close the nozzles.

(e) Weigh and record the agent tank as the "initial weight."

(f) Position the hand line nozzles at least 20 ft (6.1 m) from the fire pan so that they can be discharged onto a flat grade with no stream obstructions. Ignite the fuel.

(g) Select one of the hand line nozzles (nozzle 1). While holding it in a position 3 ft to 4 ft (0.9 m to 1.2 m) above ground level, simultaneously start the stopwatch and fully open the nozzle, and then discharge agent onto the fire.

(h) After at least 50 percent of the contents of the tank has been discharged, shut down the nozzle and stop the stopwatch. Record the time as "elapsed discharge time no. 1."

(i) Reweigh the agent tank and record as "weight after first discharge."

(j) If a second nozzle (nozzle 2) is provided, repeat 4-3.33.4(a) through (h).

(k) While holding the two hand line nozzles in a fixed horizontal position 3 ft to 4 ft (0.9 m to 1.2 m) above ground level, simultaneously start the stopwatch and fully open both nozzles.

(l) After at least 50 percent of the contents of the tank has been discharged, simultaneously shut down both nozzles and stop the stopwatch. Record the time as "elapsed discharge time no. 2."

(m) Reweigh the agent tank and record as "weight after second discharge."

(n) Calculate the flow rate from nozzle 1 as follows:

$$\frac{\text{initial weight (test 1)} - \text{initial weight (test 2)}}{\text{(elapsed discharge time no. 1)}} = \text{flow rate}$$

(o) Calculate the flow rate from nozzle 2 as follows:

$$\frac{\text{weight after first discharge} \qquad \text{weight after second discharge}}{2 \times \text{(elapsed discharge time no. 2)}} = \text{flow rate}$$

(p) If nozzle 2 is of a different configuration, repeat the fire test for this nozzle.

4-3.33.5 Test results shall be evaluated as follows:

(a) The flow rate from each nozzle shall meet the requirement.

(b) The range from each nozzle shall meet or exceed the requirements as evidenced by extinguishment of the fire(s).

(c) When discharged simultaneously, the flows from nozzle 1 and nozzle 2 shall be within 10 percent of each other.

4-3.34 Dry Chemical Turret Flow Rate and Range.

4-3.34.1 Test facilities shall consist of a level, open site suitable for discharging the agent and measuring range. The test shall be conducted in calm wind [less than 5 mph (8 km/h)].

4-3.34.2 Test equipment shall consist of the following:

(a) A calibrated scale or load cell with an accuracy of ± 1.0 percent;

(b) A stopwatch;

(c) A tape measure or other device for measuring distance;

(d) A calibrated anemometer.

4-3.34.3 All dry chemical discharge piping shall be operational, and the dry chemical tank shall be empty. The propellant gas tank(s) shall be fully charged and within proper pressure. A means of lifting the agent tank(s) for weighing without loss of agent shall be provided. Alternatively, the system shall be permitted to be tested outside of the vehicle. Where this alternative is used, the test shall be conducted with the agent tank and related piping, fittings, valves, hose, and nozzle(s) in the same configuration in which they are installed on the vehicle.

4-3.34.4 The test shall be conducted in the following manner:

(a) Using the manufacturer's recommended agent and filling procedure, charge the tank.

(b) Ensure that all fill caps are tightened securely, all propellant gas lines are connected, the discharge nozzle(s) is in the closed position, and all fittings and connections are tight.

(c) Pressurize the system using the manufacturer's recommended procedure and open the turret discharge valve until agent is observed. Close the valve.

(d) Weigh and record the agent tank as the "initial test weight."

(e) Position the dry chemical turret so that it can be discharged onto a flat grade with no stream obstructions. Position the turret to obtain maximum straight stream reach.

(f) Simultaneously, start the stopwatch and fully open the turret.

(g) During discharge, place markers at the far point where significant dry chemical strikes the ground (range marker) and at either side of the widest part of the pattern (width markers).

The operator(s) placing the markers shall wear proper safety equipment for this task. The agent manufacturer's material safety data sheet shall be consulted.

(h) After discharging at least 75 percent of the contents of the tank, simultaneously stop the stopwatch and shut down the turret. Record the elapsed time in seconds as discharge time.

(i) Measure the distance from the turret to the range marker and record as the far point range.

(j) Measure the distance between the width markers and record as the pattern width.

(k) Reweigh the agent tank and record as the weight after discharge.

(l) Calculate the flow rate as follows:

$$\frac{\text{initial test weight} - \text{weight after discharge}}{\text{elapsed discharge time}} = \text{flow rate}$$

4-3.34.5 The stream range and pattern width shall equal or exceed the requirements. The discharge flow rate shall equal the requirement.

4-3.35 Cab Interior Noise Test.

4-3.35.1 Test facilities shall consist of a flat, open, paved area suitable for operating the vehicle at a constant speed of 50 mph (80.5 km/h) that is free from any large reflecting surfaces (such as other vehicles, signboards, or hills) within a 50-ft (15.2-m) distance of the vehicle. The wind speed shall not exceed 15 mph (24.1 km/h) during the test.

4-3.35.2 Test equipment shall consist of a sound level meter that meets the requirements of ANSI S1.4, *Specification for Sound Level Meters*, for Type 1 or S1A meters. The sound level meter shall have been calibrated by a certified testing laboratory within the previous 12 months.

4-3.35.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with tires inflated to their recommended inflation pressure. The cab doors, windows, and hatch openings shall be closed during this test. The vehicle shall be driven long enough to bring the drive train components up to their normal operating temperatures prior to starting the test. Thermostatically controlled shutters or cooling fans, or both, shall be allowed to function normally. The vehicle agent system(s), the communications system, and the audible warning system and emergency warning system shall be inactive during this test.

4-3.35.4 The interior noise level of the cab shall be determined as follows:

(a) Set the sound level meter to the A-weighing network, “fast” meter response, and position the meter adjacent to the driver’s ear.

(b) Bring the vehicle up to a road speed of 50 mph (80.5 km/h) and maintain that speed while recording the noise measurements.

(c) Repeat 4-3.35.4(a) and (b) until four readings have been taken, bringing the vehicle to rest between each measurement. If any of the noise measurements differ from the others by more than 2 dBA, they should be replaced by another measurement, since they could be the result of extraneous ambient noises or equipment/measurement error.

(d) Average the four readings.

4-3.35.5 The average of the recorded noise readings shall be less than or equal to the cab interior noise level specification.

4-4 Operational Tests.

4-4.1 Weight/Weight Distribution.

4-4.1.1 Test facilities shall consist of an in-ground, certified weight scale large enough to accommodate the vehicle or a level test pad suitable for positioning the truck on top of portable wheel scales.

4-4.1.2 Instrumentation for this test is limited to the in-ground or portable scales. The accuracy of the scales shall be ± 1.0 percent.

4-4.1.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*). Ballast shall be used for the crew and equipment as necessary.

4-4.1.4 The total weight of the vehicle and weight distribution shall be determined as follows:

(a) Determine the total weight of the vehicle by driving the fully loaded vehicle onto the scale(s).

(b) Determine the individual axle loadings by measuring the weight on each axle at the ground. Since the total vehicle weight is more accurately reflected by the single weight measurement in 4-4.1.4(a), correct the individual axle loads proportionately, as necessary, so that their total equals the total vehicle weight. Subtract the lightest loaded axle weight from the heaviest loaded axle weight, and divide the difference by the weight of the heaviest axle.

(c) Determine individual tire loadings by measuring the weight on each tire at the ground. Make proportionate corrections to the individual tire loads so that their total equals the load on the respective axle. Determine the average tire weight for each axle by adding the right-hand and left-hand tire weights for each axle and dividing by 2. Subtract the lightest loaded tire weight from the heaviest loaded tire weight for each axle, and divide the difference by the average tire load for that axle.

4-4.1.5 The data shall be evaluated on the following basis:

(a) The total weight of the vehicle shall be less than or equal to the vehicle manufacturer’s gross vehicle weight rating.

(b) The difference between the heaviest loaded axle and the lightest loaded axle shall be less than or equal to the maximum difference permitted in the specification.

(c) The difference between the tire weights on any given axle shall be less than or equal to the maximum difference permitted in the specification.

4-4.2 Acceleration.

4-4.2.1 Test facilities shall consist of a dry, straight, level paved surface sufficient in length to accelerate the vehicle from rest to 50 mph (80.5 km/h) and then bring it to a safe stop.

Ambient temperatures at the test site shall be 0°F to 110°F (–17.8°C to 43.3°C), and elevations shall include heights up to 2000 ft (609.6 m) unless otherwise specified by the purchaser.

4-4.2.2 Instrumentation shall consist of the vehicle’s speedometer and tachometer, as installed by the manufacturer at the time of delivery, and a stopwatch.

4-4.2.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with the engine and the transmission at their normal operating temperatures. The tires shall be inflated to the manufacturer’s recommended pressure.

4-4.2.4 The test shall be conducted in the following manner:

(a) Start the test with the vehicle at rest, the engine at idle, and the transmission in gear.

(b) Simultaneously, start the stopwatch and accelerate the vehicle and continue accelerating to a wide-open throttle condition.

(c) At the moment the vehicle reaches 50 mph (80.5 km/h), stop the watch and record the elapsed time.

(d) To compensate for wind conditions and slope, repeat the test in the opposing direction. Record and average a minimum of three readings in each of the two directions.

4-4.2.5 The average acceleration time to 50 mph (80.5 km/h) shall be less than or equal to the requirement, as specified.

4-4.3 Top Speed.

4-4.3.1 Test facilities shall consist of a dry, paved, level surface suitable for achieving a vehicle speed of at least 65 mph (104.6 km/h) and bringing the vehicle to a safe stop.

4-4.3.2 Instrumentation shall consist of the vehicle’s speedometer as installed by the manufacturer at the time of delivery.

4-4.3.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with the engine and the transmission at their normal operating temperatures. The tires shall be inflated to the manufacturer’s recommended pressure.

4-4.3.4 The test shall be conducted in the following manner:

(a) Accelerate the vehicle to a speed of at least 65 mph (104.6 km/h).

(b) To compensate for wind conditions and slope, repeat the test in the opposing direction.

(c) If 65 mph (104.6 km/h) cannot be achieved in one of the directions, repeat 4-4.3.4(a) and (b), accelerating the vehicle to its maximum speed in each direction, record the speeds, and average the two numbers.

4-4.3.5 The test shall be considered successful if the average top speed equals or exceeds 65 mph (104.6 km/h).

4-4.4 Brake Operational Test.

4-4.4.1 Test facilities shall consist of any dry, smooth, paved surface adequate in length to reach the respective test speeds and stop safely. The test area shall be marked so that a lane that equals the width of the vehicle plus 4 ft (1.2 m) is established. A runway or taxiway with a marked centerline shall be permitted to be used.

4-4.4.2 Instrumentation shall consist of the vehicle's speedometer, as installed by the manufacturer, and a tape measure.

4-4.4.3 The vehicle shall be tested in its fully loaded condition (*see definition of Fully Loaded Vehicle in Section 1-3*) with the brakes adjusted to the manufacturer's recommended tolerances. The tires shall be inflated to the vehicle manufacturer's recommended inflation pressure. The vehicle's stopping distance shall have been certified by the vehicle manufacturer.

4-4.4.4 The test shall be conducted in the following manner:

(a) Maintain a constant speed of 20 mph (32.2 km/h) while driving down the centerline of the test site.

(b) Apply the brakes as if in a panic stop until the vehicle comes to rest.

(c) Measure and record the distance from the outer edge of the vehicle to the centerline of the lane.

(d) Repeat 4-4.4.4(a) through (c) at a constant speed of 40 mph (64.4 km/h).

4-4.4.5 The distance measured shall not exceed one-half the vehicle width plus 2 ft (0.6 m).

4-4.5 Air System/Air Compressor Test.

4-4.5.1 No special test facilities shall be required.

4-4.5.2 Instrumentation shall consist of the vehicle's air system pressure gauge(s), as installed by the manufacturer, and a stopwatch.

4-4.5.3 The vehicle's air system shall be fully operational for this test. The manufacturer previously shall have established the ratio of actual to required reservoir capacity and the spring brake release pressure. The test shall be conducted with the transmission in neutral and the parking brakes set.

4-4.5.4 The test shall be conducted as follows:

(a) Using the brake pedal, bleed off the air reservoir system pressure to a level below 85 psi (586 kPa) as indicated on the cab-mounted air gauge(s).

(b) Accelerate the engine to its wide-open throttle condition.

(c) When the air pressure indicator reaches 85 psi (586 kPa), start the stopwatch. If more than one air pressure indicator is installed on the vehicle, start the stopwatch when the first indicator registers 85 psi (586 kPa).

(d) Continue building air pressure with the engine at wide-open throttle until 100 psi (689.5 kPa) is registered on all air pressure indicators, stop the watch, and record the time.

(e) Using the brake pedal, bleed off the air reservoir system pressure to 0 psi (0 kPa), as indicated on the cab-mounted air gauge(s).

(f) Accelerate the engine to a wide-open throttle condition.

(g) When the wide-open throttle condition is reached, simultaneously start the stopwatch.

(h) Continue building air pressure with the engine at wide-open throttle until the previously established spring brake release pressure has been reached in the quick buildup system, stop the watch, and record the time.

4-4.5.5 The results shall be evaluated as follows:

(a) The time needed for a buildup of 85 psi to 100 psi (586 kPa to 689.5 kPa) shall be within 25 seconds or the permitted time as calculated for larger reservoir capacities.

(b) The quick buildup time shall be within 15 seconds.

4-4.6 Agent Discharge Pumping Test.

4-4.6.1 Test facilities shall consist of an open site suitable for discharging agent.

4-4.6.2 No test equipment shall be required.

4-4.6.3 The vehicle's agent system shall be fully operational for this test, and all primary hand lines shall be deployed.

4-4.6.4 The combined discharge of all nozzles shall be tested as follows:

(a) Fill both the water tank and the foam (or dyed water) tank completely with water and foam, respectively.

(b) Set the agent system to operate in the foam mode, set the system pressure for optimum performance, and engage the agent pumps. Simultaneously operate the pumps of vehicles with multiple pumps during this test.

(c) Initiate discharge first through the roof turret and then through the ground sweeps, (or optional bumper turret), primary hand lines, and undertruck nozzles until all are discharging simultaneously in a straight stream. As each nozzle is turned on, observe the range along with the system pressure.

(d) Continue to discharge until the system pressure has stabilized with all nozzles discharging.

4-4.6.5 Since measurements of actual flow rates are not practical in the field, the system shall be considered to have met the requirement in accordance with the procedures of 4-4.6.4, provided the nozzle ranges show no signs of deterioration as additional nozzles are engaged and the agent system pressure does not fluctuate by more than 10 percent where comparing the roof turret flowing by itself with the combined discharge pressure. Foam (or dyed water) shall be evident in the discharging stream from all nozzles at all times.

4-4.7 Dual Pumping System Test.

4-4.7.1 Test facilities shall consist of an open site suitable for discharging agent.

4-4.7.2 No special instrumentation shall be required for this test.

4-4.7.3 The vehicle's agent system shall be fully operational for this test.

4-4.7.4 The ability of a vehicle equipped with a dual pumping system to provide foam solution to all nozzles when only one system is active shall be tested as follows:

(a) Fill both the water tank and the foam tank completely with water, and add dye or foam concentrate to the foam tank.

(b) Set the agent system to operate in the foam mode, and set the system pressure for optimum performance.

(c) Set the primary turret(s) discharge rate in the half flow rate setting.

(d) Initiate discharge first through the primary turret(s) (at half rate) and then through the ground sweep nozzles (or alternate bumper turret), the primary hand line nozzles, and the undertruck nozzles, first with one pump operating, and then the other.

4-4.7.5 A foam or dye solution discharge stream shall be present at each nozzle tested when either pump is engaged.

4-4.8 Pump and Maneuver Test.

4-4.8.1 Test facilities shall consist of an open site suitable for discharging agent and operating the vehicle up to its maximum speed.

4-4.8.2 No test equipment shall be required.

4-4.8.3 The vehicle's agent system shall be fully operational for this test.

4-4.8.4 The positive pump and maneuver capability, along with the smooth engagement of the pump, shall be tested as follows:

(a) Fill both the water tank and the foam tank completely with water, and add dye or foam concentrate to the foam tank.

(b) With the vehicle being driven at 20 mph (32.2 km/h), engage and disengage the pump(s) without damage to the pump or pump drive system.

(c) Bring the vehicle to a stop, and prepare the primary turrets and ground sweeps (or optional bumper turret) for discharging.

(d) Place the agent selector in the foam mode, and set the agent system pressure relief to relieve at the recommended pressure for optimum performance.

(e) Initiate discharge through the primary turrets and ground sweeps/bumper turret nozzles, and drive the vehicle in a forward and reverse direction at speeds ranging up to 5 mph (8 km/h). Stop and start the vehicle, and change direction from forward to reverse while operating through this speed range without interrupting the discharge flow rate or range. Engage and disengage the pumps during the test.

(f) Repeat 4-4.8.4(e) both on and off the road.

4-4.8.5 During the test, there shall be no indication of proportioning, pressure, or flow rate instability. The operation of the pump shall not, under any conditions, cause the engine to stall. Engagement of the pump or vehicle drive shall be accomplished without introducing any unsafe vehicle dynamics such as severe lurching. Dye or foam solution shall be evident while discharging from all nozzles.

4-4.9 Hydrostatic Pressure Test.

4-4.9.1 Test facilities shall consist of an appropriate area in the vehicle manufacturer's plant.

4-4.9.2 Test equipment shall consist of the following:

(a) A hydraulic pressure gauge with a scale adequate for monitoring a pressure equal to $1^1/_2$ times the normal agent system pressure of the vehicle;

(b) A pressure charging device capable of developing a pressure equal to $1^1/_2$ times the normal agent system pressure of the vehicle and sustaining it for 15 minutes or longer;

(c) Miscellaneous plates or caps to isolate the suction side of the agent system, as necessary, from the hydrostatic test pressure.

4-4.9.3 The vehicle's agent system shall be fully assembled at the time of the test. As it is sometimes desirable to perform this test before the body is completely assembled and fire-fighting system controls are in place, the agent system shall not be required to be fully operational during the hydrostatic portion of the test.

4-4.9.4 The water and foam concentrate or foam solution discharge piping shall be tested as follows:

(a) Isolate all suction piping components that cannot tolerate the hydrostatic test pressures from the discharge piping and pump(s) by installing temporary plates or caps between these items and the discharge piping. Include the agent pumps in the test.

(b) Close all discharge nozzles, and seal any bypass lines from the pressure piping to the agent tanks.

(c) Connect a pressure charging device (e.g., electric motor-driven water pump or hand pump) into the discharge piping.

(d) Activate the pressure charging device, fill the agent pumps and discharge piping with water, and pressurize to at least $1^1/_2$ times the maximum recommended agent system operating pressure.

(e) Close the supply line from the pressure charging system, thereby sealing the discharge piping in a pressurized condition.

(f) Maintain the test pressure for at least 15 minutes without degradation.

(g) If leaks exist that cause the pressure to drop, repair the leaks and repeat the test.

(h) On completion of the hydrostatic test, disconnect the charging device and reassemble the suction piping.

(i) Fill the agent tanks and piping with water, and inspect the suction piping for leaks after the agent system has been operated in the foam mode.

4-4.9.5 No pressure decay shall be permitted during the 15-minute test, and no discharge or suction piping water leaks shall be permitted during or after agent system operation.

4-4.10 Foam Concentration Test.

4-4.10.1 Test facilities shall consist of an open site suitable for discharging agent. Access to a refill water supply and foam concentrate supply shall be required.

4-4.10.2 The test equipment described in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, shall be used for this test.

4-4.10.3 Each discharge nozzle on the vehicle shall have been individually verified as discharging at a flow rate within the tolerance specified. The agent system shall have been verified as capable of operating at full rate.

4-4.10.4 The test shall be conducted as follows:

(a) Fill the water and foam tank to the top, and refill as necessary throughout the test.

(b) Set the foam proportioning system to proportion foams at the concentration specified, and set the agent selector for the foam mode.

(c) Set the agent system pressure relief to the recommended pressure.

(d) Engage the agent pumps and bring them up to maximum pumping speed with all discharge outlets closed.

(e) Each foam delivery system shall be tested in accordance with NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, for the individual nozzle/flow rate as follows:

1. Roof turret(s) full rate;
2. Roof turret(s) half rate;
3. Ground sweep/bumper turret;
4. Hand line nozzles;
5. Undertruck nozzles.

4-4.10.5 The foam concentrations measured shall fall within the permitted tolerances specified in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, for each nozzle.

4-4.11 Roof Turret Flow Rate Test.

4-4.11.1 Test facilities shall consist of a level, open site suitable for discharging agent.

4-4.11.2 A stopwatch shall be required for this test.

4-4.11.3 The agent system shall be fully operational, and the agent system pressure shall be set in accordance with the manufacturer's recommendations. The water tank shall be filled completely.

4-4.11.4 The test shall be conducted as follows:

(a) Simultaneously initiate discharge through the primary turret(s) at the maximum flow rate and start the stopwatch.

(b) Continue discharging until the pump cavitates, as indicated by a significant drop in discharge pressure, and stop the watch when this occurs. Record the elapsed time.

(c) Divide the rated water tank capacity, in gallons, by the elapsed discharge time to determine the average discharge rate.

4-4.11.5 The average measured discharge rate shall be in reasonable agreement with the nominal discharge rate specified, and the total elapsed discharge time shall be no less than 1 minute nor greater than 2 minutes.

Chapter 5 Referenced Publications

5-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.1

The basic NFPA recommendations on the use and provision of this equipment are contained in NFPA 402M, *Manual for Aircraft Rescue and Fire Fighting Operations*, and NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*. Field testing procedures for aircraft rescue and fire-fighting vehicles utilizing foam are provided in NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*. NFPA 422, *Guide for Aircraft Accident Response*, is designed, in part, to provide technical data useful in evaluating the effectiveness of these vehicles.

A-1-3 Definitions.

Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

Authority Having Jurisdiction. The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Intended Airport Service. See also NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, for further information concerning aircraft rescue and fire-fighting services at airports.

Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-1-4.1

A minimum 1-year warranty should be supplied by the contractor. Purchasers should require that bids be submitted with a detailed description of the vehicles offered and drawings showing general arrangements, weights, and dimensions. Data similar to that provided in the questionnaire contained in Appendix B also should be required.

A-2-2.1.2 The intent of the weight distribution requirements is to produce the most equally divided weight distribution possible across all axles and wheels. Ideally, the front axle should not be the heaviest loaded axle. It is important to realize, however, that certain customized features not covered in the major fire-fighting vehicle chapter (such as auxiliary agent systems) might necessitate that the 5-percent allowance for the front axle be exceeded. Where these situations occur, the vehicle manufacturer needs to be consulted to determine the final weight distribution and to confirm that none of the established component weight ratings is exceeded and that the brake performance of the vehicle still complies with this standard.

A-2-2.2.2 Compromise might be necessary on overall vehicle dimensions, since the dimensions selected for optimum operational performance could be in conflict with other requirements. In order to eliminate unnecessary design restrictions, specification of vehicle dimensions should be undertaken only where a particular requirement exists.

Consideration should be given to the following factors at the time of specification to determine whether vehicle dimensions should be restricted:

(a) Fire station restrictions;

(b) Access within the airport boundaries;

(c) Access outside the airport boundaries, if necessary;

(d) Requirements that affect the dimensions of local construction, if applicable;

(e) Use regulations, if applicable.

A-2-3.1.2 At higher altitudes, the performance of a vehicle can be affected due to the reduced density of the air drawn into the engine. The resulting reduction in power is more noticeable on a normally aspirated engine, (e.g., nonturbo charged).

To assess the difference in performance at higher altitudes, it is important to obtain from the manufacturer the reduced power rating of the engine at the operating altitude. From this rating, the reduced level of acceleration performance or reduced water capacity extinguishing agent can be estimated.

A-2-7.3

The mobility and handling characteristics of the vehicle greatly depend on tire selection. The tractive limit of a tire is related to the strength of the soil, power available, wheel diameter, load, number of driving wheels, tire deflection, contact area, and tread pattern.

The following guidelines are recommended:

(a) Facilities with hard, off-pavement conditions and small snow accumulations might find it desirable to wish to specify high pressure tires with small contact area to maximize high speed performance and handling.

(b) Experience has demonstrated that tires having a large diameter, a wide base, and medium pressure can provide a reasonable compromise between mobility needs and hard surface performance and handling and are suitable for many facilities where soil is not extremely soft or wet and snow accumulations are moderate.

(c) Where local conditions require high flotation, (e.g., sand, mud) mobility traction can be improved by specifying larger wheel and tire diameters, larger tire cross section, greater tire deflection, and lower wheel loads or tire pressure. Specifications result in some degradation of high speed performance and handling characteristics. Actual performance testing could be necessary to ensure the suitability of such specifications.

A-2-8

Recovery of the vehicle from adverse conditions should be made by attaching the vehicle to the axles.

A-2-9.1

It is customary for manufacturers of rescue and fire-fighting vehicles to provide a braking system based on normal commercial practice, usually connected to a recognized standard that might have legal status in worldwide territories. These standards offer certain advantages and disadvantages that can vary from one another. Operators should consider these advantages and disadvantages with respect to their particular operating conditions and legal requirements.

A-2-9.2

By preventing wheel lock-up, anti-lock braking systems (ABS) can significantly enhance driver control and vehicle stability under certain conditions. The purchaser should consider the applicability of this option.

A-2-16.3.1 Polyvinyl chloride, epoxies, and polyesters are among the acceptable classes of resins.

A-2-16.5.7 The development of the extendable turret for aviation fire protection is a recent development. As such, the design and functional requirements, as well as the tactics and procedures for its use, are not well developed. Training curricula also need to be developed. The intent of the requirements of 2-16.5.7 is to provide minimum performance criteria so that there is no degradation in the basic turret performance, while allowing individual flexibility for specific user needs. These needs can be affected by the type of aircraft being protected, the ability to access the aircraft interior, and the ability to access shielded fires.

As now envisioned, the extendable turret can be used for primary agent application as part of a first-arriving vehicle. As such, the vehicle should be capable of applying agent quickly without the need to deploy supporting outriggers. In the future, other design features or functions might be incorporated. For example, man-rated devices for use in accessing the interior cabin after fire knockdown might be incorporated. These devices might or might not require stabilizing devices; depending on the function of the vehicle, the time to deploy such devices may be permitted. In any event, there should be a maximum time for total deployment of the boom/tower device. A maximum of 30 seconds is recommended. The requirements do not prohibit the development of an advanced device or a unit with a different function, recognizing that the primary turret performance should not be compromised.

It is not recommended that agent be applied from a vertically extended position before knockdown of the exterior exposure fire, unless the fire cannot otherwise be accessed. Preliminary data from demonstrations of extendable turrets, plus data from earlier turret testing, suggest that AFFF discharged at a low level is the most effective technique. The extendable turret should be designed to extend below the roof level of the cab to take advantage of low-level AFFF application. Extension of the extendable turret below the cab level also should provide advantages in accessing shielded/obstructed areas such as wheel-well incidents and “gear down” scenarios.

To improve operator efficiency, the movement of the boom/tower should be accomplished with a single lever located within the cab. Elevation/azimuth indicators are not needed if the turret is in the line of sight of the operator.

Where specified, the extendable turret should be fitted with the appropriate tools/devices needed for a driver/operator to perform interior aircraft and tail-mounted engine fire-fighting functions remotely. These could include a skin penetrator/agent applicator for penetration of the fuselage to access interior fires from outside the aircraft. Tactics and procedures for these evolutions are not well developed and should be given careful consideration, preplanning, and training, particularly for situations where surviving passengers/crew might still be in the aircraft. Where a penetrator/agent applicator is used, a minimum flow equal to two hand lines (as specified in 2-16-6.4.3) is recommended. Airports planning to use the device for indirect attack with a skin penetrator should preplan appropriate access locations on aircraft served and the conditions under which the device is to be used.

A-2-20.2

If desired, the driver’s siren control can be wired for selective control on the steering wheel horn button. If a combination public address-type siren is desired, an electronic type having an equivalent sound output should be substituted.

A-2-21

The purchaser should specify the particular item required for the following:

(a) One ground ladder that meets the requirements of NFPA 1931, *Standard on Design of and Design Verification Tests for Fire Department Ground Ladders*;

(b) One section of hose of minimum $2^1/_2$-in. (6.4-cm) diameter for tank fill;

(c) Appropriate spanner wrenches for the fittings on the vehicle;

(d) One hydrant wrench or other wrench necessary to activate the local water supply;

(e) A SCBA meeting the requirements of NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*, and NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, available for each assigned fire fighter;

(f) Skin penetrator/agent applicator;

(g) Appropriate wheel chocks;

(h) 100 ft (30.5 m) of utility rope;

(i) Two axes, non-wedge type;

(j) Fire-resistant blanket;

(k) Bolt cutters, minimum 24 in. (61 cm);

(l) Multipurpose, forcible entry tool;

(m) Intrinsically safe handlight(s);

(n) Two harness cutting tools;

(o) Hook, grab, or salving tool;

(p) First aid kit;

(q) 4-lb (1.8-kg) hammer.

For a detailed discussion of rescue tools, see NFPA 402M, *Manual for Aircraft Rescue and Fire Fighting Operations*.

It is important that additional features such as structural fire-fighting equipment do not interfere with the basic ability of the vehicle to perform its primary aircraft rescue and fire-fighting function. It is considered preferable to have separate vehicles for structural fire fighting equipped with the needed complement of hose and tools, since the quantity of such equipment carried on an aircraft rescue and fire-fighting vehicle needs to be limited to conserve weight and space.

Appendix B Aircraft Rescue and Fire-Fighting Vehicle Questionnaire

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

This questionnaire can be used to determine information on design features and requirements for aircraft rescue and fire-fighting vehicles.

Questionnaire

1. Chassis:

Make ________________ Model ____________

2. Type Drive: 4×4; 6×6; 8×8

3. Weights:

Vehicle	Front Axle (Bogie) (lb)	Rear Axle (Bogie) (lb)	Total (lb)
Empty:	________	________	________
With crew:	________	________	________
Expendable payload:	________	________	________
Total:	________	________	________
Average load per tire:	________	________	________

4. Gross Vehicle Weight Rating: ___________ lb

5. Dimensions (*See Figure B-1*):

Dimensions taken with:
Vehicle fully loaded @ _________ lb
Tire inflation pressure @ _______ lb
Overall length _________ in.; Overall width: ___________ in.;
Overall height _________ in.
Underaxle clearance: Front _________ in.; Rear ________ in.
Interaxle clearance angle ____________________ degrees
Underchassis clearance _________________ in.
Angle of: Approach ______________ degrees;
Departure ______________ degrees
Front bumper to center front wheels _______________ in.
Chassis wheel base _____________ in.
Center rear wheels to rear bumper ________________ in.

6. Engine:

Make ______________ Model ___________ Location ___________
Number of cylinders ___________
Piston displacement ____________ $in.^3$
Maximum brake
horsepower: Gross _______ @ ________ RPM
Net _______ @ ______ RPM
Maximum torque: Gross __________ @ _________ RPM
Net _______ @ ______ RPM
Governor: Make __________ Type _____________
Maximum governed speed ___________________________ RPM

7. Clutch, Fluid Coupling, Torque Converter:

Clutch: Make ________ Model _____________
Type ____________________________________
Rated Torque Capacity ______________________ lb-ft
Fluid Coupling: Make ____________ Model ______________
Rated Capacity ______________ HP
Torque converter: Make ___________ Model ______________
Stall torque ratio ___________ to 1
Rated capacity _____________ HP

8. Transmission:

Make _________ Model ______________ Type ____________
Maximum rated input torque
capacity _________________ lb-ft
Number of speeds: Forward _________________ Reverse _____________

Speed	**Gear Ratio**	**Mph* @ Engine-Governed RPM**
1	____________________	____________________
2	____________________	____________________
3	____________________	____________________
4	____________________	____________________
5	____________________	____________________
Rev.	____________________	____________________
Rev.	____________________	____________________

NOTE: If multiple range transfer case is provided, mph is to be measured with these components in high range.

9. Transfer Case:

Transfer case: Make _____________ Model _______________
Maximum rated input torque
capacity _______________ lb-ft
Gear ratio: High range ____________ Low range _________
Type drive to front and rear axles (bogie) ___________________
Center differential or compensating device:
Make ________________
Model _____________________
Type: Automatic locking

None
Driver selective locking
Direct drive:
Type: Connected at all times
Driver selective disconnect

10. Front Drive:

Axle
Bogie
Make ________ Model __________ Gear ratio __________ to 1
Type drive: Single reduction
Double reduction
If double reduction, type final reduction:
Spur gears at differential
Internal gears at hubs
Steering drive ends: Make _________ Model ____________
Type: Constant velocity
Cardan
Differential or compensating device:
Make __________________ Model ________________
Type: Automatic locking
Driver selective type
Nonlocking
Maximum rated input torque capacity ____________ lb-ft
Maximum rated load on tires at ground ___________ lb
Axle tread _________ in.; Bogie wheel base ___________ in.

11. Rear Drive:

Axle
Bogie
Make __________ Model __________ Gear ratio __________ to 1
Type drive: Single reduction
Double reduction
If double reduction, type final reduction:
Spur gears at differential
Internal gears at hubs
Differential or compensating device:
Make _________________ Model ___________________
Type: Automatic locking
Driver selective type
Nonlocking
Maximum rated input torque capacity ____________ lb-ft
Maximum rated load on tires at ground ___________ lb

Axle tread ____________ in.; Bogie wheel base ____________ in.

12. Suspension:

	Front	Rear
Suspension, type		
Leaf spring	_____	_____
Coil spring	_____	_____
Torsion bar	_____	_____
Air cushion	_____	_____
Diagonally opposite wheel motion	_____	_____
Axle motion before bottoming from level loaded position	_____	_____
Shock absorbers	_____	_____

Unsprung weight at full load ___________ percent

13. Wheels, Tires, and Rims:

	Front	Rear
Configuration		
Singles	_____	_____
Duals	_____	_____
Wheels, type		
Disc	_____	_____
Spoke	_____	_____
Wheels, construction		
Steel	_____	_____
Aluminum	_____	_____
Rims, type		
Single piece	_____	_____
Multiple piece	_____	_____

Rim size (in.)

Load/ply rating _____ _____

Maximum load (lb) _____ _____

Inflation pressure (psi) _____ _____

Tire, type

Bias ply _____ _____

Radial _____ _____

Tube _____ _____

Tubeless _____ _____

Tire tread design __________

14. Electrical System:

Voltage: Lighting _______________ Starting ___________
Alternator: Make __________ Model _________ Voltage ____________
Capacity rating at engine-governed speed ___________________________
Capacity rating at 50 percent engine-governed
speed ____
Batteries: Make ___________ Model __________ Number ____________
Capacity, each _________________ amp-hr @ 20-hr
Rate, each cold-cranking amp @ 0°F (-17.8°C)
Starter: Make ____________________ Model _________________________
On-board auxiliary battery charger
On-board auxiliary compressor ________________________ volts
External battery charging connection ___________________ volts
Engine coolant preheating connection ___________________ volts
Electrical system radio suppressed

15. Fuel System:

Fuel Pumps: Mechanical, number ____________________
Electrical, number __________________________
Fuel tank capacity ____________ gal; Location ______________________

16. Exhaust System:

Muffler
Construction of system ____________________
Location of exhaust discharge ________________

17. Air System:

Compressor capacity _______________ cfm
Air reservoir capacity _______________ in.^{3}
Quick buildup time ______________________________
Air dryer: Make _______________ Model ____________________

18. Service Brakes:

Make ____________________ Number ______________________
Front, type: Internal shoe
Disc
Braking area ____________ in.^{2}
Brake application system:
Make ______________________________
Type: Air-mechanical
Hydraulic, with:
Air booster
Vacuum booster
No booster
Stopping distance from 20 mph (32.2 km/h) _______________________
Stopping distance from 40 mph (64.4 km/h) ________________________

19. Emergency Brakes:

Make _____________ Location ______________________________
Braking area ________________ in.^{2}
Type: Entirely independent of service brakes
Connected to service brakes
Stopping distance from 40 mph (64.4 km/h) ________________________

20. Steering:

Steering gear: Make ______________ Model _____________________
Power assist: Make _______________ Model _____________________
Wall-to-wall turning diameter ____________ ft

21. Body:

Construction:
Chassis rigid, unitized
Chassis flexible
Frame material ____
Body construction material _____________________________________
Location of steps or ladders to working deck:
Each side
Rear
Type nonskid surface on steps, walkways __________________________

22. Cab:

Location _______________ Number of seats ______________________
Number of doors ______________ Type glass ______________________
Driver visibility: Horizontal _____________ Vertical _________________
Turret access hatch ___________
Insulation thickness/R value ______________
Cab construction material ________________
Instrument panel:
 Hinged
 Circuit quick disconnects
 Panel lighting
 Removable
 Instrument backlighting
Cab volume __________________ ft^3
Heater capacity _______________ Btu
Air conditioning capacity _______ Btu

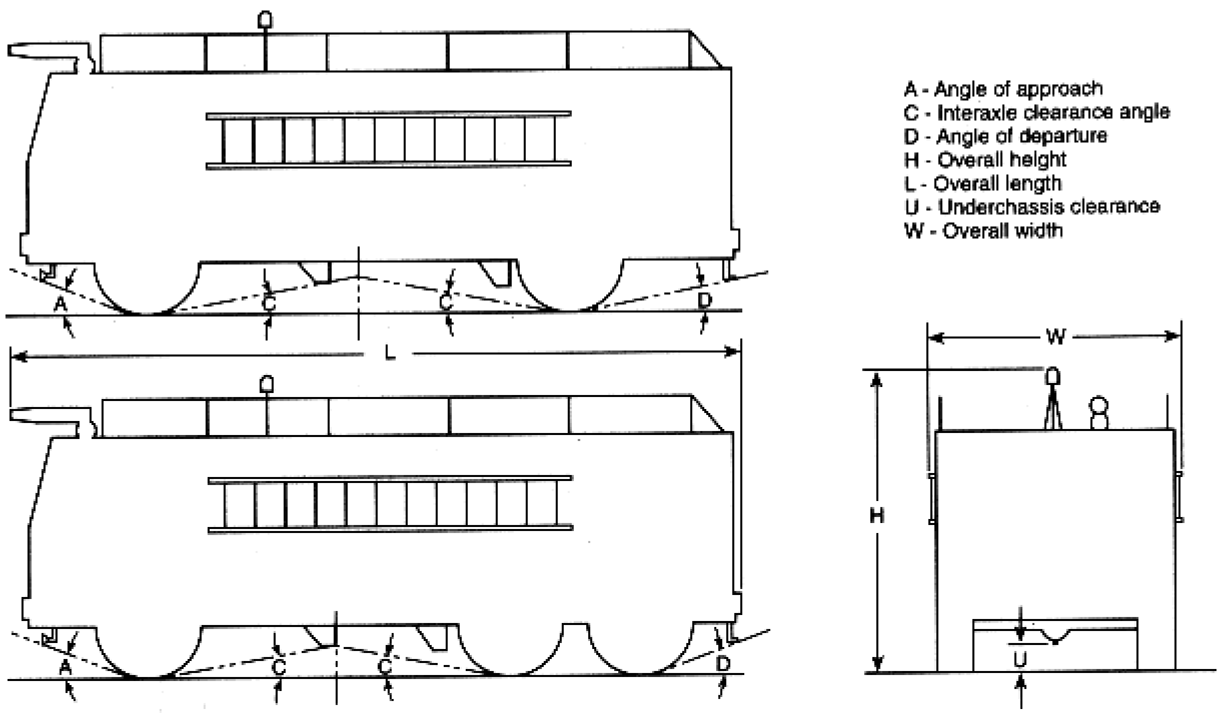

Figure B-1 Vehicle dimensions.

23. Pump(s) and Pump Drive:

Number of water pumps _________ Material _______________
Total pump capacity __________ gpm at _______ psi
Total pump drive:

Separate engine(s)
Power takeoff
If separate engine(s) drive:
Engine make _______________ Model _________________
Location _____________ Number cylinders ______________
Piston displacement ________________ $in.^3$
Maximum brake horsepower:
Gross _________ @ _________ RPM
Voltage of ignition and starting system ____________________
Type clutch, if furnished _____________
If power takeoff drive:
Location of P.T.O.:
Engine
Power divider
Torque converter
Transmission
Is power transmission uninterrupted? ______________
P.T.O. clutch type ____________
Torque capacity ______________ lb-ft
Clutch actuation ______________
Maximum engine speed at which P.T.O. can be engaged ___________ RPM
Suction piping material ______________________________________
Suction system low-point drain:
Type valve _________ Size ____________ in.
Pump discharge gates:
Number __________ Size ____________ in.; Location ___________
Pump check valve(s):
Number __________ Size ____________ in.; Location ____________
Type pressure relief device ________________
Discharge piping material ________________
Type valves ________________ Type couplings ________________
Churn line: Design __________________ Location
Open system
Closed system
Churn line valve control method ________________

24. Types and Quantities of Extinguishing Agents (Totals):

Carbon dioxide: Low pressure _____________ lb;
High pressure __________ lb
Dry chemical ____________ lb; Type dry chemical __________________
Halon ________________ lb; Type halon ________________________
Foam liquid concentrate ______________ gal;
Type concentrate ________________
[Specify if protein, fluoroprotein, or aqueous-film-forming foam

(AFFF)]
Water ____________________ gal

25. Water Tank:

Location ________ ; Usable capacity __________ gal;
No. of tanks __________
Dimensions: Height __________ in.; Length _________ in.;
Width _________ in.
Height of tank bottom above ground _____________ in.
Construction material _______________
Interior coating: Yes ___________ No ________
Coating material _____________
Baffles:
Number transverse ______________
Number longitudinal _______________
Anti-swirl: Yes _________ No __________
Top fill opening: Size _________ in.;
Number ____________ ; Type _______________
Side fill connections: Size ____________ in.; Number ____________;
Thread type _________________ ; Location ______________

26. Foam-Liquid Concentrate Tank(s):

Location _______________ Number __________________
Usable capacity (total) _________________ gal
Type: Rigid construction material ______________________
Flexible
Top fill size ____________ No. of can openers _____________
Side fill connections: Size _________ in.; Number ____________;
Thread type ______________ ; Location _________________

27. Foam Pumping and Proportioning System:

Type foam proportioning system ____________________________
Foam-liquid concentrate percentage:
Variable from ________ to _______________ percent
Foam-liquid concentrate pump: Material _________________
Capacity _______________ gpm at _____________ psi
Type pump drive __________________
Foam-liquid concentrate piping: Material __________________

28. Roof Turret Foam Nozzle(s):

Number ____________ Make ____________ Model _____________
Location __________________ Type nozzle _____________________
Single discharge
Dual discharge

Turret flow rate(s) ______________ gpm;
Operating pressure _____________ psi
Discharge: Foam-straight stream
Foam-variable pattern
Water-straight stream
Water-spray
Range-straight stream, foam
Far point ________________ ft;
Near point _______________ ft
Range-fully dispersed or spray, foam
Full width _________________ ft; Far point _________________ ft;
Near point _________________ ft
Turret control: Manual only
Power assist
Full power
Foam quality: Expansion rate __________________ to 1
25-percent drainage time _________________ min

29. Hand Line(s) Water/Foam:

Number __________ Location ___________________________
Length hose per reel ______________ ft; Size _______________
Reel mounting: Fixed
Swing-out
Height of reel top above ground ______________ in.
Nozzle: Make _____________ Model ________________
Liquid flow rate _____________ gpm
Foam quality: Expansion ratio __________ to 1
25-percent drainage time ___________ min
Foam pattern: Width ___________ ft; Range ____________ ft

30. Ground Sweep Nozzle(s):

Number ____________________ Location __________________
Liquid flow rate(s) __________________________ gpm
Foam quality: Expansion ratio _____________ to 1
25-percent drainage time __________ min
Foam pattern: Width ___________ ft; Range ____________ ft
Control locations: In cab
Outside

31. Bumper Turret Nozzle(s):

Number ___________ Make ___________ Model ______________
Location _____________ Type Nozzle _________________________
Single discharge
Dual discharge

Turret Flow Rate(s) __________ gpm;
Operating pressure __________ psi
Discharge: Foam-straight stream
Foam-variable pattern
Water-straight stream
Water-spray
Range-straight stream, foam
Far point _________ ft; Near point ___________ ft
Range-fully dispersed or spray, foam
Full width ___________ ft; Far point __________ ft;
Near point ____________ ft
Turret control: Manual only
Power assist
Full power
Foam quality: Expansion rate ________________ to 1
25-percent drainage time ____________ min

32. Undertruck Nozzle(s):

Number _______________________ Location ___________________
Liquid flow rate(s) ______________________ gpm
Control locations: In cab
Outside

33. Emergency Warning Devices:

Flashing beacon: Make ______________ Model _________________
Location ______________________
Siren: Make ______________ Model ________ Location ___________
Control location _________________
Horn: Air
Electric
Reverse alarm: Make _________________ Model ____________________

34. Auxiliary Agent Nozzle(s):

Turret: Type ____
Number _______________________ Location _________________________
Make _________________________ Model ___________________________
Range _____________ ft
Discharge rate ___________________ lb/sec
Hand line: Type ____
Number _______________________ Location __________________________
Length hose per reel __________ ft
Size ________________ in.
Reel mounting: Fixed
Swing-out

Height of reel top above ground ____________ in.
Nozzle:
Make _______________ Model _________________
Range _________________ ft
Discharge rate ______________ lb/sec

Appendix C Driver's Enhanced Vision System: A Technical Approach for Aircraft Rescue and Fire-Fighting Services

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

C-1 Introduction.

Several accidents have occurred in poor visibility conditions, and, with the proliferation of category IIIC landing systems, more requirements for fire fighting in low visibility conditions can be expected. Aircraft rescue and fire-fighting services currently have no reliable way to locate and navigate to crash sites at airports under conditions of poor visibility.

C-2 Background.

Aircraft rescue and fire-fighting services are required to demonstrate an ability to respond anywhere on the airport operational runway areas as part of earning their annual certificate. This response requirement is considered vital to the ability of ARFF services to gain control of a rapidly growing external post-crash fuel fire and their ability to protect the evacuating passengers from the aircraft fuselage. A response in 3 minutes is dependent on the vehicles' ability to accelerate rapidly from the rescue services facilities and to maintain approximately a 50-mph (80.5-km/h) approach to the accident site. Accomplishing this task under substandard visibility conditions such as fog and rain prevents the responding vehicles from reaching this speed.

There is a clear need to provide operational equipment in the rescue vehicles that maintains their response ability if low visibility flight operations are to be conducted.

The problem of poor visibility response at airports for rescue and fire-fighting services can be broken down into three components:

(a) Locating the accident sites;

(b) Navigating aircraft rescue and fire-fighting vehicles to crash sites;

(c) Negotiating terrain and obstacles in low visibility conditions.

Airport fire services need a driver's enhanced vision system (DEVS) that addresses these three components.

Aircraft rescue and fire-fighting services need to obtain an accurate position fix on the crash site within a time parameter that is comparable to their response time (under 3 minutes). The current system for locating crash sites that are not visible to aircraft rescue and fire-fighting services relies on visual observations, estimates, and verbal descriptions of airport landmarks provided by air traffic controllers. This system is prone to human error. The optimal solution to this problem is a system that locates a crash site on a digital map of the airport automatically and transmits this location to aircraft rescue and fire-fighting services.

Navigation of aircraft rescue and fire-fighting vehicles to crash sites is an issue that can be solved with today's technology. Sophisticated radio navigation systems such as the global positioning system (GPS) provide precise positioning capability. This position information, combined with digital maps of the airport area, can be displayed on a geographic map or heads-up display (HUD) to guide the crews.

Negotiating terrain and locating obstacles in low visibility conditions is an important capability that aircraft rescue and fire-fighting services currently do not possess. The only aids that rescue services currently use for improving vision under poor visibility conditions are windshield wipers and headlights. These devices often do not improve visibility enough to allow rescue teams to drive safely at the high speeds necessary to reach a crash site within a reasonable time. One aid that would provide improvement is a forward looking infrared device (FLIR). FLIRs currently are used by the military to improve visibility at night and during severe weather conditions. The FLIR system needs to be fully functional as soon as the fire equipment departs the fire station facility. Exit time typically is under 30 seconds from the time of accident notification. On-line and operational equipment should in no way impede the ability of the aircraft rescue and fire-fighting services to respond. Equipment is to be automated and is to necessitate little attention by the truck operator.

C-3 General Requirements.

A driver's enhanced vision system (DEVS) is required in an aircraft rescue and fire-fighting vehicle for airport emergency equipment. It facilitates faster and safer travel to emergency situations at night and in adverse weather conditions. It provides a substantial increase in the ability to locate people, other aircraft, vehicles, and debris at the emergency site. Its ability to allow the driver to see through flames, smoke, and fog during both the day and night provides ARFF vehicles with a significant increase in effectiveness in every phase of emergency operations.

The DEVS requires a transparent window display (TWD), which is often called a heads-up display (HUD), combined with a global positioning system (GPS) and geographic information system (GIS), on-board sensors, a central data and command RF link (radio communications), and a forward looking infrared (FLIR) sensor. These elements are to be integrated into a single functional system. A validation demonstration program is necessary to provide the quantitative information needed to justify the DEVS and refine it for the ARFF services application.

C-4 Operating Scenarios and Capabilities.

Mission Description

From the moment that an alert is received until the end of the emergency, the ARFF services mission is subject to stress and uncertainty. At any given moment, day or night, the equipment needs to be fully functional within a few seconds, regardless of adverse weather. Often vehicles and aircraft are positioned on the runways and taxiways in unusual or unexpected locations. In the event of an aircraft accident, victims and debris can be present anywhere on the airport. At the same time, the large size of modern airports, with multiple parallel runways and taxiways, places a priority on the ability to travel at high speed to the emergency site.

Once the ARFF services have arrived at the location, the ability to assess the situation is crucial to carrying out the mission. The information available to the vehicle operator contributes directly to the level of performance of the ARFF mission. This information needs to be obtained without any increase in the workload. The DEVS reduces the impact of night conditions, adverse weather, fire, and smoke so that the operator's performance approaches that achieved during the optimum daylight scenario.

To achieve this goal, information is to be provided in an easily recognizable form, without the need for vehicle operator intervention. Rescue vehicle location, the location of the emergency, the location of other vehicles (ground and aircraft), the location of people, and the location of debris are the basic data needed (and normally available during the least difficult situations). The condition of the aircraft, location of victims, presence and location of spilled burning fuel, and location of other ARFF personnel also are crucial. In addition, the possible presence of toxic gases caused by spilled or burning cargo needs to be determined to provide for a safe response to the situation. Finally, since multiple vehicles and ARFF crews are always involved in most emergency situations, a centralized command and control system is needed to coordinate the activities of all elements of the emergency response team. The DEVS is one element of this command and control system.

C-5 Required Capabilities.

The DEVS provides an increase in the knowledge available to the emergency crew. The crew are able to see through fog, rain, sleet, and snow. The crew are able to see through smoke and flames in and around the burning aircraft, to detect the position of evacuees and trapped passengers, and to distinguish among the debris to move into a position for fire fighting. They are able to apply extinguishing agents to the hottest areas of the burning fire more precisely. They also can track other fire fighters through the smoke and fire while rescue efforts are under way.

The FLIR device provides the ARFF operator with the ability to detect debris and other vehicles (stationary or moving) in the vicinity, as well as to detect passengers evacuating from the aircraft. The FLIR detector can electrocute humans in a smoke or fog environment where normal vision is inadequate. The FLIR stores information for normal driving conditions. The FLIR uses the brighter-than-background standard runway and taxiway lights, which are detected as it travels to the site.

C-6 System Elements.

The elements of the DEVS for the ARFF vehicle demonstration include a forward looking infrared device (FLIR), a transparent window display (TWD) or heads-up display (HUD), and a global positioning system (GPS) with geographic information system (GIS) or mapping.

C-7 Forward Looking Infrared Device.

The FLIR is a high resolution infrared detector. It is enhanced with wide dynamic range processing for increased penetration of smoke and fog. The FLIR contains a two-dimensional focal plane array using platinum silicide as the detector material. It operates at wavelengths from 8 micrometers to 12 micrometers and has a sensitivity of 32.2°F (0.1°C). An alternate FLIR of 3 micrometers to 5 micrometers with similar sensitivity also is implemented to establish whether the shorter wavelength provides significant benefits in the smoke environment. A key element in the use of the FLIR device for this application includes a total hands-off automation philosophy.

Rapid cool-down is another function dictated by the nature of FLIR detectors. To achieve the best performance, these detectors need to be cooled to very low temperatures [in the range of -454°F (–270.2°C)]. The cooling systems that have been developed have an operating life of about 2500 hours. Rapid cool-down or extended standby life cycle is considered essential to an ARFF application. Zero (0) or near-zero time start-up is an operational requirement for effectiveness.

C-8 Dynamic Range Issues.

To detect people and debris, the FLIR has a sensitivity of approximately 32.2°F (0.1°C). At the same time, the FLIR can be expected to deliver this sensitivity in the presence of flames that reach temperatures of 1832°F (1000°C). In order to accomplish this, the FLIR operates over an instantaneous dynamic range of about 10,000: 1.

C-9 Transparent Window Display.

The transparent window display system hardware consists of a projector, an optical element, and a symbol generator to provide information to an operational position. The symbol generator provides data to the projector by means of dedicated signal cables. The symbol generator has the capability to receive and to process data links from up to six video inputs and two serial inputs while formatting messages based on a control program. The control program uses the data's priority, refresh rate, and other site-specific criteria to implement the sequence and content of the information presentation.

C-10 Projector.

The DEVS projector is a high-brightness CRT, monochrome emitter that creates and projects a focused image onto the window of the ARFF vehicle. The projector is designed to be placed 60 in. to 72 in. (152.4 cm to 182.9 cm) from the window. There are optional mounting schemes that allow the projector to be mounted off-axis from the window to accommodate existing mechanical obstructions. The projector is to be equipped to accept standard signal inputs that include RS-170 to utilize the TWD as a simple replacement of an existing heads-down display (HDD).

C-11 Optical Element.

The optical element is mounted to the window of the ARFF vehicle to act as a dynamic display surface within the truck cab. The optical element should be 6 in.^{2} to 12 in.^{2} (38.7 cm^2 to 77.4 cm^2) and affixed to a selected location on the window with room temperature vulcanizing material. The location is to be predefined to reflect data in a uniform manner that is specified by both lateral and vertical angles perpendicular to the plane of the window. The viewing zone should offer a lateral reflection angle of 30 degrees and a vertical reflection angle of 15 degrees. The information is to be presented in a bright green color and is to be focused at the plane of the window. The DEVS is not to obstruct the view to the outside of the vehicle.

C-12 Symbol Generator.

The symbol generator is to be a microcomputer-based system designed for rack mounting in an equipment bay. This remote computer offers the capability to interface directly with a selected set of on-board data channels or discrete indicator inputs and is linked with a GPS tracker and a FLIR. The symbol generator is programmed with the mission-specific control scheme and operates in an automatic mode. There is a keyboard and monitor option that supports on-site changes of the data communications and control routines. The symbol generator formats data "pages" and routes this information to the appropriate projector based on priority or currency or on demand. The symbol generator is capable of being configured to accept a variety of standard signal inputs including RS-232, RS-422, and RS-170.

C-13 Global Positioning System.

A global positioning system (GPS) receiver is to be mounted on the ARFF vehicle and interfaced with the transparent window display system for display of position information. The GPS is to be a six-channel receiver capable of tracking up to eight satellites. The GPS receiver calculates new position data once every second. Position accuracy is specified at a maximum of 82 ft (25 m), with a typical accuracy of about 32.8 ft to 49.2 ft (10 m to 15 m). An additional ground-based differential transmitter on the airfield provides accuracy from 3.3 ft to 9.8 ft (1 m to 3 m).

C-14 Geographic Information System.

The airport mapping system by which the ARFF vehicle is navigated may be permitted to be developed by several methods. One method being considered is the digital reconstructive method. This is accomplished by taking an aerial photo- graph of the airport and digitizing it so it then can be displayed on the computer screen for mapping. This method, as it is developed, might provide the increased local terrain and hazards definition needed by the ARFF vehicle to travel on and around the airfield. Additional mapping capability with definitions of 1 mi, 3 mi, and 10 mi (1.6 m, 4.8 m, and 16.1 m) provide for call-up mapping in the event of an accident off the airport operational areas. Digital aerial mapping is an emerging technology that provides three-dimensional hazard definition of streams, swales, and drainage culverts, as well as other hazards that could impede the progress of the rescue.

C-15 Computer Information Enhancements.

Once an operational computer is placed in the ARFF vehicle, it provides a host of other fire-fighting capabilities. Fire fighters are able to have the complete airport emergency plan available in the computer with menu-driven software. Toxic and hazardous material indexes can be provided. Complete instructions on emergency door and entryway door operations for every type of commercial aircraft can be provided.

C-16 Vehicle Electrical Upgrade.

Because of the need for better power sources, vehicles with new technology equipment need to undergo some modifications to the existing electrical systems. Computers and electronically controlled devices need smooth-filtered and stable voltage sources. The equipment targeted for installation is modified to operate in the voltage ranges used on the existing vehicles. This usually is 12-volt or 24-volt DC. Special power converters and voltage stabilizers are to be considered. There also are requirements for the addition of 115-volt AC in some cases. Operating off portable generator power sources that might already exist on some of these vehicles does not, in most cases, provide, the smooth, stabilized power sources of these requirements. Transformer rectifiers and power converters do not provide a major challenge for the technological requirements of this program. Low-cost portable battery back-up systems also should be considered to provide power for start-up of the vehicle as well as accidental shutoff of the vehicle system supply. The cost for these required voltage sources is minimal when compared to the trouble-free environment that they provide for the electronic boards and computer systems.

C-17 Final Assessment.

The object of this assessment program is to provide information about the new computer-based equipment and vision enhancement devices that help the airport rescue services perform their assigned mission under suboptimal visibility conditions. The cost of installing this equipment can be justified by the need to operate aircraft under these poor visibility conditions. If operations are conducted that allow the aircraft to take off and land under poor visibility conditions, it is reasonable to expect that additional requirements for fire-fighting response under low visibility conditions will be established.

The technology needed to perform the driver's enhanced vision system (DEVS) is available now. Although the equipment can be bought off the shelf, installation necessitates some additional research effort because aircraft rescue and fire-fighting mission requirements were not considered in the research efforts that produced this technology. In each case, the individual elements of the DEVS considered the fact that the proposed system should require low operational workload by the operator. Each piece of the system endeavors to use current technological equipment with some hardware and software modifications. Finally, the DEVS should be designed for easy installation and a maintenance-free duty life cycle or at the least a modular rack installation design allowing the removal and replacement of components by current maintenance personnel without adding to the personnel burden of a rescue and fire-fighting service.

The most important issue is cost. Historically, this technology is expensive. Some of the reasons for these high costs were dictated by low production runs and the survivability conditions for which the equipment originally was designed. Equipment meeting the rigorous requirements necessary for military applications can add many thousands of dollars to the final purchase price. It is hoped that, with the careful redesign and unique adaptation of existing equipment designs and unit cost price decreases, the cost of using this technology in an aircraft rescue fire-fighting vehicle can be reduced substantially in the near future.

C-18 Driver's Enhanced Vision System Guidelines.

C-18.1 DEVS Performance Characteristics.

The driver's enhanced vision system (DEVS) is an integrated system of sensors, computers, and navigational equipment designed to improve the response and operation of ARFF crews in low visibility conditions. The DEVS consists of three components: a night or low visibility capability, a vehicle navigation capability, and a vehicle tracking capability, which are integrated using a digital radio data link.

To meet the DEVS requirements, systems need to integrate all three components cohesively. Each component should be integrated into the vehicle's normal operations through a systematic approach of understanding and adapting the technology to the needs of the fire-fighting population.

In the sections that follow, the base performance characteristics are detailed. It is important to note that technology development in the enhanced vision area is progressing rapidly; therefore, the criteria that follows should be considered minimal. Questions regarding specific production systems, new performance capabilities, or recommended systems should be directed to the

FAA's airports office.

C-18.2 Low Visibility Capability.

The intent of the low visibility capability is to provide an enhanced picture of the environmental scene through the use of a chamber or other sensor system displayed inside of the cab. For the immediate future, it appears that forward looking infrared (FLIR) technology holds the most promise for aiding visibility in smoke, fog, and haze and at night. The minimum recommended performance characteristics of the low visibility system are provided below:

(a) **General.**

Expected worst case visibility	0 ft range/0 ft ceiling
Time to operational	≤30 seconds
Detection of humans	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 55 mph (88.5 km/h), clear conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 50 mph (80.5 km/h), light fog conditions
	400 ft (121.9 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), heavy fog conditions
	400 ft (121.9 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), smoke conditions
	300 ft (91.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 35 mph (56.3 km/h), rain/snow conditions
Detection of GA aircraft	2500 ft (762.0 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 55 mph (88.5 km/h), clear conditions
	1000 ft (304.8 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 50 mph (80.5 km/h), light fog conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), heavy fog conditions
	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 40 mph (64.4 km/h), smoke conditions

	500 ft (152.4 m), temp: –20°F to 115°F (28.9°C to 46.1°C), moving 35 mph (56.3 km/h), rain/snow conditions
Detection of objects near fires	People, debris, wreckage, and equipment within 20 ft (6.1 m) of a 6-ft (1.8-m) diameter Jet A fuel fire from a range of 1000 ft (304.8 m)

(b) **FLIR Specific.**

IR waveband	Long wave IR energy (8µm to 12 µm)
Video output	RS-170 or industry standard video
Gain and level controls	Automatic
Horizontal field of view	≥28 degrees (40 degrees preferred)
Vertical field of view	>20 degrees, aspect ratio to match vertical
Lens clearing capability	Windshield wiper, high pressure air, or equivalent
Temp. and humidity changes	Changes in ambient temperature and humidity should not result in condensation inside the FLIR housing or optics assembly
Mounting	On top of vehicle with pan and tilt capability, remote-control equipped, line of sight aligned with driver's line of sight
Video monitor	8-in. to 10-in. (6.2-cm to 25.4-cm) diagonal display mounted near driver's line of sight
	Alternative: Heads-up display with field-of-view to match FLIR

C-18.3 Navigation Capability.

The intent of the navigation capability is to allow for accurate positioning of the vehicle on or around the airport surface. The navigation capability should provide a depiction of the vehicle, notable landmarks, roadways, and other guidance aids. Information should be provided to the driver in a meaningful form appropriate to the needs of the fire response.

The navigation capability consists of three main components: a global positioning system (GPS) receiver, a computer system containing supporting maps and navigation information, and a display/control system for driver information.

For full capability on the airport, the DEVS should incorporate both capabilities into the design. The performance characteristics of the components in the above list are as follows:

Position availability	Computed position within 30 sec/hr/day, 7 days/week
Accuracy	Two-dimensional position within 15 ft (4.6 m)
Dead reckoning	Coasting capability when satellite track is lost due to shadowing
Position update rate	< 1/sec
Initialization and operation	Fully automatic
Map — levels of detail	Level 1 – Airport operations area
	Level 2 – Airport property boundary
	Level 3 – 5-mile (8-km) radius of the airport center; either variable or fixed zooms within each level should be provided
Map — orientation	North-up or heading-up, selectable (Note: Heading-up orientation is required for situational awareness in low visibility conditions and unfamiliar areas)
Map — visual orientation cues	Vehicle orientation, vehicle heading, direction of low visibility coverage
Driving cues	Range/bearing indicator in line-of-sight (on FLIR display or separate)
Data link — error checking	Standard error checking
Data link — frequency selection	Selectable to airport location
Display — color	≥ 256 colors

C-18.4 Tracking Capability.

The tracking capability components include: Differential GPS (DGPS) correction software, data link hardware/software, and an integrated display/control system for command center operations. The command center can be either fixed or mobile, depending on individual airport ARFF operations. This capability is intrinsically tied to the tracking capability, which allows for the monitoring of the positions of other vehicles, the crash site, identified victims, and other factors, as well as linkage to a centralized display for emergency coordination.

Map — orientation	North-up with dynamic zoom and pan
Data link — error checking	Standard error checking
Data link — frequency selection	Selectable to airport location
Display — color	Large high-resolution monitor [>19-in. (>48.3-cm) diagonal color monitor, 1280 × 1024 resolution

C-19 Glossary of Technical Terms

Aircraft Rescue and Fire-Fighting (ARFF). Formerly known in the fire-fighting industry as crash, fire, and rescue.

Cool-down in the Operational Environment of an Infrared Detector. Term used to describe the period of time needed for the refrigeration unit of the optical sensor to cool the unit to approximately –454°F (–270.2°C) below zero (0). This cool-down mode provides the necessary sensitivity of 10,000: 1 for infrared thermal detection.

Driver's Enhanced Vision System (DEVS). A vision enhancement system utilizing several electronic and computer-based components that aids in improving sight as well as movement or navigation around the airport during reduced visibility operational conditions.

Forward Looking Infrared (FLIR). A heat detector device that allows the viewer to see radiant heat projected from objects. These devices work in the micron band of the infrared spectrum (e.g., 8 µm to 12 µm).

Geographic Information System (GIS). A device that allows an aerial map of the airport to be displayed with markers that move along the image as the vehicle changes position.

Global Positioning System (GPS). A device that picks up signals from orbiting satellites and determines positions of location on earth by reference to longitude and latitude.

Heads-Up Display (HUD). The military name for a device that allows a person to look and operate a device while viewing through the cockpit window of an aircraft. This device displays information.

Transparent Window Display (TWD). An electronic device that projects an image on a special coated glass or plastic that also allows the viewer to see through the clearplate with a slight reduction in visibility.

Appendix D Vehicle Summary

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

Performance Parameter For Fully Loaded Vehicle	Combined Agent				Major Vehicle Class						
	1	2	3	4	1	2	3	4	5	6	7
1. Water tank (gal): Minimum usable capacity	≥ 100	≥ 200	≥ 300	≥ 500	≥ 1000	≥ 1500	≥ 2500	≥ 3000	≥ 4000	≥ 5000	≥ 6000
2. Side slope stability (degrees):	30			28	30	28	26.5	24			
Percent grade:	58			53	58	53	50	45			
3. Dynamic balance (mpg): Minimum speed on a 100-ft (30.5-m) radius circle	25				22		18.5				
4. Angle of approach (degrees):	30										
5. Angle of departure (degrees):	30										
6. Interaxle clearance (degrees):	12										
7. Underbody clearance (in.):	13			18	18						
8. Underaxle clearance at differential housing bowl (in.):	8			10.5	13						
9. Wall-to-wall turning diameter:	≤ three times the vehicle's length										
10. Maximum acceleration time from 0 mph to 50 mph (0 km/h to 80.5 km/h) (sec):	25	30			23	26	35	40	45	50	
11. Top speed (mph):	≥ 65										
12. Service brake:											
Stopping distance at 20 mph (32.2 km/h) (ft):	≤35							≤ 40			
40 mph (64.4 km/h) (ft):	≤ 131							≤ 160			
Percent grade holding of fully loaded vehicle:											
Ascending:	≥ 50										
Descending:	≥ 50										
13. Emergency brake stopping distance at 40 mph (64.4 km/h) (ft):	≤ 288										
14. Percent grade holding for the parking brake:											
Ascending:	≥ 20										
Descending:	≥ 20

NFPA 415

1997 Edition

Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways

1997 Edition

This edition of NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*, was prepared by the Technical Committee on Airport Facilities and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 18-20, 1996, in Nashville, TN. It was issued by the Standards Council on January 17, 1997, with an effective date of February 7, 1997, and supersedes all previous editions.

This edition of NFPA 415 was approved as an American National Standard on February 7, 1997.

Origin and Development of NFPA 415

NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*, was first adopted in 1961. Subsequent editions were published in 1966, 1973, 1977, 1983, 1987, and 1992.

NFPA 416, *Standard on Construction and Protection of Airport Terminal Buildings*, was first adopted in 1962. Subsequent editions were published in 1967, 1972, 1973, 1975, 1983, 1987, and 1993.

NFPA 417, *Standard on Construction and Protection of Aircraft Loading Walkways*, was first adopted in 1963. Subsequent editions were published in 1968, 1973, 1977, 1985, and 1990.

The 1997 edition of NFPA 415 is a combination of the above three documents and has a new title, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*.

Mark T. Conroy, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the front of the book.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire safety for the construction and protection at airport facilities involving construction engineering but excluding airport fixed fueling systems.

NFPA 415

Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways

1997 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Appendix A.
Information on referenced publications can be found in Chapter 5 and Appendix B.

Chapter 1 Administration

1-1 Scope.

This standard specifies the minimum fire protection requirements for the construction and protection of airport terminal buildings. It specifies the minimum requirements for the design and maintenance of the drainage system of an aircraft fueling ramp to control the flow of fuel that can be spilled on a ramp and to minimize the resulting possible danger. In addition, it contains the minimum requirements for the design, construction, and fire protection of aircraft loading walkways between the terminal building and aircraft.

1-2* Purpose.

The purpose of this standard is to provide a reasonable degree of protection for life and property from fire at airport terminal complexes.

Requirements applicable to ramp drainage systems are intended to limit the fire hazard from fuel spillage by the following:

(a) Controlling the spread of a fuel spill to limit exposure to buildings, aircraft loading walkways, concourses, or elevated structures in order to prevent the fuel's liquid or vapors from reaching a source of ignition or accumulating within structures

(b) Limiting the spread of the fuel spill over the ramp surface and preventing the transmission of vapors by the drainage system from exposing aircraft or other equipment parked or operating on the ramp

The purpose of this standard is also to specify minimum criteria for fire protection of aircraft loading walkways that can serve as an egress route from an aircraft in the event of a flammable liquid spill fire on the airport ramp exposing the walkway and the aircraft.

1-3 Applicability.

It is not intended that the provisions of this document be applied to facilities, equipment, structures, or installations that were existing or approved for construction or installation prior to the effective date of the document, except in those cases where it is determined by the authority having jurisdiction that the existing situation involves a distinct hazard to life or adjacent property.

1-4 Definitions.

For the purpose of this standard, terms shall be defined as follows:

Aircraft Fueling Ramp. Any outdoor area at an airport, including aprons and hardstands, where aircraft are normally fueled or defueled.

Aircraft Loading Walkway. An aboveground device through which passengers move between a point in an airport terminal building and an aircraft. Included in this category are walkways that are essentially fixed and permanently placed, or walkways that are essentially mobile in nature and that fold, telescope, or pivot from a fixed point at the airport terminal building.

Airport Ramp. Any outdoor area, including aprons and hardstands, where aircraft can be positioned, stored, serviced, or maintained, irrespective of the nature of the surface of the area.

Airport Terminal Building.* A structure used primarily for air passenger enplaning or deplaning, including ticket sales, flight information, baggage handling, and other necessary functions in connection with air transport operations. This term includes any extensions and satellite buildings used for passenger handling or aircraft flight service functions. Aircraft loading walkways and "mobile lounges" are excluded.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Listed.* Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets identified standards or has been tested and found suitable for a specified purpose.

Potential Fuel Spill Points. The points on or around the aircraft or airport ramp where fuel can be released. These points include fueling hydrants, fuel servicing vehicles, fuel tank fill connections, fuel vent openings, and fuel dump valves.

Satellite. A structure that can be adjacent to but separated from the airport terminal building, accessible aboveground or through subway passages, and used to provide flight service operations, such as passenger check-in, waiting rooms, food service, enplaning or deplaning, etc.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Chapter 2 Airport Terminal Buildings

2-1 General.

2-1.1*

Airport terminal buildings shall be of Type I, Type II, or Type IV construction, as defined in NFPA 220, *Standard on Types of Building Construction.*

2-1.2*

Interior finish shall be limited to that permitted in Class A places of assembly as specified in NFPA *101*□, *Life Safety Code*□.

2-1.3

Aircraft fueling facilities and ramps shall be designed in accordance with NFPA 407, *Standard for Aircraft Fuel Servicing*, and Chapter 3 of this standard.

2-1.4

Belowgrade areas or blind spaces in airport terminal buildings shall be protected against flammable fuel or vapor penetration or shall be mechanically ventilated to provide at least four complete air changes per hour. The mechanical ventilation system shall be installed in accordance with Chapters 2 and 3 of NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*.

2-1.5*

Where potential fuel spill points are located less than 100 ft (30.5 m) horizontally from glazing material covered openings in airport terminal building walls facing the airport ramp, they shall be provided with an automatically activated water spray system or an automatically activated, listed fire shutter as follows:

(a) An automatically activated water spray system installed in accordance with NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection.*

1. The system shall be designed to provide a density of at least 0.25 gpm/ft^2 [10.2 (L/min)/m^2] over the exterior surface area of the glazing material.

2. Where multiple water spray systems are used, the water supply shall be capable of supplying all systems that could be expected to operate as a result of one fire incident.

3. The detection system design analysis shall include consideration of false alarms and detector response time.

(b) An automatically activated, listed fire shutter installed in accordance with its listing.

Exception No. 1: Openings covered with glazing material that have the lowest part of the glazing material not less than 7 ft (2.1 m) above the finished floor level.

Exception No. 2: Openings covered with glazing material listed for use in a fire barrier and installed in accordance with the listing.

2-2 Heating, Ventilating, and Air Conditioning.

2-2.1

Heating, ventilating, and air conditioning systems shall be installed in accordance with NFPA 31, *Standard for the Installation of Oil-Burning Equipment;* NFPA 54, *National Fuel Gas Code;* and NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems,* as applicable.

2-2.2*

Air supply intake and exhaust openings for air conditioning or ventilating equipment serving the terminal building, if located on the ramp side, shall be not less than 10 ft (3 m) above the grade level of the ramp and shall be at least 50 ft (15.2 m) from any point of flammable vapor release.

2-2.3*

Openings to rooms containing coal-, gas-, or oil-fired equipment, or any rooms containing any other open flame device, that face the ramp side of the terminal shall be above ramp grade and 50 ft (15.2 m) from any point of flammable vapor release.

2-2.4

Stacks or chimneys from a boiler, heater, or incinerator shall terminate at least 20 ft (6.1 m) above ramp grade and above the roof of the building. Stacks or chimneys from boilers or heaters using solid fuel or from any incinerator shall be fitted with double screening to control fly ash and sparks. Such stacks or chimneys shall be located so the outlet is at least 100 ft (30.5 m) horizontally from any aircraft position or point of flammable vapor release.

2-2.5

Incinerators shall conform to the requirements of Chapter 2 of NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment.*

2-2.6

Exhaust hood ventilation systems for restaurant and flight kitchens shall conform to the applicable portions of NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations.*

2-3 Exits.

2-3.1

Airport terminal building means of egress shall conform to the requirements of NFPA *101, Life Safety Code.*

2-3.2*

Exits that discharge onto an airport ramp and are provided solely for the purpose of meeting emergency egress requirements from public areas shall be placarded "Emergency Exit Only" in letters at least 2 in. (4.9 cm) high.

2-4 Electrical.

2-4.1

All electrical installations shall be in accordance with NFPA 70, *National Electrical Code*¨.

2-4.2

Ventilation and access openings for transformer or electrical service rooms or vaults located on the ramp side of an airport terminal building shall be located as outlined in 2-2.2.

2-5 Fire Protection.

2-5.1* Sprinkler Systems.

The airport terminal building shall be provided with an automatic sprinkler system installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

Exception: Terminal buildings with less than 12,000 ft^2 (1115 m^2) total floor area for the assembly portion of the occupancy.

2-5.1.1 Passenger handling areas shall be classified as Ordinary Hazard Group 1 Occupancy, as defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*, for the purpose of sprinkler system design.

2-5.1.2* Other areas of the airport terminal building shall be classified in accordance with 1-4.7 of NFPA 13, *Standard for the Installation of Sprinkler Systems*, based on the occupancy of the area.

2-5.1.3 Covered Plane-Loading Positions. Airport terminal buildings having canopy areas or roofed-over recesses at aircraft loading positions that, in effect, place the aircraft totally or substantially under such canopies or roofs shall have these canopies or roofs protected by automatic sprinkler systems in accordance with NFPA 409, *Standard on Aircraft Hangars.*

2-5.2 Fire Alarm and Communications Systems.

A fire alarm and communications system shall be installed as required by 8-3.4 of NFPA *101, Life Safety Code.*

2-5.2.1 Means to alert the public fire department or the airport fire station shall be available through manual fire alarm pull stations. Manual fire alarm services shall be installed in accordance with NFPA 72, *National Fire Alarm Code.*

2-5.2.2* Annunciation for all building fire alarm signals shall be provided near the front entrance of the building.

Exception: This annunciation shall not be required if the public fire department has two-way voice communication with a constantly attended location.

2-5.3 Fire Hydrants.

Fire hydrants shall be provided on both the ramp and street sides of airport terminal buildings. Such hydrants shall be located so that no portion of the terminal building is more than 500 ft (152.4 m) from a hydrant.

2-5.4 Standpipe and Hose Systems.

Standpipe and hose systems shall be provided for all airport terminal buildings in excess of two stories [35 ft (10.7 m)] in height or 100 ft (30.5 m) in shortest horizontal dimension. Standpipe and hose systems shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems.*

2-5.4.1 Class I standpipe systems shall be provided in buildings protected throughout by an approved automatic sprinkler system. Each $2^1/_2$-in. (63.5 mm) hose connection shall be equipped with a $2^1/_2$-in. × $1^1/_2$-in. (63.5-mm × 38.2-mm) reducer and cap.

2-5.4.2 Class III standpipe systems shall be provided in nonsprinklered buildings. The exceptions in NFPA 14, *Standard for the Installation of Standpipe and Hose Systems,* for Class III systems shall be applicable to this requirement.

2-5.5 Water Supply.

Water supply from public or private sources shall be adequate to supply maximum calculated sprinkler demand plus a minimum of 500 gpm (1893 L/min) for hose streams. The supply shall be available at the rate specified for a period of at least 1 hour.

2-5.5.1* Main sizes shall be hydraulically calculated based on the total domestic and fire protection requirements. Mains shall be not less than 8 in. (20 cm) in diameter except that laterals shall be permitted to be 6 in. (15 cm) in diameter if not over 200 ft (61 m) long.

2-5.5.2* Hydrants shall be readily accessible to fire-fighting vehicles traveling on surfaces adequate for supporting such vehicles.

2-5.5.2.1 Hydrants shall be listed.

2-5.5.2.2 Hydrants shall be located or protected to prevent mechanical or vehicular damage, including taxiing aircraft.

2-5.5.2.3 Hydrants recessed into the ground shall have identifiers in the pavement to assist in their prompt location at night and by personnel who might not be familiar with the location of the hydrants.

2-5.5.3* Water supply systems shall be regularly tested to ensure operation.

2-5.6 Portable Fire Extinguishers.

Portable fire extinguishers shall be provided throughout the airport terminal building in accordance with NFPA 10, *Standard for Portable Fire Extinguishers.*

Chapter 3 Aircraft Fueling Ramp Drainage

3-1 Aircraft Fueling Ramp Slope and Drain Design.

3-1.1*

Aircraft fueling ramps shall slope away from terminal buildings, aircraft hangars, aircraft loading walkways, or other structures, with a minimum grade of 1 percent (1:100) for the first 50 ft (15.2 m). Beyond this distance, the ramp slope to drainage inlets shall be permitted to be reduced to a minimum of 0.5 percent (1:200).

3-1.2*

Aircraft fueling ramp drainage as specified herein shall be accomplished by the provisions of 3-1.1 in conjunction with the following:

(a) The use of drain inlets with connected piping

(b) The use of open-grate trenches

3-1.3

Drainage inlets, where provided, shall be located a minimum of 50 ft (15.2 m) from structures outlined in 3-1.1.

3-1.4

The drainage system of any aircraft fueling ramp shall be so designed that the fuel or its vapor cannot enter into the drainage system of buildings, areas utilized for automobile parking, public or private streets, or the public side of airport terminal or aircraft hangar structures. In no case shall the design allow fuel to collect on the aircraft fueling ramp or adjacent ground surfaces where it could constitute a fire hazard.

3-1.5

The final separator or interceptor for the entire airport drainage system shall be designed to allow disposal of combustible or flammable liquids into a safely located, approved containment facility.

3-1.6

Grates and drain covers shall be removable to facilitate cleaning and flushing.

3-1.7*

If open-grate drainage trenches are used as a collection means, such open trenches, including branches, shall not be over 125 ft (38.1 m) in length with a minimum interval of 6 ft (1.8 m) between open-trench sections to act as fire stops. Each 125-ft (38.1-m) section shall be individually drained through underground piping. Open trenches shall not be used where they are in the line of pedestrian or passenger traffic.

3-1.8

Underground piping and components used in drainage systems shall be noncombustible and inert to fuel.

3-2 Drain and Separator Maintenance.

3-2.1*

Periodic maintenance checks shall be conducted of all ramp drainage systems and interceptors to ensure that they are clear of obstructions and function properly.

3-2.2

Large volume flushing with water shall be conducted through appropriate drainage elements to purge the residual fuel from these drainage elements after any large fuel spill on the aircraft fueling ramp enters the drainage system.

Chapter 4 Aircraft Loading Walkways

4-1 Basic Design.

4-1.1

Each aircraft loading walkway installation shall be designed to provide a safe means of egress from the aircraft for a period of five minutes under fire exposure conditions equivalent to a free-burning jet fuel spill fire.

4-1.2

Protection of the aircraft loading walkway shall be accomplished by one of the following methods:

(a) Construction design meeting the requirements of Sections 4-1, 4-2, 4-3, and 4-4

(b) Fixed fire protection meeting the requirements of Sections 4-1, 4-2, and 4-5 of this chapter

4-2 Requirements for All Aircraft Loading Walkways.

4-2.1*

Interior finish other than textiles of walls and ceilings and walkways shall be Class A as defined in 6-5.2.3 of NFPA *101*, *Life Safety Code*, and classified in accordance with NFPA 255, *Standard on Method of Tests of Surface Burning Characteristics of Building Materials.*

4-2.2

Interior textile finish of walls and ceilings in walkways shall be as limited by 6-5.2.3.5 of NFPA *101*, *Life Safety Code.*

4-2.3

Interior floor finish in walkways shall be Class I as defined in 6-5.4 of NFPA *101*, *Life Safety Code*, and classified in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source.*

4-2.4

There shall be no windows other than those located in the ramp access service door and in the cab area for the purpose of operating the aircraft loading walkway.

4-2.5*

During a ramp fire emergency, walkway interiors shall have a positive air pressure delivered from a source that shall remain uncontaminated.

4-2.6*

Any source of negative air pressure in the aircraft loading walkway shall be automatically shut down in the event of a fire emergency.

4-2.7

Any door in the egress path through the loading walkway to the terminal building shall swing in the direction of egress from the aircraft towards the terminal building and shall be equipped with panic hardware on the aircraft side.

4-2.8 Cab and Rotunda Slat Curtains.

4-2.8.1 Cab slat curtains and rotunda slat curtains shall meet the requirements of 4-4.8 by one of the following methods:

(a) Intrinsic structural features

(b) Fire-resistive coatings

(c) Automatically activated water cooling systems in accordance with 4-5.2

(d) Automatically activated fire curtains

(e) A local application of a foam system_in accordance with 4-5.3 under the cab and rotunda that is automatically activated and covers an area extending 15 ft (4.6 m) beyond the perimeter of the cab and rotunda. This shall supersede the 10-ft criteria of 4-5.3.

Exception: When the rotunda is located more than 50 ft (16 m) from the fuel fill or fuel vent point of aircraft and the rotunda slot curtain is of noncombustible construction.

4-3 Materials.

4-3.1

Exterior surfaces of floor, roof, walls, and load-bearing structural members shall be constructed entirely of materials or composite assemblies that maintain the structural integrity and heat transfer characteristics needed to meet the requirements specified in 4-1.1 and Section 4-4.

4-3.2

Flexible closures, canopies, wipers, and weather-sealing devices shall be subjected to the accelerated weathering procedures specified in Section 8-6 of NFPA 701, *Standard Methods of Fire Tests for Flame-Resistant Textiles and Films*, after which they shall meet the requirements of 4-4.7 or 4-4.10 of this standard, as applicable.

4-3.3

The manufacturer shall provide, in writing, the anticipated service life expectancy of components that contribute to fire safety.

4-4 Fire Tests.

4-4.1 Scope of Fire Tests.

4-4.1.1 Tests shall be conducted to establish the performance of materials and methods of construction, and to verify their structural integrity and heat transfer characteristics so as to satisfy the five-minute exit route criteria specified in 4-1.1.

4-4.1.2 The test methods specified in this chapter shall be applicable to assemblies of units and to composite assemblies of structural materials for aircraft loading walkways, including walls, girders, beams, slabs, and composite slab and beam assemblies for floor and walls either tested individually as floor or wall panels or as a complete assembly. Also, they shall be applicable to other assemblies and structural units that constitute permanent integral parts of a finished aircraft loading walkway.

4-4.1.3 The condition of acceptance for tests specified in this section for aircraft loading walkways shall be documented by one of the following methods. Such submittals shall be subject to acceptance by the authority having jurisdiction.

(a) Tests shall be conducted in accordance with the requirements and procedures of Section 4-4.

(b) Evidence of compliance shall be permitted to be achieved by other methods such as modeling, calculation, or testing. The submitter must show that the method used proves that components achieve a level of fire safety at least equal to that produced by the procedure in Section 4-4.

4-4.1.4 The tests shall register performance during the required period of exposure and shall not be construed as having determined suitability for use after fire exposure.

4-4.2 Time-Temperature Curve to Be Used.

The conduct of fire tests of materials and construction shall be controlled by the time-temperature curves in Figure 4-4.2 and Table 4-4.2.

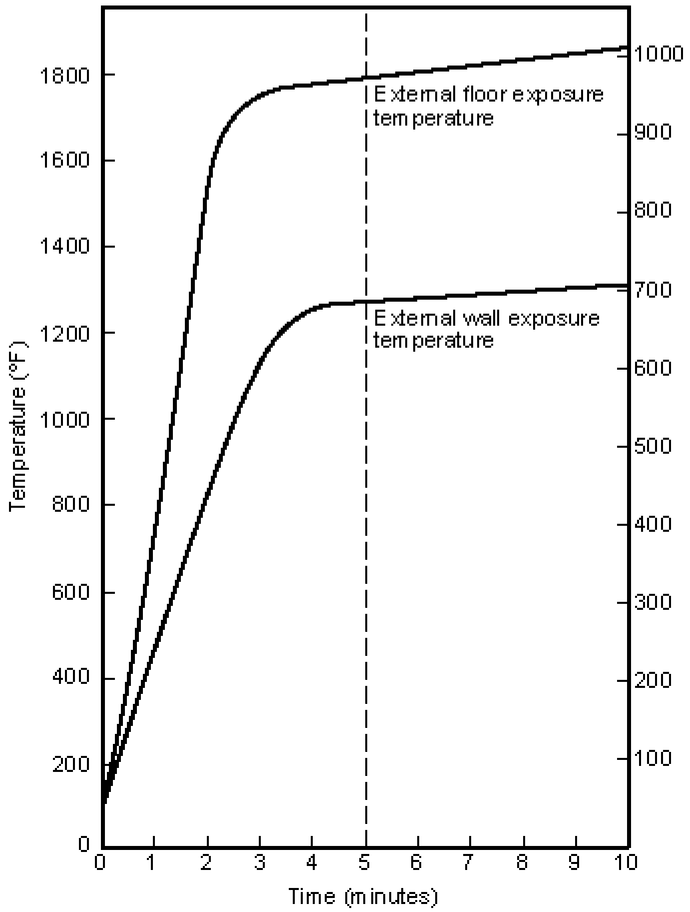

Figure 4-4.2 Typical furnace time-temperature curves for fire testing of aircraft loading walkways. (*See Table 4-4.2.*)

Table 4-4.2
Typical Furnace Time-Temperature Gradients for Fire Testing of Aircraft Loading Walkways
(See Figure 4-4.2.)

4-4.3 Furnace Temperatures.

4-4.3.1 The temperature fixed by the curve shall be deemed to be the average temperature obtained from the readings of not less than nine thermocouples for a floor or wall section. The thermocouples shall be symmetrically located and distributed to show the temperature near all parts of the sample and shall be partially enclosed in porcelain tubes $^3/_4$ in. (19 mm) in outside diameter and $^1/_8$ in. (3 mm) in wall thickness with a minimum exposed length of thermocouple wires of $1^1/_2$ in. (38 mm). The exposed length of the pyrometer tube and thermocouples in the furnace chamber shall be not less than 12 in. (305 mm). Other types of thermocouples or pyrometers that under test conditions give the same indications as those specified herein within the limit of accuracy that applies for real-time furnace temperature measurements shall be permitted to be used.

4-4.3.1.1 For floor sections, the junction of the thermocouples shall be placed 12 in. (305 mm) away from the exposed surface of the sample at the beginning of the test and during the test shall not touch the sample as a result of its deflection.

4-4.3.1.2 For walls, the thermocouples shall be placed 6 in. (152 mm) away from the exposed face of the sample at the beginning of the test and shall not touch the sample during the test as a result of its deflection.

4-4.3.2 The temperatures shall be measured and reported at intervals not exceeding 15 seconds.

4-4.3.3 The accuracy of the furnace control shall be such that at any given time the temperature obtained by averaging the results from the pyrometer readings shall not be less than 90 percent of the temperature curve shown in Figure 4-4.2.

4-4.4 Temperatures of Unexposed Surfaces of Floors and Walls.

4-4.4.1 Temperatures of unexposed surfaces shall be measured with exposed-type thermocouples placed under felted refractory fiber pads.

4-4.4.1.1 The refractory fiber pads shall be of flexible, felted material, free of organic additives, and they shall exhibit the following properties:

(a) Length and width shall be 6 ± $^1/_8$ in. (152 ± 3.18 mm).

(b) Thickness shall be 0.375 ± 0.063 in. (9.5 ± 1.6 mm).

(c) Dry weight shall be 0.147 ± 0.053 lb (67 ± 24 g).

(d) Thermal conductivity [at 150°F (66°C)] shall be 0.37 ± 0.03 Btu in./h ft^2·°F (0.053 ± 0.004 W/m·K).

(e) Hardness indentation on soft face shall be 0.075 ± 0.025 in. (1.9 ± 0.6 mm). Indentation shall be determined in accordance with ASTM Test Method C569. Modified Brinnell values of hardness are obtained by the following relationship:

$$\text{hardness} = 2.24 / y$$

where y = the measured indentation in inches

(f) The pads shall be shaped by wetting, forming, and drying to constant weight to provide complete contact on sharply contoured surfaces.

4-4.4.1.2 The thickness measurement shall be made under the light load of a $^1/_2$-in. (13-mm) diameter pad of a dial micrometer gauge.

4-4.4.1.3 The wire leads of the thermocouple shall have an immersion under the pad and shall be in contact with the unexposed surface for not less than $1^1/_2$ in. (38 mm). The hot junction of the thermocouple shall be placed approximately under the center of the pad. The outside diameter of protecting or insulating tubes shall be not more than $^5/_{16}$ in. (8 mm). The pad shall be held firmly against the surface, and shall fit closely about the thermocouples. The wires from the thermocouple in the length covered by the pad shall be not heavier than No. 18 B & S gauge 0.04 in. (1.02 mm) and shall be electrically insulated with heat-resistant and moisture-resistant coatings.

4-4.4.2 Temperature readings shall be taken at not less than nine points on the surface. Five of these shall be symmetrically located: one to be approximately at the center of the walkway specimen and four to be approximately at the center of its quarter sections. The other four shall be located at the discretion of the testing authority to obtain representative information on the performance of the walkway specimen under test. None of the thermocouples shall be located nearer to the edges of the test specimen than one and one-half times the thickness of the construction, or 12 in. (305 mm). Thermocouples shall not be located opposite or on top of beams, girders, or other structural members.

4-4.4.3 Temperature readings shall be taken at intervals not exceeding 15 seconds.

4-4.4.4 Where the conditions of acceptance place a limitation on the temperature of the unexposed surface, the temperature end point of the fire-endurance period shall be determined by the average of the measurements taken at individual points. If a temperature rise of 30 percent in excess of the specified limit occurs at any one of these points, the remainder shall be ignored and the fire-endurance period judged as ended.

4-4.5 Test Specimen.

4-4.5.1 The test specimen shall be representative of the construction for the classification desired in regard to materials, workmanship, and details such as dimensions of parts and shall be built under conditions representative of actual aircraft loading walkway construction and operation. The physical properties of the materials and ingredients used in the test specimen shall be determined and recorded.

4-4.5.2 The test specimen shall be protected during and after fabrication in order to ensure normality of its quality and condition at the time of the test. The ambient air temperature at the beginning of the test shall be within the range of 50ºF to 90ºF (10ºC to 32ºC). The velocity of air across the unexposed surface of the sample, measured just before the test begins, shall not exceed 4.4 ft/sec (1.3 m/s), as determined by an anemometer placed at right angles to the unexposed surface. If mechanical ventilation is employed during the test, an air stream shall not be directed across the surface of the specimen.

4-4.5.3* The fire-endurance test shall be continued on the specimen with its applied load, if any, until failure occurs, or until the specimen has withstood the test conditions for a period of 10 minutes.

4-4.5.4 Results shall be reported in accordance with the performance in the tests prescribed in these methods. Time-temperature results shall be reported at 15-second intervals. Reports shall include observations of significant details of the behavior of the material or construction during the test and after the furnace fire is cut off, including information on deformation, spalling, cracking, burning of the specimen or its component parts, continuance of flaming, and production of smoke.

4-4.6 Tests of Walls and Floors.

4-4.6.1 The dimensions of the sample to be tested shall be determined based upon the construction features of the specific walkway being tested. The dimensions selected shall ensure that the sample, when tested, will demonstrate the ability of the most critical elements of the walkway to withstand stress concentrations without failure and without separations that would permit fire and smoke intrusion. Verification documentation supporting the selection of the dimensions shall be approved by the authority having jurisdiction.

4-4.6.2 The effect of exposure to elevated temperatures of working stress seen as worst case load combinations during actual usage shall be accomplished by one of the following two methods:

(a) A superimposed load to the specimen shall be applied in a manner calculated to develop theoretically the design-allowable stresses contemplated by the design during the test described in 4-4.2.

(b) The yield strength of the structural medium shall be correlated to the maximum temperature recorded in 4-4.2. Structural submittals shall be made using this new yield strength showing nonfailure conditions have been met.

Worst-case load combinations shall be derived from the following:

(a) Floor Live Load:	40 lb/ft^2 (195 kg/m^2)
(b) Roof Load:	25 lb/ft^2 (122 kg/m^2)
(c) Wind Load:	2.5 lb/ft^2 (61 kg/m^2)

4-4.6.3 The test shall be successful when the following conditions of acceptance are met:

(a) The wall or floor section shall have sustained the applied load during the fire-endurance test without passage of flame for a minimum period of five minutes. Flaming shall not appear on the unexposed face.

(b) The maximum allowable surface temperature of the cool side of a wall or floor section shall not exceed 250ºF (121ºC) during a five-minute exposure as determined by 4-4.4.4.

4-4.7 Tests of Flexible Closures.

4-4.7.1 The test specimen area exposed to the test fire shall not be less than 2 ft × 2 ft (0.62 m × 0.62 m) square. The test specimen shall be representative of all elements of the flexible closure, including framework assembly and mechanisms for attachment to the aircraft loading walkway.

4-4.7.2 The test shall be successful when all of the following conditions of acceptance are met:

(a) The test specimen shall have withstood the fire-endurance test as defined by the time-temperature curve for external walkway wall exposure in Figure 4-4.2 without passage of flame for a minimum period of five minutes.

(b) The closure material also shall pass the following test, designed to measure the radiant heat flux to which a human can be subjected while exiting an aircraft under a fuel spill fire emergency condition. A specimen of the closure material that reproduces the most expanded actual field operating configuration, regarding folds and pleats, existing 6 ft (1.8 m) above the floor shall be tested in a furnace. The furnace temperature applied to the exposed exterior surface of the closure material shall be raised in accordance with the time-temperature curve for external walkway wall exposure in Figure 4-4.2. Measurements shall be taken by a radiometer positioned between a minimum distance of 39.4 in. (1 m) and a maximum distance of 78.7 in. (2 m) away from the cool side surface of the test specimen. The radiometer shall have a view angle small enough such that it "sees" only the test specimen and not the frame or furnace wall. The approximate equivalent human exposure in the walkway shall not exceed 0.65 W/cm^2. The approximate equivalent human exposure shall be calculated by multiplying the maximum actual radiometer reading for the test in W/cm^2 at the radiometer by

$$0.31(\tan^2 \theta/_2 + 1)/\tan^2 \theta/_2 \tau$$

where:

θ = the total view angle of the test radio meter

τ = the corrosion for absorption due to humidity

Table 4-4.7.2 shall be used to determine the appropriate τ.

Table 4-4.7.2 τ Factors

Relative Humidity During Test	Distance Source to Sensor 1 m	1.5 m	2 m
0 - 25%	0.96	0.95	0.94
25 - 50%	0.94	0.93	0.92
50 - 100%	0.92	0.91	0.90

(c) The framework assembly supporting the closure curtain material and mechanisms for attachment shall be capable of maintaining structural integrity when subjected to the fire defined by the time-temperature curve for external walkway wall exposure in Figure 4-4.2.

4-4.8 Test of Cab and Rotunda Slat Curtains.

4-4.8.1 The test specimen area exposed to the test fire shall not be less than 2 ft × 2 ft (0.62 m × 0.62 m) square. The test specimen shall be representative of all elements of the cab and rotunda slat curtains, including framework assembly and mechanisms for attachment to the aircraft loading walkway.

4-4.8.2 For conditions of acceptance, the test sample shall be capable of withstanding the fire-endurance test as defined by the time-temperature curve in Figure 4-4.2 appropriate for the walkway location being tested without passage of flame for a period of five minutes. Flaming shall not appear on the unexposed face.

4-4.9 Tests of Bumpers.

4-4.9.1* Bumper assemblies shall be tested in continuous contact against a simulated aircraft fuselage in a manner representative of intended usage.

4-4.9.2 The specimen shall be configured in a manner representative of actual fabrication and shall include the bumper proper and mechanism for bumper attachment to the aircraft loading walkway.

4-4.9.3 For conditions of acceptance, bumpers shall be capable of withstanding the fire-endurance test as defined by the time-temperature curve for external walkway flooring exposure in Figure 4-4.2 without passage of flame for a period of five minutes. Flaming shall not appear on the unexposed face.

4-4.10 Tests of Miscellaneous Seals and Weather-Stripping Assemblies.

4-4.10.1 The testing laboratory shall construct a steel stud wall assembly consisting of one layer of $^{1}/_{2}$-in. Type X gypsum wallboard on the exposed face. A hole shall be framed out in the center of the test wall where another steel stud/gypsum wallboard assembly shall be inserted. The smaller assembly to be inserted into the wall shall be constructed such that the opening between the test wall and the smaller assembly allows the weather stripping or seal material to fill the gap in a manner representative of end-use application. The entire assembly then shall be placed against the furnace for the required exposure.

4-4.10.2 The size of the test specimen shall not be less than 2 ft (0.62 m) long.

4-4.10.3 For conditions of acceptance, these components shall be capable of withstanding the fire-endurance test as defined by the time-temperature curve in Figure 4-4.2 appropriate for the walkway location being tested without passage of flame for a period of five minutes. Flaming shall not appear on the unexposed face.

4-5 Fire Suppression Systems.

4-5.1*

The fixed fire suppression specified in 4-1.2 shall be provided by one of the following systems:

(a) Fixed water spray system specified in 4-5.2

(b) Fixed foam system specified in 4-5.3

4-5.2

The fixed water spray system shall be of the open head, deluge type, and shall meet the requirements of NFPA 15, *Standard on Water Spray Fixed Systems for Fire Protection.* The system shall be designed so that the water is discharged directly on all walkway outer surfaces and structural members being protected. The system shall be automatically actuated, and designed for a minimum discharge duration of five minutes.

4-5.3

The fixed foam system shall be adequate to blanket the area under the walkway when positioned at the aircraft exit door(s) and for a distance of approximately 10 ft (3 m) in all directions. The system shall meet the requirements of NFPA 11, *Standard for Low-Expansion*

Foam, and NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinkler Systems and Foam-Water Spray Systems.* The system shall be automatically activated. This system shall be capable of discharging in such a manner that the protected area previously described will be free of fire for a minimum duration of five minutes.

Chapter 5 Referenced Publications

5-1

The following documents or portions thereof are referenced within this standard as mandatory requirements and shall be considered part of the requirements of this standard. The edition indicated for each referenced mandatory document is the current edition as of the date of the NFPA issuance of this standard. Some of these mandatory documents might also be referenced in this standard for specific informational purposes and, therefore, are also listed in Appendix B.

Appendix A Explanatory Material

This appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-2 The adequacy and usefulness of airport terminal buildings depends, to a large extent, on the fire resistance of their construction and the fire protection provided within the buildings.

The provision of aircraft rescue and fire-fighting equipment at airports meeting the recommendations of NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, and NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, will be useful in controlling ramp fires. The provision of hydrants on the ramp side of airport terminal buildings will assist in meeting supplemental fire protection needs in this area.

A-1-4 Airport Terminal Building. The term "Terminal" is sometimes applied to airport facilities other than those serving passengers, such as cargo and freight facilities and fueling-handling facilities. These facilities are covered by other NFPA standards such as NFPA 513, *Standard for Motor Freight Terminals*, and NFPA 30, *Flammable and Combustible Liquids Code*.

A-1-4 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-4 Authority Having Jurisdiction. The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1.1 Building construction types are defined in NFPA 220, *Standard on Types of Building Construction.* The following material is extracted verbatim from NFPA 220, 1995 edition and is included here as a convenience for users of this standard. Any requests for Formal Interpretations (FIs) or Tentative Interim Amendments (TIAs) on the following material should be directed to the Technical Committee on Building Construction.

> **3-1 Type I (443 or 332).** Type I construction shall be that type in which the structural members, including walls, columns, beams, girders, trusses, arches, floors, and roofs, are of approved noncombustible or limited-combustible materials and shall have fire resistance ratings not less than those specified in Table 3-1.

Table 3-1 Fire-Resistance Ratings (in Hours) for Type I Through Type V Construction

	Type I		Type II			Type III		Type IV	Type V	
	443	332	222	111	000	211	200	2HH	III	000
Exterior Bearing Walls -										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0[1]	2	2	2	1	0[1]
Supporting one floor only	4	3	2	1	0[1]	2	2	2	1	0[1]
Supporting a roof only	4	3	1	1	0[1]	2	2	2	1	0[1]
Interior Bearing Walls -										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	2	1	0
Supporting one floor only	3	2	2	1	0	1	0	1	1	0
Supporting a roof only	3	2	1	1	0	1	0	1	1	0
Columns -										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	H[2]	1	0
Supporting one floor only	3	2	2	1	0	1	0	H[2]	1	0
Supporting a roof only	3	2	1	1	0	1	0	H[2]	1	0
Beams, Girders, Trusses & Arches										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	H[2]	1	0
Supporting one floor only	3	2	2	1	0	1	0	H[2]	1	0
Supporting a roof only	3	2	1	1	0	1	0	H[2]	1	0

Floor Construction	3	2	2	1	0	1	0	H[2]	1	0
Roof Construction	2	$1^1/_2$	1	1	0	1	0	H[2]	1	0
Exterior Nonbearing Walls	0[1]	0[1]	0[1]	0[1]	0[1]	0[1]	0[1]	0[1]	0[1]	0[1]

Shaded areas represent those members that shall be permitted to be of approved combustible material.

[1]Requirements for fire resistance of exterior walls, the provision of spandrel wall sections, and the limitation or protection of wall openings are not related to construction type. They need to be specified in other standards and codes, where appropriate, and may be required in addition to the requirements of NFPA 220, *Standard on Types of Building Construction*, for the construction type.

[2]"H" indicates heavy timber members; see NFPA 220, *Standard on Types of Building Construction*, for requirements.

3-2 Type II (222, 111, or 000). Type II construction shall be that type not qualifying as Type I construction in which the structural members, including walls, columns, beams, girders, trusses, arches, floors, and roofs, are of approved noncombustible or limited-combustible materials and shall have fire resistance ratings not less than those specified in Table 3-1.

3-3 Type III (211 or 200). Type III construction shall be that type in which exterior walls and structural members that are portions of exterior walls are of approved noncombustible or limited-combustible materials, and interior structural members, including walls, columns, beams, girders, trusses, arches, floors, and roofs, are entirely or partially of wood of smaller dimensions than required for Type IV construction or of approved noncombustible, limited-combustible, or other approved combustible materials. In addition, structural members shall have fire resistance ratings not less than those specified in Table 3-1.

3-4* Type IV (2HH).

3-4.1 Type IV construction shall be that type in which exterior and interior walls and structural members that are portions of such walls are of approved noncombustible or limited-combustible materials. Other interior structural members, including columns, beams, girders, trusses, arches, floors, and roofs, shall be of solid or laminated wood without concealed spaces and shall comply with the provisions of 3-4.2 through 3-4.6. In addition, structural members shall have fire resistance ratings not less than those specified in Table 3-1.

Exception No. 1: Interior columns, arches, beams, girders, and trusses of approved materials other than wood shall be permitted, provided they are protected to provide a fire resistance rating of not less than 1 hr.

Exception No. 2: Certain concealed spaces shall be permitted by the exception to 3-4.4.

3-4.2 Wood columns supporting floor loads shall be not less than 8 in. (203 mm) in any dimension; wood columns supporting roof loads only shall be not less than 6 in. (152 mm) in the smallest dimension and not less than 8 in. (203 mm) in depth.

3-4.3 Wood beams and girders supporting floor loads shall be not less than 6 in. (152 mm) in width and not less than 10 in. (254 mm) in depth; wood beams and girders and other roof framing, supporting roof loads only, shall be not less than 4 in. (102 mm) in width and not less than 6 in. (152 mm) in depth.

3-4.4 Framed or glued laminated arches that spring from grade or the floor line and timber trusses that support floor loads shall be not less than 8 in. (203 mm) in width or depth. Framed or glued laminated arches for roof construction that spring from grade or the floor line and do not support floor loads shall have members not less than 6 in. (152 mm) in width and not less than 8 in. (203 mm) in depth for the lower half of the member height and not less than 6 in. (152 mm) in depth for the upper half of the member height. Framed or glued laminated arches for roof construction that spring from the top of walls or wall abutments and timber trusses that do not support floor loads shall have members not less than 4 in. (102 mm) in width and not less than 6 in. (152 mm) in depth.

Exception: Spaced members shall be permitted to be composed of two or more pieces not less than 3 in. (76 mm) in thickness where blocked solidly throughout their intervening spaces or where such spaces are tightly closed by a continuous wood cover plate not less than 2 in. (51 mm) in thickness, secured to the underside of the members.

Splice plates shall be not less than 3 in. (76 mm) in thickness.

3-4.5 Floors shall be constructed of splined or tongued and grooved plank not less than 3 in. (76 mm) in thickness that is covered with 1-in. (25-mm) tongue and groove flooring, laid crosswise or diagonally to the plank, or with $^1/_2$-in. (12.7-mm) plywood; or they shall be constructed of laminated planks not less than 4 in. (102 mm) in width, set close together on edge, spiked at intervals of 18 in. (457 mm), and covered with 1-in. (25-mm) tongue and groove flooring, laid crosswise or diagonally to the plank, or with $^1/_2$-in. (12.7-mm) plywood.

3-4.6 Roof decks shall be constructed of splined or tongued and grooved plank not less than 2 in. (51 mm) in thickness; or of laminated planks not less than 3 in. (76 mm) in width, set close together on edge, and laid as required for floors; or of $1^1/_8$-in. (28.6-mm) thick interior plywood (exterior glue); or of approved noncombustible or limited-combustible materials of equivalent fire durability.

Note: The dimensions used for sawn and glued laminated lumber in Section 3-4 are nominal dimensions.

3-5 Type V (111 or 000). Type V construction shall be that type in which exterior walls, bearing walls, columns, beams, girders, trusses, arches, floors, and roofs are entirely or partially of wood or other approved combustible material smaller than material required for Type IV construction. In addition, structural members shall have fire resistance ratings not less than those specified in Table 3-1.

A-2-1.2 Furniture, floor and wall coverings, and other furnishings in airport terminal occupancies, including passenger holding lounges, waiting areas, restaurant dining rooms, bars, retail stores, etc., should not be made of materials that have high combustibility or smoke-development characteristics, or both. Examples of materials that have high combustibility or smoke-development characteristics, or both, include some plastic foams, latex-rubber foam, some plastics, and some synthetic fibers. Such materials have a tendency to release combustible gases at relatively low temperatures, making them easily ignitable. These materials also release high amounts of heat energy at rapid rates when burning, thereby contributing greatly to fire propagation.

A-2-1.5 The use of glass and other glazing materials in airport terminal building walls facing the ramp should be avoided if the fueling ramp drainage inlets or the probable points of fuel spillage from aircraft are less than 100 ft (30.5 m) from such walls. This standard prohibits locating drainage inlets less than 50 ft (15.2 m) from any airport terminal building walls.

This recommendation is made because the radiant heat release from a serious fuel spill fire can be expected to break glass windows up to 75 ft (22.9 m) away and cause ignition of combustible materials within the building.

Protection provided by automatically operated outside spray nozzles is not intended to provide a safe refuge area for occupants. The degree of protection at the opening is intended to provide a period of time for the safe egress of building occupants in the vicinity of the exposed window area.

The presence of automatic sprinkler protection in the airport terminal building would be expected to control a fire initiated in the building due to an exposure fire. Glazing material above the 7-ft (2.1-m) level will not cause immediate exposure to building occupants.

Care should be exercised in the selection and adjustment of detection equipment to ensure proper operation and to guard against inadvertent operation of the system from normally fluctuating conditions. Due to the normal activity on the airport ramp, the radiated energy of a spill fire might not be received at a particular detector location but can still expose the building wall.

The aircraft terminal building is fairly unique since there can be a large population in the terminal building at the same time that a high hazard exposes the terminal. This combination presents the potential for a serious emergency situation.

An exposure evaluation should be developed for potential fuel spill points more than 50 ft (15.2 m) but less than or equal to 100 ft (30.5 m) from the airport terminal building. The exposure evaluation should describe the location and severity of potential fuel spill points and the design features that control exposure fire damage to the airport terminal building and occupants. Catastrophic crashes between aircraft or aircraft and the building are not part of the evaluation.

The exposure evaluation should include consideration of each of the following:

(a) Fuel spill points

(b) Fuel spill rates

(c) Fuel spill pool size

(d) Ramp drainage design

(e) Exposed wall construction

(f) Wall openings (windows, doors, etc.)

(g) Interior building fire protection features

The many factors affecting the exposure make each facility layout a different design problem. The building design, aircraft fueling ramp design, aircraft fueling system, and aircraft fueling ramp drainage system will affect the exposure.

The building design features affecting the degree of exposure include building construction characteristics, the size of windows facing the ramp, the presence of automatic sprinkler protection, and the exit arrangements. The exposed wall will provide a different degree of protection to the building interior and building occupants depending on the building wall construction material.

The presence of openings, particularly glass, will significantly increase the radiated energy inside the building. The extent to which the radiated energy transmission is affected will depend on the size of the opening, the opening location with respect to the spill fire, and the building arrangement inside the opening.

The aircraft fueling ramp design will affect the size and duration of a fuel spill fire. Both the direction and rate of drainage can influence the fire exposure to the airport terminal building. When the characteristics of the ramp design and the ramp drainage system are considered together, the variables, such as ramp construction material, ramp slope, drain inlet location, and drainage system capacity, will affect the exposure. Ramp drainage trenches present a different exposure to the airport terminal building wall from drain inlets to an underground piping system.

Aircraft fueling systems are generally fixed piping systems with strategically located fuel hydrants. Fuel servicing vehicles serve as the transfer mechanism between the fixed piping system and the aircraft. Refer to NFPA 407, *Standard for Aircraft Fuel Servicing,* for design considerations used in the airport fueling systems. Smaller or older airports may use tanker trucks. Tanker trucks are also used as backup to the fixed piping systems. The presence of a tanker truck at the aircraft puts a larger quantity of fuel on the ramp.

Exposure fire damage can be minimized in three different ways: physical separation, fire-resistance-rated exterior wall construction, and fire suppression systems. These protection methods can be utilized singularly or in combination.

A-2-2.2 Examples of points of flammable vapor release are fuel tank vent openings and fuel hydrant pits. Air supply intake and exhaust openings for air conditioning or ventilating equipment serving the terminal building should not be located on the ramp side of an airport terminal building. Fixed air conditioning and ventilating equipment serving aircraft only should be in a room having no openings communicating with the remainder of the terminal building.

A-2-2.3 Rooms containing coal-, gas-, or oil-fired equipment, or any room containing any other open flame device, should not have openings on the ramp side of the building. Combustion and ventilation air should be supplied from the street side or roof of the building or through a gravity louver from a nonhazardous area in the building.

A-2-3.2 The hazards to persons from jet intakes and blast, noise, propellers, etc., on the ramp should be taken into consideration in locating emergency exit points leading to ramps from the airport terminal building. A means of notification of unauthorized usage (such as an alarm system) of these emergency exits may be desirable.

A-2-5.1 The assembly portion of the terminal building may include areas such as the concourse waiting areas, baggage claim areas, and restaurants. This should exclude the kitchens, toilets, small office areas, and other areas not normally accessible to the public.

A-2-5.1.2 The exposure to the airport terminal building from the airport ramp is significant. The number of building sprinklers operating from the exposure fire may be greater than from an internal ignition source.

A-2-5.2.2 If the public fire department is responding to the "street" side of the airport terminal building, timely access to the normal alarm receiving point may be limited by emergency conditions or distance. Planned radio communication with a constantly attended alarm receiving point can assist in a more efficient response by the public fire department. The remote annunciator on the "street" side of the terminal building can provide building condition information if not otherwise available.

A-2-5.5.1 Valves should be installed to facilitate proper control and should be based on a calculation of the number of units (suppression systems and hydrants) that would be impaired when portions of the system are out of service for repair, maintenance, modification, or expansion. Valves should be so located and identified as to be readily accessible for operation. Particular attention should be given to valving the following locations:

(a) Points of connection of supplies to loops or grids

(b) Intervals in main loop

(c) Grid intersections

(d) Beginnings of laterals

(e) Each connection to hydrants

General fire flow requirements at airports should be based on the maximum fire flow demands (automatic sprinklers, hose, and supplemental systems) anticipated. To determine actual demands, the appropriate NFPA standard should be consulted. Table A-2-5.5.1 lists the range of fire flows and is given only as a guide.

Table A-2-5.5.1

Building Occupancy	Reference to Other Standards	Range of Fire Flows (sprinklers, hose, supplemental)
Terminal	NFPA 13, NFPA 15, and NFPA 416	1000 gpm - 3500 gpm
Hangar	NFPA 409	A wide range exists. For large hangars, this value could approximate 25,000 gpm
Cargo	NFPA 13, NFPA 15, NFPA 231, and NFPA 231C	1500 gpm - 4000 gpm

A-2-5.5.2 Hydrants should be placed in strategic locations on the loops or grids. Operational requirements should be considered when determining hydrant locations on or near taxiways and runways where snow and ice may be present.

A-2-5.5.3 All hydrants should be flushed and all valves operated at least once a year.

After extensive changes to the airport water supply system, full flow tests should be made in the areas affected to ensure that adequacy has been retained or expected improvements have been obtained.

Fire pumps or spare pumps should be given turnover tests at least weekly and full flow tests at least annually. Internal combustion engines driving pumps should be run once a week for at least one-half hour each time.

A-3-1.1 Consideration should be given to the hydraulic problem in disposal of surface water, safe disposal of fuel that might be spilled on the ramp, and the gradient to be overcome in the movement of aircraft. A ratio of 40,000 ft^2 (3716 m^2) per drainage inlet should not be exceeded with minimum flow distances to drains, but drain inlets should be located so as not to endanger aircraft placements within the ramp area so described.

A-3-1.2 Figures A-3-1.2(a) and (b) illustrate two possible fueling ramp drainage arrangements.

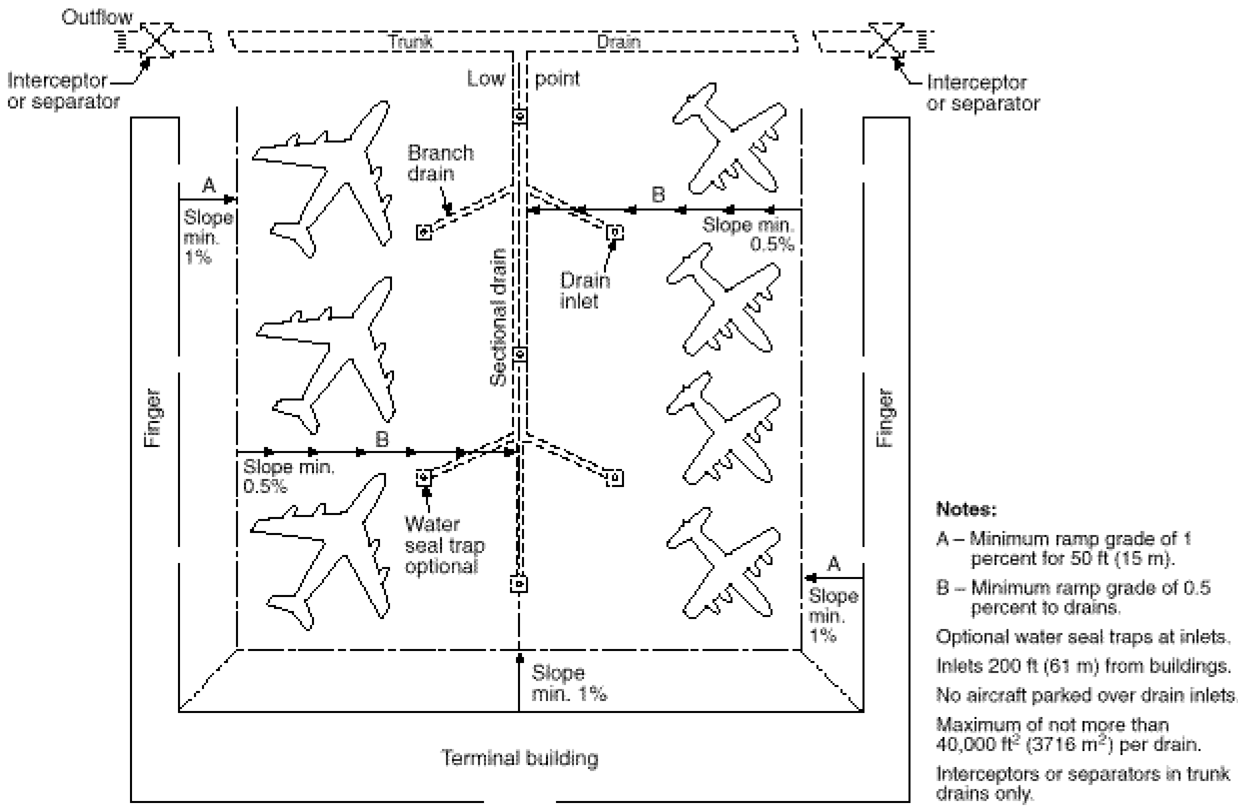

Figure A-3-1.2(a) One possible arrangement of an aircraft fueling ramp drainage system using the optional trapped drain inlets.

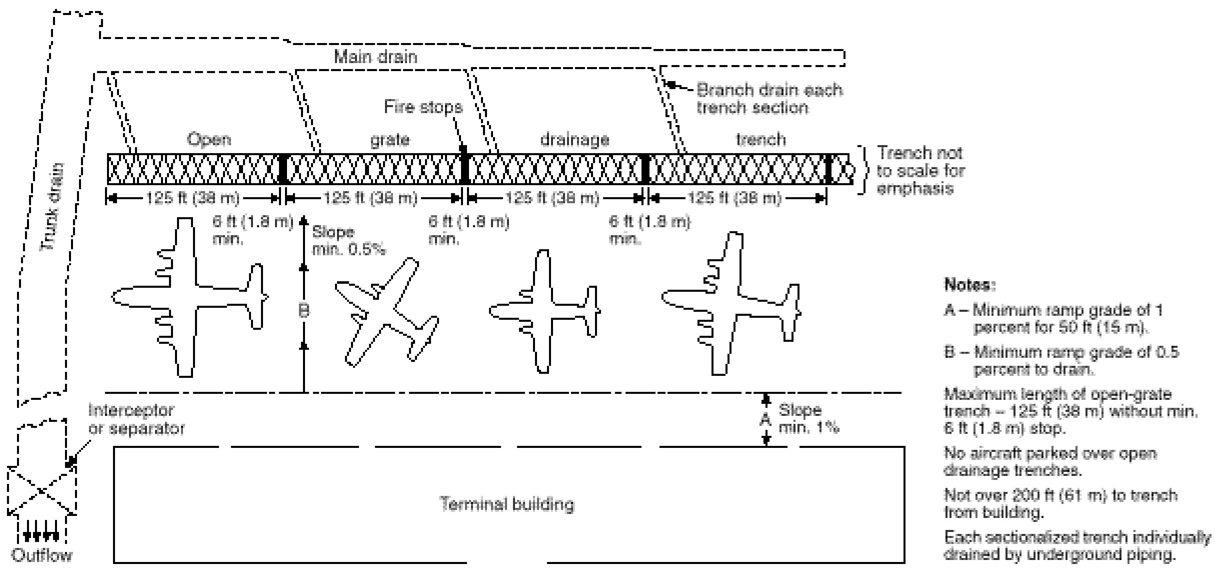

Figure A-3-1.2(b) Another possible arrangement of an aircraft fueling ramp drainage system using an open-grate drainage trench.

A-3-1.7 The individual drain is intended to prevent flow of a spill in one trench from flowing through other trenches. Refer to Figure A-3-1.2(b).

A-3-2.1 It is suggested that maintenance checks be conducted at least four times a year and more often if climatic or other local conditions dictate.

A-4-2.1 Interior Atmospheres. Fire tests have shown that smoke and toxic products generated within the walkway from the decomposition of certain materials can hinder the egress of passengers from an aircraft during a fire emergency. Existing technology does not permit establishment of performance criteria for acceptable levels of smoke density and toxic products. Where the tests specified indicate that materials used in walkway construction can degrade, thermal barriers or insulation should be used to reduce the rate of temperature rise and to delay the decomposition of susceptible materials. Of particular concern are those materials used in floor construction, such as plywood and floor coverings. The insulation materials used should produce minimal smoke under fire exposure conditions.

A-4-2.5 The source of uncontaminated air is normally from the airport terminal building.

A-4-2.6 Aircraft loading walkways can be used for a return air plenum as part of a system that provides ventilation for the aircraft. This system can create a positive or negative pressure in the walkway during normal operation and might use air from the ramp for make-up. Systems of this type, as well as any exhaust fans on the walkway, are therefore to be automatically shut down in the event of a fire emergency outlined in 4-1.1.

A-4-4.5.3 The 10-minute fire endurance test period specified is to give those conducting the tests a better opportunity to discriminate between different test samples.

A-4-4.9.1 A suggested test configuration is to construct two steel stud frames of suitable size to cover the test furnace when laying side-by-side and flat. On the exposed face of each frame, one layer of $^{1}/_{2}$-in. Type X gypsum board should be fastened to the steel stud framing. To the edge of one frame, the bumper assembly should be fastened in a manner representative of end-use application. To the edge of the other frame, a sheet of $^{1}/_{2}$-in. thick steel having dimensions such that there is a minimum of 6-in. of steel extending past the bumper assembly in all directions should be fastened to the steel studs. The steel plate is used to simulate the aircraft sidewall. The two frames are brought together such that the bumper assembly is placed in firm contact with the simulated aircraft sidewall and the two frames are fastened together. This unit becomes the test assembly and is placed on the test furnace for the fire exposure period. *(See Figure A-4-4.9.1 for a sketch of the test assembly.)*

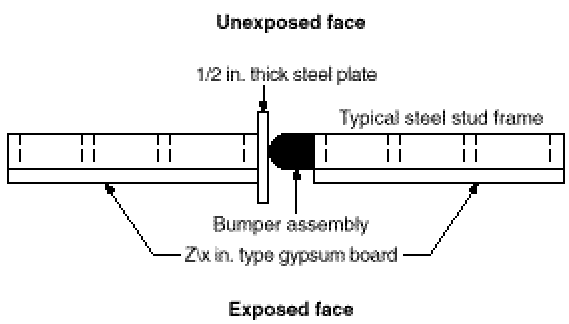

Figure A-4-4.9.1 Proposed method for testing of bumper assemblies.

A-4-5.1 Fire Protection System Actuation Design Recommendation. The design of automatic actuation equipment should take into consideration the possibility of heat or pressure sources that could exist in the areas where these systems are installed (e.g., operation of turbine engines in the vicinity, heat-creating equipment on the ramp, hot air curtains at terminal openings, etc.).

NFPA 418

1995 Edition

Standard for Heliports

1995 Edition

This edition of NFPA 418, *Standard for Heliports*, was prepared by the Technical Committee on Helicopter Facilities and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 418 was approved as an American National Standard on August 11, 1995.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 418

The development of NFPA 418 began in 1965 after the NFPA Sectional Committee on Aircraft Hangars and Airport Facilities was asked to provide guidance on the construction and protection of elevated heliports. Earlier work had been done by the NFPA Sectional Committee on Aircraft Rescue and Fire Fighting with regard to fire protection in the event of accidents during flight operations, and the NFPA Sectional Committee on Aircraft Fuel Servicing developed the safeguards needed for the prevention of fire accidents during fueling operations at such locations. In 1967, a Tentative Standard on Elevated Heliport Construction and Protection was approved at the NFPA Annual Meeting. The 1968 text was a revision of the tentative standard (including a change in title). The 1973 edition was a complete revision of the 1968 edition. Further amendments were made in 1979. The title of the 1990 edition of this standard was changed from Standard on Roof-top Heliport Construction and Protection. The 1990 edition added chapters for land-based facilities and offshore heliports.

The standard was revised for 1995.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the fire protection criteria for the design and construction of elevated and ground level heliports, helistops, and helipads; fire protection requirements for heliports, helistops, and helipads; and requirements for rescue and fire-fighting operations at heliports, helistops, and helipads.

NFPA 418

Standard for

Heliports

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 6 and Appendix B.

Chapter 1 Administration

1-1 Scope.

1-1.1

This standard specifies the minimum requirements for fire protection for heliports.

1-1.2

Temporary landing sites and emergency evacuation facilities are outside the scope of this standard.

1-2 Purpose.

The purpose of this standard is to establish minimum fire safety requirements for operation at heliports for the protection of persons, aircraft, and other property.

1-3 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Critical Area. The area calculated to be one-half the overall length of the helicopter multiplied by three times the width of the widest portion of the fuselage. (*See A-3-6.1 for additional information.*)

Emergency Evacuation Facility. A designated and clear area at rooftop or ground level intended exclusively for emergency/rescue operations by helicopters.

Foam Fire Extinguishing System. A low-expansion foam fire extinguishing system designed and installed in accordance with NFPA 11, *Standard for Low-Expansion Foam*. It can be a fixed discharge outlet system utilizing fixed storage and piping connected to fixed outlets or monitor nozzles and manually activated by pushing a button on a console or a pull station. It also can be a hose line system connected to fixed storage.

Heliport. An identifiable area located on land, on water, or on a structure, that also includes any existing buildings or facilities thereon, used or intended to be used for landing and takeoff of helicopters. The term heliport applies to all sites used or intended to be used for the landing and takeoff of helicopters.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Offshore Landing Heliport. A heliport located on fixed or mobile structures and vessels in a marine environment that do not have means of entry and egress connected directly to shore.

Overall Length. The length of the helicopter from the main rotor fully extended to the tail rotor fully extended.

Practical Critical Fire Area. The area, for foam discharge purposes, calculated as one-half the fuselage length multiplied by three times the fuselage width. (*See also A-3-6.1.*)

Rooftop Landing Pad. The entire load-bearing surface intended for the landing, takeoff, and parking of helicopters.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Temporary Landing Site. A site intended to be used for a period of less than 30 consecutive days, and for no more than 10 operations per day.

Chapter 2 General Requirements — Land-Based Facilities

2-1* Plans.

Plans for construction and protection of heliports shall be approved by the authority having jurisdiction.

2-2 Tank Locations.

Aboveground flammable liquid storage tanks, compressed gas storage tanks, and liquefied gas storage tanks shall be laterally located at least 50 ft (15.2 m) from the edge of takeoff and landing areas as defined in FAA A/C 150/5390-2, *Heliport Design Advisory Circular*.

2-3 Fire-Fighting Access.

2-3.1

The heliport shall have at least one access point for fire-fighting/rescue personnel. Where practical, a second access point shall be available and located as remotely as possible from the other.

2-3.2

Fences shall not prevent rapid access by fire-fighting/rescue personnel.

2-4 Landing Pad Pitch.

The heliport shall be pitched or sloped so that drainage flows away from access points and passenger holding areas.

2-5 No Smoking.

No smoking shall be permitted within 50 ft (15.2 m) of the landing pad edge. No smoking signs shall be erected at access/egress points to the heliport.

2-6 Fueling System.

Fueling systems shall be designed in accordance with NFPA 407, *Standard for Aircraft Fuel Servicing*.

Chapter 3 Rooftop Landing Facilities — Additional Protection

3-1 Structural Support.

Main structural support members that could be exposed to a fuel spill shall be made fire resistant using listed materials and methods to provide a fire-resistance rating of not less than 2 hours.

3-2 Landing Pad Pitch.

The rooftop landing pad shall be pitched to provide drainage that flows away from passenger holding areas, access points, stairways, elevator shafts, ramps, hatches, and other openings.

3-3 Landing Pad Construction Materials.

The rooftop landing pad surface shall be constructed of noncombustible, nonporous materials that are approved. The contiguous building roof covering within 50 ft (15.2 m) of the landing pad edge shall have a Class A rating.

3-4* Means of Egress.

At least two approved means of egress from the rooftop landing pad edge shall be provided and shall be remotely located from each other to the extent practical.

3-4.1

For heliports occupied by 50 or more people, two approved means of egress from the roof shall be provided and shall be remotely located from each other to the extent practical but shall not be located less than 30 ft (9.1 m) from each other. For heliports occupied by fewer than 50 people, one approved means of egress from the roof shall be provided.

3-4.2

Means of egress from the rooftop landing pad and roof shall not obstruct flight operations.

3-5 Fire-Fighting Access.

The helicopter rooftop landing pad shall have at least two access points for fire-fighting purposes. Access for fire-fighting personnel through the landing pad egress shall be permitted.

3-6 Fire Protection.

A foam fire extinguishing system shall be designed and installed to protect the rooftop landing pad.

Exception No. 1: A foam fire extinguishing system shall not be required for heliports located on parking garages, unoccupied buildings, or other similar unoccupied structures.

Exception No. 2: For H-1 heliports, two portable foam extinguishers, each having a rating of 20-A:160-B, shall be permitted to be used to satisfy this requirement.

3-6.1*

The foam discharge rate shall be as follows:

AFFF	0.10 gpm/ft^2 [4.1 (L/min)/m^2]
Fluoroprotein	0.16 gpm/ft^2 [6.5 (L/min)/m^2]
Protein	0.20 gpm/ft^2 [8.1 (L/min)/m^2]

3-6.2

The area of application of foam discharge for fixed discharge outlet systems shall be the entire rooftop landing pad. The duration shall be 5 minutes.

3-6.3*

The area of application of foam discharge for hose line systems shall be the practical critical fire area for the category of the helicopter landing facility. The duration shall be 2 minutes.

Table 3-6.3 Practical Critical Fire Areas

Category	Helicopter Overall Length[1]	Practical Critical Fire Area
H-1	Up to but not including 50 ft (15.2 m)	375 ft^2 (34.8 m^2)
H-2	From 50 ft (15.2 m) up to but	840 ft^2 (78.0 m^2)

	not including 80 ft (24.4 m)	
H-3	From 80 ft (24.4 m) up to but not including 120 ft (36.6 m)	1440 ft^2 (133.8 m^2)

[1]Helicopter length, including the tail boom and the rotors.

3-6.4

The water supply for the foam system shall be from a reliable source, approved by the authority having jurisdiction.

3-6.4.1 Fire pumps, if used, shall be installed in accordance with NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*.

3-6.4.2 Standpipes and hose stations, if used, shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

3-6.4.3 Where freezing is possible, adequate freeze protection shall be provided.

3-6.5

The foam components shall be installed in a readily accessible area of the heliport and shall not penetrate the primary approach, departure, and transitional surfaces defined in paragraphs 3J, 3K, 3L, 13, and 21 of FAA A/C 150/5390-2, *Heliport Design Advisory Circular*.

3-6.6

At facilities where there is more than one rooftop landing pad, the supply of foam available shall be sufficient to cover an incident on at least one of the pads.

3-6.7

Where fixed foam systems utilizing fixed deck nozzles or oscillating foam turrets, or both, are installed, system components shall be listed or approved.

3-7 Standpipes.

If a building with a rooftop heliport is supplied with a standpipe system, a Class II standpipe shall be extended to the roof level on which the rooftop heliport is located. Such standpipe systems shall be installed in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

3-8 Fire Alarm.

Where buildings are provided with a fire alarm system, a manual pull station shall be provided for each designated means of egress from the roof. (*See 3-4.1.*)

Chapter 4 Offshore Heliports

4-1* Plans.

Plans for construction and protection of heliports located on fixed and mobile offshore installations shall be approved by the authority having jurisdiction.

4-2 Fire-Fighting Access.

The heliport shall have at least one access point for fire-fighting/rescue personnel. Where practical, a second access point shall be available and shall be located as remotely as possible from the other.

4-3 Landing Pad Pitch.

Heliports shall be designed to prevent the standing collection of liquids and to prevent liquids from spreading to or spilling on accommodation spaces or working spaces.

Chapter 5 Portable Fire Extinguishers

5-1 Quantity and Rating.

At least one portable fire extinguisher as specified in Table 5-1 shall be provided for each takeoff and landing area, parking area, and fuel storage area.

Exception: This requirement shall not apply to unattended ground level heliports.

Table 5-1 Minimum Ratings of Portable Fire Extinguishers for Heliport Categories

Category	Helicopter Overall Length[1]	Minimum Rating
H-1	Up to but not including 50 ft (15.2 m)	4-A:80-B
H-2	From 50 ft (15.2 m) up to, but not including, 80 ft (24.4 m)	10-A:120-B
H-3	From 80 ft (24.4) up to, but not including, 120 ft (36.6 m)	30-A:240-B

[1]Helicopter length, including the tail boom and the rotors.

5-2 Servicing.

Portable fire extinguishers shall comply with NFPA 10, *Standard for Portable Fire Extinguishers*, Chapters 1, 4, 5, and 6.

Chapter 6 Referenced Publications

6-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

6-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 11, *Standard for Low-Expansion Foam*, 1994 edition.

NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*, 1993 edition.

NFPA 20, *Standard for the Installation of Centrifugal Fire Pumps*, 1993 edition.

NFPA 407, *Standard for Aircraft Fuel Servicing*, 1990 edition.

6-1.2 Other Publication.

6-1.2.1 FAA Publication. Federal Aviation Administration, Department of Transportation, Distribution Unit, M-494.3, Washington, DC 20590.

FAA A/C 150/5390-2, *Heliport Design Advisory Circular*, January 4, 1988.

Appendix A Explanatory Material

This Appendix is not a part of the requirements this NFPA document but is included for informational purposes only.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase “authority having jurisdiction” is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-3 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1

FAA A/C 150/5390-2, *Heliport Design Advisory Circular*, contains design and construction information on heliports. This advisory circular provides for adequate clearance between operating aircraft and buildings or structures located at the heliport. The FAA advisory circular should be consulted to ensure that adequate safe practice and facilities are maintained.

A-3-4

For further information on exit principles, see NFPA *101®*, *Life Safety Code®*.

A-3-6.1

Where personnel trained in the operations of the equipment are in attendance, a hose line system is preferred.

The calculations used to develop the minimum extinguishing agent quantities and discharge rates presented in Table A-3-6.1 for rooftop heliports include the following factors:

(a) *Aircraft Size.* Reflects the potential level of risk, e.g., passenger load; the potential fire load, e.g., fuel capacity; and the dimensions, i.e., fuselage length and width, that allow the identification of a meaningful operational objective, i.e., the area to be rendered fire-free (controlled or extinguished).

(b) *Relative Effectiveness of Agent Selected.* Represented by the specific application rate identified for each of the common generic foam concentrate types.

(c) *Time Required to Achieve Control.* Large-scale fire tests, empirical data, and field experience indicate that 1 minute is both a reasonable and a necessary operational objective.

(d) *Time Required to Maintain Controlled Area Fire-Free.* An operational objective that provides a safety factor for the initial fire attack while waiting for the arrival of backup support.

The calculation method is supported by research and experimental work done mainly at the U.S. FAA's Technical Center. It was developed by the "Rescue and Firefighting Panel II" (RFFP II), a group of international experts in the field, convened by the International Civil Aviation Organization, Montreal Canada, circa 1970.

The RFFP II initially focused on the "Theoretical Critical Fire Area," which was identified in the FAA's large-scale fire tests as "... the area adjacent to the fuselage extending outward in all directions to a limit beyond which a large fuel fire would not melt an aluminum fuselage, regardless of the fire exposure time." For this concept to be useful, specific information about the size of the area was needed. Again, using the FAA Technical Center's work as a basis, the RFFP II's working definition of the Theoretical Critical Fire Area (TC) is "the area adjacent to an aircraft in which fire must be controlled." This definition implies control of the fire within a specific area. In order to achieve this, dimensions need to be determined. Formulas 1 and 2, which follow, were developed from that earlier work. Using these formulas, the size of the area of interest can be calculated. For example:

1. Where L<65 ft: $TC = L \times (40 \text{ ft} + W)$

or

1a. L<20 m: $TC = L \times (12 \text{ m} + W)$

and

2. Where L>65 ft: $TC = L \times (100 \text{ ft} + W)$

or

2a. L>20 m: $TC = L \times (30 \text{ m} + W)$

Where: L = average aircraft length

W = average width of aircraft served at the airport of interest.

Conceptually, the TC serves as a means for assessing the magnitude of the potential fire hazard of the aircraft accident environment. It *does not represent* the average, maximum, or minimum spill fire size associated with a particular aircraft. However, it does represent a starting point for determining realistic fire extinguishing agent requirements. The formulas allow for the calculation of the TC area for different sizes of aircraft. They are widely accepted throughout the aircraft fire service community and are applied as described in the following paragraphs.

A 1970 study concluded that in survivable aircraft crashes a “practical fire area” should be considered that was smaller than the “theoretical area.” Detailed criteria for the practical fire area and the related quantities of extinguishing agents were formulated during the second meeting of the RFFP II. In developing its material, the panel’s work included a study of the quantities of agents used on actual fires. In 99 out of 106 such fires, the quantities of agents used were less than those recommended by the theoretical critical fire area calculations.

As a result, RFFP II developed material recommending that the practical area be approximately two-thirds the theoretical area [*see Figure A-3-6.1(a)*]. This principle has been adopted by the ICAO, the NFPA, and the U.S. FAA in the development of tables that show extinguishing agent volumes for their respective standards and recommended practices. The practical critical fire area (PC) for fixed-wing aircraft is commonly expressed as follows:

3. (practical critical fire area) =
(0.67) × (theoretical critical fire area)

or

3a. PC = (0.67) (TC)

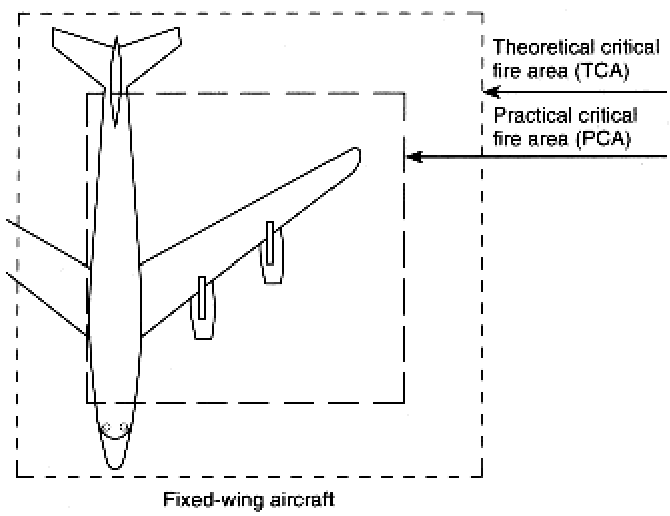

Figure A-3-6.1(a) Practical critical fire area relative to theoretical critical fire area.

In adapting the fixed-wing fire protection methodology to helicopters, the committee considered the following additional factors that make the fire protection problem of helicopters (rotary-wing aircraft) unique:

(a) *Occupied Space.* Relative to its fixed-wing counterpart, a smaller portion of the overall aircraft length is occupied.

(b) *Fuel Quantities and Location.* Fuel tanks are not located in the “wings” or rotor blades, and relatively small quantities of fuel are involved.

(c) *Impact Energy.* Relative to the fixed-wing counterpart, a helicopter accident generally occurs at slow ground speeds.

(d) *Expected Aircraft Size.* In general, heliports are designed for the largest helicopter expected to utilize the facility, not the median size for the category. (*See Table 3-6.3.*)

After considering both the factors involved in the fixed-wing methodology and those factors that are unique to helicopters, the committee arrived at a "Theoretical Critical Area" for helicopters that includes a longitudinal dimension of half the overall length of the helicopter and a width equal to three times the fuselage width. In addition, in the absence of any data that suggested a more appropriate alternative, the "practical critical fire area" has been determined to be 100 percent of the "theoretical critical area." [*See Figure A-3-6.1(b).*]

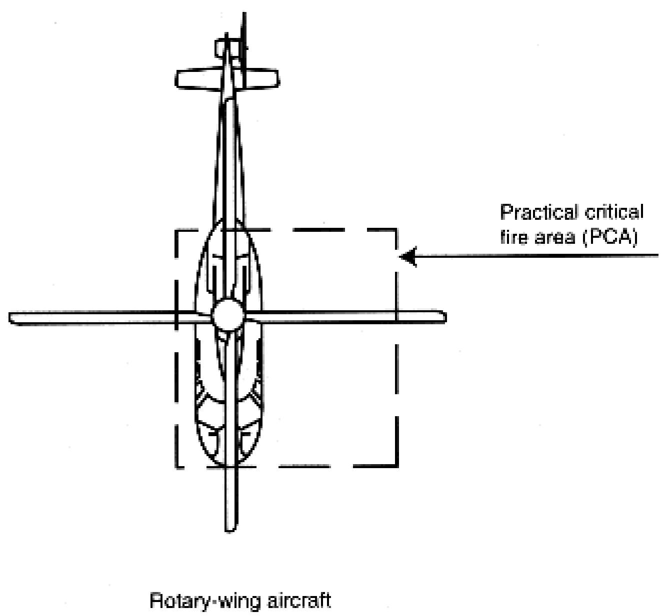

Figure A-3-6.1(b) Practical critical fire area for helicopters.

Another established principle is the distinction between control and extinguishment of a fire. Test data and a wide range of field experience indicate that the quantities of foam agent needed to control and extinguish an aircraft fire should be determined separately. This principle is expressed in items 1 through 6 as follows:

1. Where Q_1= Volume of agent needed for 1-minute control of PC

and

2. Q_2 = Volume of agent needed for continued control or complete extinguishment of fire related to PC, or both.

3. Therefore: $Q = Q_1 + Q_2$ = Minimum agent volume for effective fire service operations.

The relationship between Q_1 and Q_2 as they were developed by the committee that studied the fixed-wing fire protection problem is as follows:

4. Q_1 = (application rate) × (practical critical area)

or

4a. Q_1 = (AR)(PC) Where the "application rate" is the unit volume of agent applied to a unit area of fire in a unit time; the exact units such as gpm/ft^2 or lpm/m^2 depend on the units convention being used.

5. $Q_2 = f(Q_1)$ And it has been determined that, for all categories of heliports, f = 1.

6. Therefore: Q = 2[(AR)(PC)]

A sample calculation of the total water quantity, Q, needed where aqueous film-forming foam concentrate is to be used at each of the three categories of heliport is provided in Tables A-3-6.1(a) and (b). A similar set of water quantities can be calculated for any other foam concentrate for which an accepted application rate is known. The value for the AFFF application rate in column 5 of Tables A-3-6.1(a) and (b) is substituted and the indicated calculations are performed to obtain the value of Q for the specific foam concentrate to be used.

Table A-3-6.1(a) Method to Determine Helicopter Critical Fire Area and Required Minimum Amount of Water for a Hose Line (AFFF) System

NFPA/ICAO Heliport Category				½ × O.L. of Largest Helicopter[1]		Fuselage Width Tripled[2]		Practical Crital Fire Area		Application Rate (gpm/ft^2)		Q_1 Water to Control within 1 Min		Q_2 Reserve to Extinguish		Q Total Water to Extinguish
H-1	0 ft	<	50 ft	25 ft	×	15 ft	=	375 ft^2	×	0.10	=	37.5 U.S. gal	+	100%	=	75 U.S. gal
H-2	50 ft	<	80 ft	40 ft	×	21 ft	=	840 ft^2	×	0.10	=	89 U.S. gal	+	100%	=	168 U.S. gal
H-3	80 ft	<	120 ft	60 ft	×	24 ft	=	1440 ft^2	×	0.10	=	199 U.S. gal	+	100%	=	288 U.S. gal

[1]O.L. = Overall length, measured from tip of main rotor fully extended to tip of tail rotor fully extended.
[2]Fuselage width = Actual fuselage width (does not include landing gear) measured from outside of cabin.

Table A-3-6.1(b) Method to Determine Helicopter Critical Fire Area and Required Minimum Amount of Water for a Hose Line (AFFF) System

NFPA/ICAO Heliport Category				½ × O.L. of Largest Helicopter[1]		Fuselage Width Tripled[2]		Practical Crital Fire Area		Application Rate [(L/min)/m^2]		Q_1 Water to Control within 1 Min		Q_2 Reserve to Extinguish		Q Total Water to Extinguish
H-1	0 m	<	15.2 m	7.6 m	×	4.6 m	=	34.8 m^2	×	4.1	=	141.9 L	+	100%	=	283.9 L
H-2	15.2 m	<	24.4 m	12.2 m	×	6.4 m	=	78.0 m^2	×	4.1	=	336.9 L	+	100%	=	635.9 L
H-3	24.4 m	<	36.6 m	18.3 m	×	7.3 m	=	133.8 m^2	×	4.1	=	753.2 L	+	100%	=	1090 L

[1]O.L. = Overall length, measured from tip of main rotor fully extended to tip of tail rotor fully extended.
[2]Fuselage width = Actual fuselage width (does not include landing gear) measured from outside of cabin.

To fully appreciate the significance and simplicity of this methodology as a means of determining levels of fire protection, it should be clearly understood that Q_1 is only that minimum quantity of fire-fighting agent required for 1-minute fire control (90 percent extinguishment) of the anticipated practical critical fire area. Therefore, any fire and rescue service cannot be expected to perform an effective rescue effort where equipped with less than the quantity of primary extinguishing agent specified by the volume of Q_1 for the specific airport/heliport category. Furthermore, a fire suppression/rescue mission that is initiated using the required minimum application rate and is continued at that rate, while effectively extinguishing fire or securing unburned fuel within the practical area, ceases operations at the end of 1 minute. In other words, the agent specified by the volume Q_1 is depleted. There is no agent available for mop-up activities, foam blanket repair, or standby protection for continued rescue or salvage activities. Therefore, while the control volume Q_1 provides an operational significance that is critical to the rescue operation, it is, at the same time, limited.

It should therefore be clear that in order to extend an effective fire suppression and rescue operation beyond the initial 1-minute fire control period, an additional volume of foam agent, Q_2, needs to be available. This volume of agent is used to repair foam blanket damage that might be caused by evacuees and rescue workers walking through the foamed areas or by hot surfaces created by the initial fire. Furthermore, Q_2 is needed to extinguish all fire in the practical critical fire area and those fires outside the practical critical area that initially are determined to pose no threat to life. Agent quantity in accordance with Q_2 also provides standby protection before total extinguishment during interior aircraft search operations and for the removal of immobile survivors after fire control. It also is used for securing the fire area during initial aircraft salvage operations immediately after total fire extinguishment. Therefore, an aircraft fire service equipped with only the 1-minute fire control volume represented by Q_1 is expected to assume a significant level of risk. That risk cannot be considered a “calculated risk” unless the manager selecting the reduced agent volume knows the nature of the fire area and the potential hazard involved.

A-3-6.3

The area of application and the duration where using a hose line system is reduced because foam is applied efficiently and directly on the fire by trained personnel.

A-4-1

The design of heliports located on fixed or mobile offshore installations generally is based on landing sites of steel construction. However, in no way should this be construed as a recommendation of steel over other suitable building material.

Appendix B Referenced Publications

B-1

The following documents or portions thereof are referenced within this standard for informational purposes only and thus are not considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

1994 Edition

Guide for Aircraft Accident Response

1994 Edition

This edition of NFPA 422, *Guide for Aircraft Accident Response*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 16-18, 1994, in San Francisco, CA. It was issued by the Standards Council on July 14, 1994, with an effective date of August 5, 1994, and supersedes all previous editions.

The 1994 edition of this document has been approved by the American National Standards Institute.

Origin and Development of NFPA 422

Originally a manual, development of NFPA 422M was initiated in 1963, and it was submitted to the Association for adoption at the 1972 Annual Meeting. The document was revised in 1979 and 1984 and the 1989 edition was a reconfirmation of the 1984 edition.

The title for this 1994 edition was changed from *Manual for Aircraft Fire and Explosion Investigators* to the current title. The document was completely revised to provide a framework for the accumulation of data relative to the effectiveness of aircraft accident emergency response services in the application of principles found in the standards and guides developed by the Technical Committee on Aircraft Rescue and Fire Fighting.

This document is intended to assist the committee in collecting significant data that may be utilized to facilitate revisions to the NFPA aircraft rescue and fire fighting documents.

The work of revising this document was accomplished by a task group appointed by the chairman. The following is a list of members of the task group.

Task Group on Aircraft Fire and Explosion Investigators Guide

Ronald O. Wikander, Lockheed Aeronautical Systems Co., GA, Chair; Brian Boucher, Canadian Air Line Pilots Assn., Canada; Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA; B. V. Hewes, Airport Safety Services, GA; Thomas J. Lett, Albuquerque Fire & Safety Assoc., Inc., NM; Lawrence D. Roman, Nat'l Transportation Safety Board, DC; Emory Tate, BDM Int'l, VA

Committee on Aircraft Rescue and Fire Fighting

John F. Rooney, *Chair*
Tucson, AZ

James F. O'Regan, *Vice Chair*
Westboro, MA

Robert J. Donahue, *Secretary*
Massport, MA

Brian Boucher, Canadian Air Line Pilots Assn., Canada
Rep. Canadian Air Line Pilots Assn.

Booker T. Burley, Hartsfield Atlanta Int'l Airport, GA

Ralph Colet, John Russo Industrial Inc.

Robert L. Darwin, U.S. Dept. of the Navy, DC

Charlie L. Duncan, Atlanta Fire Dept., GA

B. V. Hewes, Airport Safety Services, GA

Paul O. Huston, Amerex Corp., AL
Rep. Fire Equipment Mfrs. Assn., Inc.

D. Steve Kiernan, Chubb Nat'l Foam Inc., PA

L. M. Krasner, Factory Mutual Research Corp., MA

Dave Lenz, Oshkosh Truck Corp., WI

Thomas J. Lett, Albuquerque Fire & Safety Assoc., Inc., NM

Rep. NFPA Fire Service Section

D. Robin Maryon, Simon Gloster Saro Limited, England

John J. O'Sullivan, British Airways, England

Davis R. Parsons, Los Angeles City Fire Dept., CA

Gaetan Perron, Dept. of Nat'l Defence, Canada

Robert G. Relyea, ARFF Working Group, TX

Robert E. Reyff, U.S. Air Force, FL

Paul R. Robinson, Kennesaw, GA
Rep. Air Line Pilots Assn.

Bertrand F. Ruggles, U.S. FAA Dept. of Transportation, DC

Joseph L. Scheffey, Hughes Assoc., Inc., MD

John M. Schuster, 3M Co., MN

John X. Stefanki, John X. Stefanki Inc., CA

William J. Wenzel, Schenectady, NY
Rep. Walter Truck Corp.

Ronald O. Wikander, Lockheed Aeronautical Systems Co., GA

Larry E. Williams, Emergency Response Training Academy, Inc., TN

Joseph A. Wright, Federal Aviation Administration Tech Ctr, NJ

Fred B. Goodnight, Amerex Corp., AL
(Alt. to P. O. Huston)

Frank M. E. Hughes, British Airways, England
(Alt. to J. J. O'Sullivan)

Robert E. Maxwell, Dept. of Nat'l Defence, Canada
(Alt. to G. Perron)

Thomas E. McMaster, Los Angeles City Fire Dept., CA
(Alt. to D. R. Parsons)

Committee Scope: This Committee shall have primary responsibility for documents on the criteria for aircraft rescue and fire fighting services and equipment, procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports, with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. This committee also will have responsibility for developing aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 422

Guide for Aircraft Accident Response

1994 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 3 and Appendix C.

Chapter 1 Introduction

1-1 Scope.

This document provides a framework for the collection of data that provides information on the effectiveness of aircraft accident emergency response services. This standard applies the principles of those standards and guides developed by the Technical Committee on Aircraft Rescue and Fire Fighting.

1-2* Purpose.

The purpose of this document is to outline a format for a comprehensive emergency response analysis and the collection of significant data that can be utilized to facilitate revisions to applicable NFPA documents.

1-2.1

Part 2 of this guide also may be effectively used to record and critique airport emergency disaster exercises.

1-3 Arrangement.

This guide contains two separate reports that are intended to provide a comprehensive emergency response analysis when completed. These report forms can be photocopied from this guide if they are not available elsewhere.

1-3.1

The forms should be completed by persons with knowledge of the pertinent subject matter.

1-3.2

No obtained information should be released to the news media or to any person unless permission has been obtained first from the chief of the official investigating team. The successful collection of information is related directly to its judicious treatment.

1-3.3

These forms may be used by any person or organization for their internal use. However, when released, copies should be sent to the Committee on Aircraft Rescue and Fire Fighting for entry into the NFPA data bank.

1-4 Units.

This guide uses metric units of measurement in accordance with the modernized metric system known as the International System of Units (SI). The liter unit, which falls outside of but is recognized by SI, is used commonly in international fire protection.

1-4.1

If a measurement value provided in this guide is followed by an equivalent value in other units, the first stated value should be regarded as the recommendation. The equivalent value might be approximate.

1-4.2

SI units have been converted from U.S. values by multiplying the U.S. value by the conversion factor and rounding the result to the appropriate number of significant digits.

Chapter 2 Aircraft Accident/Emergency Response Data

2-1

Reports on incidents and accidents that involve fires should include information on the origin of the fire, the method by which it was spread and fed, the type and effectiveness of extinguishing agents used, and whether any equipment malfunctioned. Methods for fighting fires that follow crashes and for forced entry into burning aircraft have been the subject of much research. All available facts should be reported to improve safety to life.

2-2

It should be noted if escape from the burning plane was successful and whether emergency exits were able to be used or were blocked due to the fire's intensity and location. Information and data should be solicited from flight crew, passengers, and witnesses.

2-2.1

It is important to verify the weather conditions that existed at the time of the fire, particularly the wind direction and velocity. This information, combined with information on the location and use of emergency exits, can provide data on fire spread in the cabin interior.

2-3

Reports should indicate the type of ground fire fighting equipment available and used, including the response time and effectiveness of each responding vehicle, and the quantity and type of extinguishing agents used and left unused. The level of experience and degree of training of fire fighting and rescue personnel also should be reported. The type of clothing worn by personnel involved and the degree of protection provided by this clothing is especially important. Reports should indicate any problems with communications, command and control on the scene, and problems with any emergency plans employed.

2-4

A complete report should be made on the medical findings that result from analysis of the accident. This report should differentiate between injuries and deaths due to fire and those due to impact. Pathological examinations should include toxicological analyses in order to identify all toxic products of combustion. The report also should describe the fire extinguishment and victim care procedures that were used. These reports can be completed by different persons.

2-5

Complete information on in-flight fires is essential in order to improve and develop adequate fire warning and extinguishing systems. The source of the flight crew's discovery of fire in progress and the effectiveness of extinguishment efforts should be determined. A complete, step-by-step description of the procedure used by the crew for extinguishing the fire should be recorded and compared with the approved method listed in the applicable technical manual, flight manual, and flight attendant manual. The voice recorder and the aircraft flight recorder can be most helpful to the investigator in gathering this important information.

2-6

Before completing the aircraft fire and emergency response reports, the following tasks should be completed.

2-6.1

The data collector should become familiar with the overall accident site.

2-6.2

The data collector should determine the location of the responding emergency response services at the time of response and the response routes accessed.

2-6.3

The data collector should first walk through the wreckage area to size up the layout and distribution. This provides a mental picture of the main line of distribution and is helpful for plotting and interpreting witness statements, breakup patterns, etc.

2-6.4

Upon arriving at the accident scene, the data collector should immediately contact the accident investigator in charge. For on-airport accidents, the airport authority or the FAA can provide the location of the investigator in charge. For off-airport accidents, the local enforcement authority should be contacted.

PART I INSTRUCTIONS FOR COMPLETING THE NFPA AIRCRAFT FIRE INVESTIGATION REPORT

The following instructions provide detailed information on how to complete the “Aircraft Fire Investigation Report,” which is reproduced in this guide. Sample information and data and instructions for completion appear in italics.

A. GENERAL

1. Aircraft Data:

a. Type of aircraft (common name or symbol): *Boeing 727*

b. Model no.: *Series 200*

c. Manufacturer of aircraft: *Boeing Company, Seattle, Washington*

d. Type and number of engines: *3*

e. Registration no.: *N304*

f. Name of operator: *OK Airlines*

g. Purpose of aircraft use at the time: *The aircraft was on a charter flight for the World’s Sport Society.*

h. Flight route: *Chicago to Los Angeles via airways*

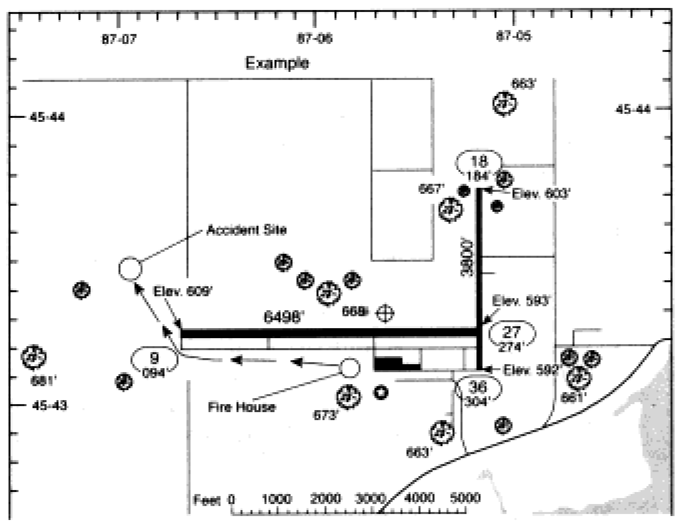
i. Other information: *Provide any additional, appropriate information regarding this aircraft or flight not indicated previously.*

2. Location of Emergency:

a. Provide name of specific airport, if applicable, or city, nearest city, or nearest airport, stating distance factors and, where applicable, compass directions: *1 mile northwest of Burbank Airport, Burbank, California.*

NOTE: In the United States, the National Transportation Safety Board (NTSB) identifies accidents by using the name of the nearest post office.

b. Prepare grid map, including terrain features: *This greatly assists in showing the exact location and helps to determine if the terrain was a factor in the accident. Use the grid map in the fire report. Please note that details of the fire scene are not included in this map but are to be entered later in the report on a separate grid map. In this sketch, show means of access to the accident site, including any perimeter roads around the airport, location of gates, etc. Indicate whether the Rescue and Fire Fighting (RFF) equipment had to travel long distances on public roads, and, if so, sketch the routing.*



3. Time Factors:

a. Date of accident: Day/Month/Year

b. Time (local and Greenwich Mean Time): Hour: minutes (local), Hour: minutes (GMT)

4. Type of Aircraft Accident: *There are eight basic types of accidents as far as the responsibilities of the aircraft fire investigator are concerned.*

a. Crash, no fire: *It is important for the investigator to determine why no fire occurred. What set of circumstances caused this crash without also causing a fire? A study of procedures that were used can be of benefit in future crashes.*

b. Crash, immediately followed by fire: *This type of accident is the opposite of item 4.a., but the object of the investigation is the same. What procedures were used?*

c. Crash, followed by fire but with delay in ignition (time interval): *What caused the delay in the ignition, and what procedures could have further delayed or prevented the ignition?*

d. Fire in air, fire extinguished in flight: *The cause of the fire should be determined, and the procedures used to extinguish the fire. How can these procedures be improved? Did the crew act rapidly enough?*

e. Fire in air, followed by crash and fire: *Crew members seldom survive this type of accident, and careful examination of the wreckage is necessary to determine the cause and location of a fire in the air. Examination of various components of the aircraft fire extinguishing system indicates the extent to which the extinguishing system was used and the procedures were* *completed. Remember to check the positions of components of other systems on the fire extinguishing checklist. It is possible that the procedure for manipulation of the fire extinguishing controls was positioned low on the checklist so that the crew did not have time to perform this function. Can the procedure be shortened? Why was the procedure unsuccessful in extinguishing the fire?*

f. Fire on the ground (no crash): *The cause of the fire should be determined to help prevent future fires of this type. The fire sequence should be examined carefully to determine if it is possible to reduce the time needed to extinguish a fire, the time needed to detect a fire, and the time needed to isolate a fire.*

g. Fire inside hanger (no crash): *The cause should be determined to aid in developing prevention techniques. Once the causal factor has been established, efforts to prevent this type of fire can be successful; however, since the cause of this type of fire usually is traced to human behavior, the procedures used and their effectiveness should be noted carefully. Can the procedures be made more effective?*

h. Fire—other (specify): *This section addresses any other type of aircraft accident. The causal factor should be determined, and the extinguishing procedures used and the extent to which they were successful should be identified. Can they be improved?*

i. In-water accident: *Determine the cause of the accident. It is important to describe the tactics, strategy, and equipment utilized to suppress fire and accomplish rescue in these circumstances. Much can be learned from this information.*

j. Other aircraft ground incidents: *It is important to describe other emergencies that necessitate an Aircraft Rescue and Fire Fighting (ARFF) response. Many times the prompt response of the ARFF prevents major aircraft damage and loss of life, and significant new response techniques are developed as a result.*

5. Flight Factors: *Observation of various flight factors prior to, during, and subsequent to initiation of an aircraft fire can supply information that leads to possible changes in procedures, structures, etc., that might prevent reoccurrence. Some pertinent flight factors include:*

a. Crash at takeoff: *Indicate the point in the takeoff roll at which the crash occurred. Had power been reduced? What was the configuration of the flaps, gear, etc.?*

b. Crash immediately after takeoff: *Indicate the approximate maximum altitude reached. Record the configuration of the flaps, gear, etc. Had power been reduced? What were the changes in the heading (if any) of the aircraft? Was any smoke or flame emitting from the aircraft? If so, from where and at what point in time?*

c. Aircraft in flight, power stall: *Was the aircraft involved in any abrupt pull-up? Was power still being applied?*

d. Aircraft in flight, explosion in air: *Was there any explosion while in the air? If so, when? Take care to differentiate between explosions and other sounds. A breaking spar can sound exactly like an explosion.*

e. Aircraft in flight, fire in air: *If a fire during flight is suspected, what indications, such as smoke or flame, are present? From what portion of the aircraft? The location of the smoke emissions from an aircraft often can provide a valuable clue to that checklist procedure last performed by the crew before fire occurred. What color and how intense is the smoke? Describe the color of the smoke as it relates to everyday items (e.g., white as a bed sheet, gray as newsprint, etc.).*

f. Aircraft in flight, structural failure: *In which phase of flight was the aircraft (takeoff,* *initial climb, cruise, etc.)? Which structure failed and when? In what manner? Was fire present? Did the fire occur before or after the structural failure?*

g. Collision with other aircraft while airborne: *In this situation, the main focus of attention should be the relative angle between the two aircraft as they approached each other.*

h. Collision with structure: *At what phase of flight did the collision occur (takeoff, initial climb-out, landing, etc.)? At what altitude above the ground did the collision occur?*

i. Collision with ground: *In which phase of flight was the aircraft? What was the angle of impact? Describe the type of terrain and surface characteristics (e.g., ditches, embankments).*

j. Crash while landing: *Did the crew give any warning of any unusual condition? Was any unusual condition evident from the ground? At what phase of the landing did the collision occur (e.g., prior to touchdown, during rollout, during taxi, etc.)?*

k. Crash while making emergency landing: *What were the indications regarding the type and nature of the emergency? In what type of terrain was the landing attempted? In what phase of the landing did the crash occur?*

l. Other:

6. Weather Factors:

a. General weather conditions: *Rain, fog, ice, snow*

b. Surface visibility, miles: *Runway visibility (RVR)*

c. Wind direction and velocity in knots:

d. Ambient temperature and dew point in °F or °C: *Specify measurement used.*

e. Ice, snow, fog, dry, wet:

f. Visibility distance:

B. FIRE FACTORS

1. Aircraft Fuel (Class B Fire):

a. Estimated amount of fuel on board at time of accident: *The quantity of fuel carried by the aircraft at the time of the incident/accident and an accounting of its status during and after the time of impact (if any) and fire (if any) are important in evaluating the effectiveness of the fuel tank construction and installation in minimizing fire hazard factors. Provide the quantities in gallons, pounds, kilos, or liters, specifying the unit used.*

b. Describe type of fuel spill and effect of terrain and soil conditions on fuel spill: *The dimensions of the fuel spill area in sq ft at time of ignition should be estimated, and the sequence of fire growth should be recorded from that time of ignition. This should include the rate of fuel leakage from tanks or broken fuel lines and the rate of growth of fuel spill area. (See NFPA 407, Standard for Aircraft Fuel Servicing, Section 3-2, for spill prevention and control.) Did the scope of the terrain affect fuel runoff?*

2. Other Flammable Liquids (Class B Fire): *Yes/No.*

Comments: Describe the part that engine oil, hydraulic fluid, alcohol, etc., played in the fire (pertinent only when original combustible or primary amount of fuel is involved): *It is common knowledge that other special purpose liquids carried aboard aircraft are not only combustible but can be destructive to foams that are likely to be used to extinguish the main fuel fire. Although the quantities of these liquids are small in comparison with the quantity of fuel load, their presence should be treated as a clue to any effectiveness deficiency in the extinguishing agents used.*

3. Combustible Metals (Class D Fire): *Yes/No.*

Comments: Describe the role of combustible metals as possible ignition source or continuing source of ignition (list types of metals involved): *What was the effect on fire control? Magnesium and titanium are the only metals likely to be encountered as factors in an aircraft fire. Metals usually are not the cause of large fires; however, they can create severe problems in a fire situation, since not only are they difficult to extinguish, but the usual agents, water and water-containing agents (e.g., foam), aggravate and often spread the burning metal. The metals themselves rarely self-ignite, but friction sparks resulting from their contact with the runway surface usually ignite fuel from any leaks in their vicinity. Metal fires usually are due to prolonged heating by the flames of liquid fuel fires or are the result of the friction of metals in contact with the runway. Titanium fires rarely occur.*

4. Ordinary Solid Combustibles (Class A Fire): *Yes/No.*

Comments: Baggage, cargo, personal effects, cabin interior furnishings, etc.: *Describe the role of solid combustibles as the original ignition source, the original combustible involved, or in terms of their effect on fire control. Fires burning in ordinary materials of construction, such as wood, cotton, rubber, synthetics, etc., are Class A fires. These fires normally are extinguished by water or foam and pose no special problem, except that they might be hidden and inaccessible to the fire fighter and, therefore, can constitute a constant reignition point for the flammable vapors.*

NOTE: Special attention should be given to radioactive substances carried in cargos under restricted conditions. See NFPA 402M, *Manual for Aircraft Rescue and Fire Fighting Operations,* Appendix C.

5. Other Combustibles Not Part of Aircraft: *Yes/No.*

Comments: Trees, grass, brush, vehicles, structures, etc.: *Describe the role of other combustibles as the original ignition source, the original combustible involved, or in terms of their effect on fire control.*

6. Oxygen Involvement: *Yes/No.*

7. Hazardous Materials/Dangerous Goods: *Yes/No.*

Comments: *Include any hazardous materials carried on the aircraft and their effect on the fire. Etiological factors should be covered in Part II.*

C. IGNITION SOURCE

1. General Location of Probable Original Ignition Source: *Ignition factors can be divided into four basic groups, as follows:*

a. Impact — frictional sparks, striking power lines, etc.: *The source of original ignition quite frequently is other than the aircraft itself. Ignition can result from a friction spark that occurs on impact or possibly from power lines or the landing area lighting system. When conducting investigations, a serious effort should be made to determine the cause of ignition. Each aircraft accident exhibits evidence of several ignition sources and usually more than one fire factor. The sources and factors of greatest concern are those that cause sustained fire progression. A close examination of the ground that runs from the aircraft back along the skid path, and even beyond the point of initial ground contact, is necessary to determine the point at which ignition occurred. This also helps determine whether fire was present prior to actual* *touchdown. Discoloration or charred material found in this area should be examined closely to attempt to determine the type of material burned and its possible location relative to the construction of the aircraft. Such material might consist of cabin furnishings, gear components, engine components, etc. Unlike structural buildings, where fire loads are somewhat static, the original ignition source in aircraft fires is not found necessarily in the areas where the most severe burning occurs. Information included in the report should describe the point of sustained ignition in relation to its position on or in the aircraft.*

b. Power plants: *In aircraft accidents where impact forces are extremely excessive, the aircraft power plants generally provide the initial ignition of aircraft fuel loads. For this reason, every attempt should be made to determine the damage to, as well as any movement of, the engines during and after initial impact. Ignition generally takes place when engines become torn loose, severing fuel and electrical power lines. This is especially true of the turbine engine, as it remains extremely hot internally and continues to rotate for a period of time after impact.*

c. Aircraft electrical circuits: *The next most common fire ignition results when electrical lines are severed in a fuel vapor atmosphere. Every effort should be made to examine broken wires and circuit breaker panels to discover possible causes of ignition, keeping in mind that there should be a source of flammable vapor or exposed combustibles in the area of the arcs, sparks, or heat if a fire was caused by such an ignition source. Examination of aircraft batteries also should be included in this investigation.*

d. Electrostatic sparks: *These often can be the cause of the original ignition source, since the aircraft itself, or portions of the aircraft that become separated during impact, builds up an electrostatic charge while moving through the air and might discharge this residual energy upon contact with the ground.*

e. Other sources of ignition not covered previously:

2. Progress of the Fire:

a. Describe the progress of fire from ignition through extinguishment: *Once the point of sustained ignition is determined, a close examination of the burn pattern, together with a study of the aircraft construction, should provide a fairly clear picture of how the fire propagated prior to fire extinguishment action. In many cases, the fire fighting efforts themselves cause fire extension in unusual patterns. These patterns generally can be distinguished from normal fire progression by the presence of extinguishing agent residue in the burn deposit. Note that normal fire behavior causes upward extension of the fire more rapidly than it causes lateral extension. Most materials, when burned or heated, become subject to air currents, and a close examination of the burn area provides an indication of fire travel by the manner in which the charred material is curved. At this point in the investigation, it is especially helpful to have an understanding of the temperature at which different metals melt or support combustion. It also is important to understand that fire can progress by radiation, convection, and conduction. Due to the aircraft construction, fire progression usually occurs by all three of the above methods. The most accurate account of fire progression usually can be obtained from eyewitnesses; however, during questioning, it is important to remember that each witness is likely to provide a different version of any given circumstance. No assumptions should be made until statements from several eyewitnesses have been received. Reported information then should be based on those facts most strongly supported by all of the accounts. When filling out the report form, chart the fire progression as closely as possible from the time of initial touchdown or sustained ignition. The progression should be recorded in minutes and seconds. This provides a more complete* *accounting of the fire progression. Also, attempt to determine any unusual problems encountered during fire extinguishment operations.*

b. Describe path and speed of flame spread; also the effect of structural breakup on flame spread; effect of open exits on flame spread; identify who opened exits and when they were opened: *These items are somewhat self-explanatory, and the answers can be obtained during the normal course of the investigation. Interrogation of survivors and eyewitnesses is the most reliable source of this information, but care should be taken in evaluating this information from individuals who are closely involved. Where possible, the most satisfactory method of determining time factors for specific conditions is to have persons furnishing factual information recreate their actions, as most people lose the awareness of time during emergency situations. If possible, survivors should recreate their actions during the accident while inside an aircraft of identical type and configuration. In reporting on this phase of the investigation, it is best to furnish a sketch of the aircraft and identify exits and other points of reference by use of a numbering system or other suitable means.*

c. Describe extent and length of time of fuselage survivability after impact: *This factor is subject to many variables, such as toxic gases, extent of carbon monoxide contamination, percentage of oxygen in the cabin, and temperature gradients. A complete laboratory analysis should be done on burn tests of the cabin interior materials to determine the toxicity of fumes. It is especially helpful to furnish a diagram of the cabin configuration showing those seats occupied at the time of impact. The diagram also should show the location of any fatalities and indicate those found in their original seat location. The survivors and flight attendants are the best source of this information, and an attempt should be made to determine how much time elapsed after impact before the last known survivor evacuated the aircraft. Investigation of fire origin and progression through the cabin also are very helpful in determining this time lapse. Examination of the items that follow will be beneficial in determining the above factors.*

(1) Inspection of metal parts: *A close investigation of metal parts involved in the fire area provides information on the severity and temperature of the fire. A basic knowledge of melting temperatures of various metals is necessary to establish temperatures. Since most aircraft metals are lightweight, they become subject to air currents when they are heated or reach the fluid state.*

(2) Fuel odors: *During the investigation, check all areas of the aircraft for residual fuel odors to determine the extent of fuel spread. This is especially important in the baggage and cabin areas. Regardless of the extent of burnout, if fuel was present, the charred remains will have produced some trace of fuel odor.*

(3) Pressurized containers: *Many types of pressurized containers can be found in the personal effects aboard the aircraft as well as in the ordinary furnishings in the cabin area. Where pressure has been released during fire, unusual burn patterns can be detected. These provide an indication of free-burn areas as well as excessive temperatures that can cause exterior venting.*

(4) Oxygen systems: *Both fixed systems and walk-around oxygen bottles contribute greatly to cabin burnout. These systems should be located and identified before a full appraisal of the fire behavior is reported.*

(5) Smoke deposits: *During the investigation, various types of smoke and ash deposits* *will be encountered. Any unusual deposits of these materials should be inspected carefully and analyzed to determine the type of material that caused the burn. Foreign material deposits in these areas also should be noted.*

D. AIRCRAFT SAFETY SYSTEMS

1. Did aircraft have any fixed fire extinguishing systems? *All transport category aircraft, as well as some light twin aircraft, have such systems. Most single-engine types do not.*

2. What type of system?

3. Specify extinguishing agent employed: *Most modern aircraft are equipped with bromotrifluoromethane (halon 1301) systems, which discharge by remote control from the cockpit into the fire zone of each engine by selection. Some aircraft also discharge agent into baggage bins, but most do not. Other agents that might be used are carbon dioxide (CO_2), chlorobromomethane (CB or CBM), or bromochlorodifluoromethane (halon 1211-BCF). The investigator should obtain all necessary details of the system installed from the fire extinguishing equipment manufacturer.*

4. Was it used? What effect did it have on fire? *If possible, determine sequence of events and the answers to these questions from conversation with crew. Sequence should include the time from fire alarm or detection to discharge of agent and the effect of agent on fire. Was entire quantity of airborne agent used on fire? If fire continued, indicate time from discharge to landing or impact. Describe airborne progression of fire. If crew is not available, determine from examination of aircraft or remains the position of the fire discharge controls, whether or not extinguishing agent cylinders are empty, etc.*

5. Were aircraft hand-operable fire extinguishers available? Were they used?

6. State effectiveness: *These questions apply only to fire originating in a cabin or in accessible baggage bins.*

7. Did the aircraft have fire alarm and detection equipment installed?

8. What type? Did it operate?

9. Other information: *Any other information pertinent to the aircraft fire detection and extinguishing system.*

E. EMERGENCY NOTIFICATION

1. How long after the accident occurred was it discovered? *If there was uncontrolled ground fire, the investigator's job is made more difficult by destruction of possible evidence and the obscuration and masking of existing evidence. If exact time is not available, a close approximation later in the investigation helps significantly in determining burn times and effect on the evidence.*

2. Who discovered the accident? *The time lapse between the occurrence of an accident and its discovery is a factor of some importance to the investigating team. Many aircraft accidents are discovered after it is too late. The reasons vary: weather conditions, aircraft out of fuel, isolated areas, and loss of communication with the aircraft. The discovery of an accident by other aircraft notification or by survivors ultimately can be of great value to the investigator.*

3. Who dispatched the fire alarm? *Agency that ordered ARFF equipment to respond.*

4. How was the fire alarm transmitted? *Box, telephone, radio, observed, other (specify). It is important for the investigator to find out from reliable sources who initiated the alarm and how it was transmitted. Many airports have a mutual aid agreement with local fire authorities whereby alarms are transmitted by a "hot line" connected directly to the fire department alarm station for use in the event that outside help is needed by the airport crash and rescue crew.*

5. Was location of accident accurately described? *If not, indicate the reason and describe the effect of any related delay in fire and rescue service. The investigator should be informed of the accuracy or inaccuracy of the original description of the accident location. In cases where an inaccurate location has been provided, valuable response time has been lost. It is then necessary to investigate the reason for the delay in the response.*

6. Consequences of erroneous response information:

7. What were the fire and evacuation conditions at the time of arrival of the rescue and fire fighting equipment? *The fire and evacuation conditions at the time of the arrival of the rescue units are highly significant in the final analysis of the accident. These conditions can indicate the extent of fire, complete engulfment by fire, presence of interior or exterior fires, type of odors, smoke, and evacuation status of passengers. Were passengers evacuating, not evacuating, or was evacuation complete on arrival of rescue equipment?*

8. Time factors: *Time factors should be determined as precisely as possible from the records, flight crew, fire department, air traffic control tower, and Air Traffic Control (ATC), etc. After analysis, the investigator should be able to determine the effectiveness of each phase of the operation. Include response time of ARFF vehicles, from alarm to arrival at the scene, and number of vehicles with VHF communications. Also include response interference factors (e.g. weather, traffic, terrain) and those that affected the response time of the ARFF vehicles such as: weather, distance from fire house, terrain, and access roads.*

9. Remarks: *Include all conclusions drawn by the data collector after analysis of the detection and alarm system used and the time factors involved. If any time factors seem implausible, the data collector should request a simulation or rerun.*

F. AIRCRAFT RESCUE AND FIRE FIGHTING (ARFF) SERVICES

1. Vehicles and Manpower Table. *This table should be filled out carefully by the investigator working in coordination with the fire department. It provides information on the effectiveness of particular vehicles and the physical details of the operation and is useful not only in assessing effectiveness for the particular fire but serves as documented experience for study by all RFF services. Make certain to note condition of each vehicle in the "Remarks" section. Note any injuries to RFF personnel during this operation as well as details of the use of any airport-based medical vehicles. The quantities provided in tables should be expressed in national units of measure of state involved.*

2. Fire Extinguishing Agents Used and Techniques Employed: *This table should be filled out carefully by the investigator working in coordination with the fire department. This table is used to assess the overall effectiveness of the fire department by determining quantities of agents used, discharge rates and time, and order of agent use. In the "Remarks" section, note any effect* *agents have had on one another. Note specifications and type of agents used and the quality of agent produced. Fire fighters on duty during the operation should be questioned regarding any deleterious effects on the foam blanket due to any other agents used. The quantities provided in tables should be expressed in national units of measure of state involved.*

a. *In the past, agent quantities were determined from fire ground tests and previous experience, since detailed accident data was unavailable.*
In order to justify the agent quantity formula, $Q = Q_1 + Q_2 + Q_3$, *it is essential that the following data be available:*

Q_1 *- water quantity for control of the fire*

Q_2 *- water quantity used for extinguishment*

Q_3 *- water used by handlines, water used for maintenance (overhaul) operations.*

3. Fire Fighting Operations: *Describe conduct of fire fighting operations after arrival of equipment. After questioning the fire department, reconstruct the operational details in chronological order. Briefly describe the extent of the blaze, effect of the fire fighting operation, start of evacuation, and completion of rescue and control of the fire situation. If the fire attack was interrupted by a lack of replenishment water, note the reason for the delay. Include a description of problems encountered and lessons learned.*

a. Training: It is important to ensure adequate and proper training by maintaining records on the type and frequency of training and the most recent training evolution employing hot drills, cabin interior drills, and aircraft pre-fire planning. Lack of sufficient training is a significant factor in the improper use of existing ARFF equipment.

b. Clothing: The type of protective clothing utilized for fire suppression is significant, since NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, mandates a minimum level of personal protective equipment for ARFF.

c. Self-Contained Breathing Apparatus (SCBA): Recording the use of SCBA and the type utilized establishes statistics that define the levels of personal protective equipment used to suppress ARFF fires.

4. Grid Map of Accident: *Sketch the details suggested in the fire report on a separate sheet of paper. When satisfied that all details are included, transfer the sketch to the grid map. In the explanatory remarks, explain all details of the diagram that are necessary.*

G. HUMAN FACTORS. *It is vitally important when analyzing an aircraft accident involving fire to obtain as much information as possible on the occupants of the aircraft. Improved aircraft structures and rescue techniques can result. Therefore, as many details as possible should be obtained by investigators. The coordinated effort of the entire investigation team should be used in this area.*

1. Personnel Table: *After consultation with those who participated in the rescue of personnel, the investigator should fill out this table carefully. If possible, a seating arrangement showing the location of passengers and crew prior to the accident (including gender and whether child or adult) should be obtained.*

2. Number of Casualties: *The investigator should create a seating arrangement chart indicating the status of passengers and crew during and after the accident, e.g., injury, burns,* *fatality, (provide cause, e.g., burns, asphyxiation, impact), escaped unaided, rescued by fire and rescue personnel.*

3. Describe Evacuation, Number of Rescue Personnel, Exits Used, Break-in Areas Used: *Extensive questioning of flight crew and passengers should help the investigator in this description. Include the extent of briefing and preplanning, if known.*

a. *Had occupants begun evacuation or were they waiting to be rescued?*
b. *Had flight crew been able to complete emergency shutdown drills?*
c. *Were passengers or crew able to operate escape hatches satisfactorily?*
d. *Was sufficient marking and lighting available to facilitate evacuation?*
e. *Describe in detail any difficulties encountered in evacuation.*

4. Time Required to Accomplish Rescue and Removal of Occupants:

a. *Did occupants respond to orders from rescue crews?*
b. *Which emergency exits were used during evacuation? Did they function properly, or were they damaged by impact or fire?*
c. *Were aircraft crew able to assist in the rescue? If so, to what extent?*
d. *How many persons used each means of egress?*

5. Time Required to Control Fire? Time Required to Extinguish Fire? *Describe in detail if passenger and crew evacuation delayed extinguishing of fire. Smoldering and small spot fires not affecting rescue should not be included in this time factor.*

Copies of each report should be sent to the appropriate government authorities involved in the investigation.

When released by these authorities, reports should be sent to the following organizations:

International Civil Aviation Organization
1000 Sherbrooke Street, W
Montreal, PQ, Canada H3A 2R2

Fire Analysis Department
National Fire Protection Association
1 Batterymarch Park
P.O. Box 9101
Quincy, MA 02269-9101 U.S.A.

Other concerned qualified authorities such as the U.S. Air Force, U.S. Navy, U.S. Flight Safety Foundation, etc.

(4) Oxygen systems ____________________

(5) Smoke deposits ____________________

D. AIRCRAFT SAFETY SYSTEMS

1. Did the aircraft have any fixed fire extinguishing systems? ____________________

2. What type of system? ____________________

3. Specify extinguishing agent employed ____________________

4. Was it used? ____________________ **What effect did it have on the cabin, lavatory, cargo, or engine fire?** ____________________

____

5. Were aircraft hand-operable fire extinguishers available? Were they used? ____________________

6. State effectiveness ____________________

7. Did the aircraft have fire alarm and detection equipment installed? ____________________

8. Which type? ____________________

Did they operate? ____________________

9. Other information ____________________

E. EMERGENCY NOTIFICATION

1. How long after the accident occurred was it discovered? ____________________

2. Who discovered it? ____________________

3. Who dispatched the fire alarm? ____________________

4. How was the fire alarm transmitted? ____________________

Box ________ Telephone ________ Radio ________ Observed ________ Other __

5. Was the location of the accident accurately described? ____________________

6. If not, indicate the reason and describe the effect of any related delay in the response of the ARFF. ____________________

7. What were the fire and evacuation conditions at the time of arrival of the ARFF?

____

8. Time Factors

a. If emergency preannounced, from announcement to touchdown (impact), ____________ minutes

b. If emergency not preannounced, from accident/incident to alert of the ARFF services, minutes

c. From alert to the arrival of the major vehicles, ____________ minutes

d. From arrival of the ARFF to fire under control, ____________ minutes

e. From arrival of the ARFF to rescue operations commencing, ____________ minutes

f. From arrival of the ARFF to rescue operations terminated, ____________ minutes

g. From arrival of the ARFF to extinguishment of the fire, ____________ minutes

h. From extinguishment of fire to return to service, ____________ minutes

i. List any factors that affected the response time of the ARFF ____________

____

9. Remarks ____________________

5. Time Required to Control the Fire, ______________ minutes

6. Time Required to Extinguish the Fire, ______________ minutes

PART II

INSTRUCTIONS FOR COMPLETING THE NFPA DISASTER RESPONSE REPORT

PURPOSE

The purpose of Part II is to provide the information associated with an accident that can be used to update and refine disaster plans for other airports and communities involved in aviation operations. It also is used to provide data for the revision of NFPA 424M, *Manual for Airport/Community Emergency Planning*. Both the positive and negative consequences of the operation should be emphasized with the objective of improving safety to life in future accidents.

1. Data Collection

The information needed to complete this report can be obtained from the FAA, airline owner, or aircraft owner or their representatives and from representatives of the responding services.

2. Disaster Plan

A copy of the plan should be obtained. This provides the investigator with access to the telephone contacts necessary for obtaining details on the effectiveness of the response and a critique of the most recent exercise.

3. How Was the Alarm Received?

4. Response Times

Response times have a direct bearing on the entire rescue operation. They usually are reported to the Chair of the NTSB Human Factors Group during interviews with the responding agencies. Response times often are recorded on tapes maintained by the airport tower, fire departments, and emergency services. Where recorded times are not available, more than one source should be used for verification.

5. Responding Agencies

5.1 Mutual Aid Fire Services

The number of vehicles used for response and their function during the rescue operation are vital pieces of information that can affect future operations. Vehicle type should be recorded and identified as pumper, ladder, hose layer, etc. The arrival time of each vehicle and its effectiveness to the operation also should be recorded. Were the vehicles used to fight the fire or to replenish the ARFF vehicles? Were they used to maintain airport protection while the ARFF vehicles were fighting the fire? Were personnel used to extricate the victims? Only mutual aid off-airport vehicles should be included. DO NOT include airport ARFF crash trucks.

5.2 Helicopters

Include any helicopters that participated in the location or evacuation of survivors. Also include helicopters for news reporting that did not participate in the evacuation but aided traffic control.

5.3 Civil Defense

Include the vehicles responding and their part in the operation. Did they provide radio communications with other responders? What was their relationship to the command post?

5.4 Military

Include any military assistance provided at the scene, such as hazardous material control, helicopter response, etc. Provide the names of those units that assisted.

5.5 Police

Include local police responsible for maintaining ready access for emergency vehicles and crowd control.

5.6 Sheriff/State Patrol

Include any local security services that were involved. Was their participation effective, or did they interfere with the operation?

5.7 Airline/Airport Personnel

The first responders to an accident often are airport personnel who are working at the time of the accident. They provide help in any way they are able, from extrication of victims to personal care of the survivors. Include the number of responders, their affiliation, and the function they performed during the accident response.

5.8 Ambulance Services

It is often difficult to verify the identity of the first ambulance service to arrive at the scene, the number of survivors that service transported, and the medical facility to which survivors were taken. This section should include the names of the responding ambulance services, their approximate response times, and the number of patients whom they transported. Information on whether or not the ambulances were used also should be recorded.

5.9 Other Responders

Other responders should include the Red Cross, clergy, coroner, postal authorities, customs and immigration officials, and any additional participants not previously identified.

6. Rescue Operation

6.1 Mobile Command Post

Identify the operator of the command post and describe the type of vehicle. Was the vehicle self-propelled? Was it equipped with full emergency communication equipment? Is the vehicle owned by the airport authority, fire department, civil defense, or police? Approximately how long after the accident was the command post ready to assume control of the operation?

6.2 There usually is a change of on-scene commander during the course of operation. The first fire chief to arrive at the scene usually assumes command until replaced by the command post. Both persons should be identified.

6.3 Describe the type of command post (e.g., van, converted bus, trailer). How was it equipped (e.g., radio, VCR, mobile telephones)?

6.4 Was the command post easily recognizable while all responding vehicles were on the scene? How was it recognized?

6.5 Describe any problems encountered with communication procedures. These should include frequency congestion, incorrect frequencies, etc.

6.6 If an emergency operations center was used, describe its location and the effectiveness of its operation.

7. Triage

7.1 The triage operation may be permitted to be initiated by the airport EMTs, fire fighters, or the first responding medical unit.

7.2 The full triage operation usually is conducted by the medical authority identified in the disaster plan and usually is the medical facility located nearest the accident scene.

7.3 The location of the triage operation is of major importance. Its location relative to the accident, wind direction, and ambulance routing should be noted. How was the triage site marked?

7.4 Were emergency medical supplies available at the site? Where were they located, and how were they transported to the scene?

7.5 What were the terrain conditions at the site (e.g., swamp, trees, hills, level ground, etc.)? Did they affect efforts to set up the triage operation or the movement of the ambulances?

7.6 Were the ambulance movements controlled or did blockages result?

7.7 Note the approximate arrival times of doctors, nurses, and EMTs in relation to the time of the accident.

7.8 Note any reported obstacle to the triage operation, such as hypothermia, heat, and rain. Note the weather conditions at the time of the accident, such as temperature, precipitation, and visibility.

7.9 How were the victims tagged?

8. Medical Services

8.1 Identify the hospitals used during the emergency, the types of hospitals, such as eye, burn, trauma, etc., their distance from the accident site, and the number of casualties taken to each.

8.2 Were those who were injured but ambulatory taken to hospitals or first aid stations? Who cared for them before their release?

8.3 What provisions were made for the uninjured? Were they transported from the site? Where where they held? Were they separated from the news media? Were they provided with food and drink?

8.4 What provisions were made for the fatalities? Were there enough body bags? Where was the morgue set up? Was it set up using refrigerated trucks or other means?

8.5 Self-explanatory.

9. Police Security

9.1 At major airports, airport police are responsible for any airport emergency. They might, however, be a part of the city or county police. In the case of off-airport accidents, the security of the scene is under the control of the local authority.

9.2 The increase in airport security has resulted in several cases where the response of the emergency services was delayed by locked gates or restricted areas. Such interference with emergency response should be documented fully.

9.3 Were the emergency services delayed by highway traffic conditions?

9.4 Was the news media access controlled, or did they reach the site without authorization?

9.5 How was the general public restrained from access to the accident site?

9.6 For accidents that occurred on the airport premises, was an escort provided for mutual aid responders? Who provided the escort?

9.7 How long after the accident was the crash site secured? How was it secured (e.g., ropes, barriers, police protection)?

9.8 How were the mutual aid responders informed of the stage areas? Were they effective?

10. General

10.1 Which types of shoring materials, such as railway ties, were available to aid in extraction of the victims? Was heavy machinery, such as cranes or bulldozers, necessary for the operation?

10.2 If there were any problems with hazardous materials at the accident site, record the type of material and how it was handled.

10.3 Were all responders easily identified? How (e.g., baseball hats, armbands, vests, uniforms)?

11. Water Accidents

11.1 Many recent accidents have occurred in the water adjacent to the airport property.

Identify all responding water rescue agencies, such as Coast Guard or police, and also record any water rescue equipment maintained by the airport authorities.

11.2 Some aircraft carry only floatable seat cushions. Others carry only life vests, while still others carry full overwater equipment, including rafts and life vests.

11.3 Was any additional flotation equipment transported to the scene? How was it used?

11.4 Record the water and weather conditions at the time. Both air and water temperatures should be recorded. Was visibility restricted by fog or darkness?

11.5 Describe any problems locating aircraft.

11.6 Underwater search and recovery

11.7 Any resuscitation of victims of hypothermia due to near-drowning in cold water?

Chapter 3 Referenced Publications

3-1

The following documents or portions thereof are referenced within this guide and should be considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

3-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 407, *Standard for Aircraft Fuel Servicing*, 1990 edition.

NFPA 424M, *Manual for Airport/Community Emergency Planning*, 1991 edition.

NFPA 1001, *Standard for Fire Fighter Professional Qualifications*, 1992 edition.

NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*, 1994 edition.

NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, 1992 edition.

NFPA 1971, *Standard on Protective Clothing for Structural Fire Fighting*, 1991 edition.

NFPA 1976, *Standard on Protective Clothing for Proximity Fire Fighting*, 1992 edition.

Appendix A Explanatory Material

This appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

A-1-2 State and International Documentation.

The purpose of preparing these reports is NOT to investigate the cause of this accident, but is to provide data that can be used to prevent injury and loss of life in future accidents.

Appendix B

This appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

The following information may be of use to persons investigating the fire.

B-1 Fire.

B-2

In most cases where there is evidence that a specific temperature has been attained, a time-temperature relationship exists, so that it is not always possible to determine a precise temperature. A temperature of 1,500°F (816°C) sustained for a few minutes can create the effect of fire that has burned at a lower temperature for a longer duration. There are sometimes specific points at which a temperature change occurs, in which case temperature ranges can be defined more closely. Laboratory analysis sometimes is needed, but investigators usually can trace or plot a fire pattern to a source point by studying the relative temperatures and the position of the burned or overheated area.

B-3

Fire resistance is not a property of a particular material but is a characteristic of a particular system comprising material, oxidant, ignition source, and environmental conditions. For example, ordinary steel at room air temperature is not ignitible with an ordinary match — unless the steel is in the form of loosely packed steel wool. Such a distinction in the form of a material often is overlooked when interpreting fire data.

B-4

Most aluminum sheet and forging ingots used for aircraft components are from the 2000 and 7000 series. The 2000 series is an alloy that uses copper as the major alloy material (approximately 4 to 5 percent); the 7000 series uses zinc as its major alloy (approximately 5 to 6 percent). All alloys are approximately 95 percent aluminum, and most include very small percentages (in terms of chemical content) of other metals, such as titanium, silicon, manganese, magnesium, etc. The melting point of the sheet used generally is around 1,180°F (639°C), but a few alloys can melt at temperatures as low as 980°F to 1,000°F (527°C to 538°C). Very few forgings or castings melt at temperatures as low as 950°F (510°C). The letters used with aluminum series numbers designate temper and strain hardening. For example, 7075-T-6 contains 5.1 to 6.1 percent zinc plus small amounts of eight other elements, is solution heat-treated, and is artificially aged.

B-5

Certain types of heat treatment and strain hardening often change the basic characteristics of metal (e.g., from ductile to brittle), and these changes can cause alterations in appearance. Plating also tends to change characteristics.

B-6

When aluminum alloys are heated to the melting range, they wrinkle and pull apart, leaving bright cracks and fissures. If heated sufficiently to form droplets, they appear as little wrinkled bags. By comparison, iron alloys tend to burn when heated to the red range, forming oxides at the edges and in thin sections.

B-7

Fire damage to metal is manifested mainly in loss of strength. For example, 7075-T-6 alloy loses 10 percent of its strength when heated for 30 minutes at 400°F (204°C); 10 minutes at 450°F (232°C); 3 minutes at 550°F (288°C); or 2 minutes at 600°F (316°C). Hardness tests can be used to determine the amount of temperature exposure, but an estimate of the length of exposure is necessary to determine the maximum temperature.

B-8

Titanium changes color from tan to light blue to dark blue to grey as the temperature increases. It reacts strongly to gases when heated, and a scale begins to form at approximately 1,100°F (593°C). This scale increases in thickness with time and turns bluish in color. At approximately 1,200°F to 1,500°F (649°C to 816°C), a grey or yellowish shade appears. At approximately 1,300°F (704°C), an appreciable oxide scale forms, which flakes off. At approximately 1,620°F (882°C), titanium undergoes an allotropic transformation (from alpha type to beta type), and the oxidation rate increases significantly. Titanium fires in turbine engines have been a cause of concern for some time; they start quickly, are difficult to detect, and are nearly impossible to extinguish. They can occur in the total absence of hydrocarbon or other fuel sources, a fact that, in itself, is evidence of a titanium fire. The mechanism of titanium (Ti) fires is complex. The scenario for a fire caused by titanium rotor blades might involve the following sequence:

(a) A Ti rotor blade can rub against the engine case and, because of the low thermal conductivity of Ti, the temperature of the blade can increase rapidly;

(b) Ti melts at about 3,100°F (1704°C);

NOTE: Steel melts at about 2,700°F (1482°C).

(c) Molten Ti absorbs O_2 to form TiO_2, which boils, burns, and stabilizes at approximately 5,600°F (3093°C);

(d) The TiO_2 continues to form and burn as long as there is an air supply. Molten Ti at very high temperatures melts through steel engine cases rapidly. (For this reason, engine design should avoid routing fuel and oil lines in the lower sector of the engine.)

B-9

Stainless steel changes color from tan to light blue to bright blue to black starting at 800°F to 900°F (427°C to 482°C). When examining stainless steel after heating, the investigator should check both sides; the lighter blue side is the side that was positioned opposite the heat source, and the heated area will be smaller in circumference.

B-10

Zinc chromate paint primers start to tan at 450°F (232°C) and turn brown at 500°F (260°C), dark brown at 600°F (316°C), and black at 700°F (371°C). Cadmium plating begins to discolor at 500°F (260°C). Glass cloth fuses at 1,200°F (649°C). Silicone rubber blisters at 700°F (371°C). Neoprene rubber blisters at 500°F (260°C). Wire insulation is a good guide for determining lower temperature ranges if the material is known [e.g., nylon spaghetti melts at 250°F to 350°F (121°C to 177°C).]

B-11

Aircraft paints soften at 400°F (204°C), discolor at 600°F (316°C), blister at 800°F to 850°F (427°C to 454°C), and burn off completely at 900°F to 950°F (482°C to 510°C). Cutting through the paint with a sharp knife discloses the depth of overheating. Severe scorching blackens the surface without further darkening it. It is unusual to find metal beneath paint damaged if the paint is not burned through completely. It is possible to char primer beneath heat-resisting aluminum paint without apparent “surface” burning.

B-12 Temperature Limits of Selected Materials.

B-12.1

The investigator should note carefully those materials that ignited, those that melted, and those that were damaged by heat.

B-12.2

Tables B-12.2(a) and B-12.2(b) provide a list of materials and their autoignition temperatures and a list of materials and those temperature limits that damage or distort them. The materials selected usually are found in private or commercial transport aircraft.

Table B-12.2(a) Autoignition Temperature of Selected Materials

	°F	°C
Canvas	204	96
Denatured alcohol	750	399
Hydraulic hose (Buna-N-Rubber)	950	510
Leather	850	454
Nylon-covered wire	1000	538
Glass matts	950	510
Lubricating oil (MIL-1-7808)	790	421
Plywood	900	482
Rubber-covered wire	900	482

Vinyl-covered wire	900	482
Rubber-asbestos material	900	482
Styrene	914	490
Teflon	1050	566

Table B-12.2(b) Temperature Limits for Selected Materials

	°F	°C
Glaze or electrical porcelain	2250	1232
Enamel flakes	1200-1400	649-760
Glass softens	1400-1600	760-871
Paraffin wax melts	129	54
Zinc melts	786	419
Silver solders melt	1165-1450	629-789
Silicone rubber (considerable softening at sustained service)	425	218
Cellulose (filled melamine, heat distortion)	400	204
Nylon (polyamide), heat distortion	300-360	149-182
Melamine-formaldehyde (filled), heat distortion	266-400	130-204
Paper phenolic, delamination and distortion	250	121
Styrene elastomer, distortion at sustained service	220	104
Polystyrene, distortion	210	99
Methyl methacrylate, heat distortion	210	99
Plastic vinyl chloride, heat distortion	185	85

B-12.3

Table B-12.3 provides melting points for metals and alloys used in current aircraft. It is essential that the investigator be familiar with various aircraft metals and alloys and well-informed regarding their purpose and their location in the aircraft.

Table B-12.3 Melting Points of Some Aircraft Metals and Alloys

	°F	°C
Aluminum alloys	1220-1250	660-677
Brass bearings	1600-2000	871-1093
Cadmium	609	321
Chromium	3430	1889
Copper	1981-2000	1083-1093
Iron	2802	1539
Lead	621	327
Magnesium alloys	1202-1250	650-677
Manganese	2273	1243
Mercury	39.9	39.9
Molybdenum	4760	2627
Nickel	2651	1455
Selenium	428	220
Silicon	2605	1429
Silver	1760	960
Stainless steel	2700	1482
Tin	449	232
Titanium	3100	1704
Tungsten	6170	3410
Vanadium	3150	1732

B-13

If electrical wire breaks when no current is flowing, the break will be clean and will display a typical cup-and-cone fracture with necking down. If current is flowing, it arcs when the wire breaks, causing little balls of oxidized metal to form on the tips of the wire strands. A fire external to the wiring bundle burns the outside first, and the conductor inside will remain clean and bright, except where the insulation has burned through. Wires burned due to excess current burn from the inside out, and the conductor will be dark and oxidized, perhaps without damage to the outer cover. The tin coating on copper wire will diffuse into the copper at temperatures above its melting point of 449°F (232°C) and become rough or even disappear. On-scene examination should be only for general observation and possible conclusions. Detailed laboratory examination should be performed to confirm the mechanism of the wire faults and failures. Additionally, chemical analysis of wire breaks can reveal the presence of combustibles during the failure.

B-14

Examination of any surviving light bulbs helps in determining if electrical power was on in a particular system at the time of impact. The filaments of small bulbs will indicate if the bulb was illuminated at impact, when the bulb was shock-loaded. If the filament was hot at impact, it will stretch and distort substantially; if the filament was cold at impact, it will break but will not distort or stretch from its original shape and pattern. If the glass shattered and the filament was exposed, it will provide the information but will oxidize and discolor quickly. This entire procedure is valuable in determining the system operational status at impact, provided failure lights and warning light bulbs survive any subsequent fire in this area. (*See ICAO DOC 6920-AN/855/4, Manual of Aircraft Accident Investigation, Part III, 7.3, "Electrical Systems," for further information on fire origin*.)

B-15

All hydrocarbon fuels used in aircraft leave a similar soot residue (except when instantaneous combustion or explosion occurs, in which case no sooting is left) so that tests might not be successful in identifying or differentiating between these and various other hydrocarbon liquids that are found about aircraft. Cleaning fluids, oils, etc., can leave similar residues. Soot does not deposit or adhere to surfaces that are above 700°F (371°C).

B-16 Flammability Characteristics of Aviation Fuels.

B-16.1

There are three basic types of aviation fuels: aviation gasoline (AVGAS), the kerosene grades (JET A, JET A-1, JP-5, JP-6), and the blends of gasoline and kerosene (JET B, JP-4). The flammability characteristics of these fuels are provided in Table B-16.4, but a brief comparison is included to focus attention on their differences.

B-16.2

In order to burn, all petroleum fuels need to be vaporized and mixed with air in specified proportions. AVGAS has a strong tendency to vaporize and, as a result, the air over the surface of the liquid always is mixed with a considerable quantity of vapor. In a closed tank, so much fuel vapor is given off by AVGAS that the fuel-air mixture can be too rich to burn. When any fuel is in contact with air, it continues to evaporate until the air is saturated.

B-16.3

Kerosene grade fuel ordinarily has a low tendency to vaporize, and, in a closed tank, the fuel vapor and air mixture can be too lean to burn. However, kerosene grade fuels can be ignited by heating them above their flash point. It also is possible to ignite such fuels without heating the bulk of the fuel to flash point. This can be achieved by wicking the fuel on an absorbent material that can be heated locally (hot spot) until the fuel ignites. The hot spot on the wick furnishes sufficient vapor to sustain the flame. Such conditions can occur accidentally during crash and post-crash conditions.

B-16.4

Fuels that contain a blend of AVGAS and kerosene retain most of the worst fire characteristics of both fuels. (*See Table B-16.4*.) The vapor mixture in a closed tank normally is neither too rich nor too lean. Flammability limits include a wide temperature range, autoignition temperature is low, and flame spread is almost as fast as when using AVGAS.

Table B-16.4 Flammability Characteristics of Aviation Fuels†

	Gasoline	Kerosene Grades	Blends of Gaso
Characteristics	**AVGAS**	**JET A, JP-5, JP-6 / JET A-1**	**JET B**
Freeze Point	–76°F	–40°F / –58°F	–
Vapor Pressure (ASTM D323)	5.5 to 7.0 lb/sq in.	0.1 lb/sq in.	2.0 to 3
Flash Point (by closed-cup method at sea level)	–50°F	+95°F to +145°F	–10°F
Flash Point (by air saturation method)	–75°F to –85°F	None	–
Flammability Limits			
Lower Limit	1.4%	0.6%	0
Upper Limit	7.6%	4.9%	5
Temp. Range for Flammable Mixtures	–40°F to +30°F	+95°F to +165°F	–10°F
Autoignition Temperature	–825°F to +960°F	+440°F to +475°F	+470°F
Boiling Points			
Initial	110°F	325°F	1
End	325°F	450°F	4
Pool Rate of Flame Spread*	700 ft-800 ft per min	100 ft per min or less	700 ft-80

For SI Units: 1°C = $^5/_9$ (°F - 32); 1 psi = 6.895 kPa; 1 ft = 0.3048 m.
† For further information, see NFPA 407, *Standard for Aircraft Fuel Servicing.*
* In mist form, rate of flame spread in all fuels is very rapid.

B-17

When heated, some hydraulic fluids vaporize into a white mist that is acrid and causes choking. When burned, the residue is first dark-colored and viscous; then it changes to a dark-charred material, and a white, fluffy deposit appears after prolonged heat. When burned, hydraulic fluids produce a yellowish flame with white smoke. If Skydrol® (a trade name hydraulic fluid commonly used in current aircraft) is heated and a piece of aluminum is placed in it, an acetylene-type odor is evident. Skydrol 500 has a flash point of approximately 440°F (227°C), and autoignition occurs at approximately 925°F (496°C). In mist form, it can ignite at room temperature.

B-18

The aging of fluids (such as oil and hydraulic fluid) is caused by an increase in their acidity over time. This acidity tends to lower the flash point, but the problem is considered negligible, since a complete fluid change by volume is performed on the average aircraft at least four times per year. The flash points provided in Table B-16.4 are based on standard sea level pressure; lower pressures reduce the flash point and increase volatility. Fuels cannot burn unless in the vapor state, and the mixture ratio determines whether a fuel can burn. Skydrol and other ester-based fluids also possess these same properties.

Appendix C Referenced Publications

C-1

The following documents or portions thereof are referenced within this guide for informational purposes only and thus are not considered part of the recommendations of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

NFPA 423

1994 Edition

Standard for Construction and Protection of Aircraft Engine

Test Facilities

1994 Edition

This edition of NFPA 423, *Standard for Construction and Protection of Aircraft Engine Test Facilities*, was prepared by the Technical Committee on Airport Facilities and acted on by the

National Fire Protection Association, Inc., at its Annual Meeting held May 16–18, 1994, in San Francisco, CA. It was issued by the Standards Council on July 14, 1994, with an effective date of August 5, 1994, and supersedes all previous editions.

The 1994 edition of this document has been approved by the American National Standards Institute.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

Origin and Development of NFPA 423

The Sectional Committee started work on this standard in 1972. It was first submitted to the association at the 1975 Fall Meeting but was returned to committee for coordination with the NFPA Committee on Fire Tests. The 1977 edition contains the results of that coordination effort. The standard was reconfirmed in 1983. The 1989 edition was a complete revision of the 1983 edition. The 1994 edition is a partial revision of the standard.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire safety for the construction and protection at airport facilities involving construction engineering but excluding airport fixed fueling systems.

NFPA 423

Standard for

Construction and Protection of

Aircraft Engine Test Facilities

1994 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix B.

Chapter 1 Administration

1-1 Scope.

1-1.1

This standard establishes the minimum fire safety practices regarding location, construction, services, utilities, fire protection, operation, and maintenance of aircraft engine test facilities. These facilities include test cells and test stands.

1-1.2

This standard does not apply to engines and engine accessories, nor to engine test facilities where other than hydrocarbon fuels are used.

1-2 Purpose.

The purpose of this standard is to provide a reasonable degree of protection, for life and property from fire, for aircraft engine test facilities, based upon sound engineering principles, test data, and field experience.

1-3 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Control Room. A room with instrumentation and devices to control, measure, record, or observe test cell and engine operation and performance.

Detection System. A system consisting of detectors, controls, control panels, automatic and manual actuating mechanisms, all wiring, and all associated equipment.

Engine Rundown Time. The time required for the engine under test to have reduced its rotational speed to 10 percent of that at full power (100 percent).

Engine Test Cell. The space in which the test engine is installed on a thrust stand during a test. This space is totally enclosed by permanent building components except where the enclosure is breached by air ducts, services, access ports, or doors.

Engine Test Facility. An integrated system of building(s), structure(s), space, and services used to test aircraft engines contained within a test cell or on a test stand.

Engine Test Stand. An integrated system for testing an aircraft engine, as in a test cell, except that the engine test space is not totally enclosed within a permanent building.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Support Room. An enclosure or area, excluding the test cell or control room, that is an integral part of engine testing, including fuel handling rooms, hydraulic rooms, preparation areas, mechanical/electrical rooms, etc.

Test Cell. See Engine Test Cell.

Chapter 2 Construction and Internal Subdivisions

2-1 Construction of Aircraft Engine Test Facilities.

2-1.1

Test cell walls, ceilings, and floor assemblies shall be at least Type II (222) construction as defined in NFPA 220, *Standard on Types of Building Construction*.

2-1.2

Materials of construction such as thermal or acoustic insulation used within the test cell shall be noncombustible as defined in Chapter 2 of NFPA 220, *Standard on Types of Building Construction*.

2-1.3

Engine test facilities shall be constructed without basements or below grade areas other than those recesses in the floor necessary to accommodate sump pumps, drainage facilities, or lifting platforms.

2-1.3.1 In existing facilities, all basement areas, tunnels, or other below grade spaces shall be eliminated; or the fuel handling system shall be segregated, drainage shall be provided, and the basement area cut off so as to eliminate the possibility of flammable vapors collecting in the basement area or a spill of flammable or combustible liquids discharging into a basement area.

2-1.4*

An explosion hazard analysis of the engine test cell shall be performed to determine if an explosion hazard exists capable of compromising the integrity of the structure. If the analysis indicates such a hazard exists, one of the following shall be incorporated:

(a) Explosion venting;

(b) Explosion suppression system;

(c) Explosion limiting construction.

2-2* Internal Subdivisions of Aircraft Engine Test Facilities.

Engine test cells, fuel handling areas, and hydraulic rooms shall be separated from adjacent areas by construction having a minimum fire rating of 2 hours.

Chapter 3 Service and Utilities

3-1 General Safeguards.

3-1.1*

All objects, such as supports, nuts, and bolts, located where they might be ingested into an aircraft turbine engine shall be positively secured by safety wires, tack welding, suitable adhesive, or approved aircraft-type locking devices; or an inlet screen of proper design shall be used to protect an engine from foreign object damage.

3-1.2

All materials likely to become exposed to fuels, oils, or hydraulic fluids shall be resistant to deterioration from the fuels being used.

3-2 Drainage Systems.

3-2.1*

Drainage systems shall be provided for engine test cells and support rooms containing flammable or combustible liquid handling systems to reduce the fire and explosion hazards.

3-2.2

Floors subject to possible spillage of flammable or combustible liquids shall be pitched a minimum of one percent toward the drain(s). Drain(s) shall be located to minimize fuel spread and exposure to equipment.

3-2.3

Curbs, ramps, or drain trenches shall be installed to prevent the flow of flammable or combustible liquids into adjacent rooms or buildings.

3-2.4*

Drainage systems shall be designed and installed to provide sufficient capacity to prevent buildup of flammable or combustible liquids and water over the drain inlet under maximum possible water discharge rate.

3-2.5*

Drain traps shall have a trap seal water head. In test cells, the seal water head shall be greater than the expected difference between the test cell operating pressure and atmospheric pressure.

3-2.6

Drain piping and joints shall be resistant to deterioration from fuels, engine oil, and aircraft hydraulic system fluids.

3-2.7

Common or separate oil separator(s) shall be provided in drains from the engine area, the exhaust plenum area, and support rooms. Separator systems shall discharge flammable or combustible liquid products to an approved, safely located tank, cistern, sump, or pond away from or cut off from the engine test facility. In aircraft engine test facilities protected by a fire protection system utilizing water, a bypass shall be provided around the separator to allow for emergency direct disposal of water and flammable liquids to an approved location.

3-2.8

Maintenance checks and flushing shall be conducted on all drains and oil separators at least annually to assure that they are clear of obstructions.

3-3 Electrical.

3-3.1

Any pit, depression, or other below floor level locations of engine test cells, fuel handling areas, and hydraulic rooms shall be classified as a Class I, Division 1 Hazardous Location as defined in Article 500, Chapter 5, of NFPA 70, *National Electrical Code*®. This classification shall extend up to floor level.

3-3.2

The engine test cell including intake and exhaust plenums, fuel handling areas, and hydraulic rooms shall be classified as a Class I, Division 2 Hazardous Location as defined in Article 500, Chapter 5, of NFPA 70, *National Electrical Code*. This classification shall extend up to a level 18 in. (0.46 m) above the floor.

3-3.3*

All wiring and equipment that is installed or operated within any of the hazardous locations specified in this section shall comply with applicable provisions of Article 501, Chapter 5, of NFPA 70, *National Electrical Code*.

3-3.4

When wiring is located in vaults, pits, or ducts below the test cell floor, drainage shall be provided.

3-3.5

All wiring in the exhaust plenum not within the hazardous location as specified in 3-3.2 of this section shall be installed in rigid conduit.

3-3.6

All other test facility wiring not within a hazardous location shall meet the requirements of Chapter 3 of NFPA 70, *National Electrical Code*.

3-3.7

All wiring not enclosed in raceways, such as harness wires connecting to the engine, shall be adequately supported, laced, or banded to minimize wear from air velocity and vibration.

3-3.8*

A means shall be provided at the control console to shut off all electric power other than emergency circuits to the test cell in the event that the engine disintegrates or fuel leaks develop during operation.

3-4 Heating and Cooling.

3-4.1*

Heating and cooling systems shall be arranged to

(a) Reduce exposure of their vital elements to fire, explosion, and damage by metal;

(b) Eliminate introduction of ignition sources by components of heating systems;

(c) Minimize passage of fire through ductwork; and

(d) Eliminate pockets in which flammable vapors can accumulate.

3-4.2*

Steam, hot water, or indirect warm-air heating systems shall be used for general room or building heating in areas where flammable or combustible liquids or flammable gases are handled. Where flammable or combustible liquids or heavier-than-air flammable gases are used, return openings in hot air systems shall be located a minimum of 10 ft (3 m) above the floor. A conveniently located remote control station shall be provided to shut down the warm-air heating system.

3-4.3*

Cooling systems utilizing flammable refrigerants shall not be installed nor used within the test cell.

3-4.4*

When direct-fired inlet air preheaters are essential to simulate hot inlet air conditions, fuel safety controls as specified in NFPA 86, *Standard for Ovens and Furnaces*, shall be provided. Interlocks shall be provided to prevent ignition of a direct-fired system until adequate airflow has been established within the test cell or the engine is running.

3-4.5

Direct-fired or indirect-fired heaters for heating test cell inlet air shall be designed in accordance with applicable sections of NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; NFPA 54, *National Fuel Gas Code*; and NFPA 58, *Standard for the Storage and Handling of Liquefied Petroleum Gases*.

3-5 Ventilation.

3-5.1*

Continuous forced ventilation using fresh air at the rate of at least 2 cu ft per min per sq ft (0.01 cu m per sec per sq m) of floor area shall be provided in all support rooms handling flammable or combustible liquids.

3-5.2

Ventilation systems shall be arranged to draw heavier-than-air vapors or gases from near the floor level and discharge to a safe location. Where lighter-than-air gases are used, similar ventilation shall be provided but arranged to exhaust from ceiling level and with calculations based on the ceiling area. Ventilation for lighter-than-air gases shall be designed to prevent pocketing of such gases at ceiling level. Rotating elements of fans shall be of nonferrous or nonsparking materials, or the casing shall consist of or be lined with such material.

3-5.3

Where ventilation is provided, each cell or room handling flammable or combustible liquids or flammable gases shall have its own ventilation system in order to avoid interconnecting multiple hazards.

3-6 Fuel Systems and Lubricating Oil Systems.

3-6.1

Fuel systems and lubricating oil systems shall meet the requirements of NFPA 30, *Flammable and Combustible Liquids Code*. Plastic, aluminum, or cast iron shall not be permitted to be used aboveground for pipe, valve bodies, and fittings in test facilities.

3-6.2*

Fuel systems shall be equipped with manually operated control valves located at strategic points both outside and inside the engine test facility so that the main fuel supplies can be shut down quickly in the event of an emergency.

3-6.3*

Emergency safety shutoff valve(s) shall be installed in the fuel supply line(s) to each test cell and shall be located outside each test cell. These valves shall close on operation of a readily accessible and placarded emergency control device.

3-6.4

Fuel lines from main fuel headers shall enter fuel handling areas and run to test cells without passing through the control room. Relief valves arranged to discharge into collection tanks or fuel return lines, or other suitable devices, shall be installed in the piping system to protect the piping and equipment against overpressure due to thermal expansion of liquid in valved-off sections.

3-6.5

Glass fuel flow measuring devices shall not be used.

3-6.6

Flexible sections in the fuel and lubricating oil systems shall be suitable for the fluid and for the temperature and pressure to be expected.

3-6.7

Fuel and lubricant piping within the test cell shall be located as to minimize exposure from physical damage.

3-7 Compressed Air.

3-7.1

Compressed air piping systems shall conform to requirements of ANSI B31.1, *Code for Power Piping*.

3-7.2

Materials in compressed air piping systems shall be rated for the conditions of pressure and temperature expected. They shall be resistant to the fuels, oils, or hydraulic fluids to which they could be exposed.

3-7.3

Hose bands and joint couplings shall be of an approved type, and shall be safety wired.

3-8 Hydraulic Fluids.

3-8.1*

Hydraulic systems shall be designed in accordance with ANSI B31.1, *Code for Power Piping*. Piping and fittings shall be designed to withstand maximum surge pressures in the system. Piping shall be securely mounted to prevent failure due to vibration or mechanical damage. Gasket materials and seals shall be suitable for the fluid used.

3-8.2*

Properly identified, manually actuated devices shall be provided in a readily accessible location to shut off hydraulic pumps in the event of leakage, pipe or hose failure, or fire. These devices shall shut off the hydraulic pump drive system.

3-9* Instrumentation.

3-9.1

Computer rooms and electronic data processing equipment shall meet the requirements of NFPA 75, *Standard for the Protection of Electronic Computer/Data Processing Equipment*, and the protection requirements specified in Chapter 4 of this standard.

3-9.2*

Signal and control wiring or tubing shall be installed to minimize exposure from fuel hazards or physical damage from engine disintegration.

3-9.3

Flow meters or sensing lines containing fuel or oil shall not be located in the control room.

Chapter 4 Fire Protection Requirements

4-1 Engine Test Facility.

4-1.1

Portable fire extinguishers shall be provided throughout the engine test facility. Portable fire extinguishers and their distribution shall meet the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*.

4-1.2

Portable fire extinguishers shall not be located within the engine test cell.

4-1.3

Class B hazards shall be classified as an Extra Hazard in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

4-1.4

Class A hazards shall be classified as at least an Ordinary Hazard in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

4-1.5

As an alternative to the requirements of 4-1.1 of this section, hand hose lines of one or more of the following types shall be permitted in place of 50 percent of the required portable fire extinguishers:

(a) Water, meeting the requirements of NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*;

(b) Carbon dioxide, meeting the requirements of Chapter 4 of NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*;

(c) Foam, meeting the requirements of NFPA 11, *Standard for Low-Expansion Foam*;

(d) Dry chemical, meeting the requirements of Chapter 6 of NFPA 17, *Standard for Dry Chemical Extinguishing Systems*.

4-1.5.1 Where hand hose lines are provided, each hose line station shall be located so it is easily accessible.

4-1.6

The engine test facility shall be provided with an alarm and communications system meeting the requirements of 28-3.4 and Section 7-6 of NFPA *101*®, *Life Safety Code*®. In addition, the alarm system shall notify personnel in the control room and engine test cell.

4-1.7*

Where provided, fire detection systems shall meet the requirements of NFPA 72, *National Fire Alarm Code*.

4-2* Engine Test Cell.

4-2.1*

At least one of the following fire protection systems shall be provided to protect each engine test cell:

(a) Carbon dioxide system, meeting the requirements of Sections 5-1 and 5-2 of this standard;

(b) Halon system, meeting the requirements of Sections 5-1 and 5-3 of this standard;

(c) Foam system, meeting the requirements of Sections 5-1 and 5-5 of this standard;

(d) Water spray system, meeting the requirements of Sections 5-1 and 5-6 of this standard;

(e) Water deluge system, meeting the requirements of Sections 5-1 and 5-6 of this standard;

(f) Automatic sprinkler system, meeting the requirements of Sections 5-1 and 5-6 of this standard.

4-2.1.1 Systems (a) through (e) shall have a manual release located within the control room.

4-2.1.2 Systems (a) through (e) shall not be required to be automatically actuated.

4-2.2

Where provided, automatic actuation shall be permitted to be bypassed during engine operation provided the control room is continuously attended. Detection and alarms shall remain in service at all times. Any such bypass function shall be electrically supervised.

4-2.3

A separate fire protection system control valve shall be provided for each engine test cell.

4-2.4

Extinguishing systems for engine test cells shall be designed to compensate for the high airflows encountered during operation and engine rundown time.

4-2.5

When provided, time delay for system discharge shall not be less than that required for safe egress of personnel, but shall be permitted to be extended to compensate for engine rundown time.

4-2.6

Piping, nozzles, and actuation systems shall be located to minimize the extent of physical damage in the event of engine disintegration.

4-3 Control Rooms.

4-3.1

Control rooms constructed of materials that are other than noncombustible or limited combustible as defined in Chapter 2 of NFPA 220, *Standard on Types of Building Construction*, shall be protected by an automatic sprinkler system meeting the requirements of Sections 5-1 and 5-6 of this standard.

4-3.2*

Control rooms constructed of either noncombustible or limited combustible materials as defined in Chapter 2 of NFPA 220, *Standard on Types of Building Construction*, shall be provided with at least one of the following automatic fire protection systems:

(a) Halon 1301 total flooding system, meeting the requirements of Sections 5-1 and 5-3 of this standard;

(b) Automatic sprinkler system, meeting the requirements of Sections 5-1 and 5-6 of this standard.

4-4* Support Rooms.

All support rooms shall be provided with at least one of the following automatic fire protection systems:

(a) Carbon dioxide system, meeting the requirements of Sections 5-1 and 5-2 of this standard;

(b) Halon 1301 system, meeting the requirements of Sections 5-1 and 5-3 of this standard;

(c) Dry chemical system, meeting the requirements of Sections 5-1 and 5-4 of this standard;

(d) Foam system, meeting the requirements of Sections 5-1 and 5-5 of this standard;

(e) Water spray system, meeting the requirements of Sections 5-1 and 5-6 of this standard;

(f) Water deluge system, meeting the requirements of Sections 5-1 and 5-6 of this standard;

(g) Automatic sprinkler system, meeting the requirements of Sections 5-1 and 5-6 of this standard.

Chapter 5 Fixed Fire Protection Systems

5-1 General Design Requirements.

5-1.1

Fire protection system control equipment shall be located outside of the hazard area.

5-1.2

All fire protection system control equipment shall be identified as to the hazard protected, the function performed, and the method of operation for manual controls.

5-1.3

Manual fire protection system controls shall be conveniently located and accessible at all times, including the time of fire.

5-2 Carbon Dioxide Systems.

5-2.1

Carbon dioxide systems shall meet the requirements of NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*.

5-2.2

The system shall have a connected reserve supply not less than 100 percent of the primary supply arranged for immediate manual discharge.

5-2.3

The actuation of the system shall

(a) Close fuel valves supplying fuel to the protected area; and

(b) Activate alarm devices to warn personnel to evacuate the protected area.

5-2.4

The actuation of a total flooding system shall do the following in addition to the requirements of 5-2.3 of this section:

(a) Provide sufficient time to allow personnel to egress before the extinguishing agent is discharged; and

(b) Shut off ventilating fans and close doors and other openings to minimize the leakage of the extinguishing agent from the protected area.

5-2.5

Closing of doors shall not prevent the safe egress of personnel from the protected area.

5-3 Halon Systems.

5-3.1

Halon systems shall meet the requirements of NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*, or NFPA 12B, *Standard on Halon 1211 Fire Extinguishing Systems*.

NOTE: Halon 1211 and Halon 1301 are included in the "Montreal Protocol on Substances that Deplete the Ozone Layer" signed September 16, 1987. The 1992 amendments to the protocol call for a cessation of production of Halon 1211 and Halon 1301, worldwide.

5-3.2

Halon systems shall have a connected reserve supply not less than 100 percent of the primary supply arranged for immediate manual discharge.

5-3.3

The actuation of the system shall

(a) Close fuel valves supplying fuel to the protected area; and

(b) Activate alarm devices to warn personnel to evacuate the protected area.

5-3.4

The actuation of a total flooding system shall do the following in addition to the requirements of 5-3.3 of this section:

(a) Provide sufficient time to allow personnel to egress before the extinguishing agent is discharged; and

(b) Shut off ventilating fans and close doors and other openings to minimize the leakage of the extinguishing agent from the protected area.

5-3.5

Closing of doors shall not prevent the safe egress of personnel from the protected area.

5-4 Dry Chemical Systems.

5-4.1

Dry chemical systems shall meet the requirements of NFPA 17, *Standard for Dry Chemical Extinguishing Systems*.

5-4.2

The actuation of the system shall

(a) Close fuel valves supplying fuel to the protected area;

(b) Activate alarm devices to warn personnel to evacuate the protected area;

(c) Provide sufficient time to allow personnel to egress before the extinguishing agent is discharged; and

(d) Cause ventilating fans to shut down.

5-5 Foam, High-Expansion Foam, Foam-Water Sprinkler, and Foam-Water Spray

Systems.

5-5.1

Low-expansion foam extinguishing systems shall meet the requirements of NFPA 11, *Standard for Low-Expansion Foam*.

5-5.2

High-expansion foam systems shall meet the requirements of NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems*.

5-5.3

Foam-water sprinkler systems and foam-water spray systems shall meet the requirements of NFPA 16, *Standard on the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems*.

5-5.4

The actuation of a foam, high-expansion foam, foam-water sprinkler, or foam-water spray system shall

(a) Close fuel valves supplying fuel to the protected area;

(b) Activate alarm devices to warn personnel to evacuate the protected area;

(c) Provide sufficient time to allow personnel to egress before the extinguishing agent is discharged; and

(d) Cause ventilating fans to shut down and doors to close automatically.

5-5.5

In engine test cells only, the total discharge rate shall be calculated on the required density over the total floor area.

5-5.6

In engine test cells only, discharge devices shall be arranged to provide coverage of the hazard area. Discharge devices located at the ceiling shall provide complete coverage over the floor area. Directional discharge devices shall project the foam onto the thrust stand regardless of the discharge device location.

5-6 Water Spray Systems, Water Deluge Systems, and Automatic Sprinkler Systems.

5-6.1

Water spray systems shall meet the requirements of NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*.

5-6.2

Water deluge systems and other automatic sprinkler systems shall meet the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*.

5-6.3*

In engine test cells, the minimum design discharge density shall be 0.50 gpm per sq ft (0.34 l per sec per sq m) of protected area.

5-6.4

In engine test cells, water supplies shall be capable of meeting the largest demand at the design rate plus hose stream demand for a period of 30 min. Hose stream demand shall be a minimum of 250 gpm (16 L per sec). The hydraulic calculation and the water supply shall be based on the assumption that all sprinklers in the test cell are operating simultaneously.

Chapter 6 Employee Organization for Fire Safety

6-1 General.

6-1.1

All personnel engaged in aircraft engine testing operations and all other persons regularly employed and working around engine test facilities shall be instructed in fire prevention practices as part of their regular training. These personnel shall also be trained in the operation of all portable fire extinguishers and hose line systems provided in the area in which they work.

6-1.2

Selected personnel on each operational shift shall be trained in operation of the fixed fire protection systems provided in the test facility. This training shall be accompanied by a comprehensive explanation of all features of such systems and the area they protect.

6-1.3

Responsibility for fire protection equipment, inspection, and maintenance shall be assigned to key personnel.

Chapter 7 Referenced Publications

7-1

The following documents or portions thereof are referenced within this standard and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-3 Approved.

The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-3 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-2-1.4

Analysis should include, but not be limited to

(a) The type of testing to be done (e.g., production, endurance, development/research);

(b) Characteristics of the fuel (e.g., flash point, vapor density, autoignition temperature);

(c) Amount of airflow and whether it is ducted to the engine;

(d) Presence of continuous ventilation;

(e) Fuel quantity in relation to volume of the enclosure;

(f) Maximum fuel pressure, temperature, flow, and delivery system;

(g) Life safety considerations.

Test cells can be subject to an explosion hazard because of the presence of flammable vapors and the confinement of same within the test cell. The potential damage from an explosion will depend on numerous factors, including

(a) The designed pressure resistance of the structure;

(b) The amount of area utilized for inlet and exhaust air;

(c) The amount of explosion venting provided;

(d) The amount of continuous ventilation provided;

(e) The presence of explosion suppression equipment.

Explosion venting, continuous ventilation, and/or explosion suppression should be considered in the design of test cells. The planned use of the cell, the supporting equipment, the type of construction, and the configuration of the cell are some factors to be considered. (*See A-3-5.1.*) The net unobstructed area of engine test cell inlet and exhaust passages can be included in the venting area. Explosion venting could be effected in the cells proper by the use of lightweight roof or wall panels or outward opening doors equipped with resisting devices to prevent the venting device from being projected with chance of injury to personnel or damage to equipment in the event of operation. Guidance for explosion venting is provided in NFPA 68, *Guide for Venting of Deflagrations*. Where the specific design or configuration of a test facility does not allow the use of explosion venting, or allows very minimal explosion venting, consideration should be given to the protection of the structure or specialized equipment by the use of explosion suppression systems. Requirements for explosion suppressions are provided in NFPA

69, *Standard on Explosion Prevention Systems*.

A-2-2

Test cell walls should not form common walls with main manufacturing buildings. Test cells should be located to minimize the exposure from openings such as doors, windows, inlet and exhaust stacks, ventilating ducts, explosion vents, or exhaust pipes to (a) combustible construction or unprotected openings at the same or higher elevation, and (b) utilities such as transformers, overhead transmission lines, overhead service piping, and cooling towers. Where test cells are of light construction, important exposed buildings and utilities should be shielded from the possible disintegration of aircraft engines.

Other walls, ceilings, and floor assemblies comprising the engine test facility should be fire resistive, protected noncombustible, or noncombustible construction. The type of construction utilized in test buildings is determined to an extent by their proximity to main buildings or vital utilities.

A-3-1.1

Parts or foreign objects that are located in front of a turbine engine or in other locations where they might be ingested into an engine are likely to cause damage to the engine or to a critical system and cause a fire. Test cell operating procedures should therefore include a thorough inspection of the test cell and engine before engine starting to check for proper safety of parts and to eliminate foreign objects (e.g., tools, lockwire, nuts, bolts, washers, stones).

A-3-2.1

Test cells and support rooms not containing flammable or combustible liquid handling systems might also require drainage systems to effectively dispose of water used for engine washing, exhaust gas cooling system malfunctions, rainwater, and water discharged from fire protection systems. Test cell floor drains should be located, where possible, downwind of probable fuel spill locations to minimize the pounding effect of high test cell air velocity. Requirements of federal, state, and local environmental agencies should be consulted.

A-3-2.4

Where deluge sprinkler systems are installed, the capacity of the drainage system can be determined by the sprinkler design rate increased by an appropriate correction for maximum main pressure. Exhaust gas cooling water rates need not be included in the determination of peak drainage if an adequate emergency shutoff system or separate drainage system is provided.

A-3-2.5

All drain traps should be provided with an automatic reseal system.

A-3-3.3

It is common practice to locate limit switches for elevating work platforms below the floor level. An accidental shorting or grounding of these circuits should not allow the elevator to move or overrun, which could result in damage to engine fuel lines and ensuing fire.

A-3-3.8

The failure of electric power supply to a test cell might deprive the operator of control of the engine, resulting in possible engine damage and ensuing fire. Battery power or other means should be provided in order to properly operate the engine during such failures.

A-3-4.1

Heating and cooling systems used in conjunction with engine test facilities require careful design and installation because of the magnitude of the hazards, the complexity of the operations, and the operational importance of the facility.

A-3-4.2

Surface temperatures of exposed heating elements should not equal or exceed the minimum auto-ignition temperature of the most hazardous flammable liquid or gas used.

A-3-4.3

Direct cooling systems are preferred to systems that utilize extensive ductwork that penetrates cell walls.

A-3-4.4

Test cell inlet preheaters used to simulate hot inlet air conditions should preferably use steam or a liquid heat exchange medium. Auxiliary fans to allow pre- and post-operation purging prior to lightoff and after running might be needed. Four complete cell air changes should be made before purging is considered complete. Preheaters utilizing gaseous fuel should have continuous gas detectors sampling all areas subject to flammable vapor accumulation. Gas detection systems should be interlocked to shut off gas and sound an alarm at 25 percent of the lower flammable limit.

A-3-5.1

Forced air ventilation at the rate of 1 cu ft per min per sq ft (0.005 cu m per sec per sq m) of floor area should be provided in engine test areas when engines are not running.

A-3-6.2

An additional fuel shutoff valve should be located before any flexible connection to the engine to isolate fuel inside the test cell if the quantity contained between the test cell wall and the engine is significant.

A-3-6.3

Consideration should be given to the automatic operation of the emergency fuel safety shutoff valve by one or more of the following methods:

(a) Operation of the fire protection system;

(b) On actuation of heat sensing devices;

(c) Excess fuel flow.

A-3-8.1

Many hydraulic systems utilize combustible oil under high pressure to transmit power or motion. The use of combustible hydraulic oils presents a potential fire and explosion hazard. Atomization of such fluids greatly increases the ease of ignition.

Use of hydraulic fluids with low fire hazard potential is encouraged. Such fluids include water-glycol, halogenated-hydrocarbon, phosphate-ester, or water-oil-emulsion types. When converting from one hydraulic fluid to another, the entire hydraulic system should be thoroughly cleaned, and seals, packings, valves, or pumps should be changed to prevent leakage. Equipment and fluid manufacturers should be consulted for proper conversion procedures in these nonengine related hydraulic systems.

Flexible connectors and hoses should be avoided.

A-3-8.2

The hydraulic line should also be shut off by these devices to minimize fluid leakage.

A-3-9

Instrumentation is an essential part of every engine testing facility and can include flow meters, pressure and temperature sensors, indicators, gauges, transducers, thrust and position indicators, vibration monitors, etc.

A-3-9.2

Control instrumentation should be arranged so that its failure will not introduce a hazard. Where combustible pneumatic tubing is grouped in cabletrays or troughs, additional fire protection might be needed to prevent extensive damage to the tubing system.

A-4-1.7

When a fire detection system is installed to sound an alarm or actuate a fire extinguishing system, the detection system design should consider airflows, engine location, heat sources from engine, and whether or not the engine is being continuously observed. In test facilities where airflow velocities in excess of 25 ft/sec (7.6 m/sec) are expected, optical detection should be used.

A-4-2

Where supplementary fire protection systems are provided for engine protection in addition to the required engine test cell fire protection, they should be designed and installed in an approved manner.

The following are the more common supplementary systems used for engine protection:

(a) *Carbon dioxide spurt system.*

1. A carbon dioxide spurt system is usually a manually actuated fixed-pipe system designed to locally apply carbon dioxide to an engine on an intermittent basis, or continuously by the operator. A spurt system can have its own agent supply or can be supplied from a total flooding or local application carbon dioxide system. Such a system is intended to provide a means for quick knockdown of fires in or around the engine while the engine is operating. There are usually no interlocks to shut down fuel flows, alarms, etc.

2. Pipings and fittings should conform to the applicable provisions of NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*.

3. The primary supply and connected reserve supply should each be designed to provide a continuous discharge for a minimum of three minutes.

(b) *Steam fire protection systems.* Steam extinguishes a fire in a manner similar to inert gases. In order to maintain steam in its true form at normal atmospheric temperatures and pressures and prevent its condensing to water vapor, very large quantities should be discharged at one time. This makes steam impractical for total flooding of a large test cell. It can be effective for engine fires when discharged within an enclosing cowl, when injected into cavities within the engine, or when injected into the main inlet air stream or into the tailpipe of an engine. Such factors as boiler maintenance, standby boilers, boiler fuel availability, normal peak steam demand, boiler feedwater availability, and availability of alternate emergency fire protection services should be considered in analyzing steam source requirements or suitability. The following guidelines are offered:

1. Steam can be used as an effective supplementary system for engine protection, provided steam is available in sufficient quantities whenever the test cell is in operation.

2. Piping for the distribution of steam from the source to the point of use should follow ANSI B31.1, *Code for Power Piping*, as applicable.

3. The steam flow rate should be sufficient to achieve a ratio of steam volume to total protected volume of 50 percent within 30 seconds. The steam supply should be capable of maintaining that concentration until the fire has been extinguished. Steam discharge to atmosphere of not less than 15 psi (103 421 Pa) can be approximated by the formula

$$W = 0.7A\,(P + 15)$$

where:

W = pounds of steam per minute

0.7 = constant including an orifice coefficient

A = orifice area (square inches)

P = gauge pressure at outlet (pounds per square inch)

For more precise determination of required orifice size, or when upstream and downstream pressure conditions are different from the above, consult a standard textbook on steam flow control.

4. The system should not be automatically actuated. Personnel hazards should be considered prior to manual actuation.

5. Steam condensate traps and lines should be provided to bleed off liquid and allow only vapor to be directed to the protected area.

6. The steam system should be inspected and tested at least semiannually.

A-4-2.1

Each agent has its advantages and disadvantages, and the choice of agent or combination of agents should be made only after careful consideration of the objective of the protection and the conditions of each individual installation. Some of the factors pertinent to each agent are

(a) *Water.* Water, particularly in spray form, is an effective agent in controlling or extinguishing kerosene-grade (e.g., JET A or A-1; JP-5 or JP-8) jet fuel fires. It is not an effective extinguishing agent for fuels containing gasoline (e.g., JET B; JP-4). The principal advantage of water is its superior cooling capacity. Other advantages are adequate supply for continuous discharge over long periods, ease of piping, and low cost. Disadvantages are drainage requirements and possible water damage to the test engine, electrical devices, wiring, and instrumentation. Deluge systems are considered more appropriate than closed head automatic sprinklers due to their speed of operation and simultaneous discharge from all nozzles. Automatic sprinklers can be effectively used in small test cells [600 sq ft (56 m^2) or less] where it is likely that all sprinklers would fuse at the same time or as a backup to a manual water spray or other manual system.

(b) *Carbon dioxide.* Carbon dioxide is an effective extinguishing agent for flammable liquid fires when applied in sufficient concentration. Its principal advantage is lack of agent damage. Other advantages are no cleanup and relatively low cost for recharging the system. Disadvantages are the need to evacuate personnel from a protected area, limited supply of agent, leakage of agent from a protected space, and lack of significant cooling effect.

(c) *Foam.* Foam is an effective extinguishing agent for all aviation fuels. It is most applicable for fires involving large spills. Other advantages are (1) the ability to cover large fuel spills before they become ignited, and (2) its insulating qualities. Disadvantages are lack of effectiveness on three-dimensional fires (e.g., fuel flowing from an elevated source), cost of agent, and cleanup. Foam systems are not effective on fires involving flammable gases.

(d) *Dry chemical.* Dry chemical extinguishing agents are effective for flammable liquid and gaseous fires. They have rapid knockdown and extinguishing capability. Dry chemical extinguishing agents are not considered desirable for test cell coverage due to extensive cleanup required and potential damage to electrical contacts and engine parts.

(e) *Halon.* Halon can be used for extinguishing fuel spill fires and engine fires and has the ability to extinguish or suppress fires in surface-burning Class A materials as well as extinguishing Class B fires and being safe to use on Class C (electrical) fires. The compatibility of the agents with engine parts should be investigated since the decomposition products might be corrosive. The only halons recommended for test facility protection are Halon 1301 and Halon 1211. Both agents require less extinguishing concentrations than carbon dioxide, resulting in smaller piping and less agent storage.

See NFPA 12A (Halon 1301) and NFPA 12B (Halon 1211) for more descriptive information.

A-4-3.2

See A-4-2.1.

A-4-4

See A-4-2.1.

A-5-6.3

Because of the nature of the test cell fire potential, deluge systems are considered more appropriate than automatic sprinklers due to their speed of operation and simultaneous discharge of all nozzles; however, automatic sprinklers can be used

(a) In small cells [600 sq ft (56 m^2) or less] where it is likely that all sprinklers would fuse at the same time; or

(b) As a backup to a manual water spray or other manual system.

1996 Edition

Guide for Airport/Community Emergency Planning

1996 Edition

This edition of NFPA 424, *Guide for Airport/Community Emergency Planning*, was prepared by the Technical Committee on Aircraft Rescue and Fire Fighting and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 20–23, 1996, in Boston, MA. It was issued by the Standards Council on July 18, 1996, with an effective date of August 9, 1996, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 424 was approved as an American National Standard on July 26, 1996.

Origin and Development of NFPA 424

The Subcommittee on NFPA 424 started work on this document in 1976. It was submitted to the Association at the 1978 Fall Meeting and released as the first edition on January 25, 1979.

The complete text was rewritten in 1986 in an informational format. The document was again rewritten in 1991. This edition is a partial revision. The work of revising this document was accomplished with the assistance of a Task Group appointed by the chair. The Task Group on Airport/Community Emergency Planning was comprised of the following members:

Davis R. Parsons, Chair, Los Angeles City Fire Dept., CA; Brian Boucher, Canadian Air Line Pilots Assn., ON, Canada; Derek K. G. Dodwell, Civil Aviation Authority, England; John J. O'Sullivan, British Airways, England; John X. Stefanki, John X. Stefanki, Inc., CA; Ronald O. Wikander, Lockheed Aeronautical Systems Co., GA; Larry E. Williams, Emergency Response Training Academy, Inc., AR; Miles Young, US Air Force, FL.

Committee Scope: This Committee shall have primary responsibility for documents on the criteria for aircraft rescue and fire fighting services and equipment, procedures for handling aircraft fire emergencies, and for specialized vehicles used to perform these functions at airports with particular emphasis on saving lives and reducing injuries coincident with aircraft fires following impact or aircraft ground fires. Develops aircraft fire investigation procedures as an aid to accident prevention and the saving of lives in future aircraft accidents involving fire.

NFPA 424
Guide for
Airport/Community Emergency Planning

1996 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Appendix C.

Chapter 1 Administration

1-1 Scope.

This guide describes the elements of an airport/community emergency plan that require consideration before, during, and after an emergency has occurred. The scope of the airport/community emergency plan should include command, communication, and coordination functions for executing the plan. Throughout this document, the airport/community emergency plan will be referred to as the "Plan."

1-2 Purpose.

This guide was written to inform airport and adjacent community authorities of current emergency planning techniques and procedures that result in the efficient utilization of personnel from all involved organizations and agencies to provide effective delivery of emergency services in the event of an aircraft related emergency. Jurisdictional problems previously identified in actual emergencies or emergency plan exercises point out the necessity of resolving the conflicts as part of the development of the Plan.

Recommendations contained herein are not intended to conflict with any local or state regulations. One of the principal purposes of this document is to alert all participants to conflicts that can exist due to multijurisdictional factors, such as conflicts between state and local regulations.

1-3 Definitions.

A wide variety of terms are in use throughout the world to describe facilities, procedures, and services related to airports. Wherever possible the terms used in this guide are those that have the widest international use. When the following terms are used in this guide they have the following meaning:

Aircraft Accident. An occurrence associated with the operation of an aircraft that takes place between the time a person boards the aircraft with the intention of flight and the time such person has disembarked, in which a person suffers death or serious injury as a result of the occurrence or in which the aircraft receives substantial damage.

Aircraft Emergency Exercise. Testing of the emergency plan and review of the results in order to improve the effectiveness of the plan.

Aircraft Incident. Any occurrence associated with the operation of an aircraft that is not considered an “aircraft accident.”

Aircraft Operator. A person, organization, or enterprise engaged in, or offering to engage in, aircraft operation.

Airline Coordinator. A representative authority delegated by an airline to represent its interests during an emergency covered by this guide.

Airport Air Traffic Control. A service established to provide air and ground traffic control for airports.

Airport/Community Emergency Plan. Establishment of procedures for coordinating the response of airport services with other agencies in the surrounding community that could be of assistance in responding to an emergency occurring on, or in the vicinity of, the airport.

Airport Control Tower. A unit established to provide air traffic control service for airport traffic.

Airport Flight Information Service. Air traffic control services units that provide airport flight information service, search and rescue, alerting service to aircraft at noncontrolled airports, and assistance to aircraft in emergency situations.

Airport Manager. The individual having managerial responsibility for the operation and safety of an airport. The manager can have administrative control over aircraft rescue and fire fighting services but normally does not exercise authority over operational rescue and fire matters.

Airside (Airport Operational Area). The movement area of an airport, adjacent terrain, and buildings or portions thereof, access to which is controlled.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Biological Agents. Living organisms that can be dangerous to human, animal, or plant life upon release.

Care Area. Location where initial medical care is given to injured.

Collection Area. Location where seriously injured are collected initially.

Command Post (CP). The location at the scene of an emergency where the incident commander is located and where command, coordination, control, and communications are centralized.

Emergency Medical Technician (EMT). A person trained to administer emergency medical treatment more advanced than basic first aid.

Emergency Operations Center. A fixed, designated area to be used in supporting and coordinating operations during emergencies.

Grid Map. A plan view of an area with a system of squares (numbered and lettered) superimposed to provide a fixed reference to any point in the area.

Holding Area. Location where the apparently uninjured aircraft occupants are transported.

Incident Command System (ICS). The combination of facilities, equipment, personnel, procedures, and communications operating within a common organizational structure with responsibility for the management of assigned resources to effectively accomplish stated objectives pertaining to an incident.

Incident Commander (IC). The person in overall command at an emergency.

In-Flight Emergency. Those emergencies that affect the operational integrity of an aircraft while in flight. The seriousness of these emergencies can be defined by using alert status guidelines stated in FAA terms.

Inner Perimeter. That area which is secured to allow effective command, communication, and coordination control and to allow for safe operations to deal with an emergency, including the immediate ingress and egress needs of emergency response personnel and vehicles.

Investigation. A process conducted for the purpose of accident prevention that includes the gathering and analysis of information, the drawing of conclusions, including the determination of cause(s) and, where appropriate, the making of safety recommendations.

Medical Transportation Area. That portion of the triage area where injured persons are staged for transportation to medical facilities under the direct supervision of a medical transportation officer.

Mobile Emergency Hospital (MEH). A specialized, self-contained vehicle that can provide a clinical environment that enables a physician to provide definitive treatment for serious injuries at the accident scene.

Moulage. A reproduction of a skin lesion, tumor, wound, or other pathological state. Applied for realism to simulate injuries in emergency exercises.

Mutual Aid. Mutual aid is synonymous with “mutual assistance,” “outside aid,” “memorandums of understanding,” “letters of agreement,” or other similar agreements, written or not, that constitute an agreed reciprocal assistance plan between emergency services.

Outer Perimeter. That area outside of the inner perimeter that is secured for immediate-support operational requirements, free of unauthorized or uncontrolled interference.

Paramedic. A medical technician who has received extensive training in advanced life support and emergency medicine. These personnel are usually permitted to administer intravenous fluids and other drugs that can arrest a life-threatening physiological condition.

Rendezvous Point. A prearranged reference point, i.e., road junction, crossroad, or other specified place, where personnel/vehicles responding to an emergency situation initially proceed to receive directions to staging areas or the accident/incident site or both.

Specialty Emergency Exercise. One or more specialty agencies fully involved in an exercise to test or give the agency practice in its specialty.

Stabilization. The medical measures used to restore basic physiologic equilibrium to a patient, to facilitate future definitive care, in order to ensure survival.

Staging Area. A prearranged, strategically placed area, where support response personnel, vehicles, and other equipment can be held in an organized state of readiness for use during an emergency.

Triage. The sorting of casualties at an emergency according to the nature and severity of their injuries.

Triage Tag. A tag used in the classification of casualties according to the nature and severity of their injuries.

Chapter 2 Elements of Emergency Planning

2-1* General.

2-1.1

The Plan should describe the coordination of the actions to be taken in an emergency occurring at an airport or in its vicinity. It should be built around an incident command system compatible with provider agencies.

2-1.2

“During the emergency” considerations depend on the exact nature or location of the incident or both. The location should dictate the agency responsible for management of the emergency. As the nature of the incident changes from emergency operations to the investigative phase, the appropriate investigative agency should assume command and responsibility for the incident scene. All agencies responding to the incident should know, in advance, their respective roles and responsibilities and who they report to and who reports to them.

2-1.3

“Post-emergency” considerations also should be given considerable attention. Transition of authority and other legal factors should be discussed and preplanned. Consideration should be given to the restoration of protective services in order to permit continuation of normal airport/aircraft operations and public protection that was disrupted by the emergency.

2-1.4

The recommendations contained in this document are based on the requirement that rescue of aircraft occupants and other related accident victims is the primary operational objective. Effective operations require a great deal of preplanning and regular exercises that provide an opportunity for realistic training of personnel from all agencies that will be involved in the incident.

2-1.5

It is crucial that response agencies consider local weather conditions and nighttime operations while developing details of the Plan. For example, low temperatures can freeze medical solutions or tubing during protracted extrication operations. Severe weather conditions also can negatively affect fire fighting foam solution.

Precautions should be taken, where necessary, to mitigate weather induced physical problems such as hypothermia and dehydration. Such considerations should apply to emergency personnel, as well as victims of the accident.

2-1.6 Amendment of the Plan.

2-1.6.1 The airport authority should maintain the master records of the Plan and transmit to each participating agency amendments, additions, and revisions as appropriate.

2-1.6.2 The scope of the Plan should include command, communication and coordination functions for executing the Plan. The Plan should be constructed using a modular and severable format in order to facilitate revisions of specific elements without having to rewrite the entire Plan. The Plan should be reviewed on an annual basis by all participants. The review should include a comprehensive analysis of lessons learned from training sessions, incidents, geographical and physical changes, legal and technical changes, and other factors that can influence the adequacy of the Plan.

2-1.7 Training Costs.

The costs of a major training exercise can be a considerable factor for even the smallest of airports. Budgetary planning for training costs should include salaries for personnel, consumables such as fuel, extinguishing agent, medical supplies, legal advice, and other necessary items, such as food for all participants.

2-2* Types of Emergencies and Emergency Alerts.

2-2.1

Many different types of emergencies can strike a community. However, when creating an airport/community emergency plan, the focus should be on aircraft related incidents. Preparation for other types of emergencies, such as floods or earthquakes, should be addressed in preplanning documents built around the special nature of those incidents.

2-2.2

Most aircraft accidents occur within the airport operational area. However, experience has shown that the most devastating aircraft accidents have been those that occur off-airport, involving structures. It is therefore necessary to design a plan that provides for the needs of both.

2-3 Essential Elements of the Plan.

The following should be considered as essential elements of an airport/community emergency plan:

(a) Establishment of formal instruments/agreements/joint powers, etc., to initiate development and implementation of the Plan;

(b) Detailed planning for 24-hour response, communications, logistics, etc;

(c) Agreement for incident command and control systems and procedures;

(d) Funding for practice;

(e) Regular and “as needed” Plan updates; and

(f) Public relations efforts that bring popular and political support to maintaining readiness.

Chapter 3 Agencies Involved

3-1 Agencies.

3-1.1

The Plan should have an up-to-date list of all agencies involved. In addition to agency identification, the list should include current telephone numbers and names of primary contact persons. This list should be reviewed, revised as necessary, and distributed to all agencies on a regular basis.

3-1.2

The first step in a viable airport emergency plan is to have the cooperation and participation of all concerned airport/community authorities and agencies. Those that should be involved are:

(a) Air traffic control services;

(b) Rescue and fire fighting services (departments);

(c) Police/security services;

(d) Airport authority;

(e) Emergency medical services, including ambulance services;

(f) Hospitals;

(g) Aircraft operators;

(h) Communication services;

(i) Airport rescue coordination center;

(j) Transportation authorities (land, sea, and air);

(k) Hospital coordination center;

(l) Civil defense;

(m) Mutual aid agencies;

(n) Military;

(o) Harbor patrol and/or coast guard;

(p) Clergy;

(q) Public information office/news media;

(r) Veterinary service;

(s) Civil engineering contractors;

(t) Post office;

(u) Environmental Protection Agency (EPA);

(v) Customs;

(w) Public utilities; and

(x) Mental health agencies.

3-2 Air Traffic Control Services.

For emergencies involving aircraft, the airport control tower (or airport flight service station) is required to contact the rescue and fire fighting service and provide information on the type of emergency, such as the type of aircraft, number of persons on board, fuel quantity, and location of the accident, if known. After the initial call, mutual aid agencies should be provided the airport grid map reference, rendezvous point, and where necessary, the airport entrances to be used. Alternately, this function can be assigned by the Plan, either in whole or in part, to another organization or unit. The Plan also may specify that air traffic control services is responsible for initiating the notification of local fire departments and other appropriate agencies in accordance with procedures established in the Plan. The Plan can assign this function to another agency, such as the local fire department dispatching center, but it is very important that this extremely crucial function be well-documented and understood by all concerned.

3-3 Rescue and Fire Fighting Services (Departments).

3-3.1*

The primary responsibility of airport rescue and fire fighting personnel is to save lives. Property endangered by aircraft incidents and accidents occurring on or near the airport should be preserved as far as practical. To achieve this objective, fire control normally is defined as “securing” the area to prevent any reignitions. There can be aircraft accidents, however, where fire does not occur or where the fire is rapidly extinguished. In every case each action taken is aimed at providing the most immediate attention possible to survivors of the accident.

3-3.2

Rescue and fire fighting personnel should receive emergency medical training that meets the minimum standards of their state and local jurisdictions. The stabilization of seriously injured victims can depend entirely upon these first-arriving personnel. Coordination with other responding personnel having advanced medical expertise (paramedics and medical doctors) should be addressed in the Plan.

3-3.3

The fire fighting officer in command should be identified by a standard distinctive uniform. In addition, the Plan should provide for a highly visible vest or other apparel with reflective lettering, front and back, that reads “INCIDENT COMMANDER.”

3-3.4

Only fire fighting and rescue personnel wearing approved fire fighting protective clothing and equipment should be allowed in close proximity to an aircraft accident site [300 ft (100 m) from any point on the aircraft or any fuel spillage is usually considered a safe distance].

3-4 Police/Security Services.

3-4.1

In an airport emergency, it should be expected that the first police or security officer to arrive at the scene will initiate site security procedures and request reinforcement as needed. It should be expected that these responsibilities will be spelled out in the Plan, identifying the responsible law enforcement agency for the accident site and providing for a smooth transition of command should responsibility for site security shift from one agency to another.

3-4.2

Congestion-free ingress and egress roads should be established immediately for emergency vehicles. The security services, police force, or other appropriate local authorities should be expected to ensure that only persons with specific tasks are allowed at the scene of the accident, and they also should be expected to route the normal traffic away from or around the accident site.

3-4.3

The Plan should provide for the prevention of unauthorized access to the accident site and for preserving the site undisturbed for investigation purposes.

3-4.4

A mutual aid program should be instituted between all potentially involved security agencies, e.g., airport, city, local, and governmental security forces; mail inspectors; and, where appropriate, military police and customs officials.

3-4.5

A method of easy identification of responding emergency personnel should be implemented at security check points to ensure that appropriate emergency personnel have immediate access to the accident site. “Emergency Access” identification can be preissued by the airport authority to emergency personnel for use during an emergency.

3-4.6

In many cases it is not possible or practicable for vehicles of mutual aid fire departments, ambulances, etc., to proceed directly to the accident/incident site. It should be essential that the emergency plan include procedures for meeting at a designated rendezvous point or points. A rendezvous point also can be used as a staging area where responding units can be held until needed at the accident site. Suitable accommodation should be provided at the rendezvous point(s) for the rendezvous point officer to facilitate the briefing of incoming officers in charge of supporting services. Adequate telephone and radio provisions should be available. Those controlling the rendezvous point should also consider the suitability of vehicles to adverse terrain conditions at the accident site in order to prevent obstruction of the access route by disabled vehicles. Staging of vehicles can prevent traffic jams and confusion at the accident scene.

3-4.7

To easily identify and distinguish the security/police officer in command, a blue, industrial hard hat and blue, highly visible apparel, such as a vest or coat, should be worn, with reflective lettering "POLICE CHIEF" displayed front and back.

3-5 Airport Authority.

3-5.1

The airport authority is responsible for establishing, promulgating, and implementing the Plan and designating a person to take charge of the overall operation at the command post. The Plan should call for the airport authority to ensure that the information on names and telephone numbers of offices or people involved in an airport emergency is kept up-to-date and distributed to all concerned. Coordination of all agencies responding to an emergency is expected to be carried out by the airport authority. It also should set up necessary meetings of the airport emergency plan coordinating committee, composed of key personnel from participating agencies for critique of the Plan, after it has been tested or implemented. The airport authority should be responsible for closing the airport, or part of it, and ensuring that aircraft operations are resumed only when circumstances permit aircraft to operate safely without interfering with rescue activities.

3-5.2

The airport operations officer in charge should be identified by an international orange hard hat and a highly visible vest or other apparel with reflective lettering, front and back, that reads “AIRPORT ADMINISTRATION.”

3-6 On-Scene Medical Services.

3-6.1

The purpose of medical services is to provide triage, medical care, and transportation to accident victims.

3-6.2

It is essential that the medical aspects of the Plan be integrated with other local community emergency plans and agreements.

3-6.3

A medical coordinator should be assigned to assume command of the emergency medical operations at the accident site. In some cases, it may be necessary to appoint an interim medical coordinator, who will be relieved when the designated medical coordinator arrives. An interim medical coordinator should be assigned by the airport rescue and fire fighting command personnel.

3-6.4

Medical and ambulance services can be an integral part of the airport services, particularly whenever an ambulance service is a part of the airport's rescue and fire fighting service. Whenever medical and ambulance services are not available at the airport, prearrangement with local, private, public, or military medical and ambulance services should be made. The plan should ensure the dispatch of a satisfactory assignment of personnel, equipment, and medical supplies. To ensure a rapid response, the plan can include arrangements for land, sea, and airborne transportation of medical services to the scene, and the subsequent transportation of persons requiring immediate medical care. Prearrangements are necessary to ensure the availability of doctors and other medical personnel for all airport emergencies.

3-6.5

The Plan should designate a medical transportation officer whose responsibilities would include:

(a) Alerting hospitals and medical personnel to the emergency;

(b) Directing transportation of casualties to hospitals properly suited to the particular injury;

(c) Accounting for casualties by recording route of transportation, hospital transported to, and casualty's name and extent of injuries;

(d) Advising hospitals when casualties are en route; and

(e) Maintaining contact with hospitals, medical transportation, the senior medical officer, on-scene command post, and the command post.

3-7 Hospitals.

3-7.1

Participating hospitals should have contingency emergency plans for blood donations and to provide for mobilization of necessary medical trauma teams to the accident site in the shortest possible time. Availability of qualified personnel and adequate facilities at the hospitals are vital. Therefore, it is important to establish in advance an accurate list of surrounding hospitals classified according to their effective receiving capacity and specialized features, such as neurosurgical ability or burn treatment.

3-7.2

The distance from the airport and the ability to receive helicopters should be considered. Reliable two-way communication between the incident command post and these entities is important. The alert of an aircraft accident should be made to a single medical authority/agency, which then alerts all appropriate facilities according to a local medical communications network.

3-7.3

It is essential that hospitals continually communicate through a central control point to facilitate distribution of critically injured patients. Information regarding availability of a specific trauma center, operating room, and ward space should be collected at a central control point, designated in the Plan, and disseminated to the medical transportation officer at the scene.

3-8* Aircraft Operators.

3-8.1*

The aircraft operator/company of an aircraft involved in an accident should be expected to provide full details of aircraft-related information, such as the number of persons on board, fuel, and cargo information. This information is vital to the incident commander and can influence the tactics and strategies used to deal with the emergency.

3-8.2

Aircraft operators also should be responsible for providing first arrangements for any uninjured survivors who need to continue their journey or require accommodation or other assistance. They also might be responsible for contacting deceased passengers' next of kin. Clergy, police, international relief agencies (Red Cross, etc.), and mental health agencies will normally assist in the accomplishment of this task.

3-8.3

The proper disposition of all cargo, mail, and baggage aboard an aircraft involved in an accident is the responsibility of the aircraft operator. Permission to remove these items from the aircraft may be granted by the incident commander after the emergency has been abated and the requirements of the accident investigators have been met.

3-9 Government Authorities. In order to avoid conflict and confusion between participants, the airport emergency plan should clearly define the obligation, controls, and limitations placed on the airport authority by government agencies. Post-accident investigation, unlawful seizure of aircraft, bomb threats, and bombings can fall into jurisdictions other than that of the airport authority.

3-10 Communication Services.

Arrangements should be made to provide all airport agencies involved in an emergency with two-way communication capabilities. The Plan also should provide an adequate communication network to be maintained with the off-airport agencies responding to an emergency. The Plan should call for the command post and emergency operations center to have the capability of freely communicating with all participating agencies. Cellular telephones can be extremely effective. Amateur, military, and civil defense radio networks are worth considering as a back-up.

3-11 Airport Tenants.

Airport tenants and their employees should be considered a prime source of readily available equipment and manpower who may have intimate knowledge of the airport and aircraft. They can be invaluable, especially if their backgrounds include medical training, food preparation, or transportation. It is important that these persons be deployed under supervision and assigned specific functions to avoid duplication of efforts and the possibility of disrupting other emergency operations.

3-12 Transportation Authorities (Land, Sea, Air).

3-12.1

In an emergency, vehicles are needed to carry out rescue operations, transport personnel, and haul supplies and debris. Responsibility for the control of vehicles to be used during an emergency should be assigned to a designated transportation officer. The emergency plan should inventory and include the function of all available drivers and transportation equipment, such as buses, trucks, maintenance vehicles, and automobiles. Arrangements in advance also might be made to obtain additional vehicles from bus companies, leasing companies, or garages. Also, by prior agreement, the use of vehicles owned by airport employees can be included in the emergency plan. All plans for vehicle use should include qualified operators for the vehicles.

3-12.2

In airport emergencies, provision should be made for an easily identifiable guide vehicle(s), equipped with two-way radio communication, to lead groups of vehicles from the rendezvous point(s) or staging area to the accident site to avoid interference with aircraft operations.

3-12.3

The transportation officer in charge should wear a lime green hard hat and lime green vest or other apparel with distinctive reflective lettering that reads "TRANSPORTATION OFFICER" displayed back and front.

3-12.4

Suitable rescue equipment and services should be available for use at an airport where the area to be covered by the appropriate services includes water or swampy areas or other difficult terrain that cannot be fully served by conventional wheeled vehicles. This is particularly important where a significant portion of approach and departure operations take place over these areas.

3-13 Rescue Coordination Center.

Rescue coordination centers can play a significant role in an aircraft accident occurring in the vicinity of an airport if the site of the accident is not known or if rescue facilities in addition to those available at or near the airport are required to be brought into action. Rescue coordination centers should have means of immediate communication with all rescue units within their areas of responsibility, including units able to provide aircraft, helicopters, and special rescue teams and, where appropriate, with coastal radio stations capable of alerting and communicating with surface vessels. Assistance from these units can be essential in responding to an accident in the vicinity of the airport. It is therefore suggested that the potential role of the rescue coordination center be specifically highlighted in the proposed airport emergency plan document in a separate paragraph.

3-14 Civil Defense.

The airport emergency plan should be integrated with the local community civil defense emergency plan and with local search and rescue teams. Consideration should be given to the role the airport may have as a result of coordination with civil defense officials and in support of any civil defense emergency plan requirements.

3-15 Mutual Aid Agencies.

3-15.1*

Airport emergencies can be of such magnitude that local rescue and fire fighting, security, law enforcement, and medical services are inadequate to handle the situation. It is therefore strongly recommended that written mutual aid agreements be initiated to ensure the prompt and orderly response of these agencies.

3-15.2

All mutual aid agreements should be reviewed or revised annually. Telephone and personnel contacts should be reviewed and updated monthly.

3-16* Harbor Patrol and Coast Guard.

Harbor Patrol and Coast Guard services are vital to airports adjacent to large bodies of water. Coordination of such services should be included in the Plan where applicable. Communication requirements to obtain the immediate response of such services (and the ability to communicate during the emergency) should be an essential ingredient of the Plan.

If the area where the boats are to be operated is subject to freezing, vehicles suitable for operation on ice (i.e., hover craft, swamp boats, etc.) should be available.

3-17 Military.

Where a military installation is located on or in the vicinity of an airport, a mutual aid agreement should be initiated to integrate personnel with command, communication, and coordination functions of the emergency plan.

3-18 Clergy.

The Plan should include advance agreements with clergy of all faiths to provide comfort to casualties and relatives.

3-19 Public Information Officer.

A public information officer should be designated. This officer should coordinate and release factual information to the news media and also should coordinate public information statements between all parties involved.

It is recommended that the television and radio news media be requested to withhold the release of accident information to allow sufficient time for adequate security to be established. Past history has shown that, as knowledge of the accident spreads, onlookers flock to the site and interfere with emergency vehicles' access to the incident.

3-20 Mental Health Agencies.

The emergency plan should include the local mental health agencies. Therapeutic treatment as well as follow-up procedures for dealing with the possible long-term effects of the emergency should be available for survivors, relatives, eyewitnesses, and emergency scene personnel.

Chapter 4 Functions of Each Agency for an Aircraft Accident on the Airport

4-1 General.

The airport/community emergency plan should be implemented immediately upon an aircraft accident occurring on the airport. Responding agencies should comply with Sections 4-2 through 4-10.

4-2 Action by Air Traffic Control (ATC) Services.

4-2.1

Air traffic control services should initiate emergency response by using the alarm communications system. (*See Figure 4-2.1.*)

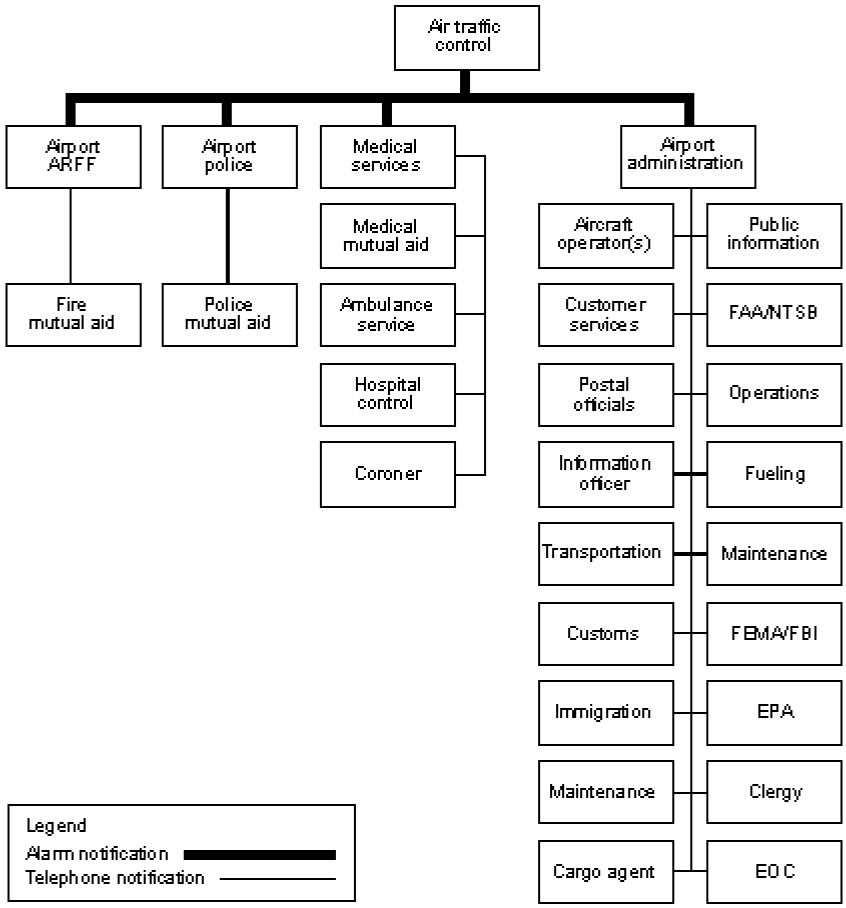

Figure 4-2.1 Sample notification chart — aircraft accident on airport.

4-2.2*

Information on the location of the accident and type of alarm, giving grid-map reference or other identifying terrain features should be immediately provided by air traffic control services. These details should include the type of aircraft.

Subsequent calls can expand this information by providing details on the number of occupants, fuel on board, aircraft operator, if appropriate, and any dangerous goods or hazardous materials on board, including quantity and location.

4-2.3

Air traffic control should restrict airport operations and minimize vehicle traffic on that runway to prevent disturbance of accident investigation evidence.

4-2.4

An appropriate Notice to Airmen (NOTAM) should be issued immediately by air traffic control services. For example:

> "Airport rescue and fire fighting service protection unavailable until (time) or until further notice. All equipment committed to an aircraft accident."

4-2.5

Air traffic control should confirm that the actions above were completed, by written or computer checklist, indicating notification time(s) and name of person completing action.

4-3 Action by Rescue and Fire Fighting (RFF) Services.

4-3.1

An alarm for an aircraft accident on the airport will normally be received from the air traffic control services. When, however, an alarm is received from any other source, or an accident is observed, or there is reason to consider that one is imminent, the airport rescue and fire fighting services should take action in the same manner as if the air traffic control services had originated the alarm. The air traffic control services should be informed by the responding fire fighting services as to the nature of the alarm, its location, and the response initiated.

4-3.2

Airport rescue and fire fighting services should:

(a) Proceed via established access routes to the incident as indicated by air traffic control services.

(b) Advise mutual aid fire departments while en route of:

1. Rendezvous point;
2. Staging area;
3. Manpower and equipment required for support if known;
4. Any other pertinent information.

(c) Immediately establish an on-scene command post.

4-3.3

Command authority at any accident site should be predetermined according to the jurisdictional responsibilities of the agencies involved and as designated in the airport/community emergency plan.

4-3.4

Prior agreement should be reached between the on-airport rescue and fire fighting service and the off-airport mutual aid fire departments as to who is best equipped to fight fires in aircraft hangars or other airport structures. Additionally, there should be prior agreement as to which agency will be in command when an accident involves an aircraft or an airport structure or both.

4-4 Action by Police/Security Services.

4-4.1

The first security/police officer to arrive should coordinate with the incident commander and, to the extent possible, immediately establish free traffic lanes on ingress and egress roads for emergency vehicles, initiate security responsibility, and request reinforcements as needed.

Traffic flow and site security should be the primary responsibility of police and security personnel. They should notify the appropriate communications center of the location of the accident and available means of access and egress. After consultation with the incident commander, they should initiate traffic control measures in order to aid responding emergency vehicles.

They should notify the airport security communications center or the incident commander (where appropriate) of the location of the accident, access, ingress, and egress roads available, and where responding security personnel should make initial response and recommendations for setting up roadblocks away from the accident site to aid responding emergency vehicles. Responding police vehicles should not proceed directly to the accident site (unless instructed by police communications center officer) to view the scene, but set up appropriate roadblocks at least two to three blocks away, as directed by the local security communications center. The local/police communication officer should set up appropriate roadblock locations as indicated on the local grid map to prevent road congestion.

4-4.2

Security personnel and police should handle traffic in the vicinity of the accident site, admit only authorized emergency personnel to the scene, keep unauthorized persons from the accident site, and be responsible for preservation of the accident scene.

4-4.3

All unnecessary traffic should be routed away from and around the accident site.

4-4.4

The emergency site should be cordoned off as soon as possible to exclude intruders, media, sightseers, onlookers, and souvenir hunters. Appropriate markings should be prominently displayed to advise all persons of possible hazards that can cause serious injury should they encroach on the area.

4-4.5

Communications between all security check points and the command post or emergency operations center or both should be established as soon as possible.

4-4.6

Identifying arm bands, site passes, or I.D. tags should be issued by the authority having jurisdiction and monitored by the security services.

4-4.7

Special security provisions should be instituted for the protection of the flight data and cockpit voice recorders, any mail involved, and any dangerous goods (hazardous materials) that may be present.

4-5 Action by Airport Authority.

4-5.1

The airport authority representative should respond to the accident site and, as needed, set up an easily identifiable mobile command post. The mobile command post should be adequately staffed by senior representatives able to make decisions involving the following types of operations:

(a) Airport;

(b) Security;

(c) Medical;

(d) Aircraft; and

(e) Aircraft recovery.

4-5.2

The airport authority should commence written check list procedures to verify that:

(a) The airport emergency operations center has been activated;

(b) Mutual aid police procedures have been initiated and secondary notification calls have been made;

(c) Medical and ambulance services have been alerted and their arrivals verified at the designated rendezvous point or staging area;

(d) Mutual aid fire departments have been notified and escort has been provided for their access to the accident site;

(e) The affected aircraft operator has been notified and information obtained on any dangerous goods or hazardous materials on board the aircraft, e.g., explosive substances, flammable gases and liquids, combustible solids, oxidizing substances, poisonous substances, radioactive materials, or corrosives;

(f) Liaison has been established with air traffic control services concerning the closure of airport areas, designation of emergency response corridors, and issuing of voice advisories and Notices to Airmen (NOTAM) advising of reduced airport rescue and fire fighting protection;

(g) Government aircraft accident investigation authorities, such as the National Transportation Safety Board (NTSB), have been notified (if military aircraft is involved the appropriate military organization should be notified);

(h) The meteorological department has been notified to make a special weather observation;

(i) Arrangements have been made for the affected runway to be surveyed immediately by the appropriate personnel to identify the location of crash debris and to ensure that the debris be secured pending release by investigating agencies;

(j) Airspace reservation coordination offices (Air Traffic Flow Control Office), if any, have been advised of reduced airport capabilities;

(k) Medical Examiner’s/Coroner’s Office has been notified to assist with fatalities if necessary; and

(l) Temporary morgue facilities have been identified and designated.

4-5.3

In conjunction with mutual aid police, the airport authority should:

(a) Designate rendezvous points and staging areas for the inner and outer perimeters;

(b) Assign security personnel at the staging area or rendezvous point or both to escort vehicles so as to ensure the orderly flow of emergency personnel to the accident site, particularly the provision of escort for ambulances responding to the rendezvous point and from the staging area; and

(c) Assign parking areas for escort vehicles and ambulances, giving consideration to the need for rapid deployment when dispatched.

4-5.4

The airport authority also should, to the extent possible, arrange to have available the following services as may be required:

(a) Portable emergency shelter for use by other than medical services;

(b) Lavatories;

(c) Drinking water;

(d) Ropes, barriers, etc.;

(e) Food service;

(f) Mobile or portable lighting;

(g) Portable heating system;

(h) Cones, stakes, flags, and signs;

(i) Machinery, heavy equipment, and extraction tools;

(j) Communications equipment such as megaphone, portable telephone, etc.; and

(k) Fuel removal equipment.

4-5.5

The airport authority should provide the initial briefing for their airport public information officer. They should then coordinate, where appropriate, with the public information officer of the aircraft operator involved to provide the following:

(a) Media releases for the various media officers from the agencies involved; and

(b) Briefings and statements that will be released to the media.

4-5.6

Upon concurrence of the chief fire officer, police/security chief, and the medical coordinator, the airport authority's incident commander should notify all participating mutual aid organizations of termination of the airport emergency. Note that this may not terminate all actions and responsibilities of participating agencies.

4-6 Action by Medical Services.

The medical coordinator should coordinate with the medical transportation officer and medical services to:

(a) Verify that mutual aid medical and ambulance services have been alerted and verify their subsequent arrival at the rendezvous point or staging area and that a medical communication network is established;

(b) Organize the necessary action for triage and treatment of the casualties and their eventual evacuation by appropriate means of transportation;

(c) Provide control and dispatch of the casualties to the appropriate hospitals by land, sea, or air;

(d) Maintain an accurate list of the casualties including their names and their destination for treatment;

(e) Coordinate, with the aircraft operator concerned, the transportation of the uninjured to the designated holding area;

(f) Arrange for the restocking of the medical supplies, if necessary; and

(g) Provide medical analysis of the walking wounded or traumatized.

4-7 Action by Hospitals.

Hospitals listed in the emergency plan should be prepared to:

(a) Provide medical care to the casualties when they arrive;

(b) Provide doctors and trauma teams in accordance with the airport/community emergency plan; and

(c) Ensure that adequate doctors and nurses, blood, operating rooms, intensive care, and surgical teams are available for emergency disaster situations, including aircraft accidents.

4-8 Action by Aircraft Operators.

4-8.1

A senior aircraft operator representative should report to the command post to coordinate the aircraft operator activities with the incident commander.

4-8.2

The senior aircraft operator representative should provide information regarding passenger load, flight crew complement, and dangerous goods or hazardous materials on the aircraft. These include explosive substances, flammable liquids or gases, combustible solids, oxidizing substances, poisonous substances, radioactive materials, and corrosives. Information of this nature should be relayed as soon as possible to the chief fire officer and the medical coordinator.

4-8.3

The senior aircraft operator representative should make arrangements for bus transportation from the accident site to the designated traumatized holding area. Transportation of the walking wounded from the scene should be permitted only after consultation with the medical coordinator. Passengers should be under medical supervision while awaiting transportation, during transport, and at the receiving processing site.

4-8.4

The aircraft operator staff should proceed to the designated uninjured holding area. The senior aircraft operator representative at the uninjured holding area should appoint a receptionist, registrars, and welfare coordinators from staff who have been previously trained in these functions.

4-8.5

The aircraft operator representative who is in command of the uninjured holding area should oversee the overall operations by making arrangements for commissary items, clothing, telephone facilities, and additional medical services if required.

4-8.6

The receptionist should meet the buses as they arrive from the scene of the accident and direct the passengers to the registrars' tables where they will be processed. The receptionist also should explain where toilet facilities, telephones, and other amenities are located. However, migration outside the holding area should be prevented until each person transported to the holding area is identified and processed according to the Plan.

4-8.7

The registrar should record the passenger's name on the manifest and determine what reservation requirements are desired, i.e., hotel accommodation, air transportation, or other modes of transportation, etc., and any persons to be notified of the passenger's physical or mental condition and potential plans. The registrar then should make out an identification tag or sticker and place it on the passenger. When their registration is completed, the registrars then should direct passengers to the welfare coordinators.

4-8.8

Welfare coordinators and mental health specialists trained in stress management should:

(a) Give support and comfort to relatives and friends of persons on board the aircraft involved;

(b) Register relatives and friends waiting at the airport for information about persons on board;

(c) Provide care, comfort, and assistance to the walking injured and uninjured survivors and responding personnel (if required); and

(d) Assist in the provision and serving of refreshments to waiting relatives and friends.

The welfare plan should provide for a suitable location to carry out the functions as well as procedures for alerting and coordinating welfare organizations.

4-8.9

The aircraft operator should provide notification of the aircraft accident to:

(a) Health and welfare agencies;

(b) Customs, where applicable;

(c) Immigration, where applicable;

(d) Post office; and

(e) Environmental protection agencies if a fuel spill, fire-fighting actions, or airborne matter can affect the environment.

4-8.10

A senior aircraft operator official should arrange for the initial notification of relatives and friends.

4-8.11

News releases by aircraft operators should be prepared in conjunction with the airport public information officer and liaison officers from other agencies involved in the accident.

4-8.12

The aircraft operator is responsible for the removal of the wrecked or disabled aircraft as soon as authorized by the National Transportation Safety Board or their designee. For aircraft removal technique see, *International Civil Aviation Organization Airport Services Manual*, Part 5, "Removal of Disabled Aircraft." Also see *International Air Transport Association — Guidelines for Airport Operators and Airport Authorities on Procedures for Removal of Disabled Aircraft*.

4-9 Action by Government Authorities. The following government authorities can be required to take appropriate action as indicated in their emergency plan:

(a) National Transportation Safety Board;

(b) Federal Aviation Administration;

(c) Health and welfare;

(d) Post office;

(e) Customs;

(f) Immigration;

(g) Agriculture; and

(h) Public works.

4-10 Action by the Public Information Officer.

4-10.1

All media personnel should be directed to a designated news media staging area for news media personnel authorized to cover an airport emergency. At this area the following should be provided:

(a) Latest briefing;

(b) Communications (telephones); and

(c) Transportation service to and from the scene of the emergency, where permissible and where it will not interfere with rescue, medical treatment of casualties, and the accident investigation.

4-10.2

Only members of the news media, freelance reporters, and photographers wearing a valid regular police working news media card should be admitted to the briefing area or permitted in the designated news media staging area or transported to the scene of the emergency.

4-10.3

In general, the official authority for news releases concerning an aircraft emergency should be that of:

(a) A public information officer designated by the airport authority; or

(b) The representative of the aircraft operator involved; or

(c) Both.

4-10.4

Under no circumstances should the news media or any other personnel not involved in life saving or fire fighting operations be permitted inside security lines until all rescue operations have been completed and the area has been declared safe by the chief fire officer. When establishing security lines, the interests of news coverage should be taken into account in so far as rescue operations permit.

4-11 Organization Charts.

4-11.1

Organization charts should be prepared for each anticipated type of emergency situation, off-airport incident, on-airport incident, earthquake, or flood.

4-11.2

These charts should depict the relationships and duties of all components of the Plan in such detail that each participating agency has a full understanding of its duties and responsibilities.

Chapter 5 Functions of Each Agency for an Aircraft Accident off the Airport

5-1 General.

The airport/community emergency plan should be implemented immediately upon an aircraft accident occurring off the airport. Responding agencies should comply with Sections 5-2 through 5-10.

5-2 Action by Air Traffic Control (ATC) Services.

5-2.1

Air traffic control services should initiate emergency response by using the alarm communications system. (*See Figure 5-2.1.*)

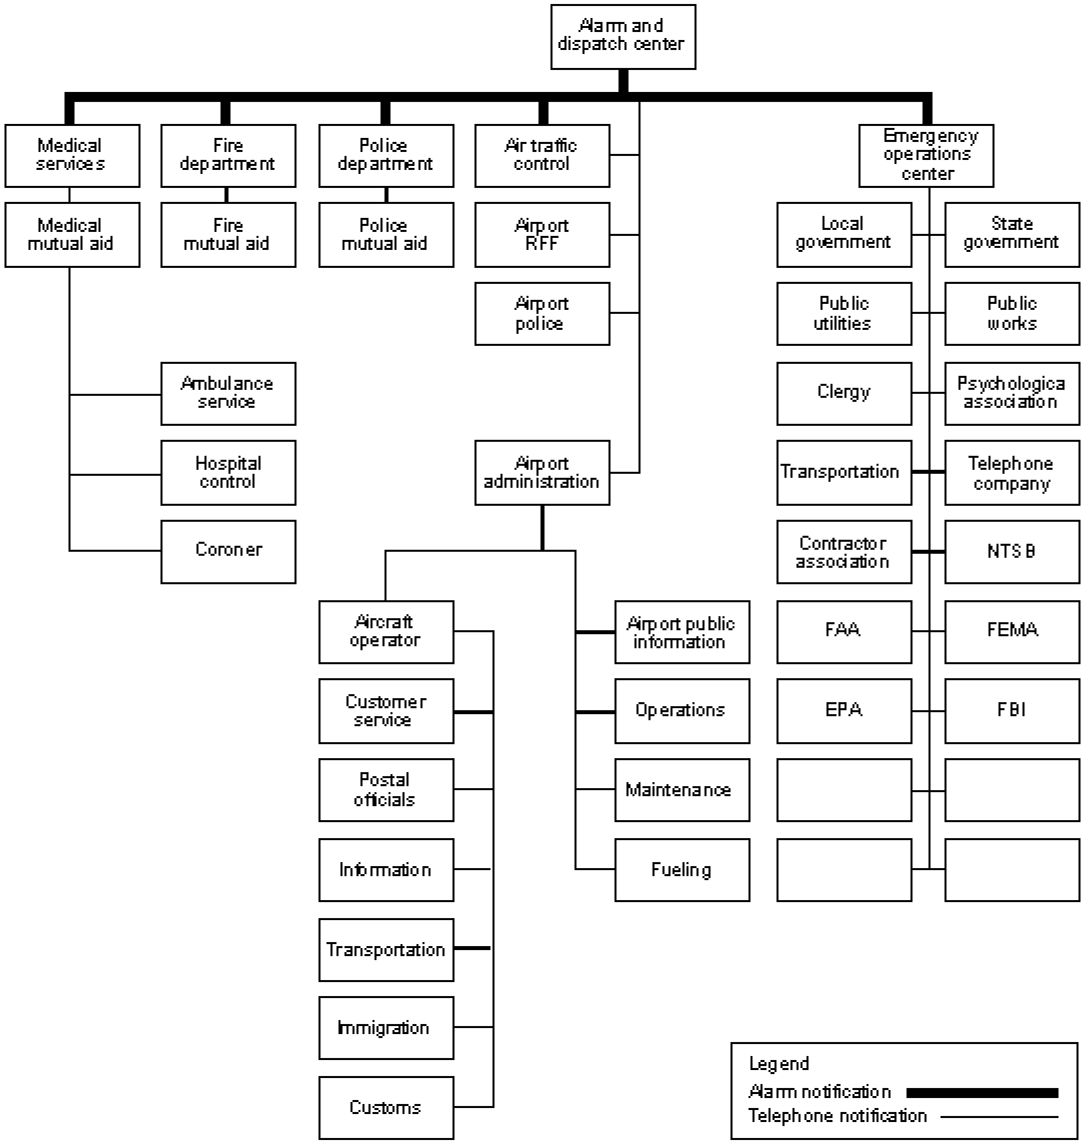

Figure 5-2.1 Sample notification chart — aircraft accident off airport.

5-2.2*

Information on the location of the accident and type of alarm, giving grid-map reference or other identifying terrain features, should be provided immediately by air traffic control services.

Subsequent calls can expand this information by providing details on the number of occupants, fuel on board, aircraft operator, if appropriate, and any dangerous goods or hazardous materials on board, including quantity and location.

5-2.3

Air traffic control should alert the airport rescue and fire fighting service, police and security services, airport authority, and medical services in accordance with the procedure in the airport/community emergency plan, giving grid-map reference.

5-2.4

If requested by the fire department having jurisdiction over the accident area, air traffic control should provide for dispatch of the RFF service in accordance with the Plan and any mutual aid agreements.

An appropriate Notice to Airmen (NOTAM) should be issued immediately. For example:

> "Airport rescue and fire fighting service protection unavailable until (time) or until further notice. All equipment committed to an aircraft accident."

5-2.5

Air traffic control should confirm that the actions above were completed, by written or computer checklist, indicating notification time(s) and name of person completing the action.

5-3 Action by Rescue and Fire Fighting (RFF) Services.

5-3.1

A call for an aircraft accident off the airport normally is received from the air traffic control services, local police, or local fire departments. Designated vehicles should be sent in accordance with the existing mutual aid department agreements.

5-3.2

Responding airport rescue and fire fighting services should:

(a) Proceed via preestablished access routes, considering vehicle weight, height, and width, to the off-airport accident site in coordination with local police/security direction.

(b) While en route, advise or request of fire department having jurisdiction over the area:

1. Rendezvous point or staging area or both;
2. Staffing and equipment responding; and
3. Any other pertinent information.

5-3.3

The senior airport fire officer should report to the senior fire officer of the fire department having jurisdiction over the area and request orders.

5-3.4

Prior agreement should be achieved between the on-airport rescue and fire fighting service and the local fire department in command and mutual aid fire departments as to who is best equipped to fight fires involving aircraft or structures or both. Additionally, there should be prior agreement as to which agency will act in command when an accident involves both an aircraft and an off-airport structure.

5-4 Action by Police/Security Services.

5-4.1

The first security/police officer to arrive should coordinate with the incident commander and, to the extent possible, immediately establish free traffic lanes on ingress and egress roads for emergency vehicles, initiate security responsibility, and request reinforcements as needed.

Traffic flow and site security are the primary responsibility of police and security personnel. They should notify the appropriate communications center of the location of the accident and available means of access and egress. After consultation with the incident commander, they should initiate traffic control measures in order to aid responding emergency vehicles.

5-4.2*

Security personnel and police will be needed to handle traffic in the vicinity of the accident site and to prevent disturbance of material scattered over the accident site.

The emergency site should be cordoned off as soon as possible to exclude intruders, media, sightseers, onlookers, and souvenir hunters. Appropriate markings should be prominently displayed to advise all persons of possible hazards that can cause serious injury should they encroach on the area. Flares should not be used within 300 ft (100 m) of the accident site to prevent ignition of fuel vapors.

5-4.3

Communications between all security checkpoints and the command post or emergency operations center or both should be implemented as soon as possible.

5-4.4

Identifying arm bands, site passes, or I.D. tags should be issued by the controlling authority and monitored by the security/police officer and his or her team.

5-4.5

Special security provisions should be made to protect the flight data and cockpit voice recorders, any mail involved, or dangerous goods or hazardous materials that might be present.

5-5 Action by Emergency Medical Services.

The medical coordinator should coordinate with the medical transportation officer and medical services to:

(a) Verify that mutual aid medical and ambulance services have been alerted and verify their subsequent arrival at the rendezvous point or staging area and that a medical communication network is established;

(b) Organize the necessary action for triage and treatment of the casualties and their eventual evacuation by appropriate means of transportation;

(c) Provide control and dispatch of the casualties to the appropriate hospitals by land, sea, or air;

(d) Maintain an accurate list of the casualties including their names and their destination for treatment;

(e) Coordinate, with the aircraft operator concerned, the transportation of the uninjured to the designated holding area;

(f) Arrange for the restocking of the medical supplies, if necessary; and

(g) Provide medical analysis of the walking wounded and uninjured.

5-6 Action by Hospitals.

Hospitals listed in the emergency plan should be prepared to:

(a) Ensure that adequate doctors and nurses, and operating room, intensive care, and surgical teams are available for emergency situations, including aircraft accidents;

(b) Provide medical care to the casualties when they arrive;

(c) Provide doctors and trauma teams to the accident site in accordance with the Plan; and

(d) Notify coroner/medical examiner.

5-7 Action by Airport Authority.

If previously agreed on in the airport mutual aid emergency agreement with the surrounding community, the following actions can be taken by the airport authority:

(a) Report to the accident site;

(b) Ensure that, if required, the airport emergency operations center and the mobile command post are activated;

(c) Extend as much emergency aid as requested by the jurisdiction agency in command of the off-airport accident/incident;

(d) Notify the aircraft operator involved; and

(e) Notify other agencies as required.

According to the mutual aid emergency agreement with the surrounding community, the airport authority can provide, if requested and if available, a part of its medical equipment (i.e., first aid equipment, stretchers, body bags, mobile shelters, etc.) and the assistance at the accident site of doctors and personnel teams qualified in emergency first aid.

5-8 Action by Aircraft Operators.

5-8.1

A senior aircraft operator representative should report to the command post to coordinate with the incident commander.

5-8.2

The senior aircraft operator representative should provide information regarding passenger load, flight crew complement, and dangerous goods or hazardous materials on the aircraft. These include explosive substances, gases, flammable liquids or solids, oxidizing substances, poisonous substances, radioactive materials, and corrosives. Information of this nature should be relayed as soon as possible to the chief fire officer and the medical coordinator.

5-8.3

The senior aircraft operator representative should make arrangements for bus transportation from the accident site to the designated uninjured holding area. Transportation of the walking wounded from the scene should be permitted only after consultation with the medical coordinator.

5-8.4

The aircraft operator staff should proceed to the designated uninjured holding area. The senior aircraft operator representative at the uninjured holding area should appoint a receptionist, registrars, and welfare coordinators from staff who have been previously trained in these functions.

5-8.5

The aircraft operator representative who is in command of the uninjured holding area should oversee the overall operations by making arrangements for commissary items, clothing, telephone facilities, and additional medical services if required.

5-8.6

The receptionist should meet the buses as they arrive from the scene of the accident and direct the passengers to the registrars' tables where they will be processed. The receptionist should know where support facilities such as toilet facilities, telephones, clothing, and drinking water are located.

5-8.7

The registrar should record the passenger's name on the manifest and determine what reservation requirements are desired, i.e., hotel accommodation, air transportation, or other modes of transportation, etc., and names of any persons to be notified of the passenger's physical or mental condition and potential plans. The registrar should make out an identification tag or sticker (available from the emergency kit) and place it on the passenger. When their registration is completed, the registrars then should direct the passengers to the welfare coordinators.

5-8.8

Where necessary, the aircraft operator should provide notification of the aircraft accident to:

(a) Health and welfare agencies;

(b) Customs, where applicable;

(c) Immigration, where applicable;

(d) Post office;

(e) Agriculture agencies;

(f) Environmental Protection Agency (EPA); and

(g) National investigative agency NTSB (FBI).

5-8.9

A senior aircraft operator official should be responsible for the initial notification of relatives and friends.

5-8.10

News releases by aircraft operators should be prepared in conjunction with the airport public information officer and liaison officers from other agencies involved in the accident.

5-8.11*

The aircraft operator is responsible for the removal of the wrecked or disabled aircraft, as soon as authorized by the aircraft accident investigation authority.

5-9 Action by Government Authorities.

The following government authorities, after being notified, can be required to take appropriate action as indicated in their emergency plan:

(a) Government accident investigation personnel;

(b) Health and welfare;

(c) Post office;

(d) Customs;

(e) Immigration; and

(f) Agriculture.

5-10 Action by the Public Information Officer.

5-10.1

The responsibility for news releases concerning an off-airport emergency should be that of:

(a) The representative of the aircraft operator;

(b) A public information officer designated by the service government authority in command; and

(c) A public information representative designated by the airport authority.

5-10.2

Under no circumstances should the media or other personnel not directly involved in the fire fighting, rescue, or emergency medical care be permitted inside security lines until all rescue operations have been completed and the area is declared safe for entry by the incident commander/chief fire officer.

Chapter 6 In-Flight Emergencies

6-1 Full Emergency Incident — Aircraft in Flight.

6-1.1

The agencies involved in the airport/community emergency plan should be alerted to “full emergency” status when it is known that an aircraft approaching the airport is, or is suspected to be, in such trouble that there is a strong likelihood of an accident.

6-1.2 Action by Air Traffic Control Services.

6-1.2.1 Air traffic control services should call the airport rescue and fire fighting service to stand by at the predetermined standby positions applicable to the runway to be used and provide as many of the following details as possible:

(a) Type of aircraft;

(b) Nature of trouble;

(c) Runway to be used;

(d) Estimated time of landing;

(e) Aircraft operator, if appropriate;

(f) Fuel on board;

(g) Number of occupants, including special occupants — handicapped, immobilized, blind, deaf, etc.; and

(h) Any dangerous goods or hazardous materials on board, including quantity and location, if known.

6-1.2.2 The calling of the mutual aid fire department(s) and other appropriate organizations should be initiated by air traffic control services in accordance with the procedure laid down in the airport/community emergency plan, giving, where necessary, rendezvous point and airport entrance to be used.

6-1.3 Action by Other Agencies.

The specific responsibilities and roles of the various agencies itemized in Sections 4-2 to 4-10 for responding to an aircraft accident on the airport can be applied for "full emergency" as required by local operating requirements.

6-2 Local Standby.

6-2.1

The agencies involved in the airport/community emergency plan should be alerted to "local standby" status when an aircraft approaching the airport is known or is suspected to have developed some defect, but the trouble is not such that would normally involve any serious difficulty in effecting a safe landing.

6-2.2 Action by Air Traffic Control Services.

6-2.2.1 Air traffic control should call the airport rescue and fire fighting service to stand by as requested by the pilot or to stand by as local airport agreements require at the predetermined standby positions applicable to the runway to be used. As many of the following details as possible should be provided:

(a) Type of aircraft;

(b) Nature of trouble;

(c) Runway to be used;

(d) Estimated time of landing;

(e) Fuel on board;

(f) Number of occupants, including special occupants — handicapped, immobilized, blind, deaf, etc.;

(g) Aircraft operator, if appropriate; and

(h) Any dangerous goods or hazardous materials on board, including quantity and location, if known.

6-2.2.2 Action by Other Agencies. The specific responsibilities and roles of the various agencies itemized in Sections 4-2 through 4-10 for responding to an aircraft accident on the airport can be applied for "local standby" as required by local operating requirements.

Chapter 7 Other Emergencies

7-1 General.

Procedures and techniques used in handling nonaircraft accident related airport emergencies should be similar to the techniques used in handling aircraft accident emergencies. It should be recognized that medical and fire emergencies can arise at any location where large numbers of persons work or congregate. At airports this problem can be severe because of the exposure associated with the commonplace activities of arriving and departing passengers and sightseers, the public service facilities provided at airports (i.e., automobile movement and parking areas, restaurants, bars, baggage handling and storage areas, etc.), and the fact that airports can be selected by malcontents as locations to demonstrate their anger against any group or activity.

7-1.1

The diverse character of persons traveling by air suggests the need for the airport authority to arrange to have available emergency medical services to treat conditions such as cardiac arrest, abdominal pains, burns, cuts, abrasions, and other medical problems. This can require immediate care facilities and detailed mutual aid plans with outside agencies.

7-1.2

The natural disasters airports can be subjected to include storms, floods, earthquakes, and seismic sea waves. The vulnerability of an airport to any of these will, in good measure, be affected by geography. While nothing can be done to avert them, there are actions that can be taken to minimize damage and expedite restoration of aircraft operations.

7-1.3

Development of weather patterns, prediction and tracking of storm movement, and notification to the public of potential danger resulting therefrom will normally be carried out by a meteorological service in the area.

7-1.4

The airport/community emergency plan should provide for initial protective measures, personnel shelter, and post-storm cleanup and restoration. Aircraft operations might be impossible for several hours before the arrival of the storm and until several hours after its passing.

7-1.5

As soon as severe storm warnings are received, all owners of aircraft based or on the ground at the airport should be notified and warnings issued to all aircraft pilots en route to the airport. Aircraft owners and pilots should be responsible for their aircraft but, if possible, all aircraft on the ground should be evacuated to airports outside the storm area. Aircraft in flight should be advised to divert to an alternative destination. Aircraft on the ground that cannot be dispersed should be put under cover or tied down so as to face into the approaching winds.

7-1.6

Power interruptions are common during a natural disaster, either by damage to generating plants or by destruction of transmission lines. Airports located in severe storm areas should take measures to ensure minimum interruption to power supply, either by providing standby electrical generators or dual sources of commercial power for essential functions.

7-1.7

Regarding building protection, specific personnel assignments should be made in the airport/community emergency plan to collect or secure all loose objects that can be blown about by the winds and to fill and place sandbags if there is any possibility that the storm is accompanied by floods.

7-1.8

Where the Aircraft Rescue and Fire Fighting (ARFF) provides a commitment to assist in non-aircraft-related emergencies, attendance at those incidents should not compromise their immediate agreed upon level of response to aircraft accidents or incidents.

7-2 Sample Notification Charts.

7-2.1

The examples illustrated in Figures 4-2.1 and 5-2.1 can assist in rapid communication in the event of an emergency. Accordingly, they should contain all the vital telephone numbers.

7-2.2

Separate sample notification charts should be developed for each type of emergency included in the Plan. It is important that the method of notification be clearly outlined in the airport/community emergency plan.

7-2.3

Telephone numbers should be verified monthly and a revised list issued if necessary. In order to require only one page to be reissued when a change occurs, each sample notification chart should be printed on one sheet.

Chapter 8 Emergency Operations Center and Mobile Command Post

8-1 General.

The emergency operations center is a fixed designated area on the airport that is usually used in supporting and coordinating operations in accidents/incidents, unlawful seizure of aircraft, and bomb threat incidents. The unit should have the necessary communication equipment and personnel to communicate with the appropriate agencies involved in the emergency, including the mobile command post, where this is deployed. The communication and electronic devices should be checked daily.

8-2 Emergency Operations Center.

8-2.1

An emergency operations center should be available for the purpose of dealing with emergency situations at each airport.

8-2.2

The emergency operations center should provide:

(a) A fixed location;

(b) Support of the incident commander in the mobile command post for aircraft accidents/incidents;

(c) A command, coordination, and communication center for unlawful seizure of aircraft and bomb threats; and

(d) Operational availability 24 hours a day.

8-2.3

The location of the emergency operations center should provide a clear view of the movement area and isolated aircraft parking position, wherever possible.

8-3 Mobile Command Post.

(*See Figure 8-3*.)Figure 8-3

Figure 8-3 Mobile command post.

8-3.1

Certain emergency situations also will require a mobile command post at the scene. This mobile unit is normally provided by the airport authority and, during the emergency, is normally under the direction of the incident commander.

8-3.2

The mobile command post is a point where cooperating agency heads assemble to receive and disseminate information and make decisions pertinent to the rescue operations. The main features of this unit are:

(a) It is a mobile facility capable of being rapidly deployed;

(b) It serves as command, coordination, and communications center for aircraft accidents or incidents; and

(c) It is operational during aircraft accidents or incidents.

8-3.3

In the event of any accident or incident, a designated, recognizable, and highly visible mobile command post should be a high-priority item. It should be established as quickly as possible and preferably with the initiation of fire control and rescue activities. It is important that a continuity of command be maintained so that each agency reporting to the mobile command post can be adequately briefed on the situation before proceeding to assume control of its individual responsibilities.

8-3.4

The mobile command post unit should contain the necessary communications equipment and personnel to communicate with all agencies involved in the emergency, including the emergency operations center. The communication and electronic devices should be checked monthly or periodically as required by local conditions.

8-3.5

Maps, charts, and other relevant equipment and information should be immediately available at the mobile command post.

8-3.6

The mobile command post should be easily recognizable by provision of an elevated distinguishing marker, such as a checkered flag, colored traffic cone, balloon, or rotating light.

8-3.7

In some cases it might be necessary to establish a subcommand post. Where this is required, one location should be designated as a “master” command post with adequate communications to the subcommand post.

Chapter 9 Communications

9-1 Communications Network.

9-1.1

A coordinated communications network should be a prerequisite to any large-scale operation that involves agencies from more than one jurisdiction.

9-1.2

A communications network should consist of a sufficient number of radio transceivers, telephones (both mobile and land line), and other communication devices to establish and maintain a primary and a secondary means of communication. These networks should link the emergency operations center and the command post with each other as well as with all participating agencies. (*See Figure 10-2.*)

9-1.3

The operational communications network should provide a primary and, where necessary, an alternate, effective means for direct communications between the following, as applicable:

(a) The alerting authority (control tower or flight service station, airport manager, fixed-base operator, or airline office) and the RFF units serving the airport;

(b) Air traffic control tower or flight service station or both, the appropriate fire department alarm room/dispatch center(s), and the fire fighting and rescue and medical services personnel en route to an aircraft emergency and at the accident/incident site;

(c) Appropriate mutual aid agencies located on or off the airport, including an alert procedure for all auxiliary personnel expected to respond; and

(d) The RFF vehicles including a communications capability between crew members on each RFF vehicle.

9-2 Communications Equipment.

9-2.1

It is important to provide serviceable communications equipment in sufficient quantity to ensure rapid response of personnel and equipment to an emergency. The following communications equipment should be available for immediate use in the event of an emergency.

9-2.2 Portable Radios.

A sufficient number of portable, two-way radios should be available to provide each participating agency with the ability to communicate with the command post.

9-2.3

Strict communication discipline should be employed to prevent jamming of emergency frequencies. Each agency should operate on its own frequency, and there should be a designated command frequency.

9-2.4

Radios should be available at the command post to provide direct communication with the aircraft or ground controllers should it become necessary.

Direct communications also can be established between the pilot or the aircraft cockpit by use of cockpit-to-ground lines. This requires a proper connector, wire, microphone, and headset. Cooperation and coordination between the airport fire and rescue service and the individual air carrier(s) are needed to establish this type of communication capability. Normally this communication capability results from the use of a ground service headset that is plugged into a wheelwell interphone jack.

9-2.5

A sufficient number of telephone lines (both listed and unlisted) or cellular phones should be available at the command post to provide direct communication with agencies outside the airport, as well as within the airport. Direct lines save time and reduce the probability of overwhelming radio communication channels.

9-2.6

Medical facilities and ambulances need communications capability in order to take advantage of advance life support systems within the medical community.

9-2.7

A dedicated vehicle equipped with necessary communications equipment and self-contained electrical power is a definite asset to a good communication system. A well-equipped communications vehicle is an indispensable part of an efficient, well-managed command post. Planning should always include a qualified vehicle driver/operator.

9-2.8

Recording devices, with time insertion units, should be installed at the operations center or mobile command post or both to ensure that all communications are recorded for later analysis. All emergency communications, including printed communication, should be recorded.

9-2.9

Runners should be assigned to the command post to augment other modes of communication. Their use can prove invaluable should a temporary lapse of communication occur.

9-3 Testing and Verification.

9-3.1

The communications system should be tested daily to verify the operability of all radio and telephone networks.

9-3.2

A complete and current list of interagency telephone numbers should be available to all agencies and to personnel responsible for the airport/community emergency plan. These phone numbers should be verified monthly to ensure that they are correct.

Chapter 10 Command and Coordination for Airport/Community Emergency Plan

10-1 General.

10-1.1

Once an accident has occurred on the airport, the direction and control of rescue and fire fighting operations should be the responsibility of the airport rescue and fire fighting service officer in charge. Any transition of authority and command responsibility should be established previously in the emergency plan and exercised accordingly. Off-airport accidents should be under the direction and control of the jurisdiction where the accident occurred.

10-1.2

The Plan should be very specific in its designation of other responsible entities and their authority and function in the command organization.

10-2 Incident Command System.

The Plan should include a flexible organization system that enhances management of all activities at the accident site. This system should include a description of each element of the Plan, the agency assigned to the specific element, and a brief summary of the authority and responsibility necessary to execute the element. A diagrammatic representation of an organization chart from a typical incident command system is shown in Figure 10-2.

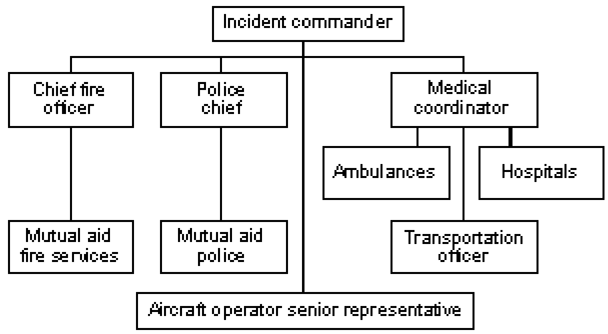

Figure 10-2 Command flow diagram.

Chapter 11 Emergency Medical Care

11-1 Basis of Recommendations.

11-1.1*

These recommendations are based upon the existence of an established level of emergency medical service that can be expanded into a comprehensive emergency medical system at the scene of an aircraft accident with numerous casualties.

11-1.2

Responsibilities of the emergency medical organization should include all aspects of medical care at the scene of an aircraft accident: triage, treatment, and transportation.

11-2 Emergency Medical Training of Airport Personnel.

11-2.1*

All airport fire department personnel assigned to fire control and rescue duties and all public contract airport employees ideally should be given first aid and CPR training. At least two full-time members of the airport fire department per shift should be trained to an EMT level and should be available to respond to any airport emergency of any severity.

11-2.2

The following subjects are the minimum that should be covered in a course of instruction to enable airport personnel to function effectively in providing emergency medical services:

(a) Airway management and cardiopulmonary resuscitation (CPR);

(b) Control of bleeding;

(c) Fractures and splinting with emphasis on spinal injuries;

(d) Burns;

(e) Shock;

(f) Emergency childbirth and immediate care of newborns, including prematures;

(g) Common medical diseases that can influence the outcome of injury (allergies, high blood pressure, diabetes, pacemaker, etc.);

(h) Basic measures for treatment and protection subsequent to spills or leaks of radioactive materials or toxic or poisonous substances;

(i) Basic measures for handling emotionally disturbed persons;

(j) Recognition and first aid for poisons, bites, and anaphylactic shock;

(k) Transportation techniques for injured persons;

(l) Heimlich maneuver—treatment of choking victims; and

(m) Protection against the spread of communicable diseases.

11-3 Airport Emergency Medical Supplies and Equipment.

11-3.1

Sufficient medical supplies to treat the capacity of the largest aircraft normally utilizing the airport should be available on or adjacent to the airport. Adequate supplies should be kept on hand to deal with routine medical emergencies (i.e., on-the-job injuries, cardiac arrest, etc.).

11-3.2

The type and quantity of such supplies should be determined by the principal medical authority for the airport.

Recent incidents have demonstrated that the unique characteristics presented by any given location should be taken into consideration when deciding on the type and quantity of supplies to be kept available for major incidents. For instance, extremes in temperatures should be considered and appropriate supplies stockpiled. Geographical conditions or topographical conditions or both also should be taken into consideration. The type and quantity of all medical supplies stockpiled should be determined by the agency responsible for providing emergency medical service to the airport.

11-3.3

Stretchers, blankets, cervical collars, backboards, and body bags should be located on the airport, preferably on a suitable vehicle (e.g., trailer) that can be transported to the accident site. Blankets are needed to alleviate the victims' exposure to shock and possible adverse weather conditions. The backboards and spine boards should be of a type designed to fit through access ways and aisles of commercial and business aircraft. They should have restraining straps available so the patient can be secured to the board. A cleat should be attached to the underside of the backboard to facilitate lifting by carrying personnel.

11-3.4

Sufficient resuscitation equipment should be available to treat smoke inhalation victims. This equipment should not be used around fuel or fuel soaked clothing.

11-4 Airport Medical Service.

11-4.1

Emergency medical service should be readily available to an airport. Minimum considerations for level of service should include:

(a) Number of passengers served;

(b) Number of persons employed at the airport;

(c) Industrial activity on airport property; and

(d) Distance from adequate medical facilities.

Ideally, each airport should have a properly staffed and equipped first aid room/medical facility on site and in addition should arrange for the emergency response of trained medical personnel with the capability to treat serious injuries and transport them to proper medical facilities.

11-4.2

The primary purpose of emergency medical services is to provide triage, treatment, and transportation in order to stabilize, provide comfort, and transport victims/patients to appropriate medical facilities.

11-4.3

The delivery to the accident site of trained medical personnel capable of treating and transporting injured victims of an aircraft accident is a vital component of the airport community emergency plan. The Plan should determine who will provide this service and should make all necessary legal and financial arrangements before the accident occurs. This includes integration with local community plans or mutual aid agreements or both.

11-4.4

Medical and ambulance services can be an integral part of the airport services, particularly the ambulance service that is, in many cases, part of the airport rescue and fire fighting service. If medical and ambulance services are not available at the airport, prearrangements with local agencies providing these services should be made. The Plan should ensure the dispatch of a satisfactory assignment of trauma-trained emergency service medical personnel, equipment, and medical supplies. The Plan should address the location of surrounding medical facilities and the level of service each provides.

11-4.5

The Plan should provide for the control of patient transport from the scene to the receiving medical facilities. The Plan’s incident command system should include a transportation control officer. This position’s responsibilities should include:

(a) Communications with medical facilities or the central communications point or both for local medical facilities;

(b) Overseeing and ensuring effective priority casualty transportation to the appropriate medical facilities; and

(c) All other aspects of medical transportation.

This has proven to be a very demanding and labor intensive responsibility, requiring a minimum of three subordinate positions. They are:

(a) Transportation control (routing of ambulances to and from the scene);

(b) Transportation recorder (responsible for documentation of all patient movement); and

(c) Medical communications (responsible for all communications regarding medical transportation).

A fourth position, that of ambulance staging leader, also should be considered.

11-4.6

Participating hospitals should have contingency emergency plans to provide for mobilization of necessary medical teams to the accident site in the shortest possible time. Availability of qualified personnel and adequate facilities at the hospitals to deal with airport emergency situations is vital. In this respect, it should be mandatory to establish in advance an accurate list of surrounding hospitals classified according to their effective receiving capacity and specialized features such as neurosurgical ability, burn treatment, etc.

11-4.7

The distance from the airport and the ability to receive helicopters should be considered. Reliable two-way communications should be provided between hospitals, and ambulances and helicopters. The alert of an aircraft accident should be made to a single communication controlling medical facility, which then alerts all other facilities according to the local medical communications network. Prior provision for police escort vehicles and helicopters for medical staff should be arranged in the Plan.

11-5 Airports without a Medical Care Facility.

At airports where a medical care facility (medical clinic or first aid room) is not available, the airport authority should make arrangements to have available sufficient personnel trained in advanced first aid to cover all active hours of airport operation. Equipment for first aid work at these airports should consist, at minimum, of an emergency medical care bag. This bag should be readily available to be carried on a designated airport emergency vehicle and should contain at least:

(a) One plastic sheet 1.80 m × 1.80 m (6 ft × 6 ft), with four spikes;

(b) Seven hemostats (one package of three, one package of four);

(c) Two field dressings one 450 mm × 560 mm (18 in. × 22 in.), one 560 mm × 910 mm (22 in. × 36 in.);

(d) Ten abdominal pads (five packages of two);

(e) Forty 100 mm × 100 mm (4 in. × 4 in.) gauze pads (four packages of ten);

(f) Two tourniquets;

(g) One artificial airway;

(h) Three disposable airways (each with No. 2, No. 4, No. 5);

(i) One bulb syringe with two catheters (No. 12, No. 14 FR);

(j) Two large bandage scissors;

(k) Twenty disposable syringes with No. 25 GA 16-mm (.6-in.) needle;

(l) Twelve ace bandages two 150 mm (6 in.), four 75 mm (3 in.), six 50 mm (2 in.);

(m) Twelve alcohol sponge packages;

(n) Four rolls of gauze bandage two 75 mm (3 in.), two 50 mm (2 in.);

(o) Two rolls of adhesive tape;

(p) Four Vaseline gauze dressings 150 mm × 910 mm (6 in. × 36 in.);

(q) One box of 100 bandaids, assorted sizes;

(r) One blood pressure cuff and gauge;

(s) Two clipboards 220 mm × 280 mm (8 in. × 11 in.);

(t) Six pencils (pens, grease pencils, etc.);

(u) Sufficient supply of casualty identification tags (*see A-11-6.7*);

(v) One set of inflatable splints;

(w) One resuscitube;

(x) One short spine board;

(y) One flashlight;

(z) Two cervical collars;

(aa) One bite-stick wedge;

(bb) One disposable obstetric kit; and

(cc) A sufficient supply of infection control equipment, including medical gloves, masks, protective eyewear, and gowns/aprons.

11-6 Immediate Need for Care of Injured in Aircraft Accidents.

(*See Figure 11-6.*)

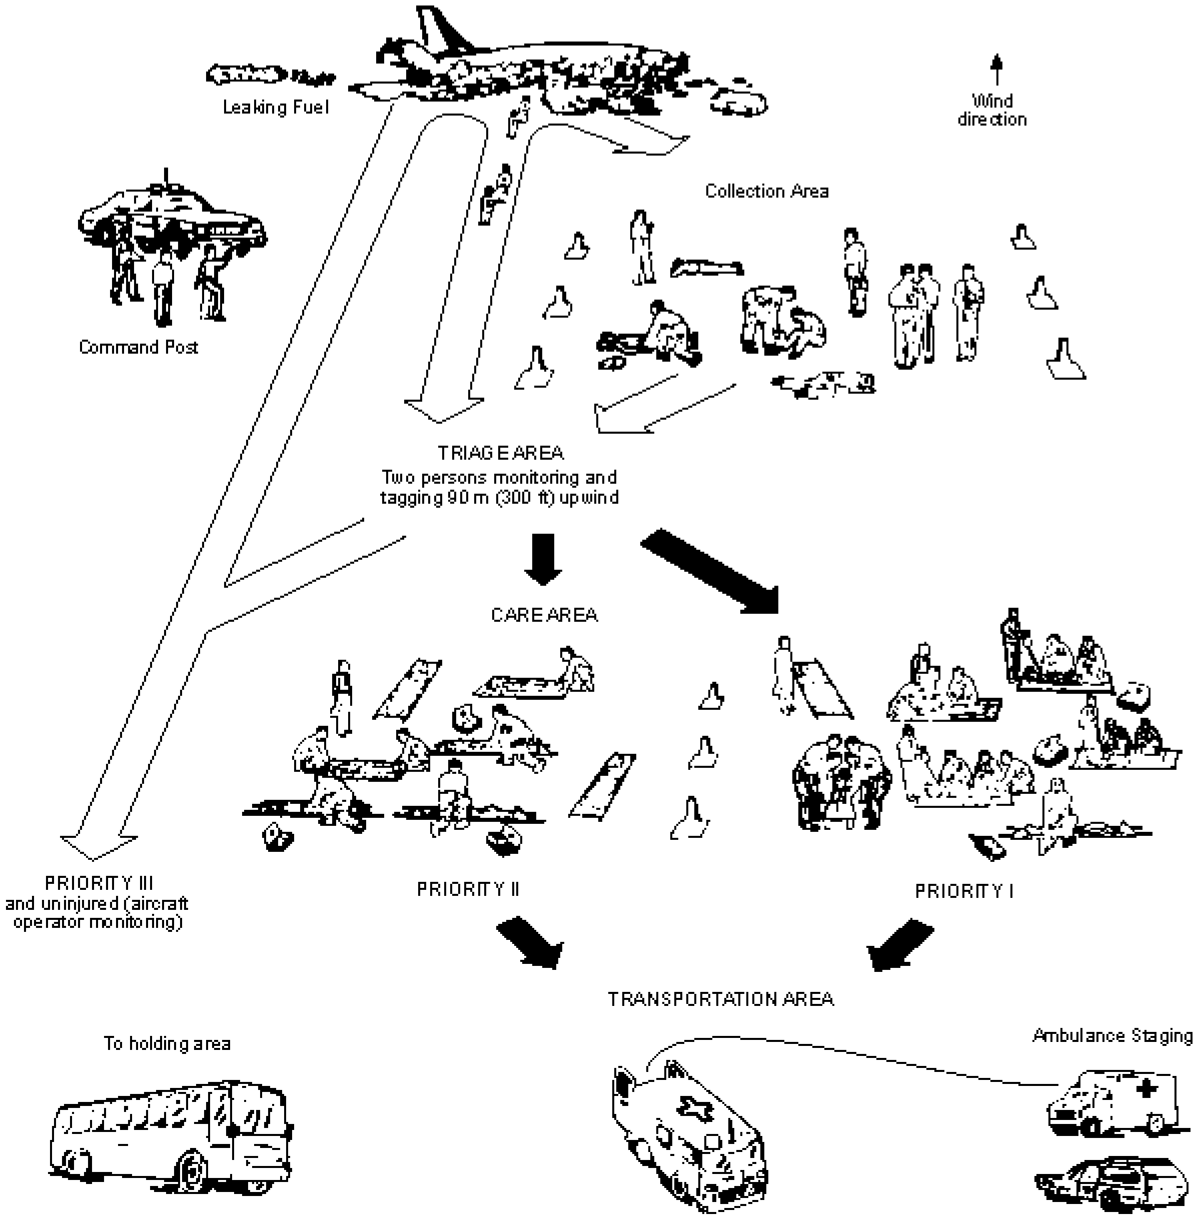

Figure 11-6 Triage and medical care at aircraft accident site.

11-6.1

In the aftermath of an aircraft accident many lives can be lost and many injuries aggravated if immediate medical attention is not provided by trauma-trained rescue personnel. Survivors should be examined, given available emergency medical aid as required, and then promptly transported to appropriate medical facilities.

11-6.2

Triage is the sorting and classification of casualties to determine the order of priority for treatment and transportation. Casualties should be classified into four categories:

Priority I:	Immediate care
Priority II:	Delayed care
Priority III:	Minor care
Priority 0:	Deceased

11-6.3

Triage should begin immediately. Qualified medical personnel should be assigned to this task. Victims are moved from the triage area to the appropriate care holding areas before definitive treatment is rendered. Casualties should be stabilized at the care holding areas and then transported to an appropriate facility.

11-6.4

Every effort should be made to ensure that "immediate" casualties are treated first and receive immediate ambulance transportation priority once they are stabilized. This should be the responsibility of the immediate care leader.

11-6.5

Triage is most efficiently accomplished in place. However, the conditions of an accident scene and wind direction can demand the immediate movement of casualties before triage can be safely accomplished. In that case, the casualties should be moved the shortest distance possible, well away from fire fighting operations, and upwind and uphill from the scene.

11-6.6*

Triage of casualties should include the use of casualty identification tags to aid in the sorting and transportation of the injured to hospitals. This technique is especially suited to multilingual situations.

11-7 Care Principles.

11-7.1

Stabilization of the seriously injured should be accomplished at the accident scene. The immediate transportation of the seriously injured before stabilization should be avoided.

11-7.2

In accidents occurring on or adjacent to the airport, rescue and fire fighting personnel are generally the first emergency personnel on the scene. It is imperative that seriously injured casualties be located and stabilized as quickly as possible. In cases where fire control or prevention does not require the efforts of all rescue and fire fighting personnel, casualty stabilization should be commenced immediately under the direction of the most qualified trauma-trained individual on the scene. First response rescue vehicles should carry initial supplies of victim-care equipment, including artificial airways, compresses, bandages, oxygen, and other related equipment used for the stabilization of smoke inhalation casualties and severe trauma. Sufficient oxygen should be available for use of rescue and fire fighting personnel.

11-7.3

Usually, the first few minutes of medical treatment are aimed at stabilizing the casualties until more qualified medical care is available. When specialized trauma teams arrive, medical care should be more sophisticated.

11-7.4

The triage procedure and subsequent medical care should be placed under the command of one authority, the designated medical coordinator, upon arrival. Prior to arrival, the command of triage should be assumed by the designee of the incident commander until relieved by the predesignated medical coordinator.

11-7.5

The medical coordinator should report directly to the incident commander and has responsibility for all medical aspects of the incident. The primary function should be administrative, not as a participant of the medical team treating the injured.

11-7.6

For distinctive and easy identification, the medical coordinator should wear a standard distinctive uniform. In addition, the Plan should provide for a highly visible vest, or other apparel, with reflective lettering, front and back, that reads "MEDICAL COORDINATOR," or other appropriate lettering, given the terminology used in the Plan.

11-7.7 Care of Priority I "Immediate" Casualties.

This type of casualty includes but is not necessarily limited to:

(a) Major hemorrhages;

(b) Severe smoke inhalation;

(c) Asphyxiating thoracic and cervico-maxillo-facial injuries;

(d) Cranial trauma with coma and rapidly progressive shock;

(e) Open fractures and compound fractures;

(f) Extensive burns (more than 30 percent);

(g) Crush injuries including internal organs;

(h) Any type of shock; and

(i) Spinal cord injuries.

11-7.8 Care of Priority II "Delayed" Casualties.

This type of casualty includes but is not necessarily limited to:

(a) Nonasphyxiating thoracic trauma;

(b) Closed fractures of the extremities;

(c) Limited burns (less than 30 percent);

(d) Cranial trauma without coma or shock; and

(e) Injuries to soft parts.

11-7.9

Care of casualties sustaining injuries that do not need emergency medical treatment to sustain life can be delayed until Priority I casualties are stabilized. Transportation of Priority II casualties should be performed following minimum care given on the site.

11-7.10 Care of Priority III "Minor" Casualties.

This type of casualty includes minor injuries only. Certain accidents/incidents will occur where passengers have either minor injuries or no injuries, or appear to be uninjured. Because this type of casualty can interfere with other priorities and operations it is important that these passengers be transported away from the accident/incident site to the designated passenger holding area where they can be re-examined.

11-7.11

It is important that provisions be made for Priority III casualty care, comfort, and identification. This should be provided through the aircraft operator, where involved, airport operations, or international relief organizations (Red Cross, etc.). Specific treatment areas such as an empty hangar, a designated area in a passenger terminal, a fire station, or other available sites of adequate size (hotel, school, etc.) should be predesignated for this purpose. Any such area selected should be equipped with heating or cooling systems, electric light and power, water, and toilet facilities. Adequate telephones should be available. A number of such preselected sites should be chosen so that when an accident occurs, the most convenient in regard to travel distance and space needs (number of casualties involved) can be selected. All aircraft operator personnel and airport tenants should know the location of such designated facilities.

11-8 Control of the Flow of the Injured.

11-8.1

The injured should pass through four areas that should be carefully located and easily identified (*see Figure 11-6*).

(a) *Collection area* — The location where initial collection of the seriously injured from the aircraft or debris is accomplished. Need for the establishment of this area will be dependent upon the type of accident and the circumstances surrounding the accident site. Custody of casualties is normally transferred from fire rescue personnel to medical services at this point.

(b) *Triage area* — The triage areas should be located at least 90 m (300 ft) upwind of the accident site if fire and smoke is imminent. If necessary, more than one triage area may be established.

(c) *Care area* — Initially this will be a single care area only. Subsequently it should be subdivided into three subareas according to the three categories of injured, i.e., Immediate Care (Priority I), Delayed Care (Priority II), and Minor Care (Priority III). Care areas can be identified by colored traffic cones, bicycle flags, colored blankets, etc. (Red — Immediate, Yellow — Delayed, and Green — Minor).

(d) *Transportation area* — A transportation area for the recording, dispatching, and evacuation of survivors should be located between the care area and the egress road. Only one transportation area is normally required; however, if there is more than one transportation area it is essential to have communication between them.

11-8.2

In remote areas, where transportation to appropriate medical facilities will be delayed, or where climatic conditions dictate, consideration should be given to the provision of mobile quarters for the stabilization and medical treatment of immediate care and delayed care casualties. Ideally these quarters should be operational upon arrival or in less than half an hour. Their design should therefore permit rapid response to the site and rapid activation to receive casualties. [*See definition of Mobile Emergency Hospital (MEH), A-11-1.1*.]

11-9 Standardized Casualty Identification Tags.

11-9.1 Need for Standardized Tags.

Casualty identification tags should be standardized through color coding and symbols to make the tags as simple as possible. Tags can help to expedite the treatment of mass casualties in a triage situation and thus permit more rapid evacuation of the injured to medical facilities.

11-9.2 Tag Design.

Standardized tags that require only minimal information to be entered thereon, are usable under adverse weather conditions, and are water resistant have been designed. An example of such a tag is illustrated in Figures A-11-6.6(a) and (b). In this tag, numerals and symbols indicating medical priority classify casualties as follows:

Priority I or immediate care: RED colored tag;
roman numeral I;
rabbit symbol.

Priority II or delayed care: YELLOW colored tag;
roman numeral II;
turtle symbol.

Priority III or minor care: GREEN colored tag;
roman numeral III;
ambulance with X symbol.

Priority 0 or deceased: BLACK colored tag;
cross symbol.

11-9.3

Where tags are unavailable, casualties can be classified using roman numerals on adhesive tape or by markings made directly on the forehead or on other exposed skin area to indicate priority and treatment needs. Where marking pens are unavailable, lipstick can be used. Felt-tipped pens are not advisable as they may smear in rain, snow, and under other climatic and body conditions.

11-10 Medical Care of Ambulatory Survivors.

11-10.1

The aircraft operator (where involved), the airport authority, or other predesignated agency selected for the purpose should be available to:

(a) Select from among the predesignated passenger holding areas designated in the airport/community emergency plan the most suitable area for the particular emergency;

(b) Provide for the transportation of uninjured passengers from the accident site to the designated holding area;

(c) Arrange for doctors, nurses, or emergency medical personnel teams qualified in first aid to examine and treat supposedly uninjured passengers, especially for nervous traumatism (shock), and smoke inhalation where pertinent;

(d) Interview uninjured passengers and record their names, addresses, and phone numbers, and where they can be reached for the next 72 hours;

(e) Notify relatives or next of kin where deemed necessary;

(f) Coordinate efforts with the designated welfare agency (Red Cross, etc.); and

(g) Provide security from unauthorized interference by persons not officially connected with the rescue operation in progress.

11-10.2

Prearrangements should be made for the immediate transportation by bus or by other suitable transport of the walking wounded and uninjured from the accident site to the designated holding area. This plan should be implemented automatically following notification of the emergency. A nurse or a person trained in first aid should accompany these survivors to the holding area. Each and every passenger should be examined for shock and smoke inhalation. Cold or inclement weather can require additional provisions for the passengers' protection and comfort.

11-10.3

Occupants evacuating an aircraft might have been barefoot when evacuation slides were used and also might be without proper wearing apparel. Prior planning should recognize this potentiality, and emergency footwear, eyeglasses, clothing, and blankets should be available to take care of this situation. Where the aircraft accident occurred in water or in a marshy area, survivors will be wet and uncomfortable. Where such potentials exist, it may be necessary to establish a special designated staging area where survivors can be stabilized prior to transporting them to the normal holding area and to preplan provision for blankets and temporary protective clothing to prevent hypothermia.

Chapter 12 Care of Deceased (Black Tag, Cross Symbol)

12-1 Basis for Recommendations.

12-1.1*

The concept of preservation of evidence should be applied when caring for the deceased at an aircraft accident site. It is important to realize that an undisturbed site can produce the most reliable evidence for determining cause and corrective action that would help prevent a similar incident in the future.

The Plan should include contingencies that address management of the deceased at the scene of the emergency. The Plan needs to designate the person responsible for contacting and coordinating with the medical examiner/coroner.

12-2 Care Prior to Site Investigation.

12-2.1

Airport fire fighters and other rescue personnel should understand the basic need for and the techniques and procedures used in aircraft accident investigation. Wherever possible, the wreckage should remain undisturbed until the arrival of the appropriate investigating agency.

12-2.2*

Areas immediately surrounding the location of the deceased should be completely secured. Areas where a large number of deceased or dismembered casualties are located should be left undisturbed until the arrival of the forensic doctor and the National Transportation Safety Board investigator or his or her designee.

12-2.3

If it becomes necessary to move bodies or parts of the wreckage, photographs should be taken showing their relative position within the wreckage, and a sketch of their respective positions prior to removal should be made. In addition, tags should be affixed to each body or part of the wreckage that was displaced, and corresponding stakes or tags should be placed where they were found in the wreckage. A journal should be kept of all tags issued. Special precautions should be taken to avoid disturbing anything in the cockpit area. Should any control be displaced, photographs, drawings, or notes should be taken.

12-2.4

Extrication of the deceased and removal of personal effects prior to the arrival of the coroner or appropriate authority should be performed only when necessary to prevent their destruction by fire or other similar compelling reasons. Where bodies must be moved, previously mentioned precautions should apply. Provisions should be made to obtain sufficient body bags to contain all bodies as well as personal effects.

12-2.5

Body bags are normally available from major local suppliers of caskets, funeral directors and their equipment and supply firms, and from nearby military facilities. Stocks of body bags at each airport are desirable.

12-3 Care after Site Examination.

12-3.1

Body identification and determination of cause of death should be conducted with the concurrence of the authority designated for this duty. This operation is generally conducted with the cooperation of forensic teams and other specialists.

12-3.2

Accidents that produce a large number of fatalities can overload normal morgue facilities. In areas where delay or temperature can contribute to the deterioration of tissue, refrigerated storage should be available. This can be provided either through a permanently located cooler or refrigerated semitrailers. The area for postmortem examination should be located near the refrigerated storage and should be arranged to provide a high level of security. This area should be large enough for initial body sorting. Electricity and running water should be provided, in addition to a suitable working area.

12-3.3

The morgue should be isolated and in an area remote from places where relatives or general public have access.

12-3.4

After identification of victims, efforts to contact next of kin should commence. Agencies such as aircraft operators representatives, public service organizations (i.e., Red Cross, Salvation Army), or clergy should be utilized.

12-3.5

The accident investigation team generally has the authority to require autopsies and toxicological analyses on crew members, and in special cases, passengers. The need for these tests should be established prior to the release of bodies.

12-3.6

As soon as practical after the emergency, all participants in the fire fighting and rescue effort should be debriefed. Their observations should be recorded by the proper authorities. Sketches, diagrams, photographs, movie films, and tape and video recordings made on the accident site as well as appropriate details on the tagging of bodies and parts of the wreckage removed from their position can be invaluable tools for investigators.

Chapter 13 Airport/Community Emergency Plan Exercise

13-1 Emergency Plan Exercise.

13-1.1

The purpose of an airport/community emergency plan exercise is to test the adequacy of the following:

(a) The airport/community emergency plan and related procedures;

(b) Response of all personnel involved; and

(c) Emergency equipment and communications.

13-1.2

It is therefore important that the Plan contain procedures requiring that the airport/community emergency plan be tested so as to correct as many deficiencies as possible and to familiarize all personnel and agencies concerned with the airport environment, the other agencies, and the role of each agency/person in the emergency plan.

13-2 Need for and Types of Airport/Community Emergency Plan Drills.

13-2.1

The airport/community emergency plan should be subject to full-scale emergency exercises to test all facilities and associated agencies at intervals of about one year. The exercise should be followed by a full debriefing, critique, and analysis. Representatives of all organizations that participate in the exercise also should actively participate in the preparation for the exercise and the final critique.

13-2.2

It is important that small-scale simulated emergency exercises be held at more frequent intervals than the full-scale emergency exercise. These more frequent exercises should be aimed at testing and reviewing the response of individual participating agencies, such as the rescue and fire fighting service, as well as parts of the plan such as the communications system.

13-2.3

It is desirable that, in addition to the full-scale and simulated emergency exercises, a "tabletop" exercise, involving the airport/community emergency plan coordinating committee, be held at least annually but not coincidental with any of the above emergency exercises.

13-3 Planning for Full-Scale Emergency Exercises.

13-3.1

The first step in planning full-scale emergency exercises should be to have the support of all airport and community authorities concerned.

13-3.2

Each agency head should be thoroughly familiar with the airport/community emergency plan and should develop a plan for his or her department in coordination with the general plan. The agency heads should meet in regular sessions to develop an understanding of their agencies' responsibilities and requirements in cooperation with other agencies.

13-3.3

An aircraft representative of the largest aircraft using the airport should be sought for the full-scale emergency exercise to add realism to the exercise and to familiarize participants with the problem of removing casualties from aircraft. If an aircraft is not available, a bus or similar large vehicle can be used.

13-3.4

The emergency exercises should be held in locations that will provide maximum realism while ensuring minimum disruption to the operations of the airport or the orderliness of the community.

13-3.5

At least 120 days prior to the scheduled full-scale emergency exercise, a meeting of all key supervisory personnel of principal participating agencies should be called by the authority in charge. At this time, the aims of the exercise should be outlined, a scenario formulated, work tasks assigned, and duties of all agencies and personnel defined. A suggested time schedule and checklist are as follows:

120 days prior	Organizational meeting of supervisory personnel of participating agencies. Aims outlined, scenario formulated, work tasks assigned, emergency plan coordinators selected.
90 days prior	First progress report on arrangements.

70 days prior	First meeting of all participating agencies (individual committee representatives).
60 days prior	Complete arrangements for full-scale emergency exercise site or staging area. Written scenario completed.
50 days prior	Training for moulage team begins. Second meeting of the individual committee representatives. A moulage chairperson can be selected from hospitals, rescue and fire fighting personnel, civil defense, military personnel, etc.
40 days prior	Arrangements for transportation, feeding, stretcher bearers, and volunteer workers completed.
30 days prior	Third meeting of the individual committee representatives. A preliminary “warm-up” communications exercise is held.
21 days prior	Fourth meeting of the individual committee representatives. Make-up team training and arrangements for volunteer casualties completed.
14 days prior	Final meeting and briefing for all participants, including critique team.
7 days prior	Final meeting of supervisory personnel to review assignments.
Day of exercise	
1–7 days after	A critique following the exercise so that all participants can hear the observers’ reports.
30 days after	The supervisory personnel meet to review written critiques submitted by observers and participants and revise procedures to correct mistakes and shortcomings indicated in the exercise.

13-3.6

In preparing the scenario, the use of real names of aircraft operators and types of aircraft should be avoided. This will prevent any possible embarrassment to companies or agencies involved in civil aviation.

13-3.7

In order to obtain the maximum benefit from a full-scale emergency exercise, it is important to review the entire proceedings. An observer critique team comprised of members who are familiar with mass casualty accident proceedings should be organized. A chairperson of the team should be appointed and should be present at all meetings. The team should be present at the final organizational meeting (seven days prior to the exercise) and, in coordination with the authority in charge, ensure that significant problems are introduced into the exercise. Each member of the critique team should observe the entire exercise and complete the appropriate emergency exercise critique forms.

13-4 Review of the Airport Emergency Plan Drill.

13-4.1

Experience has shown that quite often the provisions set forth in the airport emergency plan are found not to be practical during an exercise or an actual emergency, resulting in confusion and undue inefficiency by some of the participants.

13-4.2*

A critique and review of the procedures followed by the participants in an emergency exercise or an actual accident/incident should be scheduled as soon as all data can be acquired from all agencies. This critique should be held not more than seven days after the exercise or emergency.

13-4.3

The airport authority should make every effort to contact other airport authorities involved in actual aircraft accidents and those who have conducted full-scale emergency exercises to acquire data and procedures to correct and upgrade their airport emergency plan.

Appendix A Explanatory Material

This Appendix is not part of the recommendations of this NFPA document but is included for informational purposes only.

A-1-3 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-3 Authority Having Jurisdiction. The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-2-1 Outline of an Airport/Community Emergency Plan. This guideline is intended to ensure uniformity in the development of airport/community emergency plans. It is the function of the airport authority to develop a plan and procedures for emergencies applicable to the airport's particular characteristics and operations and, within these guidelines, to perform the following:

(a) Define the responsibilities of the airport authority and other participating agencies;

(b) Create effective lines of communication and adequate communication facilities as indicated by a flow chart; and develop a call system to include persons or agencies to be contacted. Where possible, a 24-hour coverage should be maintained;

(c) Arrange for the availability of a fixed emergency operations center and a mobile command post at the airport for use during an emergency;

(d) Integrate assistance from local support services such as fire departments, security, medical, civil defense, government agencies, and local amateur radio organizations, etc.;

(e) Describe the function of air traffic control services (airport control tower or airport flight information service) relating to emergency actions; and

(f) Give instructions for response to accidents/incidents.

Sections of the airport/community emergency plan document should contain identifiable subjects pertinent to local airport and community conditions.

The emergency plans and procedures should be issued under the airport or appropriate authority, who will define and negotiate functions of all agencies and personnel on or off the airport who would or could be involved in an emergency affecting the airport.

In developing the emergency plan and procedures, it is vital that arrangements be simple and easily understood by all involved in the Plan.

Example of Contents of Emergency Plan Document:

Section 1 — Emergency Telephone Numbers. This section should be limited to essential telephone numbers according to site needs, including:

(a) Air traffic control services;

(b) Rescue and fire fighting services (departments);

(c) Police and security;

(d) Medical services;

1. Hospitals

2. Ambulances

3. Doctors — business/residence

(e) Aircraft operators;

(f) Government authorities;

(g) Civil defense;

(h) Others.

Section 2 — Aircraft Accident on the Airport. This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by rescue and fire fighting services;

(c) Action by police and security services;

(d) Action by airport authority;

1. Vehicle escort
2. Maintenance

(e) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctors
4. Medical personnel

(f) Action by aircraft operator involved;

(g) Action by emergency operations center and mobile command post;

(h) Action by government authorities;

(i) Communications network (emergency operations center and mobile command post);

(j) Action by agencies involved in mutual aid emergency agreements;

(k) Action by transportation authorities (land, sea, and air);

(l) Action by the public information officer(s);

(m) Action by local fire departments when structures are involved;

(n) Action by all other agencies.

Section 3 — Aircraft Accident off the Airport. This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by rescue and fire fighting services;

(c) Action by local fire departments;

(d) Action by police and security services;

(e) Action by airport authority;

(f) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctors
4. Medical personnel

(g) Action by agencies involved in mutual aid emergency agreements;

(h) Action by aircraft operator involved;

(i) Action by emergency operations center and mobile command post;

(j) Action by government authorities;

(k) Communication networks (emergency operations center and mobile command post);

(l) Transportation authorities (land, sea, and air);

(m) Action by public information officer;

(n) Action by all other agencies.

Section 4 — Malfunction of Aircraft in Flight (Full Emergency or Local Standby). This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by airport rescue and fire fighting services;

(c) Action by police and security services;

(d) Action by airport authority;

(e) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctor
4. Medical personnel

(f) Action by aircraft operator involved;

(g) Action by emergency operations center and mobile command post;

(h) Action by all other agencies.

Section 5 — Structural Fires. This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by rescue and fire fighting services (local fire departments);

(c) Action by police and security services;

(d) Action by airport authority;

(e) Evacuation of structure;

(f) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctors
4. Medical personnel

(g) Action by emergency operations center and mobile command post;

(h) Action by public information officer;

(i) Action by all other agencies.

Section 6 — Sabotage Including Bomb Threat (Aircraft or Structure). This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by emergency operations center and mobile command post;

(c) Action by police and security services;

(d) Action by airport authority;

(e) Action by rescue and fire fighting services;

(f) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctors
4. Medical personnel

(g) Action by aircraft operator involved;

(h) Action by government authorities;

(i) Isolated aircraft parking position;

(j) Evacuation;

(k) Searches (dog and human) of helicopter aircraft;

(l) Handling and identification of luggage and cargo on board aircraft;

(m) Handling and disposal of suspected bomb;

(n) Action by public information officer;

(o) Action by all other agencies.

Section 7 — Unlawful Seizure of Aircraft (Hijacking). This section should detail the:

(a) Action by air traffic control services (airport control tower or airport flight information service);

(b) Action by rescue and fire fighting services;

(c) Action by police and security services;

(d) Action by airport authority;

(e) Action by medical services;

1. Hospitals
2. Ambulances
3. Doctors
4. Medical personnel

(f) Action by aircraft operator involved;

(g) Action by government authorities;

(h) Action by emergency operations center and mobile command post;

(i) Isolated aircraft parking position;

(j) Action by public information officer;

(k) Action by all other agencies.

Section 8 — Incident on the Airport.

An incident on the airport can require any or all of the action detailed in "Aircraft Accident on the Airport." Examples of incidents the airport authority should consider include fuel spills at the ramp, passenger loading bridge, and fuel storage area; dangerous goods (hazardous materials) occurrences at freight handling areas; collapse of structures; vehicle/aircraft collisions, etc.

Section 9 — Persons of Authority — Site Roles.

To include but not be limited to the following according to local requirements:

(a) On-airport;

1. Airport authority
2. Airport chief fire officer
3. Police and security — officer-in-charge
4. Medical coordinator

(b) Off-airport;

1. Local chief fire officer
2. Government authority

3. Police and security — officer-in-charge

4. Medical coordinator.

The incident commander should be designated as required from within the prearranged mutual aid emergency agreement.

Previous documented experience indicates that confusion in identifying command personnel in accident situations is a serious problem. To alleviate this problem it is suggested that distinctive colored vests with reflective lettering be issued to command personnel for easy identification. The following colors are recommended:

RED	— CHIEF FIRE OFFICER
BLUE	— POLICE CHIEF
WHITE (RED LETTERING)	— MEDICAL COORDINATOR
INTERNATIONAL ORANGE	— AIRPORT ADMINISTRATION
LIME GREEN	— TRANSPORTATION OFFICER
DARK BROWN	— FORENSIC CHIEF

An incident commander should be appointed as the person in command of the overall emergency operation. The incident commander should be easily identifiable and can be one of the persons indicated above or any other person from the responding agencies.

A-2-2 Types of Alerts. The terms used to describe various categories of aircraft alerts are not standardized. The Federal Aviation Administration (FAA) terms — Alert I, Alert II, or Alert III — and the International Civil Aviation Organization (ICAO) terms — Local Standby, Full Emergency, and Aircraft Accident—are equivalent.

Alert I — Local Standby. An aircraft that is known or suspected to have an operational defect should be considered local standby. This defect normally should not cause serious difficulty in achieving a safe landing.

Alert I also should be initiated when an aeromedical evacuation or presidential/VIP aircraft is arriving or departing.

Airports should have management policies for implementation of Alert I procedures whenever required response times cannot be achieved. Factors that can affect response time include construction work, field maintenance, and adverse weather conditions such as snow, ice, or low visibility.

Airports should have management policies for implementation of Alert I procedures during arrival and departures of certain categories or types of aircraft not normally utilizing the airport.

Under Alert I conditions, at least one aircraft rescue and fire fighting vehicle should be manned and positioned to permit immediate use in the event of an incident. The Aircraft Rescue and Fire Fighting (ARFF) personnel should be advised of:

(a) The type of aircraft;

(b) The number of passengers and crew;

(c) The type and amount of fuel;

(d) The nature of the emergency;

(e) The type, amount, and location of dangerous goods; and

(f) The number of nonambulatory passengers on board, if any.

All other ARFF vehicles should be available for immediate response.

Alert II — Full Emergency. An aircraft that is known or is suspected to have an operational defect that affects normal flight operations to the extent that there is danger of an accident is an Alert II — Full Emergency. ARFF personnel should be provided with detailed information that allows preparation for likely contingencies. A full response should be made with the emergency equipment manned and positioned with engines running and all emergency lights operating so that the fastest response to the incident/accident site can be accomplished. It is important that appropriate radio frequencies be continuously monitored by ARFF personnel. One or more major aircraft rescue and fire fighting vehicles should be able to initiate fire suppression within the briefest period of time following the aircraft's coming to rest. Standby positioning of vehicles should be established for a variety of anticipated circumstances. The ARFF personnel should be informed of any changes in a distressed aircraft's emergency conditions that could affect the touchdown point or the ultimate behavior of the aircraft.

Alert III — Aircraft Accident/Fire. This alert denotes an aircraft accident or serious aircraft fire has occurred on or in the vicinity of the airport. Regardless of the source of this alarm, full airport fire and rescue response procedures should be put into effect. Where possible, all known pertinent information should be relayed via radio by Air Traffic Control (ATC) to responding emergency units and include as accurately as possible the location of the accident using grid-map coordinates and landmarks.

Where such information is not available, the ARFF personnel should anticipate the worst situation and prepare accordingly.

The officer in charge should advise ATC of conditions at the site, particularly if such conditions could interfere with flight operations.

Emergencies not involving aircraft include:

(a) Nonaircraft accident related airport emergencies;

(b) Natural disasters; and

(c) Medical emergencies.

A-3-3.1 For a comprehensive description of training and skills required see NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications.*

A-3-8 Responsibilities of Aircraft Operations Personnel Following an Aircraft Accident. Airline personnel often are the only force on the airport available for quick response to passenger service in an emergency since fire, police, and airport operation departments are usually required to respond to the accident site.

An air carrier emergency plan should be coordinated with the airport/community emergency plan so that airline personnel know which responsibilities the airport will assume and what response is required by the airline. A checklist form should be developed by the airline for the company coordinator's use. This form should be time correlated to the documented notification time of the accident, company communications, personnel assignments, response, and other actions taken. From this log of events a critique of airline and airport/community emergency plans can be analyzed for future improvement.

Training should be initiated by the airlines to prepare all station personnel for emergency procedures. In all emergencies the individuals involved are subjected to stresses of a severity not generally encountered. It is vital for all emergency workers to be familiar with common responses by the individuals to unusual stress and apprehension and to be able to cope effectively with disturbed persons. The best possible preparation for effective behavior under disaster conditions is education and practice. Education should include instructions in the nature and actions of disturbed individuals and the general type of reaction to be expected from each. There should be participation in simulated emergency exercises to help establish effective patterns of behavior under emergency conditions and practice the basic principles of "psychological first aid."

A holding area for uninjured persons should be designated in order to assemble and process passengers not injured in the emergency. The area selected should provide for both passenger comfort and security from the news media. Upon notification of an accident, designated airline personnel should immediately respond to the holding area to receive the passengers evacuated from the accident scene. The airline personnel should be at this station before the passengers arrive. Emergency kits should be prepared and be readily available for the passenger service representatives to effectively carry out their duties. While waiting for the evacuees, an organizational meeting should be held by the person in command, delegating a receptionist, registrar, and welfare coordinator for the survivors.

The following organization and description of required duties are suggested:

The Airline Coordinator. Normally this would be the senior representative from the airline whose aircraft had the accident. In the event of a charter or nonscheduled flight, the representative of the airline designated to provide ground services for that flight should take charge. In the event of an over-flight or carrier without personnel based at the airport, representative authority would have to be determined by those responding. The person in charge should have radio communication to the airline operations or other designated emergency center. Telephones should be available in the holding areas. The person in command oversees the overall airline operations, making arrangements for additional medical services if required, commissary items, etc.

The receptionist should meet the buses as they arrive from the scene of the accident and direct the passengers to the registrars' tables where they will be processed. The receptionist should know where toilet facilities are located.

Registrars. The registrars should have emergency kits available to them. Two people should constitute one registrar team. Several teams can be required to process the passengers swiftly and efficiently. One member should enter the passenger's name on the manifest and determine what reservation requirements are desired, i.e., hotel accommodations or another flight, transportation, etc., and any persons to be notified of the passenger's condition and plans. The other member of the registrar team should make out an identification tag or sticker (available from the emergency kit) and place it on the passenger. This can assist in identifying the passenger when accommodations have been made. More importantly this will indicate that the passenger has been processed. The registrars should direct the victims to the welfare coordinators when their registration is completed.

Welfare coordinators are the nucleus of psychological first aid. They should attempt to stimulate passenger discussion. Special attention should be given to those who do not join in the group. In giving psychological first aid, it should be noted that some persons become more disturbed than others. Giving those persons sympathetic understanding can be the first step toward helping them. Overwhelming victims with pity may only increase their fear and feelings of helplessness. A person who exhibits bodily trembling, rapid breathing, rapid pulse, shortness of breath, etc., should be engaged in conversation and professional medical attention requested as soon as available.

A sizable personnel force can be provided by most air carriers; however, there can be a problem at airports with a small operation. As a result, a mutual aid assistance program of all airline personnel (and, if necessary, other airport tenants based at the airport) should be established. Training can be acquired from local mental health care and Red Cross units. This training is not extensive but would provide education for passenger service in an emergency. In addition to care for the victims evacuated from an accident site, training also should include a possible traumatic situation that could develop in the gate area of the terminal building.

Emergency Kits. Each airline should prepare an emergency kit that can be readily available to all airline personnel during all hours of operation. This kit should never be placed in an office that is locked during certain hours of the day. All station personnel should have knowledge of the location of the emergency kit. The contents of the kit should include:

(a) Tablets or forms to record the victims' names, addresses, and home phone numbers; name and phone number of person to be notified of passenger’s condition; accommodation request of passenger (i.e., future flight, hotel, transportation within the local area, etc.).

(b) Stick-on, adhesive-type name tags to identify passengers who have been processed and for identification of victim when accommodations have been made.

(c) Telephone numbers of:

1. Doctors to attend to minor injuries. Each airline should have a letter of agreement with physicians who will respond to a designated holding area.

2. Hotels where victims can be billeted. It is beneficial to place victims in the same hotel or at least in groups at hotels.

3. Linguists. Preferably people who work on the airport for quick response.

4. Caterer if commissary items are required.

5. All airline reservations offices.

6. Ambulance companies in case a victim requires hospitalization.

7. Taxicab companies.

(d) A current copy of the *Official Airline Guide* (OAG). Local airline schedules can be helpful for registrars who will be making arrangements on future flights.

(e) Sample of Registrar’s Form:

Passenger

A-3-15.1 Mutual Aid Emergency Agreements.

The close proximity of an airport to surrounding communities and the possibility of an off-airport aircraft accident gives rise to the need for mutual aid emergency agreements.

A mutual aid emergency agreement should specify initial notification and response assignments. It should not specify the responsibilities of the agency concerned, as this will be contained in the emergency plan.

Mutual aid emergency agreements should be prearranged and duly authorized. A sample of a letter of agreement is included in Figure A-3-15.1. Should more complicated jurisdictional or multiagency agreements be necessary, the airport authority may have to act as coordinating agency. This appendix contains guidelines compiled to assist with preparation of mutual aid emergency agreements with local fire departments for accidents occurring on and off the airport.

Procedure for Local Fire Department(s) — Aircraft Accident on Airport:

(a) A call to an aircraft accident on the airport will normally be received from air traffic control services.

(b) The mutual aid fire department(s) should report to the rendezvous point or staging area on arrival at the airport. Escort by airport police/security should be provided from the rendezvous point or staging area to the accident site.

(c) Upon arrival at the accident site:

1. The senior officer of the airport rescue and fire fighting service receiving mutual aid should have full authority at the scene unless other laws or agreements contradict this statement.

2. Fire department mutual aid communications should be carried out on the predesignated communications channel.

3. Communications transmissions should be prefaced by an airport rescue and fire fighting or local fire department call number.

AGENCY: (Name and Address)

____

____

____

Endorses the XYZ (International) Airport Emergency Plan, associated airport emergency plan document dated (insert date), and attached procedures (included as A-3-15.1.1 and A-3-15.1.2) and agrees to comply with all the procedures and instructions, and fulfill all applicable responsibilities therein.

____

Signature of Authorized Representative

____

Date

Figure A-3-15.1 XYZ (International) Airport

Emergency Plan

Letter of Emergency Mutual Aid Agreement.[1]

[1]See Appendix E, "Sample Mutual Aid Agreements," of NFPA 402, *Guide for Aircraft Rescue and Fire Fighting Operations*.

Procedure for Local Fire Department(s) — Aircraft Accident off Airport:

(a) A call to an aircraft accident off the airport will normally be received from air traffic control services or police. Should that not be the case, the local fire department should notify air traffic control services or police via radio or telephone that an accident has occurred, giving the approximate location on the grid map.

(b) Upon arrival at the accident site, the local fire department should:

1. Ensure that the mutual aid emergency agreement is initiated.

2. Establish a command post. (This may be a temporary post until the airport authority mobile command post is available and operative.)

3. Ensure that all communications are on the designated aircraft accident channel.

(c) The local fire department should advise air traffic control services or police of the following:

1. Exact location of the accident site.

2. Location of the command post.

3. Specific location/rendezvous points on the grid map to which fire units should respond.

4. Any request for specialized equipment, if necessary.

A-3-16 Aircraft Accidents in the Water. Where airports are situated adjacent to large bodies of water (such as rivers or lakes) or where they are located on coastlines, special provisions should be made for rescue and fire fighting operations in event of an aircraft accident/incident in the water. Specialized equipment for rescue and fire fighting may include fire/rescue boats; air-cushion vehicles (ACV); helicopters; coastal patrol boats; etc. (*See Figure A-3-16.*)

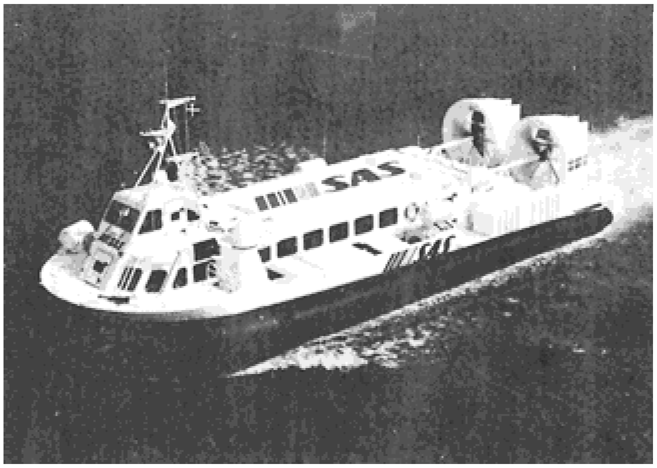

Figure A-3-16 The "Winchester" Class Hovercraft (built by the British Hovercraft Corporation), which is in service at the Auckland International Airport in New Zealand. It is utilized to protect aircraft operations that are largely over the Manukau Harbor that borders the airport. The primary mission is rescue of occupants in the event of an accident in the harbor or mudflats (which exist at low tide).

Consideration of unusual terrain and water conditions, such as tidal flats, swamps, etc., can dictate the choice of the particular type of vehicle most suitable to these conditions. Helicopters and air-cushion and amphibious vehicles as well as conventional watercraft may be found to provide this specialized service.

In developing the water rescue service, consideration should be given to private or public services (such as military search and rescue units, harbor police, or fire departments) and private rescue services (such as rescue squads, power and communication companies, pipeline or oil field operators, lumbering industry, or shipping and waterway operators) that may be available and are capable of rendering assistance. A signal system for alerting private or public services in time of emergency should be prearranged.

Many aircraft do not carry personnel flotation devices on board, especially those not engaged in extensive over-water operations. Such flotation devices should be available in numbers sufficient to meet the needs of the maximum passenger capacity of the largest aircraft in regular service at the airport. Where the largest aircraft is in scheduled over-water operation and all other operations are over-water in character, the airport may reduce the amount of personnel flotation devices by 50 percent.

Probability of Fire. In incidents of aircraft accidents over water, the possibility of fire is normally reduced, hopefully because of the suppression of ignition sources by the water contact and the cooling of heated surfaces. In situations where fire is present, its control and extinguishment present unusual problems unless the proper equipment is available.

Spillage of Fuel on Water Surfaces. It should be anticipated that the impact of the aircraft hitting the water might rupture fuel tanks and lines. It is reasonable to assume that quantities of fuel will thus be found floating on the surface of the water. Boats with exhausts at the waterline can present an ignition hazard if operated where this condition is present. Wind and water currents should be taken into consideration in order to deal effectively with floating fuel to keep it from moving into areas where it would be hazardous to rescue operations or initiate fire. As soon as possible, pockets of fuel should either be broken up or moved with large volume nozzles, neutralized by covering them with foam or a special inerting material, or boomed to contain the fuel in a safe area prior to absorption, dilution, or removal. Preplanning with the EPA's Water Pollution Control Division can provide emergency assistance during this operation.

Rescue Boats. Rescue boats should be capable of shallow water operations. Boats powered by jet-type propulsion eliminate the dangers of propellers puncturing inflatable equipment or injuring survivors during rescue operations. Boats powered by conventional propellers can diminish the hazards of puncture and injury by being equipped with fan-type guards or cowls.

Boats and other rescue vehicles should be located so that they can be brought into action in minimum time, but in any event not more than 15 minutes within the area extending up to 1000 m (3281 ft) from the end of the runway(s). Special boathouses or launching facilities should be provided where they will contribute materially to the rapidity of the launching process.

The boats should be of such size as to carry efficiently the flotation equipment required with adequate space for the crew and sufficient working space to permit rapid dispersal of the flotation devices. Inflatable life rafts should be the prime flotation equipment carried, and there should be an adequate number of life rafts to accommodate the largest aircraft occupancy served by the airport. Once this flotation equipment has been dispensed, there should be sufficient space to accommodate a limited number of litter cases brought aboard in the process of rescue.

In order to permit communications with other rescue units, such as helicopters, air-cushion or amphibious equipment, and water-land based units, adequate two-way radio equipment should be provided in all rescue boats.

A minimum of two floodlights should be provided for night operations.

Radar reflectors should be used to facilitate navigation and rendezvous efforts.

Organizing Diving Units/Use of Divers. Diving units should be dispatched to the scene. Where available, helicopters can be used to expedite the transportation of divers to the actual area of the crash. All divers who may be called for this type of service should be highly trained in both scuba diving and underwater search and recovery techniques. In areas where there are no operating governmental or municipal underwater search and recovery teams, agreements can be made with private diving clubs. The qualifications of the individual divers should be established by training and practical examination.

In all operations where divers are in the water, standard divers' flags should be flown and boats operating in the area should be warned to exercise extreme caution.

Where fire is present, approach should be made after wind direction and velocity and water current and swiftness are taken into consideration. Fire can be moved away from the area by using a sweeping technique with hose streams. Foam and other extinguishing agents should be used where necessary.

It should be anticipated that victims are more apt to be found downwind or downstream. This should be taken into consideration in planning the attack. Where only the approximate location of the crash is established upon arrival, divers should use standard underwater search patterns marking the locations of the major parts of the aircraft with marker buoys. If sufficient divers are not available, dragging operations should be conducted from surface craft. In no instance should dragging and diving operations be conducted simultaneously.

Where occupied sections of the aircraft are found submerged, the possibility remains that enough air may be trapped inside to maintain life. Entry by divers should be made at the deepest point possible.

Other Considerations. Where the distance offshore is within range, synthetic fiber-covered, rubber-lined fire hose can sometimes be floated into position by divers or boats and used to supplement other means of fire attack.

A command post should be established at the most feasible location on the adjacent shore. This should be located in a position to facilitate implementing the airport/community emergency plan in accordance with guidelines established by the authority having jurisdiction.

Great care should be exercised in maintaining the watertight integrity of occupied aircraft sections found afloat. Removal of the occupant(s) should be accomplished as smoothly and quickly as possible. Any shift in weight or lapse in time can result in its sinking, and rescuers should use caution to avoid becoming trapped themselves.

A-4-2.2 See Figure A-4-2.2.

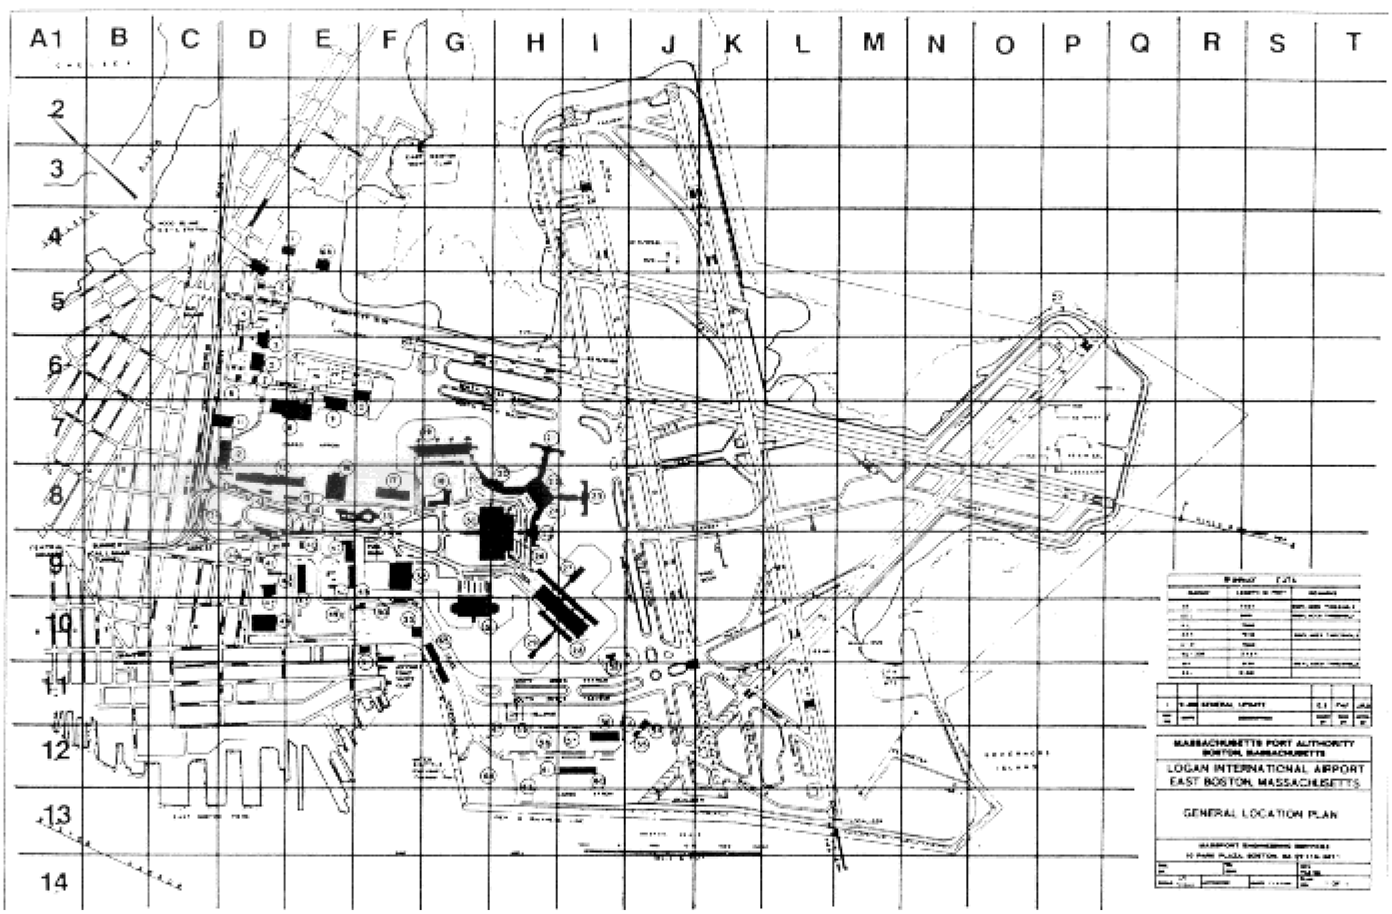

Figure A-4-2.2 Typical airport grid map.

A-5-2.2 See Figure A-5-2.2.

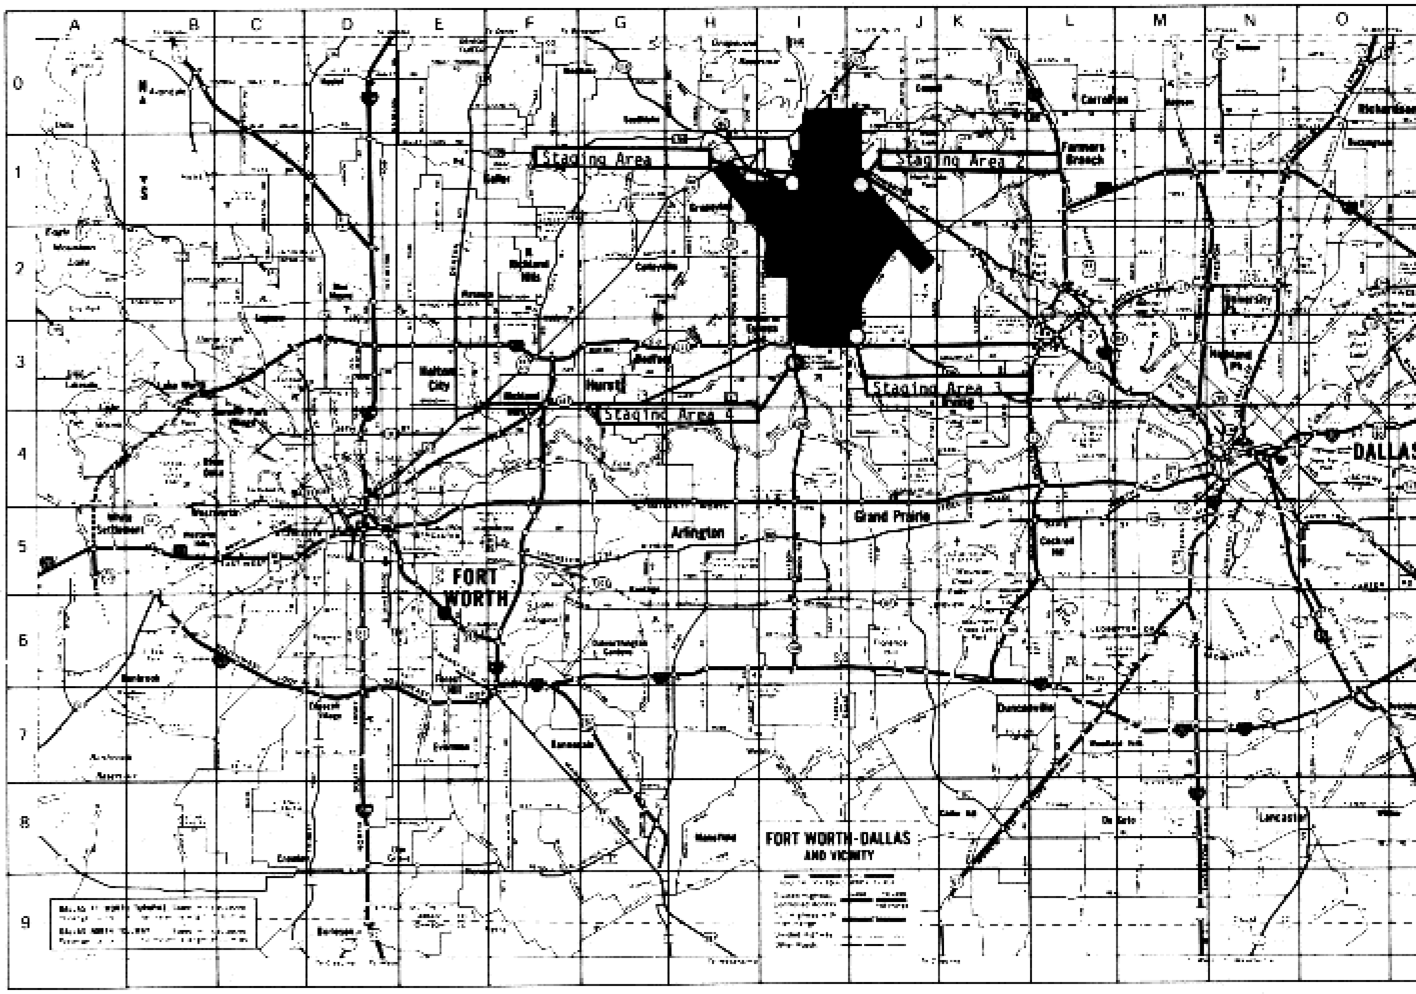

Figure A-5-2.2 Typical airport grid map.

A-5-4.2 The first security officer to arrive should assume security responsibility, survey the scene, and request reinforcements as needed. This security officer should remain in command until relieved by the appropriate security authority with jurisdiction over the area.

The security chief should be highly visible. Typically, a blue industrial hard hat with reflective lettering displayed fore and aft, and imprinted “SECURITY CHIEF,” should be issued to the security officer in charge.

Security personnel and police will be needed to handle traffic, to keep unauthorized personnel from the crash site, and to assume custody of personal effects removed from the aircraft. Ingress and egress roads should be established as congestion-free traffic lanes for emergency vehicles.

Normal traffic should be routed away from and around the crash site.

The emergency site should be cordoned off as soon as possible to exclude intruders, sightseers, onlookers, and souvenir hunters. Appropriate markings should be prominently displayed to advise all persons of possible hazards that can cause serious injury should they encroach on the area.

Arm bands, site passes, or I.D. tags should be issued by the controlling authority and monitored by the security coordinator and his or her team.

A mutual aid program should be instituted between all potentially involved security agencies, e.g., airport, city, county, state, and federal security forces; mail inspectors; and, where appropriate, military police and customs officials.

Special security provisions are necessary to protect any mail involved and any dangerous goods that may be present, and to protect against radioactive materials exposure.

A-5-8.11 For aircraft removal technique, see *International Civil Aviation Organization Airport Services Manual*, Part 5, "Removal of Disabled Aircraft."

A-11-1.1 Airport Medical Services. Medical services and supplies should be available to an airport. Provision of medical services generally should not present great difficulties at large airports or airports near a large city, as the personnel and material normally will be available. What is required is the development of the necessary coordination between the airport and the emergency medical assistance system in the community.

Provision of medical services can present some difficulties at small airports not located near populated areas. These airports, however, should arrange to have available emergency medical services to provide medical care in the event of an aircraft accident, taking into account the largest aircraft using the airport.

The capability of medical personnel can be greatly enhanced by additional resources for improving the environment of the treatment area. Many airport/community areas contain valuable support equipment that is not utilized because it was never determined that such equipment was available. Local agencies such as transportation departments, boards of health, park departments, departments of natural resources, etc., can be good sources. Federal agencies such as the Corps of Engineers, Department of Transportation, and Armed Forces (both active and reserve elements) possess a wide variety of support equipment and material. Examples of support equipment are mobile structures, auxiliary power and heating devices, water tankers, fuel supplies, lighting devices, sawhorses and lighting for roadblocks, etc.

Portable shelters such as mobile hospitals, tents, and recreation vehicles can be used where extremes in climate or weather can affect patient survivability. Consider the use of adjacent buildings such as aircraft hangars, gymnasiums, auditoriums, warehouses, etc., if distance and transportation resources are favorable.

Ideally, all personnel assigned to rescue duties and "public-contact" airport employees should be given first aid and CPR (cardiopulmonary resuscitation) training.

Rescue and fire fighting personnel should have the ability to stabilize seriously injured casualties. At least two full-time members per shift of the airport rescue and fire fighting service or other on-airport personnel should be trained to an emergency medical treatment level as determined by the local medical authority. In addition, it is recommended that as many rescue and fire fighting personnel as is practicable receive training to meet minimum standards of medical proficiency and preferably be highly qualified in first aid; preferably certified as emergency medical technicians. Accordingly, they should have sufficient medical equipment at their immediate disposal to initiate stabilization until transportation of casualties to adequate medical facilities is provided.

As many airport personnel as practicable also should be trained in CPR (cardiopulmonary resuscitation) as taught by the appropriate medical authority. Periodic exercises and drills in CPR techniques are necessary to maintain proficiency.

All rescue, fire fighting, and medical personnel should be trained to protect themselves from the spread of communicable diseases should they become exposed to blood or other body fluids during rescue or emergency medical care activities.

The everyday medical problems at large airports can serve to promote an increased proficiency in emergency medical techniques of airport-based emergency personnel. It should be noted, however, that proficiency in emergency medical techniques can be maintained only through constant practical application. Unless operations include providing advanced life support on a day-to-day basis, proficiency will decline or disappear.

Airports are encouraged to include volunteer on-airport personnel, other than rescue and fire fighting personnel, to provide an auxiliary response to assist casualties resulting from emergencies. Volunteers should be trained by accredited agencies in first aid or rescue response duties. In case of an emergency they should respond to a designated staging area for assignment. The question of liability is a matter for each appropriate authority.

Due to the many conflicting national and international standards and nomenclature of medical personnel, for the purpose of this guide, the following definitions are prescribed as guidelines:

(a) Advanced First Aid: 56 hr instruction.

(b) Emergency Medical Technician (EMT): 114 hr instruction (100 hr classroom; 10 hr hospital emergency room apprentice service; 4 hr ambulance apprentice duty).

(c) Paramedic: 500 hr instruction (200 hr classroom; 100 hr hospital emergency room apprentice service; 200 hr ambulance apprentice duty).

(d) Recurrent training should be provided in each specialty and recertification achieved at least on an annual basis, or as required by the local jurisdiction.

Emergency Medical Supplies and Equipment. The airport authority should arrange to have available on or in the vicinity of the airport sufficient medical supplies to treat the passenger capacity of the largest aircraft normally using the airport. Experience has shown, however, that more than one aircraft can be involved in an aircraft accident, and consequently medical supplies to handle this possibility should be considered. The type and quantity of such supplies should be determined by the principal medical authority for the airport using the statistical information given in Table A-11-1.1(a).

Table A-11-1.1(a) Estimated Maximum Number of Casualties at an Aircraft Accident at an Airport

Aircraft Occupants	Number of Casualties	20 Percent Casualties Immediate Care Priority I	30 Percent Casualties Delayed Care Priority II	50 Percent Casualties Minor Care Priority III
500	124	24	38	62

450	112	22	34	56
400	100	20	30	50
350	87	17	26	44
300	75	15	23	37
250	62	12	19	31
200	50	10	15	25
150	38	8	11	19
100	25	5	8	12
50	12	2	4	6

These figures are based on the assumption that the maximum number of surviving casualties at an aircraft accident occurring on or in the vicinity of an airport is estimated to be no more than 25 percent of the aircraft occupants.

To cope with an emergency involving a large aircraft, it is recommended that the general emergency medical supplies and equipment included in Table A-11-1.1(b) be available at the airport or otherwise be available from outside sources. Table A-11-1.1(b) has been prepared to cope with the largest type of aircraft at present being used for commercial air transport operations, i.e., B747, DC-10, Airbus. If, at any airport, only smaller aircraft will be handled during the foreseeable future, the suggested medical supplies and equipment should be adjusted to the largest aircraft expected to operate at the airport.

Table A-11-1.1(b) General Emergency Supplies and Equipment

Quantity	Description
100	Stretchers, adaptable to the most commonly used ambulances
10	Immobilizing mattresses for backbone fractures
10	Backboards for backbone fractures
50	Splints, either conventional or inflatable, for the various types of fractures
50	First aid kits, each containing a set of 10 tags, haemostatic pads, tourniquets, respiratory tube, scissors, dressings
20	Resuscitation chests containing material for intubation, infusion, and oxygenation on the spot for about 20 casualties
2 or 3	Manual or mechanical respirators
2 or 3	Suction devices
300 to 500	Plastic bags for the deceased

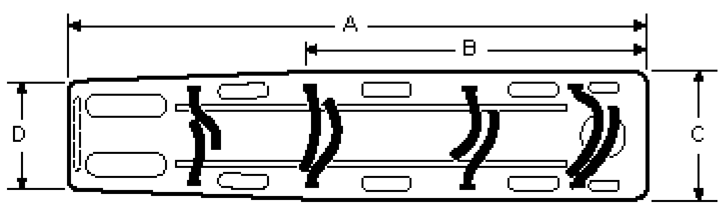
Stretchers, blankets, and backboards or immobilizing mattresses or both should be available for use, preferably on a suitable vehicle (e.g., trailer) that can be transported to the accident site. Blankets are needed to alleviate the casualty's exposure to shock and possible adverse weather conditions. Trauma victims in an aircraft accident sometimes sustain severe spinal injuries, so backboards should be used in removing such casualties from the aircraft in order to minimize the possibility of further spinal injury. The backboards should be of a type designed to fit through access ways and narrow aisles of commercial and business aircraft.

The following material describes some of the items included in Table A-11-1.1(b):

Immobilizing Mattress. This apparatus consists of a plastic bag designed like a mattress and filled with a lot of very small balls. An aspirator (mechanical or other) is used to take out the air so that the mattress is crushed by the atmospheric pressure and becomes as rigid as plaster. A human body, partly enveloped before the mattress is compressed, is completely wrapped and head, limbs, and backbone become immobilized, allowing any type of transportation, through the use of lateral rope loops. The apparatus is permeable to X-rays. Although the dimensions are variable, its length varies generally between 1.80 m and 1.90 m (74 in.) and its width between 0.80 m and 0.90 m (36 in.).

Backboards. These are classified as long and short backboards. The approximate dimensions for a long backboard are shown in Figure A-11-1.1(a). Although a backboard of 1.90 m (74 in.) is shown, some backboards of 1.83 m (72 in.) in length should be available to move through the smallest aircraft emergency exits, 510 mm × 915 mm (20 in. × 36 in.). A 75-mm (3-in.) wide velcro restraining strap is normally required for legs, hips, upper torso, and head.

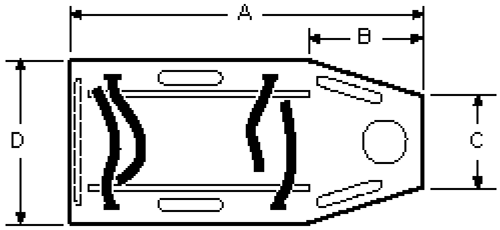
The appropriate dimensions for a short backboard are shown in Figure A-11-1.1(b). A 75-mm (3-in.) wide velcro restraining strap is normally required for lower and upper torso.



A – 1.90 m (74 in.)
B – 1.10 m (43 in.)
C – 0.46 m (18 in.)
D – 0.25 m (10 in.)
Thickness: 19-mm (¾-in.) plywood
Head hole: 140-mm (5-in.) diameter
Hand holes: 250 mm x 50 mm (10 in. x 2 in.)
Foot holes: 250 mm x 75 mm (10 in. x 3 in.)

Note: 25-mm (1-in.) cleats should be placed longitudinally on the underside of the blackboard to facilitate lifting.

Figure A-11-1.1(a) Long backboard.



A – 0.91 m (36 in.)
B – 0.30 m (12 in.)
C – 0.20 m (8 in.)
D – 0.41 m (16 in.)
Thickness: 16-mm (⅝-in.) plywood
Head hole: 114-mm (4-in.) diameter
Hand holes: 150 mm x 38 mm (6 in. x 1 in.)

Note: 25-mm (1-in.) cleats should be placed longitudinally on the underside of the blackboard to facilitate lifting.

Figure A-11-1.1(b) Short backboard.

Miscellaneous Items.

(a) Inflatable tents should have adequate heating and lighting where possible. A large tent can normally accommodate about ten serious cases and can be carried on a large all-purpose vehicle along with the other necessary medical equipment.

(b) Mobile emergency hospitals or inflatable tents, if available [*see Figures A-11-1.1(c), A-11-1.1(d), and A-11-1.1(e)*], or shelters can be used for on-site treatment of Immediate Care (Priority I — Red) and Delayed Care (Priority II — Yellow) casualties. These units should be readily available for rapid response. Planning should also include the assignment of personnel who can operate/assemble this equipment. A cardiac care ambulance unit can be used as an ideal shelter for Immediate Care (Priority I — Red) casualties.

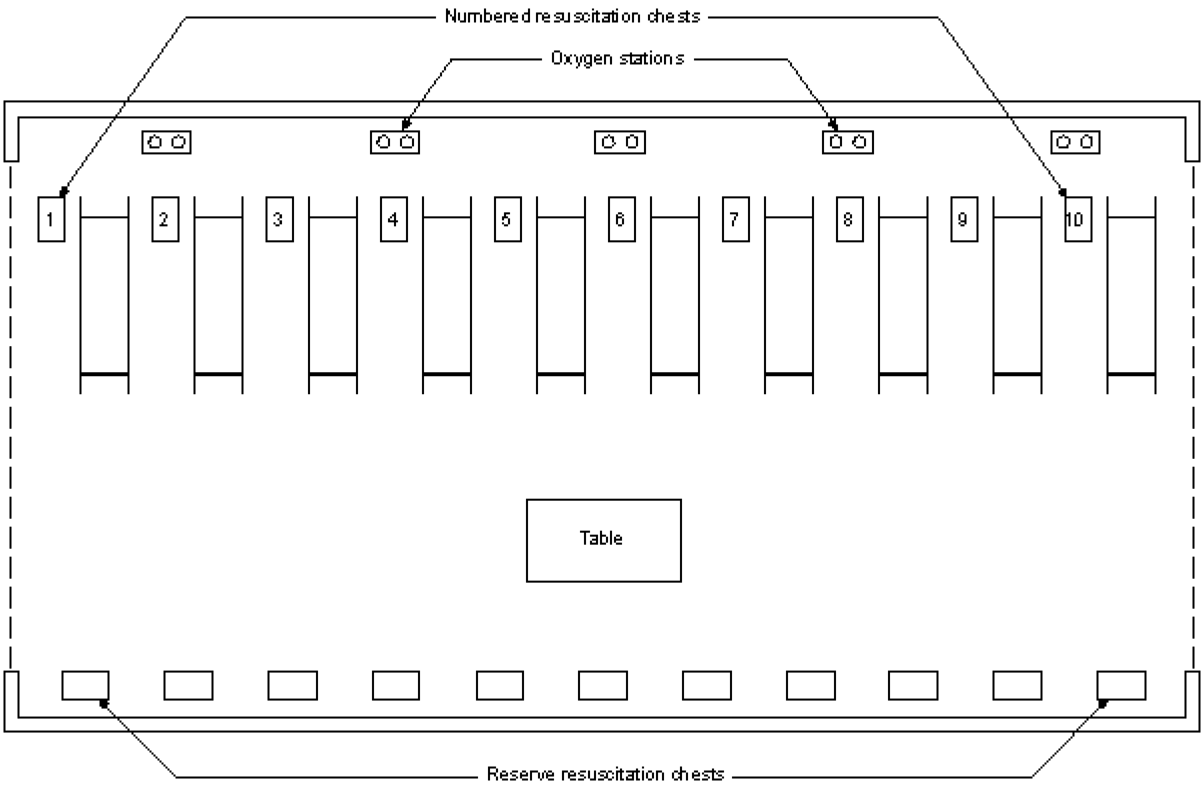


Figure A-11-1.1(c) Schematic of an inflatable tent.

Figure A-11-1.1(d) Containerized hospital emergency mobile.

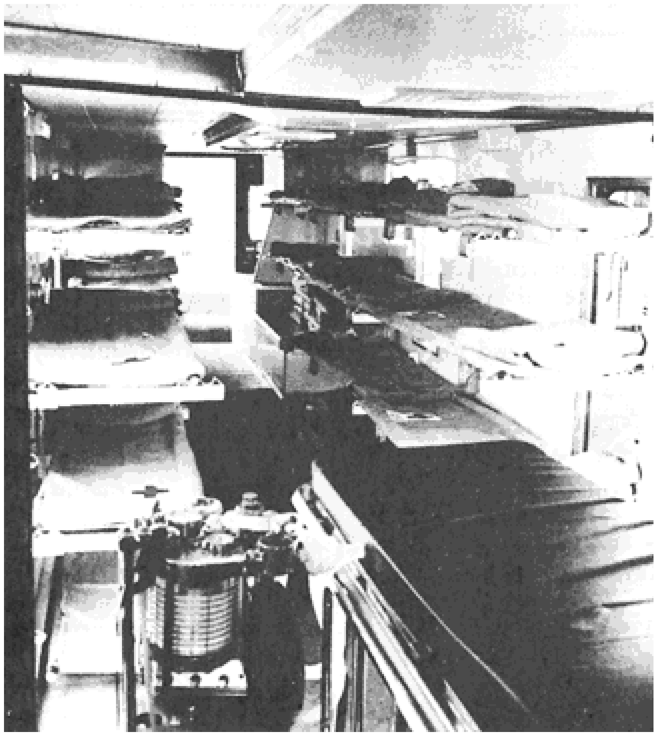

Figure A-11-1.1(e) Interior view of containerized hospital emergency mobile.

Emergency Medical Communication System. Communication is a primary requisite of an airport/community emergency medical plan. The medical service communication system should ensure adequate communication during emergencies to disseminate warning information and obtain support operations. Without communication the hospital cannot know the number and type of casualties it will be receiving, ambulances cannot be directed to the facilities most capable of rendering the needed care, supplies available from outside sources cannot be called for, and medical personnel cannot be directed to the point where they are needed most.

The participating hospitals should have the capability of communicating with one another by means of a two-way radio communication network. Ideally, each hospital should have the capability of either calling other individual hospitals or, if the occasion arises, calling all other hospitals simultaneously. This capability is invaluable for hospitals experiencing an emergency such as a need for a certain blood type or an item of equipment in short supply. It is also recommended that the medical coordinator be able to communicate with participating hospitals directly.

Emergency Medical Transportation Facilities. The dispatch of casualties to hospitals from the accident site should take into consideration the hospital(s) medical personnel on staff, medical specialties, and beds readily available. Ideally, each airport should have available at least one on-call ambulance for routine medical emergencies. Written agreements with off-airport based ambulances should be prepared to provide for emergency transportation services.

In major emergency situations, other means of transportation may be substituted for ambulances. Vans, buses, automobiles, station wagons, or other suitable airport vehicles can be used. Provision for immediate transportation should be available to transport the uninjured or apparently uninjured to a designated holding area.

An area grid map (with date of latest revision) of the airport's surrounding area should be carried by all rescue vehicles. All medical facilities should be depicted prominently on the grid map. (*See Figure A-4-2.2.*)

Assessment of Airport Medical Care Facilities' Needs (Medical Clinic or First Aid Room or Both).

General Factors Influencing Need. There are many general factors that influence the need for an airport first aid room or an airport medical clinic. Factors to be taken into consideration include:

(a) The number of passengers served annually and the number of employees based on the airport;

(b) The industrial activity on the airport property and in the surrounding community;

(c) The distance from adequate medical facilities; and

(d) Mutual aid medical services agreements.

Generally, it is recommended that an airport medical clinic be available when the airport employees number 3000 or more and that a first aid room be available at every airport. The airport medical care or first aid room personnel and facilities should be integrated into the airport/community emergency plan.

The airport medical clinic, in addition to providing emergency medical care to the airport population, can extend emergency care to communities surrounding the airport, if these communities have no emergency facilities of their own.

The airport medical clinic can be included in the community emergency services organization and planning. In the event of a large-scale nonairport local emergency, the airport medical clinic can function as the coordination site for direction of incoming medical personnel assistance as well as medical supplies and equipment.

Location of Airport Medical Care Facilities. The facilities should be readily accessible to the airport terminal building, to the general public, and to emergency transportation equipment (i.e., ambulances, helicopters, etc.). Site selection should avoid the problem of needing to move injured persons through congested areas of the airport terminal building, while providing access to the facility by emergency vehicles. The medical care facility should be located to allow access from the air side of the airport terminal building, as this provides control over unauthorized vehicles interfering with emergency equipment.

Airport Medical Care Facility Personnel. The number of trained personnel and degree of expertise needed by each individual will depend on the particular airport's requirements. The staff of the airport medical clinic should form the nucleus of the medical services planning for the airport/community emergency plan (and be responsible for implementation of the medical portion of the plan). It is recommended that the airport first aid room at least be staffed with highly qualified first aid personnel.

In general it is recommended that during the principal hours of airport activity at least one person trained to deal with the following be available within 3 minutes to 5 minutes:

(a) Cardiopulmonary resuscitation (CPR);

(b) Bleeding from a traumatic source;

(c) Heimlich maneuver (choking);

(d) Fractures and splinting;

(e) Burns;

(f) Shock;

(g) Emergency childbirth and immediate care of newborns, including prematures;

(h) Common medical conditions that can influence the outcome of injury (allergies, high blood pressure, diabetes, pacemaker, etc.);

(i) Basic measures for treatment and protection subsequent to spills or leaks of radioactive materials or toxic or poisonous substances;

(j) Treatment of emotionally disturbed persons;

(k) Recognition of, and first aid for, poisons, bites, and anaphylactic shock; and

(l) Transportation techniques for injured persons.

The person responsible should have authority to order hospitalization if necessary and to arrange any needed transportation.

The airport authority should obtain the advice and direction of a consulting emergency medical care physician as to the allotment and design of equipment for the first aid room commensurate with the anticipated needs of the particular airport.

The equipment and the medical supply inventory of the airport medical clinic should be established by the staff in charge of the clinic.

The airport medical care facility should be equipped to handle cardiac arrest and other types of injuries and illnesses associated with industrial medicine. If drugs are maintained, provision should be made to ensure full security.

Emergency oxygen and respiratory equipment should be available to treat smoke inhalation victims.

Since the majority of nonaccident related medical emergencies at airports involve coronary problems, advance life support systems including oxygen, oxygen regulators, and other elements for cardiopulmonary care should be readily available. In addition, first aid kits (containing drugs, a wide selection of bandages and splints, blood transfusion equipment, and burn and maternity kits), chains, ropes, crowbars, and metal cutters should be available.

A-11-6.6 Casualty Identification Tag. Figures A-11-6.6(a) and A-11-6.6(b) illustrate an example of a casualty identification tag suitable for multilingual applications.

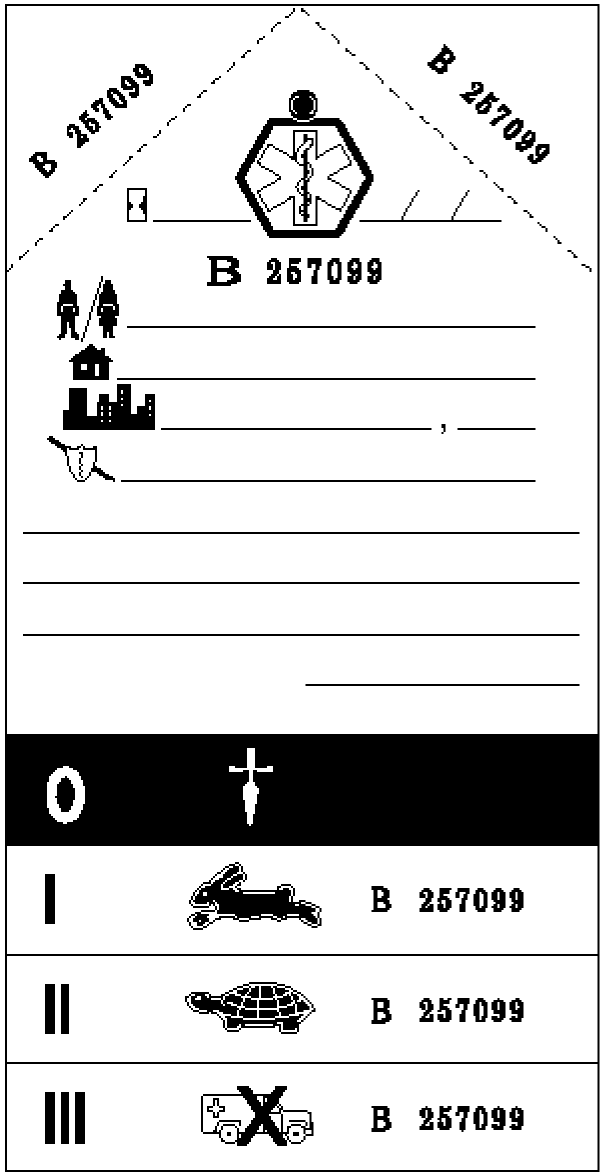

Figure A-11-6.6(a) Casualty identification tag — front.

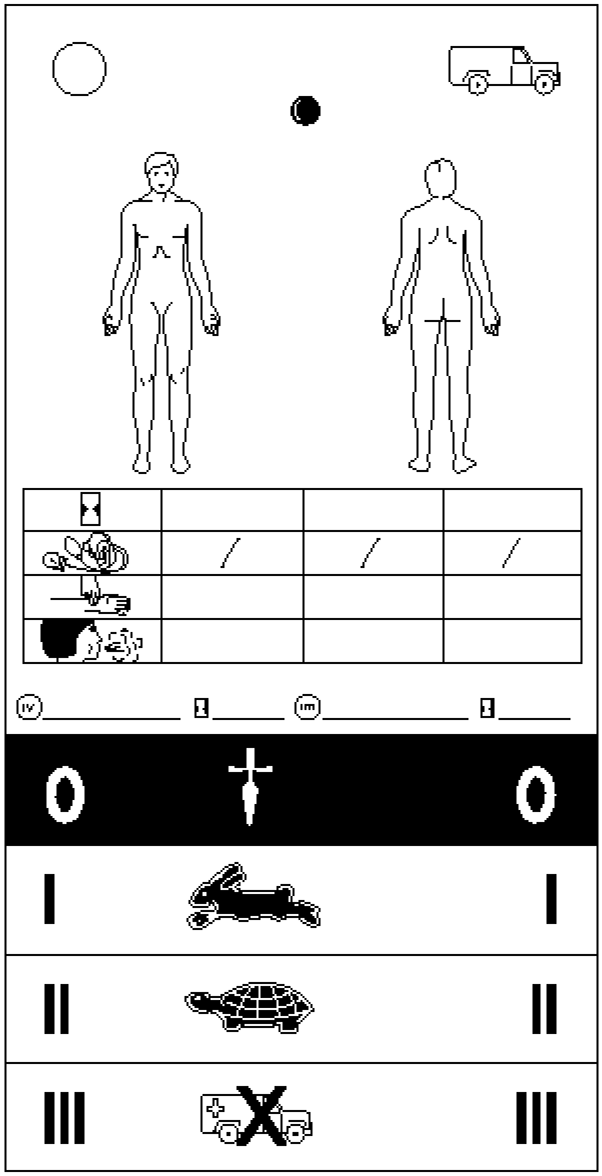

Figure A-11-6.6(b) Casualty identification tag — back.

A-12-1.1 In the United States major aircraft accidents are investigated by the National Transportation Safety Board, 800 Independence Avenue SW, Washington, DC 20591, except those delegated by the Board to the Federal Aviation Administration. Part 430 (Rules Pertaining to Aircraft Accidents, Incidents, Overdue Aircraft, and Safety Investigations) of the National Transportation Safety Board, Section 430.10 reads:

Civil aircraft accident investigation is normally conducted by a number of investigators of the National Transportation Safety Board or their designees interested in establishing the probable cause. Federal or state governments are usually charged with the official responsibility but the operators, pilot groups, airport management, and others may be active in accident investigation work. Fire officials normally make their own investigation.

For guidance on preservation of evidence, see NFPA 402, *Guide for Aircraft Rescue and Fire Fighting Operations*, Section 11-7 and Appendix E.

A-12-2.2 Security measures within the wreckage area should be established as soon as possible. All authorized personnel should have and display proper "Emergency Access" identification as required by the airport/community emergency plan.

All security personnel should be briefed on proper identification procedures. Two-way radio communication with appropriate authorities on the site can help identify any person seeking entry whose credentials are questionable.

Accident sites can be exceptionally dangerous areas, owing to the possible presence of flammable fuels, dangerous goods or hazardous materials, and scattered pieces of wreckage. All necessary safety precautions in the emergency area should be carried out rigidly; this includes exercising good judgment during fire control and throughout all rescue efforts. Safety equipment and approved protective clothing should be worn by all personnel involved. All other personnel should remain outside the security perimeter until the chief fire officer declares the area safe.

A-13-4.2

Emergency Exercise Critique Form
XYZ International Airport

Person performing critique ________________________

General

1. Date and time of emergency ________________________
2. Emergency location ____________________________
3. Type of emergency __________________________

Rescue Operations

Person performing critique ____________________

Organization ______________________

4. Time of emergency notification __________________________
5A. First agency or individual to arrive at emergency ____________________
 B. Time of arrival ______________
6A. Arrival time of airport rescue fire fighting service at emergency ______________________
 B. Approximate number of fire personnel at site ______________
 C. Time and type of first fire protection action (foam, dry chemical, etc.) ________________
7A. Time first casualty evacuated from aircraft________________
 B. How evacuated ______________________
 C. Number of casualties evacuated from inside aircraft________________

D. Time last casualty evacuated from aircraft_________________

Comments: ___________________

8A. Number of injured _____________________

B. Number of noninjured _______________________

C. Number of dead_______________________

9A. Time first casualty transported to triage area ___________________

B. Time last casualty transported to triage area ___________________

10A. Name of other services participating in first aid _________________

B. Who was in charge of these services? _______________

C. How many persons involved? _________________________

11A. Name of other organizations participating in rescue operations___________________________

B. How many persons involved? _________________________

12. Was the moulage realistic? _______________________

Security

Person performing critique _________________________

Organization _________________

13A. Time of emergency notification to police/ security ___________________

B. Who was first police/security officer to arrive at emergency site? _____________________

C. Time of arrival _______________________

14A. How many persons involved?_________________________

B. Did command of security at emergency site change at any time?___________________ If so, give sequence of command change and agency represented

15. Was the traffic satisfactorily controlled? _____________________

16. Was there any provision for the security of personal effects? ___________________

17. Any special problems at accident site with security (spectators, etc.)? ___________________

Medical Services

Person performing critique _______________________

Organization ___________________

18A. Who was first medical official to arrive at emergency site? Medical facility associated with? ___________________

B. Time of notification _______________________

C. How notified? _______________________

D. By whom?________________________
E. Arrival time at emergency site ____________________________
19A. Who was the medical coordinator in charge of medical care and evacuation of casualties? ____________________________
B. Time of notification ________________________
C. How notified? ________________________
D. By whom?__________________________
E. Arrival time at emergency site ________________________________
20A. Number of physicians responding ______________________________
B. Number of nursing personnel responding ___________________
21A. Was a triage area designated at emergency site?___________________
B. Was the triage area located to expedite the flow of casualties?
C. Were the casualties properly classified and tagged? _____________________
D. Were the casualties moved quickly to receiving hospitals? _____________________
22. How were medical and first aid personnel identified? ________________________
23A. What time were relief agencies (Red Cross, Salvation Army, etc.) notified? _____________________
B. How notified? __________________________
C. By whom?____________________________
D. Arrival time ____________________________
E. Personnel participating _________________

Ambulances

Person performing critique ________________________

Organization _____________________
24A. Time of notification to ambulances _____________________
B. How notified? ________________________
C. By whom?__________________________
D. Name of ambulance company ________________________
E. Time of arrival at accident site of first ambulance _____________________
25A. How many casualties did ambulance handle? ___________________
B. Time of departure __________________________
C. Hospital__________________________
D. Arrival time at hospital__________________________
26A. Was ingress or egress to accident site a problem? _________________

Explain: ___________________

B. Any special problems driving from accident site to hospital? _______________

Explain: ____________________

Hospitals

Person performing critique ________________________

Organization ______________________

27. Number of physicians responding______________________
28. Number of nursing personnel responding _________________
29. Number of other hospital personnel responding _________________
30. Number of casualties received ______________________
31. Kind of casualties received ______________________

32A. Time first alert was received ______________________

B. Time disaster message authenticated _________________

C. Time first casualties arrived ________________________

D. Time first casualties were seen by a physician_________________

E. Time last casualties arrived ______________________

F. Time last casualties were seen by a physician_________________

Leadership

Person performing critique ________________________

Organization ____________________

33. Did leadership by incident commander cause people to take effective action?
34. Were there any problems in the coordination of medical, fire, police, and other services? ______________________
35. Was the general spirit of the participants conducive to the success of the exercise? ____________________
36. Who demonstrated leadership? ________________________

Public Information

Person performing critique ________________________

Organization ____________________

37A. Time of notification to airport public information officer _________________

B. How notified? ______________________

C. Arrival time ____________________

38A. Who was the public relations officer? ____________________

B. From what organization? ______________________

39. What special problems were indicated? _________________

Explain: ____________________

Communications and Control

Person performing critique ______________________

Organization __________________

40. Did the command post perform effectively? ______________

41. Did the emergency operations center perform effectively? ______________

42. Was the personnel call system effective?________________

43. Was the physician call system effective?________________

44. Was the emergency message accurately received? ______________

45. Were communications with the hospitals effective? ______________

46. Were there any problems with internal communications? __________________

47. What kinds of communications systems were used? ______________

A. two-way radio ______________________

B. telephone ______________________

C. walkie-talkie ____________________

D. messenger ____________________

E. other ______________________

NARRATIVE: Make any comments that may be helpful in evaluating this exercise ________________

Appendix B Table for International Aircraft Markings

This Appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

Table B-1 International Aircraft Markings

A-2-	Botswana	TC-	Turkey
A6-	United Arab Emirates	HA-	Hungary
A7-	Qatar	HB-	Switzerland
A40-	Oman	HB-	Liechtenstein
AP-	Pakistan	HC-	Ecuador

Appendix C Recommended Reference Sources

C-1 Recommended Publications. The following documents or portions thereof are recommended within this Appendix for informational purposes only. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

C-1.1 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 10, *Standard for Portable Fire Extinguishers*, 1994 edition.

NFPA 402, *Guide for Aircraft Rescue and Fire Fighting Operations*, 1996 edition.

NFPA 403, *Standard for Aircraft Rescue and Fire Fighting Services at Airports*, 1993 edition.

NFPA 407, *Standard for Aircraft Fuel Servicing*, 1996 edition.

NFPA 408, *Standard for Aircraft Hand Fire Extinguishers*, 1994 edition.

NFPA 409, *Standard on Aircraft Hangars*, 1995 edition.

NFPA 412, *Standard for Evaluating Aircraft Rescue and Fire Fighting Foam Equipment*, 1993 edition.

NFPA 414, *Standard for Aircraft Rescue and Fire Fighting Vehicles*, 1995 edition.

NFPA 415, *Standard on Aircraft Fueling Ramp Drainage*, 1992 edition.

NFPA 416, *Standard on Construction and Protection of Airport Terminal Buildings*, 1993 edition.

NFPA 417, *Standard on Construction and Protection of Aircraft Loading Walkways*, 1990 edition.

NFPA 418, *Standard for Heliports*, 1995 edition.

NFPA 1001, *Standard for Fire Fighter Professional Qualifications*, 1992 edition.

NFPA 1002, *Standard for Fire Department Vehicle Driver/Operator Professional Qualifications*, 1993 edition.

NFPA 1003, *Standard for Airport Fire Fighter Professional Qualifications*, 1994 edition.

NFPA 1561, *Standard on Fire Department Incident Management System*, 1995 edition.

NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*, 1992 edition.

Fire Protection Guide on Hazardous Materials.

C-1.2 Aircraft Rescue and Fire Fighting Manuals.

U.S. Navy *Aircraft Firefighting and Rescue Manual*, NAVAIR 00-80R-14, 1983. (Available from Naval Air Systems Command, Code 1416C, Washington, DC 20360.)

Aircraft Rescue and Fire Fighting (3rd Edition 1992), IFSTA 206. (Available from International Fire Service Training Association, Oklahoma State University, Stillwater, OK 74074.)

Aircraft Emergency Rescue Information, Technical Manual, T.O. 00-105-9. (Available from Hq. NRAMA-MMSTD, Robins Air Force Base, Georgia 31093.)

C-1.3 Aircraft Rescue and Fire Fighting Publications.

AD 739-027, *A Proposed Method for Evaluating Fire Prevention Efforts by the Airport Manager of Non-Hub Airports*, 1970. (Available from National Technical Information Service, Springfield, VA 22151.)

AFAPL-TR-73-74, *Fire and Explosion Manual for Aircraft Accident Investigations*, August 1973, Joseph M. Kuchta, Pittsburgh Mining and Safety Research Center, Bureau of Mines Report No. 4193 published by U.S. Dept. of the Air Force, Air Force Aeoro Propulsion Laboratory, AFAPL/SFH, Wright-Patterson Air Force Base, OH 45433.

C-1.4 Typical ICAO Publications. Available from International Civil Aviation Organization, 1000 Sherbrooke St. W, Montreal, Quebec, Canada H3A 2R2.

International Standards and Recommended Practices — Aerodromes, Annex 14, Second Edition — July 1995.

Airport Services Manual, Part 1, “Rescue and Fire Fighting,” Third Edition, 1990, Doc. 9137-AN/898.

Airport Services Manual, Part 7, “Airport Emergency Planning,” Second Edition, 1991, Doc. 9137-AN/898.

Training Manual, Aerodrome Fire Services Personnel, First Edition, 1976, Doc. 7912-AN/857, Part E-2.

Manual of Aircraft Accident Investigation, Fourth Edition, 1970, Doc. 6920-AN/855/4.

Technical Instructions for the Safe Transport of Dangerous Goods by Air, 1995-1996.

C-1.5 Air Line Pilots Association. ALPA *Guide for Airport Standards*, First Edition, July 1969, Third Edition, 1981. (Available from Air Line Pilots Association, Engineering and Air Safety Department, 535 Herndon Parkway, Herndon, VA 22070.)

C-1.6 Federal Aviation Administration Publications. Send your order to:

U.S. Department of Transportation
Subsequent Distribution Office
Ardmore East Business Center
3341 Q 75th Ave.
Landover, MD 20785.

Advisory Circulars. This listing is limited to advisory circulars of substance concerning aircraft rescue and fire fighting. For a complete listing of FAA advisory circulars, write the FAA and request a copy of the latest “Advisory Circular Checklist.” This checklist is published periodically in the *Federal Register*. This listing of advisory circulars is as of April 2, 1985.

150/5200-12A, *Fire Department Responsibility in Protecting Evidence at the Scene of an Aircraft Accident* (4-8-85). (AAS-100). Furnishes general guidance for airport, employees, airport management and other personnel responsible for fire fighting and rescue operations, at the scene of an aircraft accident, on the proper presentation of evidence.

150/5200-18B, *Airport Safety Self-Inspection* (5-2-88). (AAS-310). Provides information to airport operators on airport self-inspection programs and identifies items that should be included in such a program.

150/5210-2A, *Airport Emergency Medical Facilities and Services* (11-27-84). (AAS-300). Provides information and advice so that airports may take specific voluntary pre-planning actions to assure at least minimum first-aid and medical readiness appropriate to the size of the airport in terms of permanent and transient personnel.

150/5210-5B, *Painting, Marking, and Lighting of Vehicles Used on an Airport* (7-11-86). (AAS-120). Provides guidance, specifications, and standards, in the interest of airport personnel safety and operational efficiency, for painting, marking, and lighting of vehicles operating in the airport air operations areas.

150/5210-6C, *Aircraft Fire and Rescue Facilities and Extinguishing Agents* (1-28-85). Outlines scales of protection considered as the recommended level compared with the minimum level in FAR Part 139.49 and tells how these levels were established.

150/5210-7B, *Aircraft Fire and Rescue Communications* (4-30-84). Provides airport management with information helpful in the establishment of communication and alarm facilities. Such facilities alert and guide those personnel who must deal with aircraft ground emergencies.

150/5210-13A, *Water Rescue Plans, Facilities, and Equipment* (5-31-91). (AAS-120). Provides guidance to assist airport operators in preparing for water rescue operations.

150/5220-4B, *Water Supply Systems for Aircraft Fire and Rescue Protection* (7-29-92). (AAS-120). Provides guidance for the selection of a water source and standards for the design of a distribution system to support aircraft rescue and firefighting (ARFF) service operations on airports.

150/5220-10A, *Guide Specification for Water/Foam Aircraft Rescue and Firefighting Vehicles* (7-3-91). (AAS-120). Contains performance standards, specifications, and recommendations for the design, construction, and testing of a family of aircraft rescue and firefighting (ARFF) vehicles.

150/5230-4, *Aircraft Fuel Storage, Handling, and Dispensing On Airports* (8-27-82). (AAS-300). (Consolidated reprint includes changes 1 and 2). Provides information on aviation fuel deliveries to airport storage and the handling, cleaning, and dispensing of fuel into aircraft.

150/5370-2C, *Operational Safety On Airports During Construction* (5-31-84). (AAS-300). Concerning operational safety on airports with special emphasis on safety during periods of construction activity, to assist airport operators in complying with Part 139.

139.49-1, *Programs for Training of Fire Fighting and Rescue Personnel* (11-12-74). Suggested training programs for airport fire fighting and rescue personnel.

C-1.7 ASTM Standard. This publication makes reference to the following ASTM standard, and the year date indicates the latest edition available. It is available from the American Society for Testing and Materials, 1916 Race Street, Philadelphia, Pennsylvania 19103.

ASTM E 380, *Standard for Metric Practice*, 1993.

C-1.8 Federal Aviation Regulations.

Part 139, *Certification and Operations: Land Airports Serving Certain Air Carriers*, January 1988. Sold on a subscription basis by the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

C-1.9 U.S. Air Force Technical Reports.

AGFSRS 71-3, Accident/Incident Survey Data Analysis for Aircraft Ground Fire Suppression and Rescue Systems — UDRI, October 1971.

C-1.10 U.S. Government Publications.

Code of Federal Regulations, U.S. Government Printing Office, Washington, DC 20402.

DOD-AGFSRS-75-5, *Aircraft Ground Fire Suppression and Rescue Simulation Model — UD*, August 1975.

DOD-AGFSRS-76-2, *A Study to Evaluate the Intensity of and Alternative Methods for Neutralization of DOF Aircraft Fuel Spills; Phase 1 USA MERDC*, February 1976.

NOTE: Full size or microfiche copies of the DOD listed reports are available directly from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161.

Emergency Medical Services Communications Systems, U.S. Department of Health, Education & Welfare. Health Services and Mental Health Administration Division of Emergency Health Services, 5000 Fishers Lane, Rockville, MD 20852.

DHEN Publication No. (HSM) 73-2003

What to Do and How to Report Military Aircraft Accidents, U.S. Naval Aviation Safety Center, U.S. Naval Air Station, Norfolk, VA 23511.

National Transportation Safety Board, *Civil Aircraft Accident Investigation Guidelines*, Washington, DC 20591.

C-2 Organizations. The following list provides the addresses of organizations throughout the world that may serve as useful sources of information and assistance.

C-2.1 National Operations.

Aircraft Owners and Pilots Association (AOPA), 421 Aviation Way, Frederick, MD 21701; phone: (301) 695-2000; fax: (301) 695-2375; cable address: AOPA, Washington, DC. Offices open Monday through Friday, 8:30–5:00 (EST).

Department of Transportation
400 Seventh Street, S.W.
Washington, DC 20590
Federal Aviation Administration
800 Independence Avenue, S.W.
Washington, DC 20591
Phone: (202) 366-3282

Domestic FAA Regional Offices:

Alaskan Region — Anchorage Governing Alaska and Aleutian Islands
Airports Division, AAL-600
Federal Aviation Administration

Anchorage Federal Office Building
222 West 7th Avenue, Box 14
Anchorage, AK 99513

Central Region — Kansas City Governing Iowa, Kansas, Missouri, Nebraska

NFPA 430

1995 Edition

Code for the Storage of Liquid and Solid Oxidizers

1995 Edition

This edition of NFPA 430, *Code for the Storage of Liquid and Solid Oxidizers*, was prepared by the Technical Committee on Hazardous Chemicals, and acted on by the National Fire Protection Association, Inc., at its Annual Meeting held May 22-25, 1995, in Denver, CO. It was issued by the Standards Council on July 21, 1995, with an effective date of August 11, 1995, and supersedes all previous editions.

This edition of NFPA 430 was approved as an American National Standard on August 11, 1995.

Origin and Development of NFPA 430

At the 1969 NFPA Annual Meeting, the Sectional Committee on Storage, Handling and Transportation of Hazardous Chemicals obtained tentative adoption of a *Code for the Storage and Transportation of Oxidizing Materials and Organic Peroxides*, No. 499-T. Subsequently, the Sectional Committee decided to replace No. 499-T with two codes, one for the storage of liquid and solid oxidizers and the other for organic peroxides.

The text printed here contains those requirements that the Sectional Committee believes to be essential for the safe storage of liquid and solid oxidizers. It was processed in accordance with the NFPA Regulations Governing Committee Projects. A draft was adopted as a Tentative Code in 1971. In 1972, an amended version of the 1971 edition was adopted as a Tentative Code. The 1972 edition, with further revisions, was officially adopted by the Association in 1973, Amendments were adopted in 1974, 1975, and 1980.

For the 1990 edition of NFPA 43A, the Committee initiated a complete revision of the document that incorporates revised limits for the quantities of oxidizers stored in buildings, whether they are sprinklered or nonsprinklered. The limits were revised in consideration of the burning characteristics and loss experience this class of chemicals has demonstrated over the past few years. In this edition, the Committee has provided enhanced requirements for the storage of oxidizers in retail establishments. The Committee also included an enhanced list of typical oxidizers covered by this code in the appendix as a guide to users of the document.

This 1995 edition of NFPA 430 consists of a renumbering of the former code NFPA 43A. It represents a complete revision of the document to update the requirements for the safe handling, fire prevention, and storage provisions for liquid and solid oxidizers. This edition incorporates new material into the document to reflect changes in protection technology, particularly in the requirements for sprinkler protection of oxidizers stored in rack storage configurations. The Committee completely revised the document to make it compatible with industry practices and to incorporate enhanced provisions for the safe handling and storage of liquid and solid oxidizers.

This list represents the membership at the time the Committee was balloted on the text of this edition. Since that time, changes in the membership may have occurred.

NOTE: Membership on a Committee shall not in and of itself constitute an endorsement of the Association or any document developed by the Committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on, and maintain current codes for, classes of hazardous chemicals and codes for specific chemicals where these are warranted by virtue of widespread distribution or special hazards.

NFPA 430
Code for the
Storage of Liquid and Solid Oxidizers

1995 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates explanatory material on that paragraph in Appendix A.
Information on referenced publications can be found in Chapter 7 and Appendix C.

Chapter 1 General

1-1 Scope.

1-1.1

This code shall apply to the storage of oxidizers that are liquid or solid at ambient conditions.

Exception: This code shall not apply to the storage of solid and liquid oxidizers for normal use on the premises of single-family dwellings.

1-1.1.1 Separate chapters specify requirements for storage of oxidizers by class where the quantities stored are greater than the stated minimums.

1-1.1.2* For quantities of a class of oxidizer that are less than the minimum covered by the separate chapter for that class, those parts of that chapter pertaining to fire prevention and sprinkler protection and compatibility, and all of Chapter 2 of this code shall be used as requirements.

1-1.1.3 Existing buildings storing oxidizers that do not comply with the requirements of this code that pertain to types of construction, separation of buildings, and fixed fire protection shall be used at the discretion of the authority having jurisdiction, provided they do not constitute a distinct hazard to life or adjoining property.

1-1.2

This code shall not apply to explosives or blasting agents, which are covered by NFPA 495, *Explosive Materials Code*; or to ammonium nitrate, which is covered in NFPA 490, *Code for the Storage of Ammonium Nitrate*; or to organic peroxides, which are covered in NFPA 43B, *Code for the Storage of Organic Peroxide Formulations*.

1-1.3

The quantity and arrangement limits in this code shall not apply to the storage of oxidizers at manufacturing plants where oxidizers are manufactured.

1-1.4

The quantity and arrangement limits in this code shall not apply to facilities that use ammonium perchlorate in the commercial manufacture of large-scale rocket motors.

1-2* Purpose.

The purpose of this code shall be to provide reasonable requirements for the safe storage of commercially available strengths of liquid and solid oxidizers. The hazards of stored oxidizers can manifest themselves in one or more of five distinct hazardous situations as follows:

(a) They increase the burning rate of combustible materials.

(b) They can cause spontaneous ignition of combustible materials.

(c) They can decompose rapidly.

(d) They can liberate hazardous gases.

(e) They can undergo self-sustained decomposition, which can result in an explosion.

1-3 Applicability of Other Documents.

The requirements of NFPA 30, *Flammable and Combustible Liquids Code*, and NFPA 231, *Standard for General Storage,* shall apply where applicable and where they are more restrictive than this code.

1-4 Equivalency.

Nothing in this code is intended to prevent the use of systems, methods, or devices equivalent to those prescribed by this code, provided technical documentation is submitted to the authority having jurisdiction that demonstrates equivalency, and the system, method, or device is approved for the intended purpose.

1-5 Definitions.

For the purposes of this code, the following terms are defined below:

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Combustible Containers. Containers that include paper bags, fiber drums, plastic containers, and wooden or fiber boxes or barrels. They also include noncombustible containers having removable combustible liners or packing and include noncombustible containers in combustible overpacks.

Compatible Material. A material that, when in contact with an oxidizer, will not react with the oxidizer or promote or initiate its decomposition.

Explosive Reaction.* A reaction producing a sudden rise in pressure with potentially destructive results. Such a reaction includes both deflagration and detonation.

Incompatible Material. A material that, when in contact with an oxidizer, can cause hazardous reactions or can promote or initiate decomposition of the oxidizer.

Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of labeled equipment or materials and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Listed.* Equipment or materials included in a list published by an organization acceptable to the authority having jurisdiction and concerned with product evaluation that maintains periodic inspection of production of listed equipment or materials and whose listing states either that the equipment or material meets appropriate standards or has been tested and found suitable for use in a specified manner.

Manufacturing Plants. Those facilities where oxidizers are produced by chemical means.

Noncombustible Container. A container constructed of glass or metal. The metal container can be coated with a polymeric material no more than 2 mils in thickness.

Noncombustible Material.* A material that, in the form in which it is used and under the conditions anticipated, will not ignite, supports combustion, burn, or release flammable vapors when subjected to fire or heat. Materials that are reported as having passed ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750 Degrees C*, shall be considered noncombustible materials. For the purposes of this code, noncombustible construction and limited-combustible construction are both considered to be noncombustible.

Oxidizer. Any material that readily yields oxygen or other oxidizing gas, or that readily reacts to promote or initiate combustion of combustible materials. Examples of other oxidizing gases include bromine, chlorine, and fluorine.

Pile. Material in a single contiguous storage area. Any material not properly separated by appropriate distance is considered to be part of the same pile.

Processing Plants. Those facilities not located on the premises of manufacturing plants where oxidizers are pelletized, ground, dissolved, packaged, mixed, or blended.

Retail Establishments. Those facilities where oxidizers are sold directly to the general public.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Warehouses. Those facilities where oxidizers are received, stored, and subsequently shipped in their original containers.

1-6 Classification of Oxidizers.

For the purpose of this code, oxidizers shall be classified according to the system described in this section. The classification is based on the technical committee’s evaluation of available scientific and technical data, actual experience, and its considered opinion. Classification refers to the pure oxidizer. Gross contamination can cause oxidizers of all classes to undergo exothermic or explosive reaction, particularly if they also are subjected to confinement and heating. (*See definition of oxidizer*.) (*See Sections B-1 through B-4 for oxidizer classifications.*)

1-6.1 Class 1.

An oxidizer whose primary hazard is that it slightly increases the burning rate but does not cause spontaneous ignition when it comes in contact with combustible materials.

1-6.2 Class 2.

An oxidizer that will cause a moderate increase in the burning rate or that causes spontaneous ignition of combustible materials with which it comes in contact.

1-6.3* Class 3.

An oxidizer that will cause a severe increase in the burning rate of combustible materials with which it comes in contact or that will undergo vigorous self-sustained decomposition due to contamination or exposure to heat.

1-6.4* Class 4.

An oxidizer that can undergo an explosive reaction due to contamination or exposure to thermal or physical shock. In addition, the oxidizer will enhance the burning rate and can cause spontaneous ignition of combustibles.

1-7 Classification of Storage Facilities.

1-7.1* Segregated.

Storage in the same room or inside area, but physically separated by distance from incompatible materials.

1-7.2 Cutoff.

Storage in the same building or inside area, but physically separated from incompatible materials by partitions or walls, or storage in a fixed tank.

1-7.3 Detached.

Storage in either an open outside area or a separate building containing no incompatible materials, and located away from all other structures.

Chapter 2 Basic Requirements

2-1 Hazard Management.

2-1.1

The design of a new or enlarged facility for storage of oxidizers shall be reviewed by the authority having jurisdiction. (*For existing structures, see 1-1.1.3.*)

2-1.2

Emergency plans shall be prepared for each facility. These plans shall be reviewed and training exercises shall be conducted at least annually in cooperation with local emergency organizations.

2-2 Identification of Materials in Storage.

2-2.1*

All storage areas containing oxidizers shall be conspicuously identified by the words “Class (appropriate classification number) Oxidizers,” as defined in Section 1-6.

NOTE: The hazard rating classifications for oxidizers do not correlate to the reactivity classification in NFPA 704, *Standard System for the Identification of the Fire Hazards of Materials*.

Exception: Retail display areas.

2-2.2

Where oxidizers having different classifications as defined by Section 1-6 are stored in the same area, the area shall be marked for the most severe hazard class present.

2-2.3

All packages shall be approved and individually marked with the chemical name of the oxidizer.

2-3 Storage Containers, Tanks, and Bins.

2-3.1 Shipping Containers.

Where a storage container for solid and liquid oxidizers also functions as the shipping container, the container shall meet the requirements of the U.S. Department of Transportation or the Canadian Ministry of Transport (Transport Canada).

2-3.2 Tanks and Bins.

Tanks for the storage of bulk liquid oxidizers and bins for the storage of bulk solid oxidizers shall meet the following requirements:

(a) Materials of construction shall be compatible with the oxidizer being stored.

(b) Tanks and bins shall be designed and constructed in accordance with federal, state, and local regulations, or, as a minimum, in accordance with nationally recognized engineering practices (e.g., ASME, API).

(c) Tanks and bins shall be equipped with an adequately sized vent or other relief device to prevent overpressurization due to decomposition or fire exposure.

2-3.3 Bulk Liquid Storage.

Bulk liquid storage is defined as the storage of more than 600 gal (U.S.) (2271 L) in a single container.

2-3.4 Bulk Solid Storage.

Bulk solid storage is defined as the storage of more than 6000 lb (2722 kg) in a single container.

2-3.5 Outside Storage.

Outside storage tank size shall not be limited by this code.

Exception: Class 4 oxidizers.

2-4 Storage Arrangements.

2-4.1

The arrangement and quantity of oxidizers in storage shall depend upon their classification, type of container, type of storage (segregated, cutoff, or detached), and fire protection as specified in succeeding chapters and in the manufacturer's or processor's instructions.

2-4.1.1* The arrangement and quantity of oxidizers in storage shall be permitted to deviate from the requirements of succeeding chapters where specially engineered fire prevention or fire protection systems acceptable to the authority having jurisdiction are provided.

2-4.2*

Oxidizers shall be stored to avoid contact with incompatible materials such as ordinary combustibles, combustible or flammable liquids, greases, and those materials that could react with the oxidizer or promote or initiate its decomposition. These shall not include approved packaging materials, pallets, or other dunnage.

Exception: Hydrogen peroxide (Classes 2 through 4) stored in drums shall not be stored on wooden pallets.

2-4.2.1 Special care shall be taken to prevent any contamination of oxidizers in storage.

2-4.2.2 Where oxidizers are stored in segregated warehouses with flammable liquids, the oxidizer containers and flammable liquid drums shall be separated by at least 25 ft (7.6 m). The separation shall be maintained by dikes, drains, or floor slopes to prevent flammable liquid leakage from encroaching on the separation.

2-4.3

Where Class 2, Class 3, or Class 4 liquid oxidizers are stored, means shall be provided to prevent the liquid oxidizer from flowing out of a cutoff area into an area containing incompatible materials.

2-4.4 Retail Storage of Oxidizers.

2-4.4.1 Oxidizers in retail storage in areas accessible to the public shall be arranged in retail display as described in 2-4.4.2 through 2-4.4.7.

2-4.4.2* Shelves and vertical barriers shall be placed between incompatible materials and shall be solid and of noncombustible construction.

2-4.4.3 Solid oxidizers shall not be stored directly beneath incompatible liquids.

2-4.4.4 Shelves shall be no greater than 24 in. (61 cm) deep.

2-4.4.5 Storage shall be no greater than 6 ft (1.8 m) high.

2-4.4.6 The total amount of all oxidizers in all classes shall be limited to 2 tons (1814 kg) in nonsprinklered areas and 4 tons (3630 kg) in sprinklered areas. Sprinklers shall be designed for the most severe oxidizer class stored.

2-4.4.7 The quantities provided for sprinklered retail sales areas shall be permitted to be applied to a maximum of two sales areas within one retail sales store if the two retail sales areas are separated from each other by a fire partition having at least a 1-hr fire resistance rating.

2-5* Storage Limitations.

Where two or more different classes of oxidizers are stored in the same segregated, cutoff, or detached area, the maximum quantity permitted for each class shall be limited to the sum of the maximum proportion permitted for that class. The total of the proportional amounts shall not exceed 100 percent.

2-6 Other Considerations.

2-6.1

In storage facility design, consideration shall be given to the need to provide for containment. Containment on-site or off-site shall be required where necessary to protect the environment from oxidizers, fire extinguishing agents, and their liquid decomposition products.

2-6.2

Approval of the arrangement of storage shall take into consideration the potential evolution of large quantities of smoke and toxic fumes, especially as storage affects manual fire-fighting operations, building egress, and evacuation of adjacent occupancies or communities.

2-7 Employee Instruction.

2-7.1

Personnel involved in operations where oxidizers are stored shall receive instruction in handling the materials in a safe manner, including the manufacturer's and processor's recommendations.

2-7.2

Particular attention shall be given to proper disposal of spilled material to prevent contamination.

2-8 Heating and Electrical Installations.

2-8.1

Heating shall be arranged so that stored materials cannot be placed in direct contact with heating units, piping, or ducts and oxidizers shall be separated so that they cannot be heated to within 25°F (14°C) of their decomposition temperature or to 120°F (49°C), whichever is lower.

2-8.2

Electrical installations shall be in conformance with NFPA 70, *National Electrical Code®*.

2-9 Smoking.

2-9.1

Smoking shall be prohibited in all storage areas containing oxidizers.

2-9.2

"No Smoking" signs shall be placed conspicuously within and at all entrances to storage areas.

2-10 Maintenance and Repairs.

2-10.1

The performance of maintenance work in an oxidizer storage area shall be subject to prior review and approval by supervisory personnel.

2-10.2

Cutting and welding procedures shall be in conformance with NFPA 51B, *Standard for Fire Prevention in Use of Cutting and Welding Processes*.

2-11 Fire Protection.

2-11.1

Fire hydrants and water supplies shall be provided as required by the authority having jurisdiction. Hydrants shall be installed in accordance with NFPA 24, *Standard for the Installation of Private Fire Service Mains and Their Appurtenances*.

NOTE: Conditions that affect the need for hydrant protection include nearness of the exposures, size and construction of the building, amount and class of the oxidizer stored, and availability of public fire protection.

2-11.2

The need for automatic sprinkler protection shall be determined by the nature of the materials, the manner of storage, and the construction of the buildings under consideration. Where automatic sprinkler systems are required, the systems shall be installed in conformance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

NOTE: For certain oxidizers in combustible containers, (e.g., calcium hypochlorite in plastic containers) automatic sprinkler protection is effective only for the control of exposure fires.

2-11.3

Only wet-pipe sprinkler systems shall be employed for protection of buildings or areas containing Class 2 or Class 3 oxidizers.

2-11.4 Fire Protection Water Supplies.

2-11.4.1 Water supplies shall be adequate for the protection of the oxidizer storage by hose streams and automatic sprinklers. The water system shall be capable of providing not less than 750 gpm (2840 Lpm) where protection is by means of hose streams, or 500 gpm (1890 Lpm) for hose streams in excess of the automatic sprinkler water demand.

2-11.4.2 Duration of the water supply shall be a minimum of 2 hr.

2-11.5

Water-based fire protection systems shall be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

2-11.6 Manual Fire Fighting.

Manual fire-fighting equipment in the form of portable water extinguishers or water hose reel stations shall be provided in accordance with the requirements of NFPA 10, *Standard for Portable Fire Extinguishers*, and NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

2-11.6.1* The placement and use of dry chemical extinguishers containing ammonium compounds (Class A:B:C) shall be prohibited in areas where oxidizers that can release chlorine are stored.

2-11.6.2* Halon extinguishers shall not be used in areas where oxidizers are stored.

2-12 Construction.

Combustible construction materials that could come into contact with oxidizers shall be protected with a compatible coating to prevent impregnation of the combustible materials by the oxidizers.

NOTE: Impregnation of wood for fire retardancy or to prevent decay does not protect the wood from impregnation by the oxidizer.

2-13 Housekeeping and Waste Disposal.

2-13.1

Accumulation of combustible waste in oxidizer storage areas shall be prohibited.

2-13.2

Spilled oxidizers and leaking or broken containers shall be removed immediately to a safe area to await disposal in conformance with applicable regulations and manufacturer’s and processor’s instructions. Spilled materials shall be placed in a clean, separate container and shall not be returned to the original container. The disposal of such materials shall not be combined with that of ordinary trash.

2-13.3

Used, empty, combustible containers shall be stored in a detached or sprinklered area.

2-13.4

Operations shall be arranged to prevent excessive fugitive dust accumulation.

2-13.5

Where absorptive combustible packing materials used to contain water-soluble oxidizers have become wet during either fire or nonfire conditions, the oxidizer can impregnate the packing material. This will create a serious fire hazard when the packing material dries. Wooden pallets that are exposed to water solutions of an oxidizer also can exhibit this behavior. Such material shall be relocated to a safe outside area and shall be disposed of properly.

2-14 Dust Collection Systems.

Dust collection systems shall be provided in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Materials*. Separate systems shall be provided for incompatible materials.

Chapter 3 Class 1 Oxidizers

3-1 Application.

This chapter shall apply to storage of Class 1 oxidizers where stored in quantities in excess of 4000 lb (1814 kg). Chapter 2 also applies to storage of Class 1 oxidizers.

3-2 Storage Arrangements.

3-2.1

The storage of Class 1 oxidizers shall be segregated, cutoff, or detached.

3-2.2

Storage of Class 1 oxidizers shall be in accordance with Tables 3-2.2(a) and (b).

Table 3-2.2(a) Storage of Class 1 Oxidizers Nonsprinklered Building

	Nonretail Establishment	Retail Establishment*
Building limit (tons)	200 (181 met ton)	15 (13.6 met ton)
Pile limit (tons)	20 (18 met ton)	2 (1.8 met ton)
Pile height (ft)	8 (2.4 m)	6 (1.8 m)
Pile width (ft)	16 (4.9 m)	8 (2.4 m)
Maximum distance from any container to a working aisle (ft)	8 (2.4 m)	4 (1.2 m)
Distance to next pile (ft)	** **	** **
Distance to wall (ft)	4 (1.2 m)	4 (1.2 m)
Distance to incompatible material (ft)	12 (3.7 m)	10 (3 m)

*Totals in this column are for storage in those areas of a retail occupancy not accessible to the public and separated from the sales display area by a minimum of 1-hr fire-resistive construction. For storage in retail sales display areas, see 2-4.4.

**Aisle width equal to pile height.

Table 3-2.2(b) Storage of Class 1 Oxidizers Sprinklered Building*

	Nonretail Establishment	Retail Establishment**
Building limit (tons)	2000 (1814 met ton)	30 (27 met ton)
Pile limit (tons)	200 (181 met ton)	4 (3.6 met ton)
Pile height (ft)	12 (3.7 m)	8 (2.4 m)
Pile width (ft)	24 (7.3 m)	12 (3.7 m)
Maximum distance from any container to a working aisle (ft)	12 (3.7 m)	6 (1.8 m)
Distance to next pile (ft)	*** ***	*** ***
Distance to wall (ft)	2 (0.6 m)	2 (0.6 m)
Distance to incompatible material (ft)	8 (2.4 m)	8 (2.4 m)

*If the storage is to be considered sprinklered, see Section 3-3.

**Totals in this column are for storage in those areas of a retail occupancy not accessible to the public, and separated from the sales display area by a minimum of 1-hr fire-resistive construction. For storage in retail sales display areas, see 2-4.4.

***Aisle width equal to pile height.

3-2.3

The building limit (tons) shall be permitted to be four times the quantities shown in Table 3-2.2(b) if all of the following conditions are met:

(a) Storage is cutoff or detached;

(b) Storage is located in nonretail occupancies; and

(c) Noncombustible containers are used or buildings are noncombustible.

NOTE: Only the building limit, not the pile limit, height, or width, can be increased by this provision.

3-2.4 Bulk Storage.

3-2.4.1 Bulk storage in combustible buildings shall not come in contact with combustible building members unless the members are protected by a compatible coating to prevent their impregnation by the oxidizer. (*See Section 2-12.*)

3-2.4.2 Bulk storage, either in permanent bins or in piles, shall be separated from all other materials.

3-2.4.3 Bins shall be of noncombustible construction.

Exception: Wooden bins shall be permitted to be protected with a compatible coating to prevent impregnation of the combustible material by the oxidizer.

3-2.4.4 Storage shall be managed to prevent excessive dust accumulation.

3-3 Sprinkler Protection.

3-3.1

Sprinkler protection for Class 1 oxidizers shall be in accordance with NFPA 231, *Standard for General Storage*, or NFPA 231C, *Standard for Rack Storage of Materials*, whichever is applicable.

3-3.2*

For the purpose of applying the requirements of NFPA 231, *Standard for General Storage*, or NFPA 231C, *Standard for Rack Storage of Materials*, Class 1 oxidizers in noncombustible or combustible containers (paper bags or noncombustible containers with removable combustible liners) shall be designated as a Class 1 commodity; as a Class 2 commodity where contained in fiber packs or noncombustible containers in combustible packaging; and as a Class 3 commodity where contained in plastic containers.

3-3.3

Sprinkler protection shall be installed in accordance with NFPA 13, *Standard for Installation of Sprinkler Systems*.

Chapter 4 Class 2 Oxidizers

4-1 Application.

This chapter shall apply to Class 2 oxidizers where stored in quantities in excess of 1000 lb (454 kg). Chapter 2 also applies to storage of Class 2 oxidizers.

4-2 Storage Arrangements.

4-2.1

The storage of Class 2 oxidizers shall be segregated, cutoff, or detached.

Table 4-2.3(a) Storage of Class 2 Oxidizers Nonsprinklered Building

	Segregated Storage		Cutoff Storage		Detached St

*If the storage is considered to be sprinklered, see Section 4-4.

**Totals in this column are for storage in those areas of a retail occupancy not accessible to the public and separated from the sales display area by a cutoff wall in accordance with 4-2.2. For storage in retail sales display areas see 2-4.4.

***See 4-2.7 and Table 4-4.1.

****Aisle width equal to pile height.

*****Not permitted by definition.

4-2.2

Cutoff walls shall have a fire resistance rating of at least 1 hr.

4-2.3

Storage of Class 2 oxidizers shall be in accordance with Tables 4-2.3(a) and (b).

4-2.4

The building limit (tons) shall be permitted to be four times the quantities shown in Table 4-2.3(b) if all of the following conditions are met:

(a) Storage is cutoff or detached;

(b) Storage is located in nonretail occupancies; and

(c) Noncombustible containers are used or buildings are noncombustible.

NOTE: Only the building limit, not the pile limit, height, or width, can be increased by this provision.

4-2.5

Storage in glass carboys shall not be more than two carboys high.

4-2.6

Storage in basements shall be prohibited.

Exception: Where the oxidizer is stored in fixed tanks.

4-2.7 Maximum Height of Storage.

4-2.7.1 Maximum storage height for nonsprinklered buildings shall be in accordance with Table 4-2.3(a).

4-2.7.2 Maximum storage height for sprinklered buildings shall be in accordance with Table 4-4.1.

4-3 Building Construction.

4-3.1

Construction materials that are permitted to be in contact with oxidizers, all cutoff partitions, and all construction in stories or basements below storage of liquid oxidizers shall be noncombustible.

4-3.2

Storage areas for oxidizing materials in combustible containers shall be provided with means to vent fumes in a fire emergency.

4-4 Sprinkler Protection.

4-4.1*

Sprinkler protection for Class 2 oxidizers shall be designed in accordance with Table 4-4.1.

Table 4-4.1 Sprinkler Protection for Class 2 Oxidizers

		Ceiling Sprinklers		
Type of Storage	**Storage Height ft (m)**	**Density gpm/ft² (L/min/m²)**	**Area of Application ft² (m²)**	**In-Rack Sprinklers**
Palletized or	8 (2.4)	0.20 (8)	3750 (348)	
Bulk	12 (3.7)	0.35 (14)	3750 (348)	
Rack	12 (3.7)	0.20 (8)	3750 (348)	One line above each level of storage except the top level
	16 (4.9)	0.30 (12)	2000 (186)	

4-4.2

Sprinkler protection shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems.*

4-4.3

Ceiling sprinklers shall have heads rated at 286°F (141°C).

4-4.4 Storage Protection with In-Rack Sprinklers.

4-4.4.1 In-rack sprinklers shall be heads rated at 165°F (74°C) and shall be designed to provide 30 psi (207 kPa) on the hydraulically most remote six heads on each level.

4-4.4.2 The in-rack sprinklers shall be spaced on 8-ft to 10-ft (2.4-m to 3.0-m) centers at rack uprights.

4-4.4.3 Where multiple levels are provided, the in-rack sprinklers shall be staggered and shall be provided with water shields.

4-5 Detached Storage.

4-5.1

To be considered detached, a sprinklered building for storage of Class 2 oxidizers shall be a minimum of 35 ft (10.7 m) from other buildings and from a line of property that can be built upon.

4-5.2

To be considered detached, a nonsprinklered building for storage of Class 2 oxidizers shall be located no less than 50 ft (15.2 m) from other buildings or a line of property that can be built upon.

Chapter 5 Class 3 Oxidizers

5-1 Application.

This chapter shall apply to Class 3 oxidizers where stored in quantities in excess of 200 lb (91 kg). Chapter 2 also applies to storage of Class 3 oxidizers.

5-2 Storage Arrangements.

5-2.1

The storage of Class 3 oxidizers shall be segregated, cutoff, or detached.

Exception: Storage for sodium chlorate, potassium chlorate, sodium bromate, potassium bromate, and ammonium dichromate shall only be cutoff or detached, not segregated.

Table 5-2.4(a) Storage of Class 3 Oxidizers Nonsprinklered Building

*If the storage is considered to be sprinklered, the sprinkler system shall be designed in accordance with the requirements of Section 5-4.
**Totals in this column are for storage in those areas of a retail occupancy not accessible to the public and separated from the sales display area by a cutoff wall in accordance with 5-2.3. For storage in retail sales display areas see 2-4.4.
***See 5-2.8 and Table 5-4.1.
****Aisle width equal to pile height.
*****Not permitted by definition.

5-2.2

Class 3 oxidizer storage shall be located on the ground floor only.

5-2.3

Cutoff walls shall have a fire resistance rating of at least 2 hr.

5-2.4

Storage of Class 3 oxidizers shall be in accordance with Tables 5-2.4(a) and (b).

5-2.5

The building limit (tons) shall be permitted to be twice the quantities shown in Table 5-2.4(b) if all of the following conditions are met:

(a) Storage is cutoff or detached;

(b) Noncombustible containers are used or buildings are noncombustible; and

(c) Storage is located in nonretail occupancies.

NOTE: Only the building limit, not the pile limit, height, or width, can be increased by this provision.

5-2.6

Storage in glass carboys shall be one carboy high.

5-2.7

Bulk storage in open bins or piles shall not be permitted.

5-2.8 Maximum Height of Storage.

5-2.8.1 Maximum storage height for nonsprinklered buildings shall be in accordance with Table 5-2.4(a).

5-2.8.2 Maximum storage height for sprinklered buildings shall be in accordance with Table 5-4.1.

5-3 Building Construction.

5-3.1

Buildings used for the storage of liquid Class 3 oxidizers shall not have basements.

5-3.2

Construction materials that can come in contact with oxidizers shall be noncombustible.

5-3.3

Storage areas for oxidizing materials in combustible containers shall be provided with means to vent fumes in a fire emergency.

5-4 Sprinkler Protection.

5-4.1*

Sprinkler protection for Class 3 oxidizers shall be designed in accordance with Table 5-4.1.

Table 5-4.1 Sprinkler Protection for Class 3 Oxidizers

Type of Storage	Storage Height ft (m)	Density gpm/ft^2 (L/min/m^2)	Area of Application ft^2 (m^2)	In-Rack Sprinklers
Palletized or	5 (1.5)	0.35 (14)	5000 (465)	
Bulk	10 (3)	0.65 (26)	5000 (465)	
Rack	10 (3)	0.35 (14)	5000 (465)	1 level at midpoint of rack.

5-4.2

Sprinkler protection shall be installed in accordance with NFPA 13, *Standard for Installation of Sprinkler Systems*.

5-4.3

Ceiling sprinklers shall be heads rated at 286°F (141°C).

5-4.4 Storage Protection with In-Rack Sprinklers.

5-4.4.1 In-rack sprinklers shall be heads rated at 165°F (74°C) and shall be designed to provide 30 psi (207 kPa) on the hydraulically most remote six heads on each level.

5-4.4.2 The in-rack sprinklers shall be spaced on 8-ft to 10-ft (2.4-m to 3.0-m) centers at rack uprights.

5-4.4.3 Where multiple levels are provided, the in-rack sprinklers shall be staggered and shall be provided with water shields.

5-5 Detached Storage.

To be considered detached, a building for storage of Class 3 oxidizers shall be separated from flammable or combustible liquid storage, flammable gas storage, combustible material in the open, and from any inhabited building, passenger railroad, public highway, or other tanks. The minimum separation distance shall be:

(a) 50 ft (15 m) for a sprinklered building, or

(b) 75 ft (23 m) for an unsprinklered building.

Chapter 6 Class 4 Oxidizers

6-1 Application.

This chapter shall apply to Class 4 oxidizers where stored in quantities in excess of 10 lb (4.5 kg). Chapter 2 also applies to storage of Class 4 oxidizers.

6-2 Storage Arrangements.

6-2.1

The storage of Class 4 oxidizers shall be detached.

6-2.2

Storage in glass carboys shall be one carboy high. Storage in drums or in containers or in cases shall not exceed the limits outlined in Table 6-2.2.

Table 6-2.2 Storage of Class 4 Oxidizers in Drums, Containers, Cases

	Nonsprinklered Building	Sprinklered Building

Piles		
Length (ft)	10 (3.0 m)	10 (3.0 m)
Width (ft)	4 (1.2 m)	4 (1.2 m)
Height (ft)	4 (1.2 m)	8 (2.4 m)
Distance to next pile (ft)	6 (1.8 m)	8 (2.4 m)
Quantity Limit per building (tons)	1 (0.9 met tons)	No Limit

6-2.3

Bulk storage in piles or fixed bins shall not be permitted.

6-3 Building Construction and Location.

6-3.1

Buildings shall be constructed as one story without basement. Construction materials that could come in contact with oxidizers shall be noncombustible.

6-3.2

Storage areas shall be provided with means to vent fumes in an emergency.

6-3.3

A storage building or storage tank shall be located not less than the minimum distance provided in Table 6-3.4 from flammable liquid storage, combustible material in the open, and from any inhabited building, passenger railroad, public highway, property line, or tank (other than oxidizer storage).

6-3.4*

Where tanks are not separated from each other by 10 percent of the distance specified in Table 6-3.4 for the largest tank, the total contents of all tanks shall be used when using Table 6-3.4.

Table 6-3.4 Separation of Buildings, Tanks Containing Class 4 Oxidizers

Weight of Class 4 Oxidizer		**Distance**	
(lb)	**(kg)**	**(ft)**	**(m)**
over 10 to 100	(4.5 to 45.4)	75	(23)
101 to 500	(45.8 to 227)	100	(30)
501 to 1,000	(227 to 454)	125	(38)
1,001 to 3,000	(454 to 1361)	200	(61)
3,001 to 5,000	(1361 to 2268)	300	(91)
5,001 to 10,000	(2268 to 4536)	400	(122)

over 10,000	(over 4536)	Subject to approval by the authority having jurisdiction.

6-4 Sprinkler Protection.

6-4.1

Sprinkler protection for Class 4 oxidizers shall be installed on a deluge sprinkler system to provide water density of 0.35 gal/min/ft^2 (14.4 L/min/m^2) over the entire storage area.

6-4.2

Sprinkler protection shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

Chapter 7 Referenced Publications

7-1

The following documents or portions thereof are referenced within this code and shall be considered part of the requirements of this document. The edition indicated for each reference is the current edition as of the date of the NFPA issuance of this document.

Appendix A Explanatory Material

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.1.2 NFPA 49, *Hazardous Chemicals Data*, and NFPA 491M, *Manual of Hazardous Chemical Reactions*, should be used for guidance.

A-1-2

The decomposition of stored commercially available strengths of liquid and solid oxidizers can emit toxic gases. Additionally, the runoff from spills of stored oxidizers or from oxidizers mixed with fire extinguishing agents can contain materials hazardous to the environment.

A-1-5 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization concerned with product evaluations that is in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-5 Authority Having Jurisdiction.

The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-5 Explosive Reaction.

For further information on venting explosive reactions, see NFPA 68, *Guide for Venting of Deflagrations*.

A-1-5 Listed.

The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-1-5 Noncombustible Material.

See NFPA 220, *Standard on Types of Building Construction*.

A-1-6.3

The term contamination in this definition means minor contamination that can occur if the material is spilled or placed into improperly cleaned equipment. It does not mean gross contamination with large quantities of combustibles or incompatible materials.

A-1-6.4

The term contamination in this definition means minor contamination that can occur if the material is spilled or placed into improperly cleaned equipment. It does not mean gross contamination with large quantities of combustibles or incompatible materials.

A-1-7.1

Sills, curbs, or intervening storage of nonhazardous compatible materials and aisles should be used as aids in maintaining separation.

A-2-2.1

The classification system described in Section 1-7 should be used only to determine the storage requirements established by this code. It is not meant to be a substitute for the hazard identification system established by NFPA 704, *Standard System for the Identification of the Fire Hazards of Materials*. Since the hazard characteristics of oxidizers vary widely depending on the type of oxidizer and its relative concentration, each oxidizer should be rated individually according to the criteria established in NFPA 704.

NFPA 704 is designed to apprise fire fighters or emergency personnel of the inherent hazards related to the manufacture, storage, or use of hazardous materials. It is concerned with the health, fire, reactivity, and other related hazards created by short-term exposure that might be encountered under fire or related emergency conditions.

A-2-4.1.1 Automatic sprinklers should not be relied upon to control all fires involving oxidizers packed in plastic containers.

A-2-4.2

Care should be exercised, since some oxidizers are mutually incompatible. Triazinetriones (chlorinated isocyanurates) and hypochlorites are examples of oxidizers that are incompatible. NFPA 491M, *Manual of Hazardous Chemical Reactions*, lists many oxidizers and other materials that result in hazardous interactions.

A-2-4.4.2 Recommended retail store arrangements for mutually incompatible oxidizers are shown in Figures A-2-4.4.2(a) and (b). These two diagrams illustrate arrangements that minimize the chance of contamination between incompatible materials. Wherever possible, vertical separation should be maintained between incompatible materials.

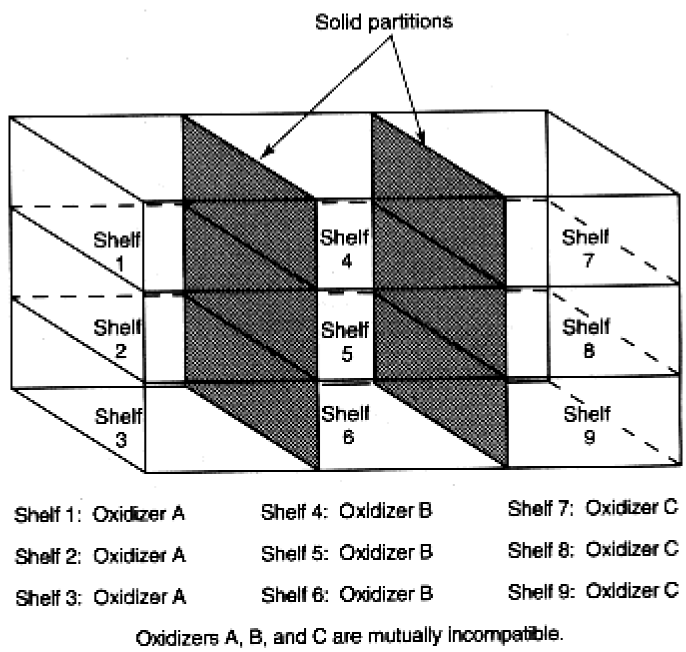

Figure A-2-4.4.2(a) Recommended retail store arrangement for mutually incompatible oxidizers.

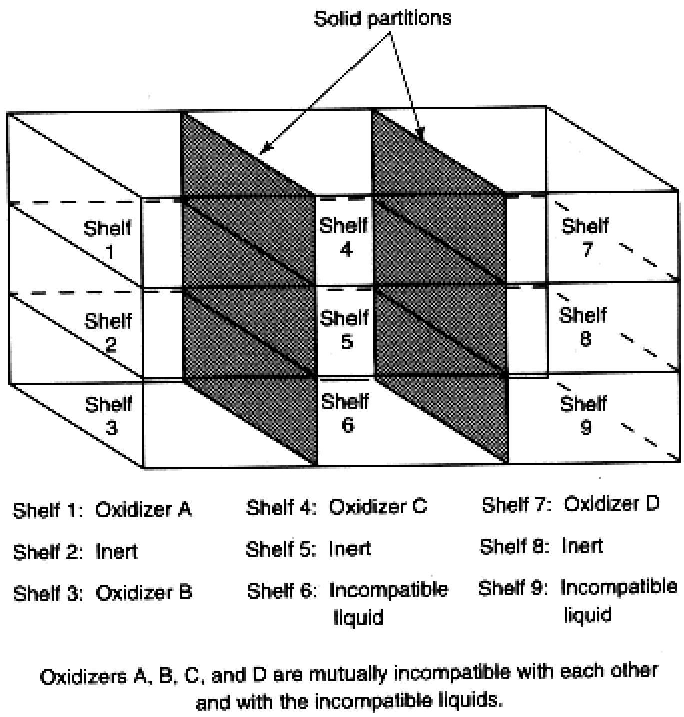

Figure A-2-4.4.2(b) Recommended retail store arrangement for mutually incompatible oxidizers and other incompatible materials.

A-2-5

Example: A sprinklered warehouse containing both Class 2 and Class 3 oxidizers in combustible containers that are cut off from other storage by a 2-hr fire separation is permitted to contain 500 tons (454,000 kg) of Class 2 oxidizers and 250 tons (227,000 kg) of Class 3 oxidizers in accordance with the following ratios:

$$\frac{500 \text{ tons}}{1000 \text{ tons (max)}} \times 100 = 50\% \text{ Class 2}$$

$$\frac{250 \text{ tons}}{500 \text{ tons (max)}} \times 100 = 50\% \text{ Class 3}$$

SI units: 1 lb = 0.454 kg

In no case should a quantity in storage exceed the maximum for its class, nor should the sum of the percentages exceed 100 percent.

A-2-11.6.1 A dry chemical fire extinguishing agent containing ammonium compounds (such as some A:B:C agents) should not be used on oxidizers that contain chlorine. The reaction between the oxidizer and the ammonium salts in the fire extinguishing agent can produce an explosive compound (NCl_3). Carbon dioxide or other extinguishing agents that function by a smothering action for effective use are of no value in extinguishing fires involving oxidizers.

A-2-11.6.2 Halon extinguishers should not be used on fires involving oxidizers, since they can react with the oxidizer.

A-3-3.2

Commodity refers to the definition in NFPA 231, *Standard for General Storage*, or NFPA 231C, *Standard for Rack Storage of Materials*, as appropriate.

A-4-4.1

For the purposes of Table 4-4.1, the fire hazard potential of Class 2 oxidizers has been considered as approximately equal to Group A plastic (non-expanded), stable cartoned, in accordance with NFPA 231, *Standard for General Storage*, and comparable sections of NFPA 231C, *Standard for Rack Storage of Materials.*

A-5-4.1

For the purposes of Table 5-4.1, the sprinkler density has been derived from fire loss history.

A-6-3.4

For example, two tanks contain 4000 lb (1814 kg) and 3000 lb (1360 kg) of Class 4 oxidizer and they are separated by 25 ft (7.6 m). Since they are separated by less than 10 percent of 300 ft (92 m), the total quantity of 7000 lb (3175 kg) requires a minimum separation of 400 ft (122 m) to the nearest important structure in accordance with 6-3.3.

Appendix B Typical Oxidizers
(Unless concentration is specified, undiluted material is referenced.)

This Appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

B-1 Typical Class 1 Oxidizers.

All inorganic nitrates (unless otherwise classified)

All inorganic nitrites (unless otherwise classified)

Ammonium persulfate

Barium peroxide

Calcium peroxide

Hydrogen peroxide solutions (greater than 8 percent up to 27.5 percent)

Lead dioxide

Lithium hypochlorite (39 percent or less available chlorine)

Lithium peroxide

Magnesium peroxide

Manganese dioxide

Nitric acid (40 percent concentration or less)

Perchloric acid solutions (less than 50 percent by weight)
Potassium dichromate
Potassium percarbonate
Potassium persulfate
Sodium carbonate peroxide
Sodium dichloro-s-triazinetrione dihydrate
Sodium dichromate
Sodium perborate (anhydrous)
Sodium perborate monohydrate
Sodium perborate tetrahydrate
Sodium percarbonate
Sodium persulfate
Strontium peroxide
Trichloro-s-triazinetrione (trichloroisocyanuric acid) (all forms)
Zinc peroxide

B-2 Typical Class 2 Oxidizers.

Barium bromate
Barium chlorate
Barium hypochlorite
Barium perchlorate
Barium permanganate
1-Bromo-3-chloro-5,5-dimethylhydantoin (BCDMH)
Calcium chlorate
Calcium chlorite
Calcium hypochlorite (50 percent or less by weight)
Calcium perchlorate
Calcium permanganate
Chromium trioxide (chromic acid)
Copper chlorate
Halane (1,3-dichloro-5,5-dimethylhydantoin)
Hydrogen peroxide (greater than 27.5 percent up to 52 percent)
Lead perchlorate
Lithium chlorate
Lithium hypochlorite (more than 39 percent available chlorine)
Lithium perchlorate
Magnesium bromate

Magnesium chlorate
Magnesium perchlorate
Mercurous chlorate
Nitric acid (more than 40 percent but less than 86 percent)
Nitrogen tetroxide
Perchloric acid solutions (more than 50 percent but less than 60 percent)
Potassium perchlorate
Potassium permanganate
Potassium peroxide
Potassium superoxide
Silver peroxide
Sodium chlorite (40 percent or less by weight)
Sodium perchlorate
Sodium perchlorate monohydrate
Sodium permanganate
Sodium peroxide
Strontium chlorate
Strontium perchlorate
Thallium chlorate
Urea hydrogen peroxide
Zinc bromate
Zinc chlorate
Zinc permanganate

B-3 Typical Class 3 Oxidizers.

Ammonium dichromate
Calcium hypochlorite (over 50 percent by weight)
Chloric acid (10 percent maximum concentration)
Hydrogen peroxide solutions (greater than 52 percent up to 91 percent)
Mono-(trichloro)-tetra-(monopotassium dichloro)-penta-s-triazinetrione
Nitric acid, fuming (more than 86 percent concentration)
Perchloric acid solutions (60 percent to 72 percent by weight)
Potassium bromate
Potassium chlorate
Potassium dichloro-s-triazinetrione (potassium dichloroisocyanurate)
Sodium bromate
Sodium chlorate

Sodium chlorite (over 40 percent by weight)

Sodium dichloro-s-triazinetrione (sodium dichloroisocyanurate)

B-4 Typical Class 4 Oxidizers.

Ammonium perchlorate (particle size greater than 15 microns)

Ammonium permanganate

Guanidine nitrate

Hydrogen peroxide solutions (greater than 91 percent)

Tetranitromethane

NOTE: Ammonium perchlorate less than 15 microns is classified as an explosive and, as such, is not covered by this code. (*See NFPA 495, Explosive Materials Code.*)

Appendix C Referenced Publications

Recommended Practice for Responding to Hazardous Materials Incidents

1997 Edition

This edition of NFPA 471, *Recommended Practice for Responding to Hazardous Materials Incidents*, was prepared by the Technical Committee on Hazardous Materials Response Personnel and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 18-20, 1996, in Nashville, TN. It was issued by the Standards Council on January 17, 1997, with an effective date of February 7, 1997, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 471 was approved as an American National Standard on February 7, 1997.

Origin and Development of NFPA 471

At the July 1985 NFPA Standards Council meeting, approval was given to the concept of a new project on Hazardous Materials Response Personnel. The Council directed that a proposed scope and start-up roster for the new Committee be prepared, taking into account the need to expand the Committee membership beyond the fire service and the application beyond “professional qualifications.”

When establishment of the Committee was formally announced, many requests for membership were received, and similar requests continued to arrive during the first year of its existence. The first meeting of the Committee took place in October 1986. Since that opening session, five additional meetings were held to complete work on this document.

Interest in the subject of hazardous materials, especially as it relates to the emergency responder, continues at a high level. Some of this interest is due to an increased awareness of the magnitude of the problem; much of it can be credited to federal regulations that will have an impact on all responders.

In 1993 the Committee began reviewing this document for the purpose of revising it. The Committee has made several changes to this 1997 edition in order to ensure that the document remains consistent with NFPA 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents*.

The gratitude of the Committee is extended to all who participated in the development process, and especially to the non-Committee members who helped so much.

Technical Committee on Hazardous Materials Response Personnel

Peter A. McMahon, *Chair*
Principal Financial Group, NY [U]
Rep. Grand Island Fire Dept.

Gerald L. Grey, *Vice Chair*
San Francisco Fire Dept., CA [U]
Rep. The Alliance for Fire & Emergency Mgmt.

Charles J. Wright, *Secretary*
Union Pacific Railroad Co., NE [SE]

Donald Beckering, Hennepin Technical College, MN [U]

Glenn P. Benarick, Fairfax County Fire & Rescue, VA [E]

Bud Berry, 3M, MN [M]
Rep. American Society of Safety Engr

Gene P. Carlson, Oklahoma State University, OK [U]
Rep. Int'l Fire Service Training Assn.

Committee Scope: This Committee shall have primary responsibility for documents on the requirements for the professional competence, training, procedures, and equipment for emergency responders to hazardous materials incidents.

NFPA 471

Recommended Practice for

Responding to Hazardous Materials Incidents

1997 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Appendix A.
Information on referenced publications can be found in Chapter 9 and Appendix B.

Chapter 1 Administration

1-1* Scope.

This recommended practice applies to all organizations that have responsibilities when responding to hazardous materials incidents and recommends standard operating guidelines for responding to such incidents. Planning procedures, policies, and application of procedures for incident levels, personal protective equipment, decontamination, safety, and communications are specifically covered in this recommended practice.

1-2 Purpose.

The purpose of this document is to outline the minimum requirements that should be considered when dealing with responses to hazardous materials incidents and to specify operating guidelines for responding to hazardous materials incidents. It is not the intent of this recommended practice to restrict any jurisdiction from using more stringent guidelines.

1-3 Application.

The recommendations contained in this document should be followed by organizations that respond to hazardous materials incidents and by incident commanders responsible for managing hazardous materials incidents.

1-4 Definitions.

Absorption. The process in which materials hold liquids through the process of wetting. Absorption is accompanied by an increase in the volume of the sorbate/sorbent system through the process of swelling. Some of the materials typically used as absorbents are sawdust, clays, charcoal, and polyolefin-type fibers. These materials can be used for confinement, but it should be noted that the sorbed liquid can be desorbed under mechanical or thermal stress. When absorbents become contaminated, they retain the properties of the absorbed liquid and are, therefore, considered to be hazardous materials and must be treated and disposed of accordingly. *(See* ASTM F 716*, Method of Testing Sorbent Performance of Absorbents, for further information*.*)*

Adsorption. The process in which a sorbate (hazardous liquid) interacts with a solid sorbent surface. See ASTM F 726, *Method of Testing Sorbent Performance of Adsorbents*, for further information. The principal characteristics are the following:

(a) The sorbent surface is rigid and no volume increase occurs as is the case with absorbents.

(b) The adsorption process is accompanied by heat of adsorption whereas absorption is not.

(c) Adsorption occurs only with activated surfaces, e.g., activated carbon, alumina, etc.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

Confinement. Those procedures taken to keep a material, once released, in a defined or local area.

Containment. The actions taken to keep a material in its container (e.g., stop a release of the material or reduce the amount being released).

Contaminant. A hazardous material that physically remains on or in people, animals, the environment, or equipment, thereby creating a continuing risk of direct injury or a risk of exposure.

Contamination. The process of transferring a hazardous material from its source to people, animals, the environment, or equipment, which may act as a carrier.

Control. The defensive or offensive procedures, techniques, and methods used in the mitigation of a hazardous materials incident, including containment, extinguishment, and confinement.

Control Zones. The areas at a hazardous materials incident that are designated based upon safety and the degree of hazard. Many terms are used to describe the zones involved in a hazardous materials incident. For purposes of this document, these zones are defined as the hot, warm, and cold zones.

Decontamination (Contamination Reduction). The physical and/or chemical process of reducing and preventing the spread of contamination from persons and equipment used at a hazardous materials incident.

Decontamination Corridor. The area, usually located within the warm zone, where decontamination procedures take place. This area is also referred to as the "decontamination area" in other documents.

Degradation.

(a) A chemical action involving the molecular breakdown of a protective clothing material or equipment due to contact with a chemical.

(b) The molecular breakdown of the spilled or released material to render it less hazardous during control operations.

Disinfection. The process used to destroy recognized pathogenic microorganisms. Proper disinfection results in a reduction in the number of viable organisms to some acceptable level. It may not totally destroy 100 percent of the microorganisms.

Emergency. A sudden and unexpected event calling for immediate action.

Emergency Decontamination. The physical process of immediately reducing contamination of individuals in potentially life-threatening situations without the formal establishment of a contamination corridor.

Environmental Hazard. A condition capable of posing an unreasonable risk to air, water, or soil quality and to plants or wildlife.

Exposure. The process by which people, animals, the environment, and equipment are subjected to or come in contact with a hazardous material. The magnitude of exposure is dependent primarily upon the duration of exposure and the concentration of the hazardous material. This term is also used to describe a person, animal, the environment, or a piece of equipment.

Gross Decontamination. The initial phase of the decontamination process during which the amount of surface contaminant is significantly reduced. This phase can include mechanical removing and initial rinsing.

Hazard/Hazardous. Capable of posing an unreasonable risk to health, safety, or the environment; capable of causing harm.

Hazard Sector. That function within an overall incident management system that deals with the mitigation of a hazardous materials incident. It is directed by a sector officer and deals principally with the technical aspects of the incident.

Hazard Sector Officer. The person responsible for the management of the hazard sector.

Hazardous Material.* A substance (gas, liquid, or solid) capable of creating harm to people, the environment, and property. *(See specific regulatory definitions in Appendix A.)*

Incident. An emergency involving the release or potential release of a hazardous material, with or without fire.

Incident Commander. The person responsible for all decisions relating to the management of the incident. The incident commander is in charge of the incident site. This term is equivalent to the on-scene incident commander.

Incident Management System. An organized system of roles, responsibilities, and standard operating procedures used to manage and direct emergency operations. Such systems are sometimes referred to as incident command systems (ICS).

Mitigation. Actions taken to prevent or reduce product loss, human injury or death, environmental damage, and property damage due to the release or potential release of hazardous materials.

Monitoring Equipment. Instruments and devices used to identify and quantify contaminants.

National Contingency Plan.* Policies and procedures of the federal agency members of the National Oil and Hazardous Materials Response Team. This document provides guidance for responses, remedial action, enforcement, and funding mechanisms for hazardous materials incident responses.

Neutralization. The process of applying acids or bases to a corrosive product to form a neutral salt.

Penetration. The movement of a material through a suit's closures, such as zippers, buttonholes, seams, flaps, or other design features of chemical-protective clothing, and through punctures, cuts, and tears.

Permeation. A chemical action involving the movement of chemicals, on a molecular level, through intact material.

Protective Clothing. Equipment designed to protect the wearer's skin or eyes from heat and hazardous materials. Protective clothing is divided into the following three types:

(a) Chemical-protective clothing:

1. Liquid splash-protective clothing
2. Vapor-protective clothing

(b) High temperature-protective clothing

(c) Structural fire-fighting protective clothing

Response. That portion of incident management in which personnel are involved in controlling (defensively or offensively) a hazardous materials incident. The activities in the response portion of a hazardous materials incident include analyzing the incident, planning the response, implementing the planned response, and evaluating progress.

Sampling. The process of collecting a representative amount of gas, liquid, or solid for analytical purposes.

Secondary Contamination. The process by which a contaminant is carried out of the hot zone and subsequently contaminates people, animals, the environment, or equipment.

Should. Indicates a recommendation or that which is advised but not required.

Solidification. The process whereby a hazardous liquid is treated chemically so that solid material results.

Stabilization. The point in an incident at which the adverse behavior of the hazardous material is controlled.

Sterilization. The process of destroying all microorganisms in or on an object.

Waste Minimization. Treatment of hazardous spills by procedures or chemicals designed to reduce the hazardous nature of the material and to minimize the quantity of waste produced.

Chapter 2 Incident Response Planning

2-1 Developing an Incident Response Plan.

2-1.1

Planning is an essential part of emergency preparedness. The development of both facility response plans and community emergency plans is required by numerous state and federal laws, including Superfund Amendments and Reauthorization Act (SARA), Title III, "The Emergency Planning and Community Right to Know Act of 1986." Planning guides and reference materials are listed in Appendix C.

2-1.2

A planning team is necessary for developing the hazardous materials emergency plan. Local, state, and federal planning guidelines should be reviewed and consulted by the planning team when preparing plans for hazardous materials incidents.

2-2 Review and Training.

2-2.1

As a minimum, an annual review and update of the hazardous materials emergency plan should be conducted.

2-2.2

As a minimum, a training exercise should be conducted annually to determine the adequacy and effectiveness of the hazardous materials emergency plan.

Chapter 3 Response Levels

3-1* Planning Guide.

Table 3-1 is a planning guide intended to provide the user with assistance in determining incident levels for response and training. Potential applications to a jurisdiction's response activities can include development of standard operating procedures; implementation of a training program using the competency levels of NFPA 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents;* acquisition of necessary equipment; and development of community emergency response plans. When consulting this table, the user should refer to all of the incident condition criteria to determine the appropriate incident level.

Table 3-1 Planning Guide for Determining Incident Levels, Response, and Training

	Incident Level		
Incident Conditions	**One**	**Two**	**Three**
Product identifications	Placard not required, NFPA 0 or 1 all categories, all Class 9 and ORM-D	DOT placarded, NFPA 2 for any categories, PCBs without fire, EPA regulated waste	Class 2, Division 2.3 poisonous gases, Class 1, Division 1.1 and 1.2 explosives, organic peroxide, flammable solid, materials dangerous when wet, chlorine, fluorine, anhydrous ammonia, radioactive materials, NFPA 3 & 4 for any categories including special hazards, PCBs & fire, DOT inhalation hazard, EPA extremely hazardous substances, and cryogenics
Container size	Small (e.g., pail, drums, cylinders except1-ton, packages, bags)	Medium (e.g., 1-ton cylinder, portable containers, nurse tanks, multiple small packages)	Large (e.g., tank cars, tank trucks, stationary tanks, hopper cars/trucks, multiple medium containers)
Fire/explosion potential	Low	Medium	High
Leak severity	No release or small release contained or confined with readily available resources	Release may not be controllable without special resources	Release may not be controllable even with special resources
Life safety	No life-threatening situation from materials involved	Localized area, limited evacuation area	Large area, mass evacuation area
Environmental impact (potential)	Minimal	Moderate	Severe
Container integrity	Not damaged	Damaged but able to contain the contents to allow handling or transfer of product	Damaged to such an extent that catastrophic rupture is possible

Chapter 4 Site Safety

4-1 Emergency Incident Operations.

4-1.1

Emergency incident operations should be conducted in compliance with Chapter 6 of NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*, or Title 29, *Code of Federal Regulations*, Part 1910.120 or EPA.

4-1.2*

An incident management system should be implemented at all hazardous materials incidents. Operations should be directed by a designated incident commander and follow established written standard operating procedures.

4-1.2.1 Personnel Accountability. The incident management system should include a standard personnel identification system to maintain accountability for each member engaged in activities at an incident scene. This personnel identification system should have the ability to provide a rapid accounting of all members on the incident scene.

4-1.2.1.1 The personnel identification system should include a means to specifically identify and keep track of members entering and leaving the hot zone and any area where special protective equipment is required.

4-1.2.1.2 The incident management system should include a standard operating procedure to evacuate personnel from an area where an imminent hazard condition is found to exist and account for the safety of personnel. This system should include a method to immediately notify all personnel in the affected area of an imminent hazard condition by means of audible warning devices.

4-1.2.2 Rest and Rehabilitation. The incident commander should consider the circumstances of each incident and make suitable provisions for rest and rehabilitation for members operating at the scene. These considerations should include medical evaluation and treatment, food and fluid replenishment, and relief from extreme climatic conditions, according to the circumstances of the incident.

All incident commanders should maintain an awareness of the condition of members operating within their span of control and ensure that adequate steps are taken to provide for their safety and health. The command structure should be utilized to request relief and reassignment of fatigued members.

4-1.3

An emergency response plan describing the general safety procedures that are to be followed at an incident should be prepared in accordance with Title 29, *Code of Federal Regulations,* Part 1910.120. These procedures should be thoroughly reviewed and tested.

4-2 Ignition Sources.

Ignition sources should be eliminated whenever possible at incidents involving releases, or probable releases, of ignitable materials. Whenever possible, electrical devices used within the hot zone should be certified as intrinsically safe by recognized organizations.

4-3 Control Zones.

Control zone names have not been consistently applied at incidents. The intent of this section is to show areas of responder control. The various zones or areas at a typical emergency response site are shown in Figure 4-3.

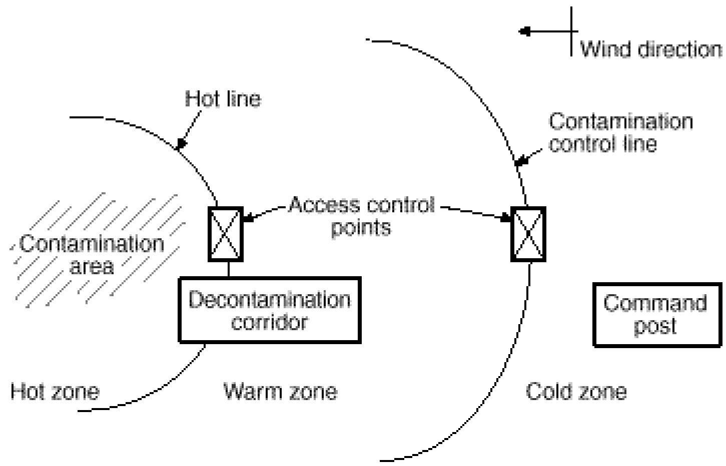

Figure 4-3 Diagram of control zones.

4-3.1* Hot Zone.

The hot zone is the area immediately surrounding a hazardous materials incident, extending far enough to prevent adverse effects from hazardous materials releases to personnel outside the zone. This zone is also referred to as the exclusion zone or restricted zone in other documents.

4-3.2 Warm Zone.

The warm zone is the area where personnel and equipment decontamination and hot zone support take place. It includes control points for the access corridor and thus assists in reducing the spread of contamination. This zone is also referred to as the decontamination, contamination reduction, or limited access zone in other documents.

4-3.3 Cold Zone.

The cold zone contains the command post and such other support functions as are deemed necessary to control the incident. This zone is also referred to as the clean zone or support zone in other documents.

4-4 Communications.

4-4.1

When personal protective clothing or remote operations inhibit communications, an effective means of communication, such as radios, should be established.

4-4.2

The frequencies employed in these radios should be “dedicated” and not used or shared with other local agencies.

4-4.3

Communication should be supplemented by a prearranged set of hand signals and hand-light signals to be used when primary communication methods fail. Hand-lights employed for this purpose should be in accordance with NFPA 70, *National Electrical Code*®, for use in hazardous environments.

4-5 Monitoring Equipment.

4-5.1

Monitoring equipment operates on several different principles and measures different aspects of hazardous materials releases. Examples of this equipment include the following:

(a) Oxygen meters

(b) Combustible gas indicator (explosimeter)

(c) Carbon monoxide meter

(d) pH meter

(e) Radiation detection instruments

(f) Colorimetric detector tubes

(g) Organic vapor analyzer

(h) Photoionization meter

(i) Air sampling devices

(j) Other meters to measure specific products such as chlorine, hydrogen sulfide, or ethylene oxide

(k) pH paper or strips

(l) Organic vapor badge or film strip

(m) Mercury badge

(n) Formaldehyde badge or strip

4-5.2

All monitoring equipment should be operationally checked prior to use and periodically calibrated in accordance with manufacturers' specifications.

Chapter 5 Personal Protective Equipment

5-1 General.

It is essential that personal protective equipment meeting appropriate NFPA and OSHA standards be provided, maintained, and used. Protection against physical, chemical, and thermal hazards should be considered when selecting personal protective equipment.

5-1.1

A written personal protective equipment program should be established in accordance with Title 29, *Code of Federal Regulations*, Part 1910.120. Elements of the program should include personal protective equipment selection and use; storage, maintenance, and inspection procedures; and training considerations. The selection of personal protective clothing should be based on the hazardous materials and conditions present and should be appropriate for the hazards encountered.

5-1.2

Protective clothing and equipment used to perform fire suppression operations, beyond the incipient stage, should meet the requirements of Chapter 5 of NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program*. Structural fire-fighting protective clothing is not intended to provide chemical protection to the user.

5-2 Respiratory Protective Equipment.

5-2.1

Self-contained breathing apparatus (SCBA) should meet the requirements of NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters*.

5-2.2

Personal alert safety systems should meet the requirements of NFPA 1982, *Standard on Personal Alert Safety Systems (PASS) for Fire Fighters*.

5-2.3 Air Purifying Respirators.

These devices are worn to filter particulates and contaminants from the air. They should be worn only in atmospheres where the type and quantity of the contaminants are known and sufficient oxygen is known to be present.

5-3 Chemical-Protective Clothing.

5-3.1

Chemical-protective clothing (CPC) is made from special materials and is designed to prevent the contact of chemicals with the body. Chemical-protective clothing is of two types: totally encapsulating and nonencapsulating.

5-3.2

A variety of materials are used to make the fabric from which chemical-protective clothing is manufactured. Each material provides protection against certain specified chemicals or mixtures of chemicals but might afford little or no protection against certain other chemicals. It is most important to note that there is no material that provides satisfactory protection from all chemicals. Protective clothing material needs to be compatible with the chemical substances involved, consistent with manufacturers' instructions.

5-3.3*

Performance requirements need to be considered in selecting the appropriate chemical-protective material. These requirements would include chemical resistance, permeation, penetration, flexibility, abrasion, temperature resistance, shelf life, and sizing criteria.

5-4 Thermal Protection.

5-4.1 Proximity Suits.

These suits provide short duration and close proximity protection at radiant heat temperatures as high as 2,000ºF (1093ºC) and can withstand some exposure to water and steam. Respiratory protection needs to be provided with proximity suits.

5-4.2 Fire Entry Suits.

These suits provide protection for brief entry into a total flame environment at temperatures as high as 2,000ºF (1093ºC). They are not effective or meant to be used for rescue operations.

Respiratory protection needs to be provided with fire entry suits.

5-4.3 Overprotection Garments.

These garments are worn in conjunction with chemical-protective encapsulating suits.

5-4.3.1 Flash Cover Protective Suits. Flash cover suits are neither proximity nor fire entry suits. They provide limited overprotection against flashback only. They are worn outside of other protective suits and are used only when the risks require them.

5-4.3.2 Low Temperature Suits. Low temperature suits provide some degree of protection of the encapsulating chemical-protective clothing from contact with low temperature gases and liquids. They are worn outside of the encapsulating chemical-protective clothing and are used only when the risks require them.

5-5 Levels of Protection.

Personal protective equipment is divided into four categories based on the degree of protection afforded.

5-5.1 Level A.

A Level A equipment is to be selected when the greatest level of skin, respiratory, and eye protection is required. The following constitute Level A equipment and should be used as appropriate:

(a) Pressure-demand, full facepiece, self-contained breathing apparatus (SCBA), or pressure-demand air line respirator with escape SCBA, approved by the National Institute of Occupational Safety and Health (NIOSH)

(b) Vapor-protective suits: totally encapsulating chemical-protective suits (TECP suits) constructed of protective clothing materials that meet the following criteria:

1. Cover the wearer's torso, head, arms, and legs

2. Include boots and gloves that may either be an integral part of the suit or separate and tightly attached

3. Completely enclose the wearer by itself or in combination with the wearer's respiratory equipment, gloves, and boots

(All components of a TECP suit, such as relief valves, seams, and closure assemblies, should provide equivalent chemical resistance protection. Vapor-protective suits should meet the requirements in NFPA 1991, *Standard on Vapor-Protective Suits for Hazardous Chemical Emergencies*.)

(c) Coveralls (optional)

(d) Long underwear (optional)

(e) Gloves, outer, chemical-resistant

(f) Gloves, inner, chemical-resistant

(g) Boots, chemical-resistant, steel toe and shank

(h) Hard hat (under suit) (optional)

(i) Disposable protective suit, gloves, and boots (depending on suit construction, can be worn over totally encapsulating suit)

(j) Two-way radios (worn inside encapsulating suit)

5-5.2 Level B.

Level B personal protective equipment should be used when the highest level of respiratory protection is necessary but a lesser level of skin protection is needed. The following constitute Level B equipment and should be used as appropriate:

(a) Pressure-demand, full facepiece, self-contained breathing apparatus (SCBA), or pressure-demand air line respirator with escape SCBA, NIOSH approved

(b) Hooded chemical-resistant clothing that meets the requirements of NFPA 1992, *Standard on Liquid Splash-Protective Suits for Hazardous Chemical Emergencies* (overalls and long-sleeved jacket, coveralls, one- or two-piece chemical-splash suit, disposable chemical-resistant overalls)

(c) Coveralls (optional)

(d) Gloves, outer, chemical-resistant

(e) Gloves, inner, chemical-resistant

(f) Boots, outer, chemical-resistant, steel toe and shank

(g) Boot covers, outer, chemical-resistant (disposable) (optional)

(h) Hard hat

(i) Two-way radios (worn inside encapsulating suit)

(j) Face shield (optional)

5-5.3* Level C.

Level C personal protective equipment should be used when the concentration(s) and type(s) of airborne substance(s) is known and the criteria for using air purifying respirators are met. The following constitute Level C equipment and should be used as appropriate:

(a) Full-face or half-mask, air purifying respirators, self-contained positive pressure breathing apparatus, NIOSH approved

(b) Hooded chemical-resistant clothing that meets the requirements of NFPA 1993, *Standard on Support Function Protective Garments for Hazardous Chemical Operations* (overalls, two-piece chemical-splash suit, disposable chemical-resistant overalls)

(c) Coveralls (optional)

(d) Gloves, outer, chemical-resistant

(e) Gloves, inner, chemical-resistant

(f) Boots, outer, chemical-resistant, steel toe and shank

(g) Boot covers, outer, chemical-resistant (disposable) (optional)

(h) Hard hat

(i) Escape mask (optional)

(j) Two-way radios (worn under outside protective clothing)

(k) Face shield (optional)

5-5.4 Level D.

A work uniform affording minimal protection, Level D personal protective equipment should be used for nuisance contamination only. The following constitute Level D equipment and should be used as appropriate:

(a) Coveralls

(b) Gloves (optional)

(c) Boots/shoes, chemical-resistant, steel toe and shank

(d) Boots, outer, chemical-resistant (disposable) (optional)

(e) Safety glasses or chemical-splash goggles

(f) Hard hat

(g) Escape mask (optional)

(h) Face shield (optional)

5-6 Types of Hazards.

The types of hazards for which Levels A, B, C, and D protection are appropriate are described in this section.

5-6.1

Level A protection should be used under any of the following conditions:

(a) When the hazardous material has been identified and requires the highest level of protection for skin, eyes, and the respiratory system based on either the measured (or potential for) high concentration of atmospheric vapors, gases, or particulates; or the site operations and work functions involve a high potential for splash, immersion, or exposure to unexpected vapors, gases, or particulates of material that are harmful to skin or capable of being absorbed through the intact skin

(b) When substances with a high degree of hazard to the skin are known or suspected to be present, and skin contact is possible

(c) When operations need to be conducted in confined, poorly ventilated areas, and the absence of conditions requiring Level A has not yet been determined

5-6.2

Level B protection should be used under any of the following conditions:

(a)* When the type and atmospheric concentration of substances have been identified and require a high level of respiratory protection, but less skin protection

(b) When the atmosphere contains less than 19.5 percent oxygen

(c) When the presence of incompletely identified vapors or gases is indicated by a direct-reading organic vapor detection instrument, but the vapors and gases are known not to contain high levels of chemicals harmful to skin or capable of being absorbed through the intact skin

(d) When the presence of liquids or particulates is indicated, but they are known not to contain high levels of chemicals harmful to skin or capable of being absorbed through the intact skin

5-6.3

Level C protection should be used under any of the following conditions:

(a) When the atmospheric contaminants, liquid splashes, or other direct contact will not adversely affect or be absorbed through any exposed skin

(b) When the types of air contaminants have been identified, concentrations have been measured, and an air purifying respirator is available that can remove the contaminants

(c) When all criteria for the use of air purifying respirators are met

(d)* Atmospheric concentration of chemicals must not exceed IDLH levels. The atmosphere must contain at least 19.5 percent oxygen.

5-6.4

Level D protection should be used when both of the following conditions exist:

(a) The atmosphere contains no known hazard

(b)* Work functions preclude splashes, immersion, or the potential for unexpected inhalation of or contact with hazardous levels of any chemicals

Chapter 6 Incident Mitigation

6-1 Control.

This chapter addresses those actions necessary to ensure confinement and containment (the first line of defense) in a manner that will minimize risk to both life and the environment in the early, critical stages of a spill or leak. Both natural and synthetic methods can be employed to limit the releases of hazardous materials so that effective recovery and treatment can be accomplished with minimum additional risk to the environment or to life.

6-2 Types of Hazardous Materials.

6-2.1 Chemical Materials.

Chemical materials are those materials that pose a hazard based upon their chemical and physical properties.

6-2.2 Biological Materials.

Biological materials are those organisms that have a pathogenic effect to life and the environment and can exist in normal ambient environments.

6-2.3 Radioactive Materials.

Radioactive materials are those materials that emit ionizing radiation.

6-3 Physical States of Hazardous Materials.

Hazardous materials can be classified into three states, namely gases, solids, and liquids. They can be stored or contained at a high or low pressure. All three states can be affected by the environment in which the incident occurs. The emergency responder needs to take into account such conditions as heat, cold, rain, or wind, which can have a significant effect on the methods used to accomplish a safe operation.

6-4 Methods of Mitigation.

There are two basic methods for mitigation of hazardous materials incidents: physical and chemical. Table 6-4.1 lists many physical methods and Table 6-4.2 lists many chemical methods that are acceptable for mitigation of hazardous materials incidents. Recommended practices should be implemented only by personnel appropriately prepared by training, education, or experience.

6-4.1* Physical Methods.

Physical methods of control involve any of several processes or procedures to reduce the area of the spill, leak, or other release mechanism. In all cases, methods used should be acceptable to the incident commander. The selection of personal protective clothing should be based on the hazardous materials and/or conditions present and should be appropriate for the hazards encountered. Refer to Table 6-4.1.

Table 6-4.1 Physical Methods of Mitigation of Hazardous Materials

	Chemical				Biological				Radiological			
	Gases				Gases				Gases			
Method	**LVP***	**HVP****	**Liq.**	**Sol.**	**LVP**	**HVP**	**Liq.**	**Sol.**	**LVP**	**HVP**	**Liq.**	**Sol.**
Absorption	yes	yes	yes	no	no	no	yes[4]	no	no	no	yes	no

Vapor suppression (blanketing)	no	no	yes	yes	no	no	yes	yes	no	no	no	no

Vacuuming	no	no	yes	yes	no	no	yes	yes	no	no	yes	yes
Venting[1]	yes	yes	yes	no	yes	no	no	no	yes[2]	no	no	no

NOTE: For substances involving more than one type, the most restrictive control measure should be used.
*Low Vapor Pressure
**High Vapor Pressure
1. Venting of low-vapor-pressure gases is recommended only when an understanding of the biological system is known. Venting is allowed when the bacteriological system is known to be nonpathogenic, or if methods can be employed to make the environment hostile to pathogenic bacteria.
2. Venting of low-vapor-pressure radiological gases is allowed when the gas(es) is/are known to be alpha or beta emitters with short half-lives. Further, this venting is only to be allowed after careful consultation with a certified health physicist.
3. Covering should be done only after consultation with appropriate experts.
4. Absorption of liquids containing bacteria is permitted where the absorption bacteria or environment is hostile to the bacteria.
5. Water dispersion on certain vapors and gases only.

6-4.1.1* Absorption. Absorption is the process in which materials hold liquids through the process of wetting. Absorption is accompanied by an increase in the volume of the sorbate/sorbent system through the process of swelling. Some of the materials typically used as absorbents are sawdust, clays, charcoal, and polyolefin-type fibers. These materials can be used for confinement, but it should be noted that the sorbed liquid can be desorbed under mechanical or thermal stress. When absorbents become contaminated, they retain the properties of the absorbed hazardous liquid and are, therefore, considered to be hazardous materials and must be treated and disposed of accordingly. *(See ASTM F716, Method of Testing Sorbent Performance of Absorbents, for further information.)*

6-4.1.2 Covering. Covering is a temporary form of mitigation for radioactive, biological, and some chemical substances such as magnesium. It should be done after consultation with a certified health physicist (in the case of radioactive materials) or other appropriate experts.

6-4.1.3 Dikes, Dams, Diversions, and Retention. These terms refer to the use of physical barriers to prevent or reduce the quantity of liquid flowing into the environment. Dikes or dams usually refer to concrete, earth, and other barriers temporarily or permanently constructed to hold back the spill or leak. Diversion refers to the methods used to physically change the direction of flow of the liquid. Vapors from certain materials, such as liquefied petroleum gas (LPG), can be dispersed by means of a water spray.

6-4.1.4 Dilution. Dilution is the application of water to water-miscible hazardous materials. The goal is to reduce the hazard to safe levels.

6-4.1.5 Overpacking. The most common form of overpacking is accomplished by the use of an oversized container. Overpack containers should be compatible with the hazards of the materials involved. If the material is to be shipped, DOT specification overpack containers need to be used. (The spilled materials still should be treated or properly disposed of.)

6-4.1.6 Plug and Patch. Plugging and patching is the use of compatible plugs and patches to reduce or temporarily stop the flow of materials from small holes, rips, tears, or gashes in containers. The repaired container should not be reused without proper inspection and certification.

6-4.1.7 Transfer. Transfer is the process of moving a liquid, gas, or some forms of solids, either manually, by pump, or by pressure, from a leaking or damaged container or tank. Care needs to be taken to ensure the pump, transfer hoses and fittings, and container selected are compatible with the hazardous material. When a product transfer presents fire or explosion hazard, proper concern for electrical continuity (such as bonding/grounding) needs to be observed.

6-4.1.8 Vacuuming. Many hazardous materials may be placed in containment simply by vacuuming them up. This has the advantage of not causing an increase in volume. Care needs to be taken to ensure compatibility of materials. The exhaust air can be filtered, scrubbed, or treated as needed. The method of vacuuming will depend on the nature of the hazardous material.

6-4.1.9 Vapor Dispersion. Vapors from certain materials can be dispersed or moved by means of a water spray. With other products, such as liquefied petroleum gas (LPG), the gas concentration may be reduced below the lower flammable limit through rapid mixing of the gas with air, using the turbulence created by a fine water spray. Reducing the concentration of the material through the use of water spray may bring the material into its flammable range.

6-4.1.10* Vapor Suppression (Blanketing). Vapor suppression is the reduction or elimination of vapors emanating from a spilled or released material through the most efficient method or application of specially designed agents. A recommended vapor suppression agent is an aqueous foam blanket.

6-4.1.11 Venting. Venting is a process that is used to deal with liquids or liquefied compressed gases where a danger, such as an explosion or mechanical rupture of the container or vessel, is considered likely. The method of venting will depend on the nature of the hazardous material. In general, it involves the controlled release of the material to reduce and contain the pressure and diminish the probability of an explosion.

6-4.2* Chemical Methods.

Chemical methods of control involve the application of chemicals to treat spills of hazardous materials. Chemical methods may involve any one of several actions to reduce the involved area affected by the release of a hazardous material. *(See Table 6-4.2.)* In all cases, methods used should be acceptable to the incident commander. The selection of personal protective clothing should be based on the hazardous materials and/or conditions present and should be appropriate for the hazards encountered.

Table 6-4.2 Chemical Methods of Mitigation of Hazardous Materials

	Chemical				Biological				Radiological			
	Gases				Gases				Gases			
Method	**LVP***	**HVP****	**Liq.**	**Sol.**	**LVP**	**HVP**	**Liq.**	**Sol.**	**LVP**	**HVP**	**Liq.**	**Sol**

Vapor suppression	yes	yes	yes	yes	yes	yes	yes	yes	yes	yes	yes	yes
Vent/Burn	yes	yes	yes	no	yes	yes	yes	no	no	no	no	no

*Low Vapor Pressure
**High Vapor Pressure
1. Technique may be possible as a liquid or solid neutralizing agent, and water can be applied.
2. When solid neutralizing agents are used, they must be used simultaneously with water.
3. Technique is permitted only if resulting material is hostile to the bacteria.
4. The use of this procedure requires special expertise and technique.

6-4.2.1* Adsorption. Adsorption is the process in which a sorbate (hazardous liquid) interacts with a solid sorbent surface. See ASTM F 726, *Method of Testing Sorbent Performance of Adsorbents*, for further information. The principal characteristics of this interaction are the following:

(a) The sorbent surface, unlike absorbents, is rigid and no volume increase occurs.

(b) The adsorption process is accompanied by heat of adsorption whereas absorption is not.

(c) Adsorption occurs only with activated surfaces, e.g., activated carbon, alumina, etc.

6-4.2.2 Controlled Burning. For purposes of this practice, controlled combustion is considered a chemical method of control. However, it should be used only by qualified personnel trained specifically in this procedure.

In some emergency situations where extinguishing a fire will result in large, uncontained volumes of contaminated water, or threaten the safety of responders or the public, controlled burning is used as a technique. It is recommended that consultation be made with the appropriate environmental authorities when this method is used.

6-4.2.3 Dispersants, Surface Active Agents, and Biological Additives. Certain chemical and biological agents can be used to disperse or break up the materials involved in liquid spills. The use of these agents results in a lack of containment and generally results in spreading the liquid over a much larger area. Dispersants are most often applied to spills of liquids on water. The dispersant breaks down a liquid spill into many fine droplets, thereby diluting the material to acceptable levels. Use of this method may require the prior approval of the appropriate environmental authority. See ASTM STP 659, *Chemical Dispersants for the Control of Oil Spills*, and ASTM STP 840, *Oil Spill Chemical Dispersants: Research, Experience, and Recommendations*, for further information.

6-4.2.4 Flaring. Flaring is a process that is used with high-vapor-pressure liquids or liquefied compressed gases for the safe disposal of the product. Flaring is the controlled burning of material in order to reduce or control pressure and/or dispose of a product.

6-4.2.5 Gelation. Gelation is the process of forming a gel. A gel is a colloidal system consisting of two phases, a solid and a liquid. The resulting gel is considered to be a hazardous material and needs to be disposed of properly.

6-4.2.6 Neutralization. Neutralization is the process of applying acids or bases to a spill to form a neutral salt. The application of solids for neutralizing can often result in confinement of the spilled material. Special formulations are available that do not result in violent reactions or local heat generation during the neutralization process. In cases where special neutralizing formulations are not available, special considerations should be given to protecting persons applying the neutralizing agent, as heat is generated and violent reactions can occur. One of the advantages of neutralization is that a hazardous material can be rendered nonhazardous.

6-4.2.7 Polymerization. Polymerization is a process in which a hazardous material is reacted in the presence of a catalyst, in the presence of heat or light, or with itself or another material to form a polymeric system.

6-4.2.8 Solidification. Solidification is the process whereby a hazardous liquid is treated chemically so that a solid material results. Adsorbents can be considered an example of a solidification process. There are other materials that can be used to convert hazardous liquids into nonhazardous solids. Examples are applications of special formulations designed to form a neutral salt in the case of spills of acids or caustics. The advantage of the solidification process is that a spill of small scale can be confined relatively quickly and treatment effected immediately.

6-4.2.9 Vapor Suppression. Vapor suppression is the use of solid activated materials to treat hazardous materials so as to effect suppression of the vapor off-gasing from the materials. This process results in the formation of a solid that affords easier handling but that may result in a hazardous solid that must be disposed of properly.

6-4.2.10 Venting and Burning. This process involves the use of shaped charges to vent the high vapor pressure at the top of the container and then the use of additional charges to release and burn the remaining liquid in the container in a controlled fashion.

Chapter 7 Decontamination

7-1 Decontamination Plan.

At every incident involving hazardous materials, there is a possibility that personnel, their equipment, and members of the general public will become contaminated. The contaminant poses a threat, not only to the persons contaminated, but to other personnel who may subsequently come into contact with the contaminated personnel and equipment. The entire process of decontamination should be directed toward confinement of the contaminant within the hot zone and the decontamination corridor to maintain the safety and health of response personnel, the general public, and the environment. Sound judgment should be exercised and the potential effects of the decontamination process upon personnel should be considered when developing the decontamination plan.

7-1.1

Although decontamination is typically performed following site entry, the determination of proper decontamination methods and procedures needs to be considered before the incident as part of the overall pre-incident planning and hazard and risk evaluation process. No entry into the hot zone should be permitted until appropriate decontamination methods are determined and established based on the hazards present, except in those situations where a rescue may be possible and emergency decontamination is available.

7-1.2

Emergency response personnel should be familiar with the definitions of the following terminology:

(a) Contaminant

(b) Contamination

(c) Decontamination (contamination reduction)

(d) Decontamination corridor

(e) Emergency decontamination

(f) Exposure

(g) Gross decontamination

(h) Secondary contamination

7-2 Decontamination.

Decontamination consists of reducing and preventing the spread of contamination from persons and equipment used at a hazardous materials incident by physical and/or chemical processes. Emergency response personnel should implement a thorough, technically sound decontamination procedure until it is determined or judged to be no longer necessary.

7-2.1

Emergency response personnel should have an established procedure to minimize contamination or contact, to limit migration of contaminants, and to properly dispose of contaminated materials. The primary objective of decontamination is to avoid becoming contaminated or contaminating other personnel or equipment outside of the hot zone. If contamination is suspected, decontamination of personnel, equipment, and apparatus should be performed.

7-2.2

Procedures for all phases of decontamination need to be developed and implemented to reduce the possibility of contamination to personnel and equipment. Initial procedures should be upgraded or downgraded as additional information is obtained concerning the type of hazardous materials involved, the degree of hazard, and the probability of exposure of response personnel. Reference guides for the development of decontamination procedures can be found in Appendix C. Assuming protective equipment is grossly contaminated, appropriate decontamination methods should be used for the chemicals encountered.

7-2.3

The decision to implement all or part of a decontamination procedure should be based upon a field analysis of the hazards and risks involved. This analysis generally consists of referring to technical reference sources to determine the general hazards, such as flammability and toxicity, and then evaluating the relative risks. Decontamination procedures should be implemented upon arrival at the scene, should provide an adequate number of decontamination stations and personnel, and should continue until the incident commander determines that decontamination procedures are no longer required.

7-2.4 Precautionary Decontamination.

There are occasions when an apparently normal alarm response turns into a hazardous materials incident. Frequently, most of the initial assignment crews will have already gone into the incident area and exposed themselves to the contamination threat.

It is essential that all members so involved remove themselves from the area at once, call for decontamination capability, and stay together in one location. They must not wander around, climb on and off apparatus, and mix with other personnel since there is a potential for them to be contaminated.

Fire fighters so exposed should be given gross decontamination as a precautionary measure. Knowledgeable hazardous materials personnel, such as the decontamination sector officer, in conjunction with the incident commander, should determine whether more definitive decontamination is necessary.

Remember, the primary objective of decontamination is to avoid contaminating anyone or anything beyond the hot zone. When in doubt about contamination, decontaminate all involved personnel, equipment, and apparatus.

7-3 Decontamination Methods.

7-3.1 Physical Methods.

Physical methods generally involve the physical removal of the contaminant from the contaminated person or object and containment of the contaminant for appropriate disposal. While these methods can reduce the contaminant's concentration, generally the containment remains chemically unchanged. Examples of physical decontamination methods include the following:

(a) Absorption

(b) Brushing and scraping

(c) Isolation and disposal

(d) Vacuuming

(e) Washing

7-3.2 Chemical Methods.

Chemical methods are used on equipment, not people, and generally involve decontamination by changing the contaminant through some type of chemical reaction in an effort to render the contaminant less harmful. In the case of etiologic contaminants, chemical methods are actually biologically "killing" the organism. Examples of chemical methods include the following:

(a) Adsorption

(b) Chemical degradation

(c) Disinfection or sterilization

(d) Neutralization

(e) Solidification

7-3.3 Prevention Methods.

If contact with a contaminant can be controlled, the risk of exposure is reduced and the need for decontamination can be minimized. The following points should be considered to prevent contamination:

(a) Stress work practices that minimize contact with hazardous substances.

(b) Wear limited-use or disposable protective clothing and equipment, where appropriate.

7-4 Decontaminating Personal Protective Equipment (PPE).

During doffing of personal protective equipment, the clothing should be removed in a manner such that the outside surfaces do not touch or make contact with the wearer. A log of personal protective equipment used during the incident should be maintained. Personnel wearing disposable personal protective equipment should proceed through the decontamination process setup in the decontamination area, and the disposable protective equipment should be containerized and identified for disposal in accordance with established procedures.

7-4.1

The physical and chemical compatibility of decontamination solutions needs to be determined before they are used. Any decontamination method that permeates, degrades, damages, or otherwise impairs the safe function of PPE should not be used unless there are plans to isolate and dispose of the PPE.

7-4.2

Water or other solutions for washing or rinsing may have to be confined, collected, containerized, and analyzed for proper treatment and disposal. Consult with environmental and public health agencies or other appropriate reference sources and guidelines to determine the need for confinement and the appropriate disposal methods for collected decontamination fluids and personal protective equipment.

7-4.3

Decontamination methods vary in their effectiveness for removing different substances. The effectiveness of any decontamination method should be assessed throughout the decontamination operation. If decontamination does not appear to be effective, a different method should be selected and implemented. Before initiating decontamination, the following questions should be considered:

(a) Can decontamination be conducted safely?

(b) Are existing resources adequate and immediately available to perform decontamination of personnel and equipment? If not, where can they be obtained, and how long will it take to get them?

7-4.4

Criteria that can be used for evaluating decontamination effectiveness during field operations include the following:

(a) Contamination levels are reduced as personnel move through the decontamination corridor.

(b) Contamination is confined to the hot zone and decontamination corridor.

(c) Contamination is reduced to a level that is as low as reasonably achievable.

7-4.5*

Methods that may be useful in assessing the effectiveness of decontamination include the following:

(a) Visual observation (stains, discolorations, corrosive effects, etc.)

(b) Monitoring devices (Devices such as photoionization detectors (PIDs), detector tubes, radiation monitors, and pH paper strips/meters can show that contamination levels are at least below the device's detection limit.)

(c) Wipe sampling (Such sampling provides for after-the-fact information on the effectiveness of decontamination. Once a wipe swab is taken, it is analyzed by chemical means, usually in a laboratory. Both protective clothing, equipment, and skin may be tested using wipe samples.)

7-4.6*

Large items of equipment, such as vehicles and trucks, should be subjected to decontamination by washes, high-pressure washes, steam, or special solutions. Water or other solutions used for washing or rinsing may have to be confined, collected, containerized, analyzed, and treated prior to disposal. Consult with environmental and public health agencies to determine the appropriate disposition.

If a large number of vehicles need to be decontaminated, the following recommendations should be considered:

(a) Establish a decontamination pad as a primary wash station. The pad may be a coarse gravel pad, concrete slab, or a pool liner. It may be necessary to collect these decontamination fluids, and the decontamination pad may be bermed or diked with a sump or some form of water recovery system.

(b) Completely wash and rinse vehicles several times with detergent. Pay particular attention to wheel wells, radiators, engines, and chassis. Depending on the nature of the contaminant, it may be necessary to collect all runoff water from the initial gross rinse, particularly if there is contaminated mud and dirt on the underside of the chassis.

(c) Vehicles should be inspected thoroughly by qualified personnel for possible mechanical or electrical damage. Areas of concern include air intakes, filters, cooling systems, and air-operated systems.

(d) Empty completely and thoroughly wash any outside compartments that were opened. The equipment should be washed and rinsed prior to being replaced.

(e) Equipment sprayed with acids should be flushed or washed as soon as possible with a neutralizing agent such as baking soda and then flushed again with rinse water.

(f) If vehicles have been exposed to minimal contaminants such as smoke and vapors, they may be decontaminated on-site and then driven to an off-site car wash for a second, more thorough washing. Car washes may be suitable if the drainage area is fully contained and all runoff drains into a holding tank.

(g) Verification of adequacy of decontamination, where necessary, may consist of samples collected from the cab and exterior surfaces that are analyzed in an off-site laboratory.

7-4.7

Personnel assigned to the decontamination team should wear an appropriate level of personal protective equipment (PPE) and may require decontamination themselves. Personal protective equipment can be upgraded or downgraded as additional information is obtained concerning the type of hazardous materials involved, the degree of hazard, and the probability of exposure of response personnel.

7-4.8

If personnel display any symptoms of heat exhaustion or possible exposure, appropriate emergency measures need to be implemented to doff PPE, while protecting the individual from contaminants and preventing the spread of any contaminants. These individuals should be transferred to the care of emergency medical services personnel who have completed training in accordance with applicable standards (e.g., NFPA 473, *Standard for Competencies for EMS Personnel Responding to Hazardous Materials Incidents*).

7-4.9

A debriefing should be held for those involved in decontamination as soon as practical. Exposed persons should be provided with as much information as possible about the delayed health effects of the hazardous materials involved in the incident. If necessary, follow-up examinations should be scheduled with medical personnel.

7-4.10

Exposure records should be maintained for future reference by the individual's personal physician and employer.

Chapter 8 Medical Monitoring

8-1 Introduction.

8-1.1 Purpose.

The purpose of this chapter is to provide guidelines for local jurisdictions to perform medical monitoring for hazardous materials response personnel. It is not the intent of this recommended practice to restrict any jurisdiction's medical authority from using different or modified guidelines. Locally established guidelines for medical monitoring should not be negated by a decision of command personnel.

8-1.2 Definition.

Medical monitoring is the ongoing, systematic evaluation of response personnel who are at risk of suffering adverse effects of heat/cold exposure, stress, or hazardous materials exposure. This monitoring is done for the purpose of achieving early recognition and prevention of these effects in order to maintain the optimal health and safety of on-scene personnel.

8-1.3 Objectives.

Medical monitoring is performed at the site of a hazardous materials incident for the following reasons:

(a) To obtain baseline vital signs and physical assessment

(b) To identify and preclude from participation in the hot zone and warm zone activities individuals at increased risk for sustaining injury and illness as a result of on-scene activities

(c) To provide early recognition and treatment of personnel with adverse physiological responses as a result of on-scene activities

8-1.4

Pre-entry medical monitoring should be completed on all individuals wearing chemical liquid splash- and vapor-protective clothing and performing hazardous materials operations. It should be completed within one hour prior to entry.

8-2 Components of Pre-Entrance Medical Monitoring.

8-2.1 Vital Signs.

Pre-entrance medical monitoring should include the evaluation of the following vital signs:

(a) Blood pressure

(b) Pulse

(c) Respiratory rate

(d) Temperature

(e) EKG rhythm strip (10 seconds), if available

8-2.2 Skin Evaluation.

Pre-entrance medical monitoring should include an examination of the individual's skin for the following:

(a) Rashes

(b) Open sores/wounds

8-2.3 Mental Status.

The individual should be alert and oriented to time and place, have clear speech and a normal gait, and be able to respond appropriately to the situation.

8-2.4 Medical History.

A recent medical history should be obtained that includes the following:

(a) Medications, including over the counter, taken within the past 72 hours

(b) Alcohol consumption within the past 24 hours

(c) Any new medical treatment or diagnosis made within the past two weeks

(d) Symptoms of fever, nausea, vomiting, diarrhea, or cough within the past 72 hours

8-2.5 Weight.

The individual's weight should be recorded.

8-2.6 Hydration.

It should be determined whether the individual has consumed 8 - 16 ounces of water or diluted activity drink.

8-3 Exclusion Criteria.

8-3.1

The following exclusion criteria should be applied to findings of all medical monitoring completed on hazardous materials response personnel. These criteria provide the EMS Control Officer and the Hazardous Materials Branch Officer with guidelines to determine medical/physical fitness for entry.

(a) Blood pressure - diastolic greater than 105 mm Hg

(b) Pulse - greater than 70 percent maximum heart rate (220- age)

Table 8-3.1(b) Age-Predicted Heart Rates

Age	70 Percent
20 - 25	140
25 - 30	136
30 - 35	132
35 - 40	128
40 - 45	125
45 - 50	122

(c) Respiratory rate - greater than 24 per minute

(d) Temperature - greater than 99.5ºF (oral) or greater than 100.5ºF (core) or less than 97.0 ºF (oral) or less than 98.0ºF (core)

(e) Weight - no pre-entry exclusion

(f) EKG - dysrhythmia not previously detected (must be cleared by medical control)

(g) Skin evaluation - open sores, large area of rash or significant sunburn

(h) Mental status - altered mental status (i.e., slurred speech, clumsiness, weakness)

(i) Recent medical history:

1. Presence of nausea, vomiting, diarrhea, fever, upper respiratory infection, heat illness, or

heavy alcohol intake within past 72 hours, all of which contribute to dehydration

2. New prescription medications taken within past two weeks or over the counter medications such as cold, flu, or allergy medicines, taken within past 72 hours (must be cleared through local medical control or hazardous materials medical director)

3. Any alcohol within past six hours

4. Pregnancy

8-4 Components of Medical Monitoring During Entry.

8-4.1

Changes in gait, speech, or behavior that require entry personnel to undergo immediate decontamination, doffing of protective clothing, and assessment should be monitored.

8-4.2

If entry personnel complain of chest pain, dizziness, shortness of breath, weakness, nausea, or headache, they should undergo immediate decontamination, doffing of protective clothing, and assessment.

8-5 Post-Entry Medical Monitoring.

8-5.1 Objectives.

Post-entry medical monitoring is performed to determine the following:

(a) Whether an individual has suffered any immediate effects from exposure to a hazardous material or the environment

(b) An individual's health status for future assignment during or following incident (This assessment should include both physiological and psychological considerations.)

8-5.2

Components of post-entry medical monitoring should include the following:

(a) History - any symptom of hazardous material exposure, environmental exposure, or cardiovascular collapse

(b) Vital signs:

1. Blood pressure

2. Pulse

3. Respiratory rate

4. Temperature

5. EKG (if available)

(c) Weight

(d) Skin evaluation

(e) Mental status

8-6 Post-Medical Monitoring Follow-Up.

8-6.1

Post-medical monitoring follow-up should include the following:

(a) Repeat monitoring of vital signs every 5 - 10 minutes until they return to less than 85 percent of maximum pulse rate. If at 10 minutes the signs have not returned to within 10 percent of baseline, perform orthostatic vital signs.

(b) Determine from medical control what information regarding latent reactions/symptoms should be communicated to response personnel.

(c) If any of the following symptoms are present, contact medical control for direction and preparation for possible transport to a medical facility:

1. Body weight loss of greater than 3 percent or positive orthostatic (pulse increase by 20 beats per minute or systolic blood pressure decrease by 20 mm of Hg at two minutes standing)

2. Greater than 85 percent maximum pulse at 10 minutes

3. Temperature greater than 101ºF (oral) or 102ºF (core)

4. Nausea, vomiting, diarrhea, altered mental status, or respiratory, cardiac, or dermatologic complaints

8-7 Treatment Protocol for Hazardous Materials Team Members.

8-7.1

Rest time for all personnel should equal at least minimum suit time. Individuals may require additional time for oral rehydration. All personnel should be informed of signs and symptoms to watch for.

8-7.2

If the team member is not within 10 percent of baseline within 10 minutes, orthostatic vital signs should be taken.

8-7.3

If personnel experience greater than 3 percent body weight loss (4 $^1/_2$ pounds in a 150-pound person); positive orthostatic (pulse increases by 20 beats per minute or systolic blood pressure decreases by 20 mm of Hg at two minutes standing); greater than 85 percent of maximum pulse at 10 minutes; temperature greater than 101ºF oral (102º F core); nausea, altered mental status, or any other symptoms, the following treatment should be performed:

(a) Intravenous fluids hydration with Ringers Lactate or Normal Saline at rate (usually wide open) to get pulse less than 100 beats per minute, systolic blood pressure greater than 110 mm of Hg

(b) Administration of oxygen 4 L to 6 L per minute via nasal cannula, may increase as needed

(c) Consultation of reference protocols or medical control for treatment of specific symptoms/types of exposure

Chapter 9 Referenced Publications

9-1

The following documents or portions thereof are referenced within this recommended practice and should be considered as part of its recommendations. The edition indicated for each referenced document is the current edition as of the date of the NFPA issuance of this recommended practice. Some of these documents might also be referenced in this recommended practice for specific informational purposes and, therefore, are also listed in Appendix B.

9-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 70, *National Electrical Code,* 1996 edition.

NFPA 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents,* 1997 edition.

NFPA 473, *Standard for Competencies for EMS Personnel Responding to Hazardous Materials Incidents,* 1997 edition.

NFPA 1500, *Standard on Fire Department Occupational Safety and Health Program,* 1992 edition.

NFPA 1981, *Standard on Open-Circuit Self-Contained Breathing Apparatus for Fire Fighters,* 1992 edition.

NFPA 1982, *Standard on Personal Alert Safety Systems (PASS) for Fire Fighters,* 1993 edition.

NFPA 1991, *Standard on Vapor-Protective Suits for Hazardous Chemical Emergencies,* 1994 edition.

NFPA 1992, *Standard on Liquid Splash-Protective Suits for Hazardous Chemical Emergencies,* 1994 edition.

NFPA 1993, *Standard on Support Function Protective Clothing for Hazardous Chemical Operations,* 1994 edition.

Appendix A Explanatory Material

This appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

A-1-1 Many of the recommendations in this document are based on U.S. federal laws and regulations that were in effect at the time of adoption. Users should carefully review laws and regulations that may have been added or amended or that may be required by other authorities. Users outside the jurisdiction of the United States should determine what requirements may be in force at the time of application of this document.

A-1-4 Authority Having Jurisdiction. The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-4 Hazardous Material. There are many definitions and descriptive names being used for the term hazardous material, each of which depends on the nature of the problem being addressed.

Unfortunately, there is no one list or definition that covers everything. The U.S. agencies involved, as well as state and local governments, have different purposes for regulating hazardous materials that, under certain circumstances, pose a risk to the public or the environment.

Hazardous Materials. The U.S. Department of Transportation (DOT) uses the term *hazardous materials* to cover 11 hazard classes, some of which have subcategories called divisions. DOT includes in its regulations hazardous substances and hazardous wastes as Class 9 (Miscellaneous Hazardous Materials) both of which are regulated by the U.S. Environmental Protection Agency (EPA), if their inherent properties would not otherwise be covered.

Hazardous Substances. EPA uses the term *hazardous substances* for the chemicals that, if released into the environment above a certain amount, must be reported, and, depending on the threat to the environment, federal involvement in handling the incident can be authorized. A list of the hazardous substances is published in Title 40, *Code of Federal Regulations,* Part 302, Table 302.4. The U.S. Occupational Safety and Health Administration (OSHA) uses the term *hazardous substance* in Title 29, *Code of Federal Regulations*, Part 1910.120, which resulted from Title I of Superfund Amendments and Reauthorization Act (SARA) and covers emergency response. OSHA uses the term differently than EPA. Hazardous substances, as used by OSHA, cover every chemical regulated by both DOT and EPA.

Extremely Hazardous Substances. EPA uses the term *extremely hazardous substances* for chemicals that must be reported to the appropriate authorities if released above the threshold reporting quantity. Each substance has a threshold reporting quantity. The list of extremely hazardous substances is identified in Title III of SARA of 1986 (Title 40, *Code of Federal Regulations*, Part 355).

Toxic Chemicals. EPA uses the term *toxic chemicals* for chemicals whose total emissions or releases must be reported annually by owners and operators of certain facilities that manufacture, process, or otherwise use a listed toxic chemical. The list of toxic chemicals is identified in Title III of SARA.

Hazardous Wastes. EPA uses the term *hazardous wastes* for chemicals that are regulated under the Resource, Conservation, and Recovery Act (Title 40, *Code of Federal Regulations*, Part 261.33). Hazardous wastes in transportation are regulated by DOT (Title 49, *Code of Federal Regulations*, Parts 170-179).

Hazardous Chemicals. OSHA uses the term *hazardous chemicals* to denote any chemical that would be a risk to employees if exposed in the workplace. Hazardous chemicals cover a broader group of chemicals than the other chemical lists.

Dangerous Goods. In Canadian transportation, hazardous materials are called dangerous goods.

Class 1 (Explosives)

An explosive is any substance or article, including a device, that is designed to function by explosion (i.e., an extremely rapid release of gas and heat) or that, by chemical reaction within itself, is able to function in a similar manner even if not designed to function by explosion. Explosives in Class 1 are divided into six divisions. Each division will have a letter designation.

Division 1.1 consists of explosives that have a mass explosion hazard. A mass explosion is one that affects almost the entire load instantaneously.

Examples of Division 1.1 explosives include black powder, dynamite, and TNT.

Division 1.2 consists of explosives that have a projection hazard but not a mass explosion hazard.

Examples of Division 1.2 explosives include aerial flares, detonating cord, and power device cartridges.

Division 1.3 consists of explosives that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard.

Examples of Division 1.3 explosives include liquid-fueled rocket motors and propellant explosives.

Division 1.4 consists of explosive devices that present a minor explosion hazard. No device in the division may contain more than 25 g (0.9 oz) of a detonating material. The explosive effects are largely confined to the package and no projection of fragments of appreciable size or range are expected. An external fire must not cause virtually instantaneous explosion of almost the entire contents of the package.

Examples of Division 1.4 explosives include line-throwing rockets, practice ammunition, and signal cartridges.

Division 1.5 consists of very insensitive explosives. This division is comprised of substances that have a mass explosion hazard but are so insensitive that there is very little probability of initiation or of transition from burning to detonation under normal conditions of transport.

Examples of Division 1.5 explosives include prilled ammonium nitrate fertilizer-fuel oil mixtures (blasting agents).

Division 1.6 consists of extremely insensitive articles that do not have a mass explosive hazard. This division is comprised of articles that contain only extremely insensitive detonating substances and that demonstrate a negligible probability of accidental initiation or propagation.

Class 2 (Gases)

Division 2.1 (flammable gas) consists of any material that is a gas at 20ºC (68ºF) or less and 101.3 kPa (14.7 psi) of pressure, a material that has a boiling point of 20ºC (68ºF) or less at 101.3 kPa (14.7 psi), and that

(a) Is ignitable at 101.3 kPa (14.7 psi) when in a mixture of 13 percent or less by volume with air

(b) Has a flammable range at 101.3 kPa (14.7 psi) with air of at least 12 percent regardless of the lower limit

Examples of Division 2.1 gases include inhibited butadienes, methyl chloride, and propane.

Division 2.2 (nonflammable, nonpoisonous compressed gas, including compressed gas, liquefied gas, pressurized cryogenic gas, and compressed gas in solution) consists of any material (or mixture) that exerts in the packaging an absolute pressure of 280 kPa (41 psia) at 20ºC (68ºF).

A cryogenic liquid is a refrigerated liquefied gas having a boiling point colder than - 90ºC (-130ºF) at 101.3 kPa (14.7 psi) absolute.

Examples of Division 2.2 gases include anhydrous ammonia, cryogenic argon, carbon dioxide, and compressed nitrogen.

Division 2.3 (poisonous gas) consists of a material that is a gas at 20ºC (68ºF) or less and a pressure of 101.3 kPa (14.7 psi or 1 atm), a material that has a boiling point of 20ºC (68ºF) or less at 101.3 kPa (14.7 psi), and that

(a) Is known to be so toxic to humans as to pose a hazard to health during transportation

(b) In the absence of adequate data on human toxicity, is presumed to be toxic to humans because, when tested on laboratory animals, it has an LC_{50} value of not more than 5,000 ppm

Examples of Division 2.3 gases include anhydrous hydrogen fluoride, arsine, chlorine, and methyl bromide.

Hazard zones associated with Division 2.3 materials are the following:

Hazard zone A — LC_{50} less than or equal to 200 ppm

Hazard zone B — LC_{50} greater than 200 ppm and less than or equal to 1,000 ppm

Hazard zone C — LC_{50} greater than 1,000 ppm and less than or equal to 3,000 ppm

Hazard zone D — LC_{50} greater than 3,000 ppm and less than or equal to 5,000 ppm

Class 3 (Flammable Liquid)

Flammable liquid is any liquid having a flash point of not more than 60.5ºC (141ºF).

Examples of Class 3 liquids include acetone, amyl acetate, gasoline, methyl alcohol, and toluene.

Hazard zones associated with Class 3 materials are the following:

Hazard zone A — LC_{50} less than or equal to 200 ppm

Hazard zone B — LC_{50} greater than 200 ppm and less than or equal to 1,000 ppm

Combustible Liquid

Combustible liquid is any liquid that does not meet the definition of any other hazard class and has a flash point above 60ºC (140ºF) and below 93ºC (200ºF). Flammable liquids with a flash point above 38ºC (100ºF) may be reclassified as a combustible liquid.

Examples of combustible liquids include mineral oil, peanut oil, and No. 6 fuel oil.

Class 4 (Flammable Solids)

Division 4.1 (flammable solid) consists of any of the following three types of materials:

(a) Wetted explosives — explosives wetted with sufficient water, alcohol, or plasticizers to suppress explosive properties

(b) Self-reactive materials — materials that are liable to undergo, at normal or elevated temperatures, a strongly exothermic decomposition caused by excessively high transport temperatures or by contamination

(c) Readily combustible solids — solids that may cause a fire through friction and any metal powders that can be ignited

Examples of Division 4.1 materials include magnesium (pellets, turnings, or ribbons) and nitrocellulose.

Division 4.2 (spontaneously combustible material) consists of any of the following materials:

(a) Pyrophoric material — a liquid or solid that, even in small quantities and without an external ignition source, can ignite within 5 minutes after coming in contact with air

(b) Self-heating material — a material that, when in contact with air and without an energy supply, is liable to self-heat

Examples of Division 4.2 materials include aluminum alkyls, charcoal briquettes, magnesium alkyls, and phosphorus.

Division 4.3 (dangerous when wet material) consists of materials that, by contact with water, are liable to become spontaneously flammable or to give off flammable or toxic gas at a rate greater than 1 L/kg of the material per hour.

Examples of Division 4.3 materials include calcium carbide, magnesium powder, potassium metal alloys, and sodium hydride.

Class 5 (Oxidizers and Organic Peroxides)

Division 5.1 (oxidizer) consists of materials that can, generally by yielding oxygen, cause or enhance the combustion of other materials.

Examples of Division 5.1 materials include ammonium nitrate, bromine trifluoride, and calcium hypochlorite.

Division 5.2 (organic peroxide) consists of any organic compound containing oxygen (O) in the bivalent -O-O- structure that may be considered a derivative of hydrogen peroxide, where one or more of the hydrogen atoms have been replaced by organic radicals.

Division 5.2 (organic peroxide) materials are assigned to one of the following seven types:

Type A — organic peroxide that can detonate or deflagrate rapidly as packaged for transport. Transportation of Type A organic peroxides is forbidden.

Type B — organic peroxide that neither detonates nor deflagrates rapidly, but that can undergo a thermal explosion.

Type C — organic peroxide that neither detonates nor deflagrates rapidly and cannot undergo a thermal explosion.

Type D — organic peroxide that detonates only partially or deflagrates slowly, with medium to no effect when heated under confinement.

Type E — organic peroxide that neither detonates nor deflagrates and shows low, or no, effect when heated under confinement.

Type F — organic peroxide that will not detonate, does not deflagrate, shows only a low, or no, effect if heated when confined, and has low, or no, explosive power.

Type G — organic peroxide that will not detonate, does not deflagrate, shows no effect if heated when confined, and has no explosive power, is thermally stable, and is desensitized.

Examples of Division 5.2 materials include dibenzoyl peroxide, methyl, ethyl ketone peroxide, and peroxyacetic acid.

Class 6 (Poisonous Materials)

Division 6.1 (poisonous material) consists of materials, other than gases, that either are known to be so toxic to humans as to afford a hazard to health during transportation, or in the absence of adequate data on human toxicity, are presumed to be toxic to humans, including materials that cause irritation.

Examples of Division 6.1 materials include aniline, arsenic compounds, carbon tetrachloride, hydrocyanic acid, and tear gas.

Division 6.2 (infectious substance) consists of viable microorganisms, or their toxin, that cause or may cause disease in humans or animals. Infectious substance and etiologic agent are synonymous.

Examples of Division 6.2 materials include anthrax, botulism, rabies, and tetanus.

Class 7 (Radioactive Materials)

Radioactive material is any material having a specific activity greater than 0.002 microcuries per gram (μCi/g).

Examples of Class 7 materials include cobalt, uranium hexafluoride, and “yellow cake.”

Class 8 (Corrosive Materials)

Corrosive material is a liquid or solid that causes visible destruction or irreversible alterations in human skin tissue at the site of contact, or a liquid that has a severe corrosion rate on steel or aluminum.

Examples of Class 8 materials include nitric acid, phosphorus trichloride, sodium hydroxide, and sulfuric acid.

Class 9 (Miscellaneous)

Miscellaneous hazardous material is a material that presents a hazard during transport, but that is not included in another hazard class, including the following:

(a) Any material that has an anesthetic, noxious, or other similar property that could cause extreme annoyance or discomfort to a flight crew member so as to prevent the correct performance of assigned duties

(b) Any material that is not included in any other hazard class, but is subject to the DOT requirements (a hazardous substance or a hazardous waste)

Examples of Class 9 materials include adipic acid, hazardous substances (e.g., PCBs), and molten sulfur.

ORM-D Material

An ORM-D material is a material that presents a limited hazard during transportation due to its form, quantity, and packaging.

Examples of ORM-D materials include consumer commodities and small arms ammunition.

Forbidden

Forbidden is defined as prohibited from being offered or accepted for transportation. Prohibition does not apply if these materials are diluted, stabilized, or incorporated in devices.

A-1-4 National Contingency Plan. See Title 40, *Code of Federal Regulations*, Part 300, Subchapters A through J.

A-3-1 These incidents can be considered as requiring either offensive operations or defensive operations.

Offensive operations include actions taken by a hazardous materials responder, in appropriate chemical-protective clothing, to handle an incident in such a manner that contact with the released material may result. These actions include patching or plugging to slow or stop a leak; containing a material in its own package or container; and cleanup operations that may require overpacking or transfer of a product to another container.

Defensive operations include actions taken during an incident where there is no intentional contact with the material involved. These actions include elimination of ignition sources, vapor suppression, and diking or diverting to keep a release in a confined area. Defensive operations require notification and possible evacuation, but does not involve plugging, patching, or cleanup of spilled or leaking materials.

Jurisdictions have the responsibility to develop standard operating procedures that equate levels of response to levels of training indicated in NFPA 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents*. Depending on the capabilities and training of personnel, the first responder operational level may equate to incident level one and the technician level may equate to incident level two.

Response personnel should operate only at that incident level that matches their knowledge, training, and equipment. If conditions indicate a need for a higher response level, then additional personnel, appropriate training, and equipment should be summoned.

A-4-1.2 Although Title 29, *Code of Federal Regulations*, Part 1910.120 is cited in the text, it should be understood that some states will adopt these regulations under state OSHA plans and others will adopt these regulations through adoption of a similar regulation established by EPA and appropriate state agencies.

A-4-3.1 Access into the hot zone is to be limited to those persons necessary to control the incident. A log is to be maintained at the access control point to record entry and exit time of all personnel in the hot zone.

A-5-3.3 Chemical resistance is the ability of the material from which the protective garment is made to prevent or reduce degradation and permeation of the fabric by the attack chemical. Degradation is a chemical action involving the molecular breakdown of the material due to contact with a chemical. The action may cause the fabric to swell, shrink, blister, or discolor; become brittle, sticky, or soft; or deteriorate. These changes permit chemicals to penetrate the suit more rapidly or increase the probability of permeation.

Permeation is a chemical action involving the movement of chemicals, on a molecular level, through intact material. There is usually no indication that this process is occurring. Permeation is defined by two terms, permeation rate and breakthrough time. Permeation rate is the quantity of chemical that will move through an area of protective garment in a given period of time, usually expressed as micrograms of chemical per square centimeter per minute. Breakthrough time is the time required for the chemical to be measured on the inside surface of the fabric. The most desirable protective fabric is one that has the longest breakthrough time and a very low permeation rate. Breakthrough times and permeation rates are not available for all the common suit materials and the variety of chemicals that exist. Manufacturers' data and reference sources should be consulted. Generally, if a material degrades rapidly, permeation will occur rapidly.

Penetration is the movement of material through a suit's closures, such as zippers, buttonholes, seams, flaps, or other design features. Torn or ripped suits will also allow penetration.

A-5-5.3 Refer to OSHA Title 29, *Code of Federal Regulations*, Part 1910.134.

A-5-6.2(a) This situation involves atmospheres with IDLH (immediately dangerous to life and health) concentrations of specific substances that do not represent a severe skin hazard or that do not meet the criteria for use of air purifying respirators.

A-5-6.3(d) Refer to OSHA Title 29, *Code of Federal Regulations*, Part 1910.134.

A-5-6.4(b) Combinations of personal protective equipment other than those described for Levels A, B, C, and D protection may be more appropriate and may be used to provide the proper level of protection.

A-6-4.1 Procedures described in 6-4.1.1 through 6-4.1.11 should be completed only by personnel trained in those procedures.

A-6-4.1.1 Absorbents saturated with volatile liquid chemicals can create a more severe vapor hazard than the spill alone because of severely enlarged surface area for vapor release.

A-6-4.1.10 One technique available for handling a spill of a hazardous liquid is the application of foams to suppress the vapor emanating from the liquid. This technique is ideally suited for liquid spills that are contained, i.e., diked. It can also be used where the spill is not confined. In all cases this technique should be undertaken only by personnel who have been trained in the use of foam concentrate for vapor suppression. Training in the use of foam as a fire extinguishing agent is not sufficient to qualify an individual for applying foam application as a vapor-suppressing agent.

Vapor-suppressing foam concentrates vary in their effectiveness depending on a number of factors. These factors can include the type of foam, the 25 percent drainage time of the foam, the rate of application of the foam, and the depth of the foam blanket. These variables serve to emphasize the need for training of the person selecting this technique for applying foam as a vapor-suppressing medium.

Foams are produced by mechanically mixing a dilute solution of the foam concentrate and water with air, producing an expanded foam. Foams have been developed basically as fire extinguishing agents. Data have also been developed on their capability to suppress vapor release from water-immiscible flammable or combustible hydrocarbon liquids.

Foam and specific foam concentrates for each category, along with the definitions of appropriate terms, can be obtained by consulting NFPA 11, *Standard for Low-Expansion Foam;* NFPA 11A, *Standard for Medium- and High-Expansion Foam Systems;* NFPA 16, *Standard for the Installation of Deluge Foam-Water Sprinklers and Foam-Water Spray Systems;* and ASTM Standard Guide F 1129, *Using Aqueous Foams to Control the Vapor Hazard from Immiscible Volatile Liquids*.

The use of fire-fighting foam as a vapor suppressant involves some considerations that are different from those required for fire-extinguishing agents. It should be noted that fire-fighting foams are predominantly restricted to use on water-immiscible hydrocarbon liquids or polar compounds. They are not usually effective on inorganic acids or bases, nor on liquefied gases, including the hydrocarbon gases such as methane and propane, in controlling vapor release. One of the obvious issues of concern is the stability of the foam blanket as a function of time. This can be approached by looking at what is referred to as the foam quality.

Foam quality is generally measured in terms of foam expansion ratio and foam 25 percent drainage time. Foam expansion ratio refers to the volume of foam solution. AFFF is often used in nonaspirating equipment such as water fog nozzles. Nonaspirated AFFF solutions have significantly limited effectiveness in comparison with aspirated foam solutions in vapor suppression.

The 25 percent drainage time is that time which is required for 25 percent of the foam solution to drain from the foam. This is the property that is generally used to measure the stability of the foam. The slower the drainage of any expanded foam, regardless of expansion, the more effective and longer lasting is the foam blanket. This formula assumes weather conditions are ideal.

An important factor is the vapor pressure of the liquid that is being suppressed. Liquid vapor pressures can vary widely. The higher the vapor pressure, the slower the control time. The key to effective use of foam as a vapor-suppressing agent is to have a continuous foam blanket on the fuel surface. Films from AFFF/FFFP are no guarantee of effective vapor control.

It is important to recognize that there are some limitations in the use of foam fire extinguishing agents in vapor suppression. As indicated, these materials are basically designed for flammable hydrocarbon liquids. They have severe shortcomings for inorganic acids or bases or liquefied gases. They should not be used for vapor suppression of these categories of volatile hazardous chemicals without consultation with the manufacturer of the specific foam agent being considered.

Most fire-fighting foam concentrates have a limited range of pH tolerance. The pH is a measure of the acidity or alkalinity of inorganic acids or bases. The pH tolerance is the level that the bubble wall of the foam can tolerate before collapsing catastrophically. A few surfactant foams and the polar compound-type foams have good pH tolerance. Most of the protein, fluoroprotein, AFFFs, and high-expansion foams are not suitable for inorganic acids or bases.

Liquefied gas spills may be controlled by the application of high-expansion foam blankets. Low-expansion foams are not effective for liquefied gas spill control. Because of the large temperature differential between the liquefied gas and the foam, the drainage from the foam initially exaggerates boiloff from the spill. The higher the expansion, the lesser the effect of the drainage. For liquefied gases and all water-reactive inorganic materials, the foam should exhibit the best chemical resistance and expansion ratios to ensure maximum water retention consistent with the condition of the spill site. Since each spilled material can have unique properties, the manufacturer of the foam concentrate should be consulted for directions.

The great differences in the chemistry of flammable hydrocarbon liquids and the water-reactive inorganic materials have resulted in the development of foam concentrates specifically applicable to the inorganic chemicals. Few fire fighting foams have capabilities of vapor suppression of the inorganic acids and bases. For effective control, special foam concentrates should be employed.

Some special foam concentrates are specific for either acids or alkalis but not both. Further, they are not applicable to all inorganic materials, nor are they effective in fire suppression. In many cases, their effectiveness is limited, and intermittent foam make-up may be required to maintain the foam blanket. Others, usually containing a polymer modification, can cover a wide range of materials, both acids and bases, and may possess some degree of fire resistance. This is important for those inorganic materials that may also pose a fire hazard.

At present, there is no single foam concentrate that is truly effective against all categories of volatile hazardous chemicals. A few possess limited capabilities in most categories, but they are compromise materials, sacrificing in one category to provide some capability in other categories. These may, however, be the best choice for first responders where an overall capability is essential.

In all cases, however, the foam manufacturer or the manufacturer's literature should be consulted to provide specific guidance for the chemical to be treated.

Vapor suppression can also be considered a chemical method of mitigation.

A-6-4.2 The procedures described in 6-4.2.1 through 6-4.2.10 should be used only by personnel trained in those procedures.

A-6-4.2.1 Spontaneous ignition can occur through the heat of adsorption of flammable materials and caution should be exercised.

Adsorbents saturated with volatile liquid chemicals can create a more severe vapor hazard than the spill alone because of the severely enlarged surface area for vapor release.

A-7-4.5 It should be noted that for etiologic hazards and many chemical hazards, there is no real-time way to determine the effectiveness of decontamination in the field.

A-7-4.6 Additional information can be found in NFPA 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents,* A-15-2.3.4.5

Appendix B Referenced Publications

B-1 The following documents or portions thereof are referenced within this recommended practice for informational purposes only and are thus not considered part of its recommendations. The edition indicated here for each reference is the current edition as of the date of the NFPA issuance of this recommended practice.

Appendix C Suggested Reading List

This appendix is not a part of the recommendations of this NFPA document but is included for informational purposes only.

C-1 Introduction.

This list provides the titles of references and organizations that may be of value to those responding to hazardous materials incidents. This list can be expanded based on personal preferences and requirements.

The references are categorized by subject. The title, author, publisher, and place of publication are given for each. The year of publication is not always given because many are revised annually. The user should attempt to obtain the most recent edition.

The last section lists sources of these references as well as other information that might be useful. Usually, these agencies or associations will provide a catalog on request. Where available, phone numbers are also listed.

1997 Edition

This edition of NFPA 472, *Standard on Professional Competence of Responders to Hazardous Materials Incidents*, was prepared by the Technical Committee on Hazardous Materials Response Personnel and acted on by the National Fire Protection Association, Inc., at its Fall Meeting held November 18-20, 1996, in Nashville, TN. It was issued by the Standards Council on January 17, 1997, with an effective date of February 7, 1997, and supersedes all previous editions.

Changes other than editorial are indicated by a vertical rule in the margin of the pages on which they appear. These lines are included as an aid to the user in identifying changes from the previous edition.

This edition of NFPA 472 was approved as an American National Standard on February 7, 1997.

Origin and Development of NFPA 472

At the July 1985 NFPA Standards Council meeting, approval was given to the concept of a new project on Hazardous Materials Response Personnel. The Council directed that a proposed scope and start-up roster for the new Committee be prepared, taking into account the need to expand the Committee membership beyond the fire service and the people beyond "professional qualifications."

When establishment of the Committee was formally announced, many requests for membership were received, and similar requests continued to arrive during the first year of its existence. The first meeting of the Committee took place in October 1986.

Interest in the subject of hazardous materials, especially as it relates to the emergency responder, continues at a high level. Some of this is due to an increased awareness of the magnitude of the problem; much of it can be credited to federal regulations that have an impact on all responders.

In 1990 the Committee began reviewing the document for the purpose of revising it. The Committee established a task group that conducted a task analysis relating to hazardous materials response. Based on the task group's recommendations, the Committee revised the original document. The 1992 edition changed the original format and presented the competencies in a more complete manner.

Since 1992, several task groups have created two new levels, the Hazardous Materials Branch Officer and the Safety Officer. These new levels have been incorporated into the 1997 edition. Three new specialty levels, for tank cars, cargo tanks, and intermodal tanks, are also now included in the standard. The Committee found it necessary to make changes to clarify existing requirements, especially for the Technician level.

The gratitude of the Committee is extended to all who assisted in the development of this standard, and especially to those non-Committee members who participated so fully in this process.

Committee Scope: This Committee shall have primary responsibility for documents on the requirements for the professional competence, training, procedures, and equipment for emergency responders to hazardous materials incidents.

NFPA 472

Standard for

Professional Competence of Responders to

Hazardous Materials Incidents

1997 Edition

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Appendix A.
Information on referenced publications can be found in Chapter 12 and Appendix D.

Chapter 1 Administration

1-1 General.

1-1.1

Scope. This standard identifies the levels of competence required of responders to hazardous materials incidents. It specifically covers the competencies for first responders at the awareness level, first responders at the operational level, hazardous materials technicians, incident commanders, hazardous materials branch officers, hazardous materials branch safety officers, and other specialist employees.

1-1.2* Purpose.

The purpose of this standard is to specify minimum competencies for those who will respond to hazardous materials incidents. It is not the intent of this standard to restrict any jurisdiction from exceeding these minimum requirements.

One purpose of the competencies contained herein is to reduce the numbers of accidents, injuries, and illnesses during response to hazardous materials incidents and to help prevent exposure to hazardous materials to reduce the possibility of fatalities, illness, and disabilities affecting emergency response personnel.

1-2 Definitions.

Approved.* Acceptable to the authority having jurisdiction.

Authority Having Jurisdiction.* The organization, office, or individual responsible for approving equipment, an installation, or a procedure.

CANUTEC. The Canadian Transport Emergency Center operated by Transport Canada. CANUTEC provides emergency response information and assistance on a 24-hour basis for responders to hazardous materials incidents.

Chemical. Regulated and nonregulated hazardous materials (solids, liquids, and gases, whether natural or man-made, including petroleum products) with the potential for creating harm to people, the environment, and property when released.

Chemical Protective Clothing. Items made from chemical-resistive materials, such as clothing, hood, boots, and gloves, that are designed and configured to protect the wearer's torso, head, arms, legs, hands, and feet from hazardous materials. Chemical-protective clothing (garments) can be constructed as a single- or multipiece garment. The garment can completely enclose the wearer either by itself or in combination with the wearer's respiratory protection, attached or detachable hood, gloves, and boots.

CHEMTREC. The Chemical Transportation Emergency Center, a public service of the Chemical Manufacturers Association. CHEMTREC provides emergency response information and assistance on a 24-hour basis for responders to hazardous materials incidents.

Cold Zone. The control zone of a hazardous materials incident that contains the command post and such other support functions as are deemed necessary to control the incident. This zone is also referred to as the clean zone or support zone in other documents.

Competence. Possessing knowledge, skills, and judgment needed to perform indicated objectives satisfactorily.

Confined Space. A space that by design has limited openings for entry and exit, that has unfavorable natural ventilation that could contain or produce dangerous concentrations of air contaminants, and that is not intended for continuous occupancy. Examples of confined spaces include, but are not limited to, storage tanks, compartments of ships, process vessels, pits, silos, vats, degreasers, reaction vessels, boilers, ventilation and exhaust ducts, sewers, tunnels, underground utility vaults, and pipelines.

Confinement. Those procedures taken to keep a material, once released, in a defined or local area.

Container. Any vessel or receptacle that holds material, including storage vessels, pipelines, and packaging (*see definition of "Packaging*"). Containers include the following:
(a) Nonbulk packaging, such as bags, bottles, boxes, carboys, cylinders, drums, jerricans, multicell packages, and wooden barrels

(b) Bulk packaging, such as bulk bags, bulk boxes, cargo tanks, covered hopper cars, freight containers, gondolas, pneumatic hopper trailers, portable tanks and bins, protective overpacks for radioactive materials, tank cars, ton containers, and van trailers

(c) Fixed containers, such as piping, reactors, storage bins, tanks, and storage vessels

Containment. The actions taken to keep a material in its container (e.g., stop a release of the material or reduce the amount being released).

Contaminant. A hazardous material that physically remains on or in people, animals, the environment, or equipment, thereby creating a continuing risk of direct injury or a risk of exposure.

Contamination. The process of transferring a hazardous material from its source to people, animals, the environment, and/or equipment, which may act as a carrier.

Control. The procedures, techniques, and methods used in the mitigation of a hazardous materials incident, including containment, extinguishment, and confinement.

Control Zones. The areas at hazardous materials incidents that are designated based upon the degree of hazard. Many terms are used to describe these control zones; however, for the purposes of this standard, these zones are defined as the hot, warm, and cold zones.

Coordination. The process used to get people, who might represent different agencies, to work together integrally and harmoniously in a common action or effort.

Decontamination. The physical or chemical process of reducing and preventing the spread of contaminants from persons and equipment used at a hazardous materials incident.

Decontamination Corridor. The area usually located within the warm zone where decontamination procedures take place. This area is also referred to as the decontamination area in other documents.

Degradation.

(a) A chemical action involving the molecular breakdown of a protective clothing material or equipment due to contact with a chemical.

(b) The molecular breakdown of the spilled or released material to render it less hazardous during control operations.

Demonstrate. To show by actual performance. This performance can be supplemented by simulation, explanation, illustration, or a combination of these.

Describe. To explain verbally or in writing using standard terms recognized in the hazardous materials response community.

Emergency Decontamination. The physical process of immediately reducing contamination of individuals in potentially life-threatening situations with or without the formal establishment of a decontamination corridor.

Emergency Response Plan. A plan that establishes guidelines for handling hazardous materials incidents as required by relevant legislation such as Title 29, *Code of Federal Regulations*, Part 1910.120 (q) (1).

Endangered Area. The actual or potential area of exposure from a hazardous material. This area is sometimes referred to as the engulfed area.

Exposure. The process by which people, animals, the environment, and equipment are subjected to or come in contact with a hazardous material. The magnitude of exposure is dependent primarily upon the duration of exposure and the concentration of the hazardous material. This term is also used to describe a person, animal, the environment, or a piece of equipment.

Gross Decontamination. The initial phase of the decontamination process during which the amount of surface contaminant is significantly reduced. This phase can include mechanical removal or initial rinsing.

Hazard/Hazardous. Capable of posing an unreasonable risk to health, safety, or the environment; capable of causing harm.

Hazardous Material.* A substance (solid, liquid, or gas) that when released is capable of creating harm to people, the environment, and property.

Hazardous Materials Branch. That function within an overall incident management system that deals with the mitigation of the hazardous materials portion of a hazardous materials incident. It is directed by a hazardous materials branch officer and deals principally with the technical aspects of the incident.

Hazardous Materials Branch Officer. The person responsible for the management of the hazardous materials branch.

Hazardous Materials Response Team. An organized group of trained response personnel operating under an emergency response plan and appropriate standard operating procedures who handle and control actual or potential leaks or spills of hazardous materials requiring possible close approach to the material. The team members respond to releases or potential releases of hazardous materials for the purpose of control or stabilization of the incident.

High Temperature-Protective Clothing. Protective clothing designed to protect the wearer for short-term high temperature exposures. This type of clothing is usually of limited use in dealing with chemical commodities.

Hot Zone. The control zone immediately surrounding a hazardous materials incident, which extends far enough to prevent adverse effects from hazardous materials releases to personnel outside the zone. This zone is also referred to as the exclusion zone or the restricted zone in other documents.

Identify. To select or indicate verbally or in writing using standard terms to establish the identity of; the fact of being the same as the one described.

Incident. An emergency involving the release or potential release of a hazardous material, with or without fire.

Incident Commander. The person responsible for all decisions relating to the management of the incident. The incident commander is in charge of the incident site. This is equivalent to the on-scene incident commander.

Incident Management System.* An organized system of roles, responsibilities, and standard operating procedures used to manage and direct emergency operations. Such systems are sometimes referred to as incident command systems (ICS).

Individual Area of Specialization. The qualifications or functions of a specific job(s) associated with chemicals and/or containers used within an organization.

Liquid Splash-Protective Clothing. The garment portion of a chemical-protective clothing ensemble that is designed and configured to protect the wearer against chemical liquid splashes but not against chemical vapors or gases. Liquid splash-protective clothing must meet the requirements of NFPA 1992, *Standard on Liquid Splash-Protective Suits for Hazardous Chemical Emergencies.* This type of protective clothing is a component of EPA Level B chemical protection.

Listed.* Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets identified standards or has been tested and found suitable for a specified purpose.

Local Emergency Response Plan. The plan promulgated by the authority having jurisdiction, such as the local emergency planning committee for the community or a facility.

Match. To provide with a counterpart.

Material Safety Data Sheet (MSDS). A form, provided by manufacturers and compounders (blenders) of chemicals, containing information about chemical composition, physical and chemical properties, health and safety hazards, emergency response, and waste disposal of the material.

Monitoring Equipment. Instruments and devices used to identify and quantify contaminants.

North American Emergency Response Guidebook (NAERG). A reference book, written in plain language, to guide emergency responders in their initial actions at the incident scene.

Objective. A goal that is achieved through the attainment of a skill, knowledge, or both, that can be observed or measured.

Organization's Area of Specialization. Any chemicals and containers used by the private sector specialist employee's employer.

Packaging. Any container that holds a material (hazardous and nonhazardous). Packaging for hazardous materials includes bulk and nonbulk packaging.

Bulk Packaging. Any packaging, including transport vehicles, having a capacity meeting one of the criteria listed below. Bulk packaging can be either placed on or in a transport vehicle or vessel or constructed as an integral part of the transport vehicle.

(a) Liquid - internal volume of more than 119 gal (450 L)

(b) Solid - capacity of more than 882 lb (400 kg)

(c) Compressed gas - water capacity of more than 1,001 lb (454 kg)

Nonbulk Packaging. Any packaging having a capacity meeting one of the following criteria:

(a) Liquid - internal volume of 119 gal (450 L) or less

(b) Solid - capacity of 882 lb (400 kg) or less

(c) Compressed gas - water capacity of 1,001 lb (454 kg) or less

Penetration. The movement of a material through a suit's closures, such as zippers, buttonholes, seams, flaps, or other design features of chemical-protective clothing, and through punctures, cuts, and tears.

Permeation. A chemical action involving the movement of a chemical, on a molecular level, through intact material.

Personal Protective Equipment. The equipment provided to shield or isolate a person from the chemical, physical, and thermal hazards that can be encountered at a hazardous materials incident. Personal protective equipment includes both personal protective clothing and respiratory protection. Adequate personal protective equipment should protect the respiratory system, skin, eyes, face, hands, feet, head, body, and hearing.

Planned Response.* The plan of action, with safety considerations, consistent with the local emergency response plan and an organization's standard operating procedures for a specific hazardous materials incident.

Protective Clothing. Equipment designed to protect the wearer from heat and/or hazardous materials contacting the skin or eyes. Protective clothing is divided into three types:

(a) Structural fire-fighting protective clothing

(b) Chemical protective clothing

1. Liquid splash-protective clothing
2. Vapor-protective clothing

(c) High temperature-protective clothing

Qualified. Having satisfactorily completed the learning objectives.

Radioactive Material. Any material that spontaneously emits ionizing radiation.

Respiratory Protection. Equipment designed to protect the wearer from the inhalation of contaminants. Respiratory protection is divided into three types:

(a) Positive pressure self-contained breathing apparatus

(b) Positive pressure airline respirators

(c) Air purifying respirators

Response. That portion of incident management in which personnel are involved in controlling a hazardous materials incident. The activities in the response portion of a hazardous materials incident include analyzing the incident, planning the response, implementing the planned response, evaluating progress, and terminating the emergency phase of the incident.

Safely. To perform the assigned tasks without injury to self or others, to the environment, or to property.

Secondary Contamination. The process by which a contaminant is carried out of the hot zone and contaminates people, animals, the environment, or equipment.

SETIQ. The Emergency Transportation System for the Chemical Industry in Mexico.

Shall. Indicates a mandatory requirement.

Should. Indicates a recommendation or that which is advised but not required.

Stabilization. The point in an incident at which the adverse behavior of the hazardous material is controlled.

State. Any outlying U.S. areas where this standard is in effect. Use of the noun "state" shall also imply "provinces and territories" in Canada.

Structural Fire-Fighting Protective Clothing. Often called turnout or bunker gear, the protective clothing normally worn by fire fighters during structural fire-fighting operations. It includes a helmet, coat, pants, boots, gloves, PASS device, and a hood to cover parts of the head not protected by the helmet and facepiece. Structural fire fighters' protective clothing provides limited protection from heat but might not provide adequate protection from the harmful gases, vapors, liquids, or dusts that are encountered during hazardous materials incidents.

Termination. That portion of incident management in which personnel are involved in documenting safety procedures, site operations, hazards faced, and lessons learned from the incident. Termination is divided into three phases: debriefing the incident, post-incident analysis, and critiquing the incident.

UN/NA Identification Number. Four-digit numbers assigned to a hazardous material. The number is used to identify and cross-reference products in the transportation mode.

Vapor-Protective Clothing. The garment portion of a chemical-protective clothing ensemble that is designed and configured to protect the wearer against chemical vapors or gases. Vapor-protective clothing must meet the requirements of NFPA 1991, *Standard on Vapor-Protective Suits for Hazardous Chemical Emergencies.* This type of protective clothing is a component of EPA Level A chemical protection.

Warm Zone. The control zone at a hazardous materials incident site where personnel and equipment decontamination and hot zone support takes place. It includes control points for the decontamination corridor, thus helping to reduce the spread of contamination. This zone is also referred to as the decontamination zone or limited access zone in other documents.

Chapter 2 Competencies for the First Responder at the Awareness Level

2-1 General.

2-1.1 Introduction.

First responders at the awareness level shall be trained to meet all competencies of this chapter. They also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

2-1.2 Definition.

First responders at the awareness level are those persons who, in the course of their normal duties, could be the first on the scene of an emergency involving hazardous materials. First responders at the awareness level are expected to recognize the presence of hazardous materials, protect themselves, call for trained personnel, and secure the area.

2-1.3 Goal.

The goal of the competencies at the awareness level shall be to provide first responders with the knowledge and skills to perform the following tasks safely. Therefore, when first on the scene of an emergency involving hazardous materials, the first responder at the awareness level shall be able to:

(a) Analyze the incident to determine both the hazardous materials present and the basic hazard and response information for each hazardous material by completing the following tasks:

1. Detect the presence of hazardous materials

2. Survey a hazardous materials incident from a safe location to identify the name, UN/NA identification number, or type placard applied for any hazardous materials involved

3. Collect hazard information from the current edition of the *North American Emergency Response Guidebook*

(b) Implement actions consistent with the local emergency response plan, the organization's standard operating procedures, and the current edition of the *North American Emergency Response Guidebook* by completing the following tasks:

1. Initiate protective actions
2. Initiate the notification process

2-2 Competencies - Analyzing the Incident.

2-2.1 Detecting the Presence of Hazardous Materials.

Given various facility or transportation situations, or both, with and without hazardous materials present, the first responder at the awareness level shall identify those situations where hazardous materials are present. The first responder at the awareness level shall be able to:

2-2.1.1* Identify the definition of hazardous materials (or dangerous goods, in Canada).

2-2.1.2* Identify the DOT hazard classes and divisions of hazardous materials and identify common examples of materials in each hazard class or division.

2-2.1.3* Identify the primary hazards associated with each of the DOT hazard classes and divisions of hazardous materials by hazard class or division.

2-2.1.4 Identify the difference between hazardous materials incidents and other emergencies.

2-2.1.5 Identify typical occupancies and locations in the community where hazardous materials are manufactured, transported, stored, used, or disposed of.

2-2.1.6 Identify typical container shapes that can indicate hazardous materials.

2-2.1.7 Identify facility and transportation markings and colors that indicate hazardous materials, including the following:

(a) UN/NA identification numbers

(b) NFPA 704 markings

(c) Military hazardous materials markings

(d) Special hazard communication markings

(e) Pipeline markings

(f) Container markings

2-2.1.8 Given an NFPA 704 marking, describe the significance of the colors, numbers, and special symbols.

2-2.1.9 Identify U.S. and Canadian placards and labels that indicate hazardous materials.

2-2.1.10 Identify the basic information on material safety data sheets (MSDS) and shipping papers that indicates hazardous materials.

2-2.1.10.1 Identify where to find material safety data sheets (MSDS).

2-2.1.10.2 Identify entries on a material safety data sheet that indicate the presence of hazardous materials.

2-2.1.10.3 Identify the entries on shipping papers that indicate the presence of hazardous materials.

2-2.1.10.4 Match the name of the shipping papers found in transportation (air, highway, rail, and water) with the mode of transportation.

2-2.1.10.5 Identify the person responsible for having the shipping papers in each mode of transportation.

2-2.1.10.6 Identify where the shipping papers are found in each mode of transportation.

2-2.1.10.7 Identify where the papers can be found in an emergency in each mode of transportation.

2-2.1.11* Identify examples of clues (other than occupancy/location, container shape, markings/color, placards/labels, MSDS, and shipping papers) that use the senses of sight, sound, and odor to indicate hazardous materials.

2-2.1.12 Describe the limitations of using the senses in determining the presence or absence of hazardous materials.

2-2.2 Surveying the Hazardous Materials Incident from a Safe Location.

Given examples of facility and transportation situations involving hazardous materials, the first responder at the awareness level shall identify the hazardous material(s) in each situation by name, UN/NA identification number, or type placard applied. The first responder at the awareness level shall be able to:

2-2.2.1 Identify difficulties encountered in determining the specific names of hazardous materials in both facilities and transportation.

2-2.2.2 Identify sources for obtaining the names of, UN/NA identification numbers for, or types of placard associated with hazardous materials in transportation.

2-2.2.3 Identify sources for obtaining the names of hazardous materials in a facility.

2-2.3* Collecting Hazard Information.

Given the identity of various hazardous materials (name, UN/NA identification number, or type placard), the first responder at the awareness level shall identify the fire, explosion, and health hazard information for each material by using the current edition of the *North American Emergency Response Guidebook*. The first responder at the awareness level shall be able to:

2-2.3.1* Identify the three methods for determining the appropriate guide page for a hazardous material.

2-2.3.2 Identify the two general types of hazards found on each guide page.

2-3 Competencies - Planning the Response.

(No competencies currently required at this level.)

2-4 Competencies - Implementing the Planned Response.

2-4.1* Initiating Protective Actions.

Given examples of facility and transportation hazardous materials incidents, the local emergency response plan, the organization's standard operating procedures, and the current edition of the *North American Emergency Response Guidebook*, first responders at the awareness level shall be able to identify the actions to be taken to protect themselves and others and to control access to the scene. The first responder at the awareness level shall be able to:

2-4.1.1 Identify the location of both the local emergency response plan and the organization's standard operating procedures.

2-4.1.2 Identify the role of the first responder at the awareness level during a hazardous materials incident.

2-4.1.3 Identify the basic precautions to be taken to protect themselves and others in a hazardous materials incident.

2-4.1.3.1 Identify the precautions necessary when providing emergency medical care to victims of hazardous materials incidents.

2-4.1.3.2 Identify typical ignition sources found at the scenes of hazardous materials incidents.

2-4.1.3.3* Identify the ways hazardous materials are harmful to people, the environment, and property at hazardous materials incidents.

2-4.1.3.4* Identify the general routes of entry for human exposure to hazardous materials.

2-4.1.4* Given the identity of various hazardous materials (name, UN/NA identification number, or type placard), identify the following response information:

(a) Emergency action (fire, spill, or leak and first aid)

(b) Personal protective equipment necessary

(c) Initial isolation and protective action distances

2-4.1.4.1 Given the name of a hazardous material, identify the recommended personal protective equipment from the following list:

(a) Street clothing and work uniforms

(b) Structural fire-fighting protective clothing

(c) Positive pressure self-contained breathing apparatus

(d) Chemical-protective clothing and equipment

2-4.1.4.2 Identify the definitions for each of the following protective actions:

(a) Isolation of the hazard area and denial of entry

(b) Evacuation

(c)* Sheltering in-place protection

2-4.1.4.3 Identify the shapes of recommended initial isolation and protective action zones.

2-4.1.4.4 Describe the difference between small and large spills as found in the table of Initial Isolation and Protective Action Distances.

2-4.1.4.5 Identifying the circumstances under which the following distances are used at a hazardous materials incident:

(a) Table of initial isolation and protective action distances

(b) Isolation distances in the numbered guides

2-4.1.4.6 Describe the difference between the isolation distances in the orange-bordered guide pages and the protective action distances in the green-bordered pages in the document.

2-4.1.5 Identify the techniques used to isolate the hazard area and deny entry to unauthorized persons at hazardous materials incidents.

2-4.2 Initiating the Notification Process.

Given either a facility or transportation scenario involving hazardous materials, the first responder at the awareness level shall identify the appropriate initial notifications to be made and how to make them, consistent with the local emergency response plan or the organization's standard operating procedures.

2-5 Competencies - Evaluating Progress.

(No competencies currently required at this level.)

2-6 Competencies - Terminating the Incident.

(No competencies currently required at this level.)

Chapter 3 Competencies for the First Responder at the Operational Level

3-1 General.

3-1.1 Introduction.

First responders at the operational level shall be trained to meet all competencies at the first responder awareness levels and the competencies of this chapter. First responders at the operational level also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

3-1.2 Definition.

First responders at the operational level are those persons who respond to releases or potential releases of hazardous materials as part of the initial response to the incident for the purpose of protecting nearby persons, the environment, or property from the effects of the release. First responders at the operational level are expected to respond in a defensive fashion to control the release from a safe distance and keep it from spreading.

3-1.3 Goal.

The goal of the competencies at the operational level shall be to provide first responders with the knowledge and skills to perform the following tasks safely. Therefore, in addition to being competent at the awareness level, the first responder at the operational level shall be able to:

(a) Analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Survey the hazardous materials incident to identify the containers and materials involved, determine whether hazardous materials have been released, and evaluate the surrounding conditions

2. Collect hazard and response information from material safety data sheets (MSDS), CHEMTREC/CANUTEC/SETIQ, and shipper/manufacturer contacts

3. Predict the likely behavior of a material as well as its container

4. Estimate the potential harm at a hazardous materials incident

(b) Plan an initial response within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Describe the response objectives for hazardous materials incidents

2. Describe the defensive options available for a given response objective

3. Determine whether the personal protective equipment provided is appropriate for implementing each defensive option

4. Identify the emergency decontamination procedures

(c) Implement the planned response to favorably change the outcomes consistent with the local emergency response plan and the organization's standard operating procedures by completing the following tasks:

1. Establish and enforce scene control procedures including control zones, emergency decontamination, and communications

2. Initiate an incident management system (IMS) for hazardous materials incidents

3. Don, work in, and doff personal protective equipment provided by the authority having jurisdiction

4. Perform defensive control functions identified in the plan of action

(d) Evaluate the progress of the actions taken to ensure that the response objectives are being met safely, effectively, and efficiently by completing the following tasks:

1. Evaluate the status of the defensive actions taken in accomplishing the response objectives

2. Communicate the status of the planned response

3-2 Competencies - Analyzing the Incident.

3-2.1* Surveying the Hazardous Materials Incident.

Given examples of both facility and transportation scenarios involving hazardous materials, the first responder at the operational level shall survey the incident to identify the containers and materials involved, determine whether hazardous materials have been released, and evaluate the surrounding conditions. The first responder at the operational level shall be able to:

3-2.1.1* Given three (3) examples each of liquid, gas, and solid hazardous materials, identify the general shapes of containers in which the hazardous materials are typically found.

3-2.1.1.1 Given examples of the following tank cars, identify each tank car by type:

(a) Nonpressure tank cars with and without expansion domes

(b) Pressure tank cars

(c) Cryogenic liquid tank cars

3-2.1.1.2 Given examples of the following intermodal tank containers, identify each intermodal tank container by type:

(a) Nonpressure intermodal tank containers

(b) Pressure intermodal tank containers

3-2.1.1.3 Given examples of the following cargo tanks, identify each cargo tank by type:

(a) MC-306/DOT 406 cargo tanks

(b) MC-307/DOT-407 cargo tanks

(c) MC-312/DOT-412 cargo tanks

(d) MC-331 cargo tanks

(e) MC-338 cargo tanks

(f) Dry bulk cargo tanks

3-2.1.1.4 Given examples of the following facility tanks, identify each fixed facility tank by type:

(a) Nonpressure facility tanks

(b) Pressure facility tanks

(c) Cryogenic liquid tanks

3-2.1.1.5 Given examples of the following nonbulk packages, identify each package by type:

(a) Bags

(b) Carboys

(c) Cylinders

(d) Drums

3-2.1.2 Given examples of facility and transportation containers, identify the markings that differentiate one container from another.

3-2.1.2.1 Given examples of the following marked transport vehicles and their corresponding shipping papers, identify the vehicle or tank identification marking:

(a) Rail transport vehicles, including tank cars

(b) Intermodal equipment including tank containers

(c) Highway transport vehicles, including cargo tanks

3-2.1.2.2 Given examples of facility containers, identify the markings indicating container size, product contained, and/or site identification numbers.

3-2.1.3 Given examples of facility and transportation situations involving hazardous materials, identify the name(s) of the hazardous material(s) in each situation.

3-2.1.3.1 Identify the following information on a pipeline marker:

(a) Product

(b) Owner

(c) Emergency telephone number

3-2.1.3.2 Given a pesticide label, identify each of the following pieces of information; then match the piece of information to its significance in surveying the hazardous materials incident:

(a) Name of pesticide

(b) Signal word

(c) Pest control product (PCP) number (in Canada)

(d) Precautionary statement

(e) Hazard statement

(f) Active ingredient

3-2.1.4* Identify and list the surrounding conditions that should be noted by the first responders when surveying hazardous materials incidents.

3-2.1.5 Give examples of ways to verify information obtained from the survey of a hazardous materials incident.

3-2.2 Collecting Hazard and Response Information.

Given known hazardous materials, the first responder at the operational level shall collect hazard and response information using material safety data sheets (MSDS), CHEMTREC/CANUTEC/SETIQ, and contacts with the shipper/manufacturer. The first responder at the operational level shall be able to:

3-2.2.1 Match the definitions associated with the DOT hazard classes and divisions of hazardous materials, including refrigerated liquefied gases and cryogenic liquids, with the class or division.

3-2.2.2 Identify two ways to obtain a material safety data sheet (MSDS) in an emergency.

3-2.2.3 Using a material safety data sheet (MSDS) for a specified material, identify the following hazard and response information:

(a) Physical and chemical characteristics

(b) Physical hazards of the material

(c) Health hazards of the material

(d) Signs and symptoms of exposure

(e) Routes of entry

(f) Permissible exposure limits

(g) Responsible party contact

(h) Precautions for safe handling (including hygiene practices, protective measures, procedures for cleanup of spills or leaks)

(i) Applicable control measures including personal protective equipment

(j) Emergency and first aid procedures

3-2.2.4 Identify the following:

(a) Type of assistance provided by CHEMTREC/CANUTEC/SETIQ

(b) Procedure for contacting CHEMTREC/CANUTEC/SETIQ

(c) Information to be furnished to CHEMTREC/CANUTEC/SETIQ

3-2.2.5 Identify two methods of contacting the manufacturer or shipper to obtain hazard and response information.

3-2.3* Predicting the Behavior of a Material and its Container.

Given an incident involving a single hazardous material, the first responder at the operational level shall predict the likely behavior of the material and its container. The first responder at the operational level shall be able to:

3-2.3.1 Given two examples of scenarios involving known hazardous materials, interpret the hazard and response information obtained from the current edition of the *North American Emergency Response Guidebook*, material safety data sheets (MSDS), CHEMTREC/CANUTEC/SETIQ, and shipper/manufacturer contacts.

3-2.3.1.1 Match the following chemical and physical properties with their significance and impact on the behavior of the container and/or its contents:

(a) Boiling point

(b) Chemical reactivity

(c) Corrosivity (pH)

(d) Flammable (explosive) range (LEL & UEL)

(e) Flash point

(f) Ignition (autoignition) temperature

(g) Physical state (solid, liquid, gas)

(h) Specific gravity

(i) Toxic products of combustion

(j) Vapor density

(k) Vapor pressure

(l) Water solubility

3-2.3.1.2 Identify the differences among the following terms:

(a) Exposure and hazard

(b) Exposure and contamination

(c) Contamination and secondary contamination

3-2.3.2* Identify three types of stress that could cause a container system to release its contents.

3-2.3.3* Identify five ways in which containers can breach.

3-2.3.4* Identify four ways in which containers can release their contents.

3-2.3.5* Identify at least four dispersion patterns that can be created upon release of a hazardous material.

3-2.3.6* Identify the three general time frames for predicting the length of time that exposures can be in contact with hazardous materials in an endangered area.

3-2.3.7* Identify the health and physical hazards that could cause harm.

3-2.3.8* Identify the health hazards associated with the following terms:

(a) Asphyxiant

(b)* Chronic health hazard

(c) Convulsant

(d) Irritant/corrosive

(e) Sensitizer/allergen

3-2.4* Estimating the Potential Harm.

The first responder at the operational level shall estimate the potential harm within the endangered area at a hazardous materials incident. The first responder at the operational level shall be able to:

3-2.4.1* Identify a resource for determining the size of an endangered area of a hazardous materials incident.

3-2.4.2 Given the dimensions of the endangered area and the surrounding conditions at a hazardous materials incident, estimate the number and type of exposures within that endangered area.

3-2.4.3 Identify resources available for determining the concentrations of a released hazardous material within an endangered area.

3-2.4.4* Given the concentrations of the released material, identify the factors for determining the extent of physical, health, and safety hazards within the endangered area of a hazardous materials incident.

3-3 Competencies - Planning the Response.

3-3.1 Describing Response Objectives for Hazardous Materials Incidents.

Given at least two scenarios involving hazardous materials incidents (one facility and one transportation), the first responder at the operational level shall describe the first responder's response objectives for each problem. The first responder at the operational level shall be able to:

3-3.1.1 Given an analysis of a hazardous materials problem and the exposures already lost, identify the steps for determining the number of exposures that could be saved by the first responder with the resources provided by the authority having jurisdiction and operating in a defensive fashion.

3-3.1.2 Given an analysis of a hazardous materials incident, describe the steps for determining defensive response objectives.

3-3.2 Identifying Defensive Options.

Given simulated facility and transportation hazardous materials problems, the first responder at the operational level shall identify the defensive options for each response objective. The first responder at the operational level shall be able to:

3-3.2.1 Identify the defensive options to accomplish a given response objective.

3-3.2.2 Identify the purpose for, and the procedures, equipment, and safety precautions used with, each of the following control techniques:

(a) Absorption

(b) Dike, dam, diversion, retention

(c) Dilution

(d) Remote valve shutoff

(e) Vapor dispersion

(f) Vapor suppression

3-3.3 Determining Appropriateness of Personal Protective Equipment.

Given the name of the hazardous material involved and the anticipated type of exposure, the first responder at the operational level shall determine whether available personal protective equipment is appropriate for implementing a defensive option. The first responder at the operational level shall be able to:

3-3.3.1* Identify the appropriate respiratory protection required for a given defensive option.

3-3.3.1.1 Identify the three types of respiratory protection and the advantages and limitations presented by the use of each at hazardous materials incidents.

3-3.3.1.2 Identify the required physical capabilities and limitations of personnel working in positive pressure self-contained breathing apparatus.

3-3.3.2 Identify the appropriate personal protective clothing required for a given defensive option.

3-3.3.2.1 Identify skin contact hazards encountered at hazardous materials incidents.

3-3.3.2.2 Identify the purpose, advantages, and limitations of the following levels of protective clothing at hazardous materials incidents:

(a) Structural fire-fighting protective clothing

(b) High temperature-protective clothing

(c) Chemical-protective clothing

1. Liquid splash-protective clothing

2. Vapor-protective clothing

3-3.4* Identifying Emergency Decontamination Procedures.

The first responder at the operational level shall identify emergency decontamination procedures. The first responder at the operational level shall be able to:

3-3.4.1 Identify ways that personnel, personal protective equipment, apparatus, and tools and equipment become contaminated.

3-3.4.2 Describe how the potential for secondary contamination determines the need for emergency decontamination procedures.

3-3.4.3 Identify the purpose of emergency decontamination procedures at hazardous materials incidents.

3-3.4.4 Identify the advantages and limitations of emergency decontamination procedures.

3-4 Competencies - Implementing the Planned Response.

3-4.1 Establishing and Enforcing Scene Control Procedures.

Given scenarios for facility and/or transportation hazardous materials incidents, the first responder at the operational level shall identify how to establish and enforce scene control including control zones, emergency decontamination, and communications. The first responder at the operational level shall be able to:

3-4.1.1 Identify the procedures for establishing scene control through control zones.

3-4.1.2 Identify the criteria for determining the locations of the control zones at hazardous materials incidents.

3-4.1.3 Identify the basic techniques for the following protective actions at hazardous materials incidents:

(a) Evacuation

(b) Sheltering in-place protection

3-4.1.4 Identify the considerations associated with locating emergency decontamination areas.

3-4.1.5* Demonstrate the ability to perform emergency decontamination.

3-4.1.6* Identify the items to be considered in a safety briefing prior to allowing personnel to work on a hazardous materials incident.

3-4.2* Initiating the Incident Management System (IMS).

Given simulated facility and/or transportation hazardous materials incidents, the first responder at the operational level shall initiate the incident management system (IMS) specified in the local emergency response plan and the organization's standard operating procedures. The first responder at the operational level shall be able to:

3-4.2.1 Identify the role of the first responder at the operational level during hazardous materials incidents as specified in the local emergency response plan and the organization's standard operating procedures.

3-4.2.2 Identify the levels of hazardous materials incidents as defined in the local emergency response plan.

3-4.2.3 Identify the purpose, need, benefits, and elements of an incident management system (IMS) at hazardous materials incidents.

3-4.2.4 Identify the considerations for determining the location of the command post for a hazardous materials incident.

3-4.2.5 Identify the procedures for requesting additional resources at a hazardous materials incident.

3-4.2.6* Identify the authority and responsibilities of the safety officer.

3-4.3 Using Personal Protective Equipment.

The first responder at the operational level shall demonstrate the ability to don, work in, and doff the personal protective equipment provided by the authority having jurisdiction. The first responder at the operational level shall be able to:

3-4.3.1 Identify the importance of the buddy system in implementing the planned defensive options.

3-4.3.2 Identify the importance of the backup personnel in implementing the planned defensive options.

3-4.3.3 Identify the safety precautions to be observed when approaching and working at hazardous materials incidents.

3-4.3.4 Identify the symptoms of heat and cold stress.

3-4.3.5 Identify the physical capabilities required for, and the limitations of, personnel working in the personal protective equipment as provided by the authority having jurisdiction.

3-4.3.6 Match the function of the operational components of the positive pressure self-contained breathing apparatus provided to the hazardous materials responder with the name of the component.

3-4.3.7 Identify the procedures for cleaning, disinfecting, and inspecting respiratory protective equipment.

3-4.3.8 Identify the procedures for donning, working in, and doffing positive pressure self-contained breathing apparatus.

3-4.3.9 Demonstrate donning, working in, and doffing positive pressure self-contained breathing apparatus.

3-4.4 Performing Defensive Control Actions.

Given a plan of action for a hazardous materials incident within their capabilities, the first responder at the operational level shall demonstrate defensive control actions set out in the plan. The first responder at the operational level shall be able to:

3-4.4.1 Using the type of fire-fighting foam or vapor suppressing agent and foam equipment furnished by the authority having jurisdiction, demonstrate the proper application of the fire-fighting foam(s) or vapor suppressing agent(s) on a spill or fire involving hazardous materials.

3-4.4.2 Identify the characteristics and applicability of the following foams:

(a) Protein

(b) Fluoroprotein

(c) Special purpose

1. Polar solvent alcohol-resistant concentrates
2. Hazardous materials concentrates

(d) Aqueous film-forming foam (AFFF)

(e) High expansion

3-4.4.3 Given the appropriate tools and equipment, demonstrate how to perform the following defensive control activities:

(a) Absorption

(b) Damming

(c) Diking

(d) Dilution

(e) Diversion

(f) Retention

(g) Vapor dispersion

(h) Vapor suppression

3-4.4.4 Identify the location and describe the use of the mechanical, hydraulic, and air emergency remote shutoff devices as found on cargo tanks.

3-4.4.5 Describe the objectives and dangers of search and rescue missions at hazardous materials incidents.

3-5 Competencies - Evaluating Progress.

3-5.1 Evaluating the Status of Defensive Actions.

Given simulated facility and/or transportation hazardous materials incidents, the first responder at the operational level shall evaluate the status of the defensive actions taken in accomplishing the response objectives. The first responder at the operational level shall be able to:

3-5.1.1 Identify the considerations for evaluating whether defensive options are effective in accomplishing the objectives.

3-5.1.2 Describe the circumstances under which it would be prudent to withdraw from a hazardous materials incident.

3-5.2 Communicating the Status of the Planned Response.

The first responder at the operational level shall communicate the status of the planned response to the incident commander and other response personnel. The first responder at the operational level shall be able to:

3-5.2.1 Identify the methods for communicating the status of the planned response to the incident commander through the normal chain of command.

3-5.2.2 Identify the methods for immediate notification of the incident commander and other response personnel about critical emergency conditions at the incident.

3-6 Competencies - Terminating the Incident.

(No competencies currently required at this level.)

Chapter 4 Competencies for the Hazardous Materials Technician

4-1 General.

4-1.1 Introduction.

Hazardous materials technicians shall be trained to meet all competencies at the first responder awareness and operational levels and the competencies of this chapter. Hazardous materials technicians also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

4-1.2 Definition.

Hazardous materials technicians are those persons who respond to releases or potential releases of hazardous materials for the purpose of controlling the release. Hazardous materials technicians are expected to use specialized chemical protective clothing and specialized control equipment.

4-1.3* Goal.

The goal of this chapter shall be to provide the hazardous materials technician with the knowledge and skills to perform the following tasks safely. Therefore, in addition to being competent at both the first responder awareness and operational levels, the hazardous materials technician shall be able to:

(a) Analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Survey the hazardous materials incident to identify special containers involved, to identify or classify unknown materials, and to verify the presence and concentrations of hazardous materials through the use of monitoring equipment

2. Collect and interpret hazard and response information from printed resources, technical resources, computer data bases, and monitoring equipment

3. Determine the extent of damage to containers

4. Predict the likely behavior of released materials and their containers when multiple materials are involved

5. Estimate the size of an endangered area using computer modeling, monitoring equipment, or specialists in this field

(b) Plan a response within the capabilities of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the response objectives for hazardous materials incidents

2. Identify the potential action options available by response objective

3. Select the personal protective equipment required for a given action option

4. Select the appropriate decontamination procedures

5. Develop a plan of action, including safety considerations, consistent with the local emergency response plan and the organization's standard operating procedures, and within the capability of the available personnel, personal protective equipment, and control equipment

(c) Implement the planned response to favorably change the outcomes consistent with the organization's standard operating procedures and safety considerations by completing the following tasks:

1. Perform the duties of an assigned hazardous materials branch position within the local incident management system (IMS)

2. Don, work in, and doff appropriate personal protective clothing, including, but not limited to, both liquid splash- and vapor-protective clothing with appropriate respiratory protection

3. Perform the control functions identified in the plan of action

(d) Evaluate the progress of the planned response by evaluating the effectiveness of the control functions

(e) Terminate the incident by completing the following tasks:

1. Assist in the incident debriefing

2. Assist in the incident critique

3. Provide reports and documentation of the incident

4-2 Competencies - Analyzing the Incident.

4-2.1 Surveying the Hazardous Materials Incident.

The hazardous materials technician shall identify special containers involved and, given the appropriate equipment, identify or classify unknown materials, verify the identity of the hazardous materials, and determine the concentration of hazardous materials. The hazardous materials technician shall be able to:

4-2.1.1 Given examples of various specialized containers, identify each container by name and identify the material, and its hazard class, that is typically found in the container.

4-2.1.1.1 Given examples of the following railroad cars, identify each car by type and identify at least one material, and its hazard class, that is typically found in each car:

(a) Cryogenic liquid tank cars

(b) High-pressure tube cars

(c) Nonpressure tank cars

(d) Pneumatically unloaded hopper car

(e) Pressure tank cars

4-2.1.1.2 Given examples of the following intermodal tanks, identify each intermodal tank by type and identify at least one material, and its hazard class, that is typically found in each tank:

(a) Nonpressure intermodal tanks:

1. IM-101 (IMO Type 1 internationally) portable tank

2. IM-102 (IMO Type 2 internationally) portable tank

(b) Pressure intermodal tanks (DOT 51) (IMO Type 5 internationally)

(c) Specialized intermodal tanks:

1. Cryogenic intermodal tanks (IMO Type 7 internationally)

2. Tube modules

4-2.1.1.3 Given examples of the following cargo tanks, identify at least one material, and its hazard class, that is typically found in each tank:

(a) Dry bulk cargo tanks

(b) MC306/DOT-406 cargo tanks

(c) MC307/DOT-407 cargo tanks

(d) MC312/DOT-412 cargo tanks

(e) MC331 cargo tanks

(f) MC-338 cargo tanks

4-2.1.1.4 Given examples of the following facility tanks, identify at least one material, and its hazard class, that is typically found in each tank:

(a) Nonpressure tank

(b) Pressure tank

4-2.1.1.5 Given examples of the following nonbulk containers, identify at least one material, and its hazard class, that is typically found in each container:

(a) Bags

(b) Carboys

(c) Cylinders

(d) Drums

4-2.1.1.6 Given examples of the following radioactive materials packages, identify each package by type and identify at least one typical material found in each package:

(a) Type A

(b) Type B

4-2.1.2 Given three examples of facility and transportation containers, identify the approximate capacity of each container.

4-2.1.2.1 Using the markings on the container, identify the capacity (by weight and/or volume) of the following examples of transportation vehicles:

(a) Cargo tanks

(b) Tank cars

(c) Tank containers

4-2.1.2.2 Using the markings on the container and other available resources, identify the capacity (by weight and/or volume) of each of the following facility containers:

(a) Nonpressure tank

(b) Pressure tank

(c) Cryogenic liquid tank

4-2.1.3* Given at least three unknown materials, one of which is a solid, one a liquid, and one a gas, identify or classify by hazard each unknown material.

4-2.1.3.1 Identify the steps in an analysis process for identifying unknown solid and liquid materials.

4-2.1.3.2 Identify the steps in an analysis process for identifying an unknown atmosphere.

4-2.1.3.3 Identify the type(s) of monitoring equipment, test strips, and reagents used to determine the following hazards:

(a) Corrosivity (pH)

(b) Flammability

(c) Oxidation potential

(d) Oxygen deficiency

(e) Radioactivity

(f) Toxic levels

4-2.1.3.4* Identify the capabilities and limiting factors associated with the selection and use of the following monitoring equipment, test strips, and reagents:

(a) Carbon monoxide meter

(b) Colorimetric tubes

(c) Combustible gas indicator

(d) Oxygen meter

(e) Passive dosimeter

(f) Photoionization detectors

(g) pH indicators and/or pH meters

(h) Radiation detection instruments

(i) Reagents

(j) Test strips

4-2.1.3.5* Given three hazardous materials, one of which is a solid, one a liquid, and one a gas, and the following monitoring equipment, test strips, and reagents, select the appropriate equipment and demonstrate the proper techniques to identify and quantify the materials:

(a) Carbon monoxide meter

(b) Colorimetric tubes

(c) Combustible gas indicator

(d) Oxygen meter

(e) pH indicators and/or pH meters

(f) Radiation detection instruments

(g) Reagents

(h) Test strips

4-2.1.3.6 Demonstrate the field maintenance and testing procedures for the monitoring equipment, test strips, and reagents provided by the authority having jurisdiction.

4-2.1.4 Given a label for a radioactive material, identify vertical bars, contents, activity, and transport index, then describe the labeled item and its significance in surveying a radioactive materials incident.

4-2.2 Collecting and Interpreting Hazard and Response Information.

Given access to printed resources, technical resources, computer data bases, and monitoring equipment, the hazardous materials technician shall collect and interpret hazard and response information not available from the current edition of the *North American Emergency Response Guidebook* or a material safety data sheet (MSDS). The hazardous materials technician shall be able to:

4-2.2.1* Identify and interpret the types of hazard and response information available from each of the following resources and explain the advantages and disadvantages of each resource:

(a) Hazardous materials data bases

(b) Maps and diagrams

(c) Monitoring equipment

(d) Reference manuals

(e) Technical information centers (i.e., CHEMTREC/CANUTEC/SETIQ)

(f) Technical information specialists

4-2.2.2 Describe the following terms and explain their significance in the risk assessment process:

(a) Acid, caustic

(b) Air reactivity

(c) Boiling point

(d) Catalyst

(e) Chemical interactions

(f) Chemical reactivity

(g) Compound, mixture

(h) Concentration

(i) Corrosivity (pH)

(j) Critical temperatures and pressure

(k) Expansion ratio

(l) Flammable (explosive) range (LEL & UEL)

(m) Fire point

(n) Flash point

(o) Halogenated hydrocarbon

(p) Ignition (autoignition) temperature

(q) Inhibitor

(r) Instability

(s) Ionic & covalent compounds

(t) Maximum safe storage temperature (MSST)

(u) Melting point/freezing point

(v) Miscibility

(w) Organic and inorganic

(x) Oxidation potential

(y) pH

(z) Physical state (solid, liquid, gas)

(aa) Polymerization

(bb) Radioactivity

(cc) Saturated, unsaturated, and aromatic hydrocarbons

(dd) Self-accelerating decomposition temperature (SADT)

(ee) Solution, slurry

(ff) Specific gravity

(gg) Strength

(hh) Sublimation

(ii) Temperature of product

(jj) Toxic products of combustion

(kk) Vapor density

(ll) Vapor pressure

(mm) Viscosity

(nn) Volatility

(oo) Water reactivity

(pp) Water solubility

4-2.2.3 Describe the heat transfer processes that occur as a result of a cryogenic liquid spill.

4-2.2.4* Given five hazardous material scenarios and the appropriate reference materials, identify the signs and symptoms of exposure to each material and the target organ effects of exposure to that material.

4-2.2.5 Given the scenario of a domestic gas line break and the readings from a combustible gas indicator, determine the area of evacuation.

4-2.2.6 Identify two methods for determining the pressure in bulk packaging or facility containers.

4-2.2.7 Identify one method for determining the amount of lading remaining in damaged bulk packaging or facility containers.

4-2.3* Describing the Condition of the Container Involved in the Incident.

Given simulated facility and transportation container damage, the hazardous materials technician shall describe the damage. The hazardous materials technician shall be able to:

4-2.3.1* Given three examples of containers, DOT specification markings for nonbulk and bulk packaging, and the appropriate reference guide, identify the basic design and construction features of each container.

4-2.3.1.1 Identify the basic design and construction features, including closures, of the following bulk containers:

(a) Cargo tanks:

1. Dry bulk cargo tanks
2. MC-306/DOT-406 cargo tanks
3. MC-307/ DOT-407 cargo tanks
4. MC-312/DOT-412 cargo tanks
5. MC-331 cargo tanks
6. MC-338 cargo tanks

(b) Fixed facility tanks:

1. Nonpressure tank
2. Pressure tank

(c) Intermodal tanks:

1. Nonpressure intermodal tanks:

a. IM- 101 portable tank

b. IM-102 portable tank

2. Pressure intermodal tanks (specification 51)

3. Specialized intermodal tanks:

a. Cryogenic intermodal tanks

b. Tube modules

(d) One-ton containers

(e) Pipelines

(f) Railroad cars:

1. Cryogenic liquid tank cars
2. High-pressure tube cars
3. Nonpressure tank cars
4. Pneumatically unloaded hopper cars
5. Pressure tank cars

(g) Intermediate bulk containers (also known as tote tanks)

4-2.3.1.2 Identify the basic design and construction features including closures of the following nonbulk containers:

(a) Carboys

(b) Drums

(c) Pressurized cylinders

4-2.3.1.3 Identify the basic design and construction features of the following radioactive materials containers:

(a) Type A package

(b) Type B package

4-2.3.2 Describe how a liquid pipeline can carry different products.

4-2.3.3 Given an example of a pipeline, identify the following:

(a) Ownership of the line

(b) Procedures for checking for gas migration

(c) Procedure for shutting down the line or controlling the leak

(d) Type of product in the line

4-2.3.4* Identify the types of damage that a pressure container could incur.

4-2.3.5 Given examples of tank car damage, identify the type of damage in each example by name.

4-2.4 Predicting Likely Behavior of Materials and Their Containers When Multiple Materials are Involved.

Given examples of both facility and transportation incidents involving multiple hazardous materials, the hazardous materials technician shall predict the likely behavior of the material in each case. The hazardous materials technician shall be able to:

4-2.4.1 Identify at least three resources available that indicate the effects of mixing various hazardous materials.

4-2.4.2 Identify the impact of the following fire and safety features on the behavior of the products during an incident at a bulk storage facility and explain their significance in the risk assessment process:

(a) Fire protection systems

(b) Monitoring and detection systems

(c) Product spillage and control (impoundment and diking)

(d) Tank spacing

(e) Tank venting and flaring systems

(f) Transfer operations

4-2.5 Estimating the Likely Size of an Endangered Area.

Given various facility and transportation hazardous materials incidents, the hazardous materials technician shall estimate the likely size, shape, and concentrations associated with the release of materials involved in the incident by using computer modeling, monitoring equipment, or specialists in this field. The hazardous materials technician shall be able to:

4-2.5.1 Identify local resources for dispersion pattern prediction and modeling including computers, monitoring equipment, or specialists in the field.

4-2.5.2 Given the concentrations of the released material, identify the steps for determining the extent of the hazards (e.g., physical, safety, and health) within the endangered area of a hazardous materials incident.

4-2.5.2.1 Describe the following toxicological terms and exposure values and explain their significance in the risk assessment process:

(a) Parts per million (ppm)

(b) Parts per billion (ppb)

(c) Lethal dose (LD_{50})

(d) Lethal concentrations (LC_{50})

(e) Permissible exposure limit (PEL)

(f) Threshold limit value time-weighted average (TLV-TWA)

(g) Threshold limit value short-term exposure limit (TLV-STEL)

(h) Threshold limit value ceiling (TLV-C)

(i) Immediately dangerous to life and health value (IDLH)

4-2.5.2.2* Describe the following radiological terms and explain their significance in predicting the extent of health hazards and environmental impact in a hazardous materials incident:

(a) Types

(b) Measurement

(c) Protection

4-2.5.2.3 Identify two methods for predicting the areas of potential harm within the endangered area of a hazardous materials incident.

4-2.5.3* Identify a method for estimating the outcomes within an endangered area of a hazardous materials incident.

4-3 Competencies - Planning the Response.

4-3.1 Identifying Response Objectives.

Given simulated facility and transportation problems, the hazardous materials technician shall describe the response objectives for each problem. The hazardous materials technician shall be able to describe the steps for determining response objectives (defensive, offensive, nonintervention) given an analysis of a hazardous materials incident.

4-3.2 Identifying the Potential Action Options.

Given simulated facility and transportation hazardous materials incidents, the hazardous materials technician shall identify the possible action options (defensive, offensive, and nonintervention) by response objective for each problem. The hazardous materials technician shall be able to identify the possible action options to accomplish a given response objective.

4-3.3 Selecting Personal Protective Equipment.

Given situations with known and unknown hazardous materials, the hazardous materials technician shall determine the appropriate personal protective equipment for the action options specified in the plan of action in each situation. The hazardous materials technician shall be able to:

4-3.3.1 Identify the four levels of personal protective equipment (EPA/NIOSH or NFPA 471) and describe the equipment for each level and the condition under which each level is used.

4-3.3.2 Identify the factors to be considered in selecting the proper respiratory protection for a specified action option.

4-3.3.2.1 Describe the advantages, limitations, and proper use of the following types of respiratory protection at hazardous materials incidents:

(a) Positive pressure self-contained breathing apparatus

(b) Positive pressure air line respirators with required escape unit

(c) Air purifying respirators

4-3.3.2.2 Identify the process for selecting the proper respiratory protection at hazardous materials incidents.

4-3.3.2.3 Identify the operational components of air purifying respirators and air line respirators by name and describe their functions.

4-3.3.3 Identify the factors to be considered in selecting the proper chemical-protective clothing for a specified action option.

4-3.3.3.1 Describe the following terms and explain their impact and significance on the selection of chemical-protective clothing:

(a) Degradation

(b) Penetration

(c) Permeation

4-3.3.3.2 Identify at least three indications of material degradation of chemical-protective clothing.

4-3.3.3.3* Identify the three types of vapor-protective and splash-protective clothing and describe the advantages and disadvantages of each type.

4-3.3.3.4 Identify the relative advantages and disadvantages of the following heat exchange units used for the cooling of personnel in chemical-protective clothing:

(a) Air cooled

(b) Ice cooled

(c) Water cooled

4-3.3.3.5 Identify the process for selecting the proper protective clothing at hazardous materials incidents.

4-3.3.3.6 Given three examples of various hazardous materials, determine the appropriate protective clothing construction materials for a given action option using chemical compatibility charts.

4-3.3.3.7 Identify the physical and psychological stresses that can affect users of specialized protective clothing.

4-3.4 Developing Appropriate Decontamination Procedures.

Given a simulated hazardous materials incident, the hazardous materials technician shall select an appropriate decontamination procedure and determine the equipment required to implement that procedure. The hazardous materials technician shall be able to:

4-3.4.1 Identify the advantages and limitations and describe an example where each of the following decontamination methods would be used:

(a) Absorption

(b) Adsorption

(c) Chemical degradation

(d) Dilution

(e) Disposal

(f) Evaporation

(g) Neutralization

(h) Solidification

(i) Vacuuming

(j) Washing

4-3.4.2 Identify three sources of technical information for selecting appropriate decontamination procedures and identify how to contact those sources in an emergency.

4-3.5 Developing a Plan of Action.

Given simulated hazardous materials incidents in facility and transportation settings, the hazardous materials technician shall develop a plan of action, including safety considerations. The plan shall be consistent with the local emergency response plan and the organization's standard operating procedures and be within the capability of available personnel, personal protective equipment, and control equipment for that incident. The hazardous materials technician shall be able to:

4-3.5.1 Describe the purpose of, procedures for, equipment required, and safety precautions used with the following techniques for hazardous materials control:

(a) Adsorption

(b) Neutralization

(c) Overpacking

(d) Patching

(e) Plugging

4-3.5.2 Given MC-306/DOT-406, MC-307/DOT-407, MC-312/DOT-412, MC-331, and MC-338 cargo tanks, identify the common methods for product transfer from each type of cargo tank.

4-3.5.3 Given a simulated hazardous materials incident, develop the safety considerations that must be included in the plan of action.

4-3.5.3.1 List and describe the safety considerations to be included.

4-3.5.3.2 Identify the points that should be made in a safety briefing prior to working at the scene.

4-3.5.4* Identify the atmospheric and physical safety hazards associated with hazardous materials incidents involving confined spaces.

4-3.5.5 Identify the pre-entry activities to be performed.

4-4 Competencies - Implementing the Planned Response.

4-4.1 Performing Incident Management Duties.

Given the local emergency response plan or organization's standard operating procedures and a simulated hazardous materials incident, the hazardous materials technician shall demonstrate the duties of an assigned hazardous materials branch position within the local incident management system (IMS). The hazardous materials technician shall be able to:

4-4.1.1 Identify the role of the hazardous materials technician during an incident involving hazardous materials.

4-4.1.2 Identify the duties and responsibilities of the following hazardous materials branch functions within the incident management system:

(a) Backup

(b) Decontamination

(c) Entry

(d) Hazardous Materials Branch Management

(e) Hazardous Materials Branch Safety

(f) Information/research

(g) Reconnaissance

(h) Resources

4-4.1.3 Demonstrate setup of the decontamination corridor as specified in the planned response.

4-4.1.4 Demonstrate the decontamination process specified in the planned response.

4-4.2 Using Protective Clothing and Respiratory Protection.

The hazardous materials technician shall demonstrate the ability to don, work in, and doff both liquid splash- and vapor-protective chemical-protective clothing and any other specialized personal protective equipment provided by the authority having jurisdiction, including the appropriate respiratory protection. The hazardous materials technician shall be able to:

4-4.2.1 Describe three safety procedures for personnel wearing vapor-protective clothing.

4-4.2.2* Describe three emergency procedures for personnel wearing vapor-protective clothing.

4-4.2.3* Identify the procedures for donning, working in, and doffing the following types of respiratory protection:

(a) Air line respirator with required escape unit

(b) Air purifying respirator

4-4.2.4 Demonstrate donning, working in, and doffing chemical-protective clothing in addition to any other specialized protective equipment provided by the authority having jurisdiction.

4-4.2.5 Demonstrate the ability to record the use, repair, and testing of chemical-protective clothing according to manufacturer's specifications and recommendations.

4-4.2.6 Describe the maintenance, testing, inspection, and storage procedures for personal protective equipment provided by the authority having jurisdiction according to the manufacturer's specifications and recommendations.

4-4.3 Performing Control Functions Identified in Plan of Action.

Given various simulated hazardous materials incidents involving nonbulk and bulk packaging and facility containers, the hazardous materials technician shall select the tools, equipment, and materials for the control of hazardous materials incidents and identify the precautions for controlling releases from those packaging/containers. The hazardous materials technician shall be able to:

4-4.3.1* Given a pressure vessel, select the appropriate material or equipment and demonstrate a method(s) to contain leaks from the following locations:

(a) Fusible metal of plug

(b) Fusible plug threads

(c) Side wall of cylinder

(d) Valve blowout

(e) Valve gland

(f) Valve inlet threads

(g) Valve seat

(h) Valve stem assembly blowout

4-4.3.2* Given the fittings on a pressure container, demonstrate the ability to perform the following:

(a) Close valves that are open

(b) Replace missing plugs

(c) Tighten loose plugs

4-4.3.3 Given a 55-gal (208-L) drum, demonstrate the ability to contain the following types of leaks using appropriate tools and materials:

(a) Bung leak

(b) Chime leak

(c) Forklift puncture

(d) Nail puncture

4-4.3.4 Given a 55-gal (208-L) drum and an overpack drum, demonstrate the ability to place the 55-gal drum into the overpack drum using the following methods:

(a) Rolling slide-in

(b) Slide-in

(c) Slip-over

4-4.3.5 Identify the maintenance and inspection procedures for the tools and equipment provided for the control of hazardous materials releases according to the manufacturer's specifications and recommendations.

4-4.3.6 Identify three considerations for assessing a leak or spill inside a confined space without entering the area.

4-4.3.7* Identify three safety considerations for product transfer operations.

4-4.3.8 Given an MC-306/DOT-406 cargo tank and a dome cover clamp, demonstrate the ability to install the clamp on the dome properly.

4-4.3.9 Identify the methods and precautions used when controlling a fire involving an MC-306/DOT-406 aluminum shell cargo tank.

4-4.3.10 Describe at least one method for containing each of the following types of leaks in MC-306/DOT-406, MC-307/DOT-407, and MC-312/DOT- 412 cargo tanks:

(a) Dome cover leak

(b) Irregular-shaped hole

(c) Puncture

(d) Split or tear

4-4.3.11* Describe three product removal and transfer considerations for overturned MC-306/DOT-406, MC-307/DOT-407, MC-312/DOT-412, MC-331, and MC-338 cargo tanks.

4-5 Competencies -- Evaluating Progress.

4-5.1 Evaluating the Effectiveness of the Control Functions.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging and the plan of action, the hazardous materials technician shall evaluate the effectiveness of any control functions identified in the plan of action.

4-6 Competencies -- Terminating the Incident.

4-6.1 Assisting in the Debriefing.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials technician shall participate in the debriefing of the incident. The hazardous materials technician shall be able to:

4-6.1.1 Describe three components of an effective debriefing.

4-6.1.2 Describe the key topics of an effective debriefing.

4-6.1.3 Describe when a debriefing should take place.

4-6.1.4 Describe who should be involved in a debriefing.

4-6.2 Assisting in the Incident Critique.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials technician shall provide operational observations of the activities that were performed in the hot and warm zones during the incident. The hazardous materials technician shall be able to:

4-6.2.1 Describe three components of an effective critique.

4-6.2.2 Describe who should be involved in a critique.

4-6.2.3 Describe why an effective critique is necessary after a hazardous materials incident.

4-6.2.4 Describe which written documents should be prepared as a result of the critique.

4-6.3 Providing Reports and Documentation.

Given a simulated hazardous materials incident, the hazardous materials technician shall complete the reporting and documentation requirements consistent with the organization's emergency response plan and standard operating procedures. The hazardous materials technician shall be able to:

4-6.3.1 Identify the reports and supporting documentation required by the local emergency response plan and the organization's standard operating procedures.

4-6.3.2 Demonstrate the proper completion of the reports required by the local emergency response plan and the organization's standard operating procedures.

4-6.3.3 Describe the importance of personnel exposure records.

4-6.3.4 Describe the importance of debriefing records.

4-6.3.5 Describe the importance of critique records.

4-6.3.6 Identify the steps in keeping an activity log and exposure records.

4-6.3.7 Identify the steps to be taken in compiling incident reports that meet federal, state, local, and organizational requirements.

4-6.3.8 Identify the requirements for compiling hot zone entry and exit logs.

4-6.3.9 Identify the requirements for compiling personal protective equipment logs.

4-6.3.10 Identify the requirements for filing documents and maintaining records.

Chapter 5 Competencies for the Incident Commander

5-1 General.

5-1.1 Introduction.

The incident commander shall be trained to meet all the competencies for the first responder awareness and operational levels and the competencies of this chapter. Incident commanders also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

5-1.2 Definition.

The incident commander is that person who is responsible for all decisions relating to the management of the incident. The incident commander is in charge of the incident site.

5-1.3* Goal.

The goal of this chapter shall be to provide the incident commander with the knowledge and skills to perform the following tasks safely. Therefore, in addition to being competent at the awareness and operational levels, the incident commander shall be able to:

(a) Analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Collect and interpret hazard and response information from printed resources, technical resources, computer data bases, and monitoring equipment

2. Estimate the potential outcomes within the endangered area at a hazardous materials incident

(b) Plan response operations within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the response objectives for hazardous materials incidents

2. Identify the potential action options (defensive, offensive, and nonintervention) available by response objective

3. Approve the level of personal protective equipment required for a given action option

4. Develop a plan of action, including safety considerations, consistent with the local emergency response plan and the organization's standard operating procedures and within the capability of available personnel, personal protective equipment, and control equipment

(c) Implement a response to favorably change the outcome consistent with the local emergency response plan and the organization's standard operating procedures by completing the following tasks:

1. Implement an incident management system (IMS), including the specified procedures for notification and utilization of nonlocal resources, e.g., private, state, and federal government personnel

2. Direct resources (private, governmental, and others) with expected task assignments and on-scene activities and provide management overview, technical review, and logistical support to private and governmental sector personnel

3. Provide a focal point for information transfer to media and local elected officials through the IMS structure

(d) Evaluate the progress of the planned response to ensure the response objectives are being met safely, effectively, and efficiently and adjust the plan of action accordingly by evaluating the effectiveness of the control functions

(e) Terminate the incident by completing the following tasks:

1. Transfer command (control) when appropriate

2. Conduct an incident debriefing

3. Conduct a multi-agency critique

4. Report and document the hazardous materials incident and submit the report to the proper entity

5-2 Competencies - Analyzing the Incident.

5-2.1 Collecting and Interpreting Hazard and Response Information.

Given access to printed and technical resources, computer data bases, and monitoring equipment, the incident commander shall collect and interpret hazard and response information not available from the current edition of the *North American Emergency Response Guidebook* or a material safety data sheet (MSDS). The incident commander shall be able to identify and interpret the types of hazard and response information available from each of the following resources and explain the advantages and disadvantages of each resource:

(a) Reference manuals

(b) Hazardous materials data bases

(c) Technical information centers

(d) Technical information specialists

(e) Monitoring equipment

5-2.2 Estimating Potential Outcomes.

Given simulated facility or transportation incidents involving hazardous materials, the surrounding conditions, and the predicted behavior of the container and its contents, the incident commander shall estimate the potential outcomes within the endangered area. The incident commander shall be able to:

5-2.2.1 Identify the steps for estimating the number of exposures within the endangered area.

5-2.2.2 Describe the following toxicological terms and exposure values and explain their significance in the risk assessment process:

(a) Parts per million (ppm)

(b) Parts per billion (ppb)

(c) Lethal dose (LD_{50})

(d) Lethal concentrations (LC_{50})

(e) Permissible exposure limit (PEL)

(f) Threshold limit value time-weighted average (TLV-TWA)

(g) Threshold limit value short-term exposure limit (TLV-STEL)

(h) Threshold limit value ceiling (TLV-C)

(i) Immediately dangerous to life and health value (IDLH)

5-2.2.3* Describe the following radiological materials terms and explain their significance in predicting the extent of health hazards and environmental impact in a hazardous materials incident:

(a) Types

(b) Measurement

(c) Protection

5-2.2.4 Identify two methods for predicting the areas of potential harm within the endangered area of a hazardous materials incident.

5-2.2.5 Identify the methods available to the organization for obtaining local weather conditions and predictions for short-term future weather changes.

5-2.2.6 Explain the basic toxicological principles relative to assessment and treatment of personnel exposed to hazardous materials, including the following:

(a) Acute and delayed toxicity (chronic)

(b) Routes of exposure to toxic materials

(c) Local and systemic effects

(d) Dose response

(e) Synergistic effects

5-3 Competencies - Planning the Response.

5-3.1 Identifying Response Objectives.

Given simulated facility and transportation hazardous materials incidents, the incident commander shall identify the possible action options (defensive, offensive, and nonintervention) by response objectives for each problem. The incident commander shall be able to describe the steps for determining response objectives (defensive, offensive, and nonintervention) given an analysis of a hazardous materials incident.

5-3.2 Identifying the Potential Action Options.

Given simulated facility and transportation hazardous materials incidents, the incident commander shall identify the possible action options (defensive, offensive, and non-intervention) by response objective for each problem. The incident commander shall be able to:

5-3.2.1

Identify the possible action options to accomplish a given response objective.

5-3.2.2 Identify the purpose of each of the following techniques for hazardous materials control:

(a) Adsorption

(b) Neutralization

(c) Overpacking

(d) Patching

(e) Plugging

5-3.3 Approving the Level of Personal Protective Equipment.

Given situations with known and unknown hazardous materials, the incident commander shall approve the appropriate personal protective equipment for the action options specified in the plan of action in each situation. The incident commander shall be able to:

5-3.3.1 Identify the four levels of chemical protection (EPA/NIOSH) and describe the equipment required for each level with the conditions under which each level is used.

5-3.3.2 Describe the following terms and explain their impact and significance on the selection of chemical- protective clothing:

(a) Degradation

(b) Penetration

(c) Permeation

5-3.3.3 Describe three safety considerations for personnel wearing vapor-protective, liquid splash-protective, and high temperature-protective clothing.

5-3.3.4 Identify the physical and psychological stresses that can affect users of personal protective equipment.

5-3.4 Developing a Plan of Action.

Given simulated facility and transportation hazardous materials incidents, the incident commander shall develop a plan of action consistent with the local emergency response plan and the organization's standard operating procedures that is within the capability of the available personnel, personal protective equipment, and control equipment. The incident commander shall be able to:

5-3.4.1 Identify the steps for developing a plan of action.

5-3.4.2 Identify the factors to be evaluated in selecting public protective actions including evacuation and sheltering in-place.

5-3.4.3 Given the local emergency response plan and/or the organization's standard operating procedures, identify which agency will perform the following:

(a) Receive the initial notification

(b) Provide secondary notification and activation of response agencies

(c) Make ongoing assessments of the situation

(d) Command on-scene personnel (incident management system)

(e) Coordinate support and mutual aid

(f) Provide law enforcement and on-scene security (crowd control)

(g) Provide traffic control and rerouting

(h) Provide resources for public safety protective action (evacuation or shelter in-place)

(i) Provide fire suppression services when appropriate

(j) Provide on-scene medical assistance (ambulance) and medical treatment (hospital)

(k) Provide public notification (warning)

(l) Provide public information (news media statements)

(m) Provide on-scene communications support

(n) Provide emergency on-scene decontamination when appropriate

(o) Provide operational-level hazard control services

(p) Provide technician-level hazard mitigation services

(q) Provide environmental remedial action ("cleanup") services

(r) Provide environmental monitoring

5-3.4.4 Identify the process for determining the effectiveness of an action option on the potential outcomes.

5-3.4.5 Identify the safe operating practices/procedures that are required to be followed at a hazardous materials incident.

5-3.4.5.1 Identify the importance of pre-incident planning relating to safety during responses to specific sites.

5-3.4.5.2 Identify the procedures for presenting a safety briefing prior to allowing personnel to work on a hazardous materials incident.

5-3.4.5.3* Identify at least three safety precautions associated with search and rescue missions at hazardous materials incidents.

5-3.4.5.4 Identify the advantages and limitations and describe an example where each of the following decontamination methods would be used:

(a) Absorption

(b) Adsorption

(c) Chemical degradation

(d) Dilution

(e) Disposal

(f) Evaporation

(g) Neutralization

(h) Solidification

(i) Vacuuming

(j) Washing

5-3.4.5.5* Identify the atmospheric and physical safety hazards associated with hazardous materials incidents involving confined spaces.

5-4 Competencies - Implementing the Planned Response.

5-4.1 Implementing the Incident Management System.

Given a copy of the local emergency response plan, the incident commander shall identify the requirements of the plan, including the required procedures for notification and utilization of nonlocal resources (private, state, and federal government personnel). The incident commander shall be able to:

5-4.1.1 Identify the role of the incident commander during an incident involving hazardous materials.

5-4.1.2 Identify the duties and responsibilities of the following hazardous materials branch functions within the incident management system:

(a) Backup

(b) Decontamination

(c) Entry

(d) Hazardous Materials Branch Management

(e) Hazardous Materials Branch Safety

(f) Information/research

(g) Reconnaissance

(h) Resources

5-4.1.3 Identify the steps for implementing the local and related emergency response plans as required under SARA Title III (EPCRA) Section 303 of the federal regulations or other state and local emergency response planning legislation.

5-4.1.4 Given the local emergency response planning documents, identify the elements of each of the documents.

5-4.1.5 Identify the elements of the incident management system necessary to coordinate response activities at hazardous materials incidents.

5-4.1.6 Identify the primary local, state, regional, and federal government agencies and identify the scope of their regulatory authority (including the regulations) pertaining to the production, transportation, storage, and use of hazardous materials and the disposal of hazardous wastes.

5-4.1.7 Identify the government agencies and private sector resources offering assistance during a hazardous materials incident and identify their role and the type of assistance or resources available.

5-4.2* Directing Resources (Private and Governmental).

Given a simulated hazardous materials incident and the necessary resources to implement the planned response, the incident commander shall demonstrate the ability to direct the resources in a safe and efficient manner consistent with the capabilities of those resources.

5-4.3 Providing a Focal Point for Information Transfer to Media and Elected Officials.

Given a simulated hazardous materials incident, the incident commander shall identify appropriate information to provide to the media and local, state, and federal officials. The incident commander shall be able to:

5-4.3.1 Identify the local policy for providing information to the media.

5-4.3.2 Identify the responsibilities of the public information officer at a hazardous materials incident.

5-5 Competencies - Evaluating Progress.

5-5.1 Evaluating Progress of the Plan of Action.

Given simulated facility and transportation hazardous materials incidents, the incident commander shall evaluate the progress of the plan of action to determine whether the efforts are accomplishing the response objectives. The incident commander shall be able to:

5-5.1.1 Identify the procedures for evaluating whether the action options are effective in accomplishing the objectives.

5-5.1.2 Identify the steps for comparing actual behavior of the material and the container to that predicted in the analysis process.

5-5.1.3 Determine the effectiveness of the following:

(a) Personnel being used

(b) Personal protective equipment

(c) Established control zones

(d) Decontamination process

5-6 Competencies - Terminating the Incident.

5-6.1 Transfering Command/Control.

Given the details of a simulated incident, the local emergency response plan, and the organization's standard operating procedures, the incident commander shall be able to:

5-6.1.1*

Identify the appropriate steps to be taken to transfer command/control of the incident.

5-6.1.2 Demonstrate the transfer of command/control.

5-6.2 Conducting a Debriefing.

Given the details of a simulated hazardous materials incident, the incident commander shall conduct a debriefing of the incident. The incident commander shall be able to:

5-6.2.1 Describe three components of an effective debriefing.

5-6.2.2 Describe the key topics in an effective debriefing.

5-6.2.3 Describe when a debriefing should take place.

5-6.2.4 Describe who should be involved in a debriefing.

5-6.2.5 Identify the procedures for conducting incident debriefings at a hazardous materials incident.

5-6.3 Conducting a Multi-Agency Critique.

Given details of a simulated multi-agency hazardous materials incident, the incident commander shall conduct a critique of the incident. The incident commander shall be able to:

5-6.3.1 Describe three components of an effective critique.

5-6.3.2 Describe who should be involved in a critique.

5-6.3.3 Describe why an effective critique is necessary after a hazardous materials incident.

5-6.3.4 Describe what written documents should be prepared as a result of the critique.

5-6.3.5 Implement the procedure for conducting a critique of the incident.

5-6.4 Reporting and Documenting the Hazardous Materials Incident.

Given a simulated hazardous materials incident, the incident commander shall demonstrate the ability to report and document the incident consistent with the local, state, and federal requirements. The incident commander shall be able to:

5-6.4.1 Identify the reporting requirements of the federal, state, and local agencies.

5-6.4.2 Identify the importance of documentation for a hazardous materials incident, including training records, exposure records, incident reports, and critique reports.

5-6.4.3 Identify the steps in keeping an activity log and exposure records for hazardous materials incidents.

5-6.4.4 Identify the requirements for compiling hazardous materials incident reports found in the local emergency response plan and the organization's standard operating procedures.

5-6.4.5 Identify the requirements for filing documents and maintaining records found in the local emergency response plan and the organization's standard operating procedures.

Chapter 6 Competencies for Private Sector Specialist Employees

6-1 General.

6-1.1 Introduction.

Private sector specialist employees are those persons who, in the course of their regular job duties, work with or are trained in the hazards of specific chemicals or containers within their organization's area of specialization. In response to emergencies involving hazardous materials in their organization's area of specialization, they could be called upon to provide technical advice or assistance to the incident commander relative to specific chemicals or containers for chemicals. Private sector specialist employees shall receive training or demonstrate competency in their area of specialization annually. Private sector specialist employees also shall receive any additional training to meet applicable United States Department of Transportation (DOT), Occupational Safety and Health Administration (OSHA), United States Environmental Protection Agency (EPA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

Private sector specialist employees respond to hazardous materials incidents under different circumstances. They respond to incidents within their facility, in and outside their assigned work area, and outside their facility. Persons responding away from the facility or within the facility outside their assigned work area respond as a member of a hazardous materials response team or as a private sector specialist employee as outlined in this chapter. When responding to incidents away from their assigned work area, private sector specialist employees shall be permitted to perform only at the response level at which they have been trained.

Persons responding to a hazardous materials incident within their work area are not required to be trained to the levels specified by this chapter. Persons within their work area who have informed the incident management structure of an emergency as defined in the facility's emergency response plan; who have adequate personal protective equipment and adequate training in the procedures they are to perform; and who have employed the buddy system can take limited action in the danger area (e.g., turning a valve) before the emergency response team arrives. The limited action taken must be addressed in the emergency response plan. Once the emergency response team arrives, these persons shall be restricted to the actions that their training level allows and must operate under the incident command structure.

6-1.2 Scope.

This chapter will address competencies for the following private sector specialist employees:

(a) Private sector specialist employee C

(b) Private sector specialist employee B

(c) Private sector specialist employee A

6-2 Private Sector Specialist Employee C.

6-2.1 General.

6-2.1.1 Introduction. The private sector specialist employee C shall meet the competencies at the first responder awareness level (Chapter 2) relative to their organization's area of specialization and the additional competencies in Section 6-2 of this chapter.

6-2.1.2 Definition. The private sector specialist employee C is that person who responds to emergencies involving chemicals and/or containers within his or her organization's area of specialization. Consistent with the organization's emergency response plan and standard operating procedures, the private sector specialist employees C can be called upon to gather and record information, provide technical advice, and/or arrange for technical assistance. A private sector specialist employee C does not enter the hot or warm zone at an emergency.

6-2.1.3 Goal. The private sector specialist employee C shall be competent at the first responder awareness level relative to their organization's area of specialization. The private sector specialist employee C shall have the knowledge and skills to perform the following duties and tasks safely:

(a) Assist the incident commander in analyzing the magnitude of an emergency involving chemicals or containers for chemicals by completing the following tasks:

1. Provide information on the hazards and harmful effects of specific chemicals

2. Provide information on the characteristics of specific containers for chemicals

(b) Assist the incident commander in planning a response to an emergency involving chemicals or containers for chemicals by completing the following tasks:

1. Provide information on the potential response options for chemicals or containers for chemicals

6-2.2 Competencies - Analyzing the Incident.

6-2.2.1 Providing Information on the Hazards and Harmful Effects of Specific Chemicals. Given a specific chemical(s) used in his or her organization's area of specialization and the appropriate material safety data sheet (MSDS) or other appropriate resource, the private sector specialist employee C shall advise the incident commander of the chemical's hazards and harmful effects. The private sector specialist employee C shall be able to:

6-2.2.1.1 Identify the following hazard information from the material safety data sheet (MSDS) or other appropriate resource:

(a) Physical and chemical characteristics

(b) Physical hazards of the chemical (including fire and explosion hazards)

(c) Health hazards of the chemical

(d) Signs and symptoms of exposure

(e) Routes of entry

(f) Permissible exposure limits

(g) Reactivity hazards

(h) Environmental concerns

6-2.2.1.2 Identify how to contact CHEMTREC/CANUTEC/SETIQ.

6-2.2.1.3 Identify the resources available from CHEMTREC/CANUTEC/SETIQ.

6-2.2.1.4 Given their organization's emergency response plan and standard operating procedures, identify additional resources of hazard information, including a method of contact.

6-2.2.2 Providing Information on Characteristics of Specific Containers. Given examples of facility and transportation containers for chemicals in their organization's area of specialization, the private sector specialist employee C shall advise the incident commander of the characteristics of the containers. The private sector specialist employee C shall be able to:

6-2.2.2.1 Identify each container by name.

6-2.2.2.2 Identify the markings that differentiate one container from another.

6-2.2.2.3 Given their organization's emergency response plan and standard operating procedures, identify the resources available that can provide information about the characteristics of the container.

6-2.3 Competencies - Planning the Response.

6-2.3.1 Providing Information on Potential Response Options for Specific Chemicals. Given a specific chemical used in their organization's area of specialization and an appropriate material safety data sheet (MSDS) or other appropriate resource, the private sector specialist employee C shall advise the incident commander of the response information for that chemical by being able to:

6-2.3.1.1 Obtain the following response information:

(a) Precautions for safe handling, including hygiene practices, protective measures, and procedures for cleanup of spills/leaks

(b) Applicable control measures, including personal protective equipment

(c) Emergency and first aid procedures

6-2.3.1.2 Identify additional resources for obtaining response information.

6-3 Private Sector Specialist Employee B.

6-3.1 General.

6-3.1.1 Introduction. The private sector specialist employee B shall be trained to meet the competencies at the private sector specialist employee C level and the additional competencies in Section 6-3 of this chapter.

6-3.1.2* Definition. The level B private sector specialist employee is that person who, in the course of their regular job duties, works with or is trained in the hazards of specific chemicals or containers within their individual area of specialization. Because of their education, training, or work experience, the private sector specialist employee B can be called upon to respond to incidents involving these chemicals or containers. The private sector specialist employee B can be used to gather and record information, provide technical advice, and provide technical assistance (including work within the hot zone) at the incident consistent with their organization's emergency response plan and standard operating procedures and the local emergency response plan.

6-3.1.3* Goal. The goal of these competencies is to ensure that the private sector specialist employee B has the knowledge and skills to safely perform the duties and responsibilities assigned in their organization's emergency response plan and standard operating procedures. Therefore, within their individual area of specialization, the private sector specialist employee B shall be able to:

(a) Assist the incident commander in analyzing the magnitude of an incident involving chemicals or containers for chemicals by completing the following tasks:

1. Provide and interpret information on the hazards and harmful effects

2. Provide and interpret information on the characteristics of specific containers

3. Provide information on concentrations of chemicals from exposure monitoring, dispersion modeling, or any other predictive method

(b) Assist the incident commander in planning a response to an incident involving chemicals or containers for chemicals by completing the following tasks:

1. Provide information on the potential response options and their consequences for specific chemicals or containers for chemicals

2. Provide information on the personal protective equipment requirements for a specific chemical

3. Provide information on the decontamination methods for a specific chemical

4. Provide information on the federal/provincial regulations that relate to the handling and disposal of a specific chemical

5. Develop a plan of action (within the capabilities of the available resources), including safety considerations, for handling chemicals or containers for chemicals consistent with their organization's emergency response plan and standard operating procedures

(c) Implement the planned response, as developed with the incident commander, for chemicals or containers for chemicals, consistent with their organization's emergency response plan and standard operating procedures and within the capabilities of the available resources, by completing the following tasks:

1. Perform response options specified in the plan of action, as agreed upon with the incident commander and consistent with their organization's emergency response plan and standard operating procedures (within the capabilities of the available resources)

2. Don, work in, and doff personal protective equipment needed to implement the response options

(d) Assist the incident commander to evaluate the results of implementing the planned response by completing the following tasks:

1. Provide feedback on the effectiveness of the response options taken

2. Provide reporting and subsequent documentation of the incident involving chemicals as required

6-3.2 Competencies - Analyzing the Incident.

6-3.2.1 Providing and Interpreting Information on Hazards of Specific Chemicals. Given a specific chemical within their individual area of specialization and an appropriate material safety data sheet (MSDS) or other appropriate resource, the private sector specialist employee B shall advise the incident commander of the chemical's hazards and harmful effects and the potential consequences based on the incident. The private sector specialist employee B shall be able to:

6-3.2.1.1 Given a specific chemical, identify and interpret the following hazard information:

(a) Physical and chemical characteristics

(b) Physical hazards of the chemical (including fire and explosion hazards)

(c) Health hazards of the chemical

(d) Signs and symptoms of exposure

(e) Routes of entry

(f) Permissible exposure limits

(g) Reactivity hazards

(h) Environmental concerns

6-3.2.1.2 Given examples of specific chemicals and the appropriate resources (as identified in their organization's emergency response plan and standard operating procedures), predict the potential behavior of the chemicals based on the damage found, including the consequences of that behavior.

6-3.2.1.3 Identify the general types of hazard information available from the other resources identified in their organization's emergency response plan and standard operating procedures.

6-3.2.2 Providing Information on Characteristics of Specific Containers. Given a container for specific chemicals, the private sector specialist employee B shall advise the incident commander of the characteristics and potential behavior of that container. The private sector specialist employee B shall be able to:

6-3.2.2.1 Given examples of containers for specific chemicals, identify the purpose and operation of the closures found on those containers.

6-3.2.2.2 Given a chemical container, list the types of damage that could occur.

6-3.2.2.3 Given examples of containers for specific chemicals and the appropriate resources (as identified in their organization's emergency response plan and standard operating procedures), predict the potential behavior of the containers and the consequences, based on the damage found.

6-3.2.2.4 Given their organization's emergency response plan and standard operating procedures, identify resources (including a method of contact) knowledgeable in the design, construction, and damage assessment of containers for chemicals.

6-3.2.3 Providing Information on Concentrations of Chemicals. Given a chemical and the applicable monitoring equipment provided by their organization for that chemical or the available predictive capabilities (e.g., dispersion modeling, exposure modeling), the private sector specialist employee B shall advise the incident commander of the concentrations of the released chemical and the implications of that information to the incident. The private sector specialist employee B shall be able to:

6-3.2.3.1 Identify the appropriate monitoring equipment.

6-3.2.3.2 Use the appropriate monitoring equipment provided by their organization to determine the actual concentrations of a specific chemical.

6-3.2.3.3 Given information on the concentrations of a chemical, interpret the significance of that concentration information to the incident relative to the hazards and harmful effects of the chemical.

6-3.2.3.4 Demonstrate field calibration and testing procedures, as necessary, for the monitoring equipment provided by their organization.

6-3.2.3.5 Given their organization's emergency response plan and standard operating procedures, identify the resources (including a method of contact) capable of providing monitoring equipment, dispersion modeling, or monitoring services.

6-3.3 Competencies - Planning the Response.

6-3.3.1 Providing Information on Potential Response Options and Consequences for Specific Chemicals. Given specific chemicals or containers within their individual area of specialization and the appropriate resources, the private sector specialist employee B shall advise the incident commander of the potential response options and their consequences. The private sector specialist employee B shall be able to:

6-3.3.1.1 Given a specific chemical and an appropriate material safety data sheet (MSDS), identify and interpret the following response information:

(a) Precautions for safe handling, including hygiene practices, protective measures, and procedures for cleanup of spills or leaks

(b) Applicable control measures, including personal protective equipment

(c) Emergency and first aid procedures

6-3.3.1.2 Given their organization's emergency response plan and standard operating procedures, identify additional resources for interpreting response information for a chemical.

6-3.3.1.3 Describe the advantages and limitations of the potential response options for a specific chemical.

6-3.3.1.4 Given their organization's emergency response plan and standard operating procedures, identify resources (including a method of contact) capable of:

(a) Repairing containers for chemicals

(b) Removing the contents of containers for chemicals

(c) Cleanup and disposal of chemicals or containers for chemicals

6-3.3.2 Providing Information on Personal Protective Equipment Requirements. Given specific chemicals or containers for chemicals within their individual area of specialization and the appropriate resources, the private sector specialist employee B shall advise the incident commander of the appropriate personal protective equipment necessary for various response options. The private sector specialist employee B shall be able to:

6-3.3.2.1 Given a specific chemical and an appropriate material safety data sheet (MSDS), identify personal protective equipment, including the materials of construction, that will be compatible with that chemical.

6-3.3.2.2 Given their organization's emergency response plan and standard operating procedures, identify other appropriate resources (including a method of contact) capable of identifying the personal protective equipment that is compatible with a specific chemical.

6-3.3.2.3 Given an incident involving a specific chemical and the response options for that problem, determine whether the personal protective equipment provided by the organization is appropriate for the options presented.

6-3.3.3 Providing Information on Decontamination Methods. Given a specific chemical within their individual area of specialization and the available resources, the private sector specialist employee B shall identify appropriate decontamination methods for various response options. The private sector specialist employee B shall be able to:

6-3.3.3.1 Given a specific chemical and a material safety data sheet (MSDS) or other resource, obtain the potential methods for removing or neutralizing that chemical.

6-3.3.3.2 Given a specific chemical and a material safety data sheet (MSDS) or other resource, identify the circumstances under which disposal of contaminated equipment would be necessary.

6-3.3.3.3 Given their organization's emergency response plan and standard operating procedures, identify resources (including a method of contact) capable of identifying potential decontamination methods.

6-3.3.4 Providing Information on Handling and Disposal Regulations. Given a specific chemical within their area of specialization and the available resources, the private sector specialist employee B shall advise the incident commander of the federal or provincial regulations that relate to the handling, transportation, and disposal of that chemical. The private sector specialist employee B shall be able to:

6-3.3.4.1 Given a specific chemical and a material safety data sheet (MSDS) or other resource, identify federal or provincial regulations that apply to the handling, transportation, and disposal of that chemical.

6-3.3.4.2 Given a specific chemical and a material safety data sheet (MSDS) or other resource, identify the agencies (including a method of contact) responsible for compliance with the federal or provincial regulations that apply to the handling, transportation, and disposal of a specific chemical.

6-3.3.4.3 Given their organization's emergency response plan and standard operating procedures, identify resources for information pertaining to federal or provincial regulations relative to the handling and disposal of a specific chemical.

6-3.3.5 Developing a Plan of Action. Given a simulated incident involving chemicals or containers used in their individual area of specialization, the private sector specialist employee B shall (in conjunction with the incident commander) develop a plan of action, consistent with their organization's emergency response plan and standard operating procedures, for handling chemicals or containers in that incident. The plan of action developed shall be within the capabilities of the available resources and shall include safety considerations. The private sector specialist employee B shall be able to:

6-3.3.5.1 Given the organization's emergency response plan and standard operating procedures, identify the process for development of a plan of action, including safety considerations.

6-3.4 Competencies - Implementing the Planned Response.

6-3.4.1 Performing Response Options Specified in the Plan of Action. Given an assignment by the incident commander in their individual area of specialization, the private sector specialist employee B shall perform the assigned actions consistent with their organization's emergency response plan and standard operating procedures. The private sector specialist employee B shall be able to:

6-3.4.1.1 Perform assigned tasks consistent with their organization's emergency response plan and standard operating procedures and the available personnel, tools, and equipment (including personal protective equipment), including the following:

(a) Confinement activities

(b) Containment activities

(c) Product removal activities

6-3.4.1.2* Identify factors that can affect an individual's ability to perform the assigned tasks.

6-3.4.2 Using Personal Protective Equipment. Given an assignment within their individual area of specialization that is consistent with their organization's emergency response plan and standard operating procedures, the private sector specialist employee B shall be able to:

6-3.4.2.1 Don, work in, and doff the appropriate respiratory protection and protective clothing for the assigned tasks.

6-3.4.2.2 Identify the safety considerations for personnel wearing personal protective equipment, including:

(a) Buddy system

(b) Backup personnel

(c) Symptoms of heat and cold stress

(d) Limitations of personnel working in personal protective equipment

(e) Indications of material degradation of chemical-protective clothing

(f) Physical and psychological stresses on the wearer

(g) Emergency procedures and hand signals

6-3.4.2.3 Identify the procedures for cleaning, sanitizing, and inspecting personal protective equipment provided by the organization.

6-3.5 Competencies - Evaluating Progress.

6-3.5.1 Providing an Evaluation of the Effectiveness of Selected Response Options. Given an incident involving specific chemicals or containers for chemicals within their individual area of specialization, the private sector specialist employee B shall advise the incident commander of the effectiveness of the selected response options. The private sector specialist employee B shall be able to:

6-3.5.1.1 Identify the criteria for evaluating whether or not the selected response options are effective in accomplishing the objectives.

6-3.5.1.2 Identify the circumstances when it would be prudent to withdraw from a chemical incident.

6-3.5.2 Reporting and Documenting the Incident. Given a simulated incident involving chemicals or containers for chemicals used in their individual area of specialization, the private sector specialist employee B shall complete the reporting and subsequent documentation requirements consistent with their organization's emergency response plan and standard operating procedures. The private sector specialist employee B shall be able to:

6-3.5.2.1 Identify the importance of documentation (including training records, exposure records, incident reports, and critique reports) for an incident involving chemicals.

6-3.5.2.2 Identify the steps used in keeping an activity log and exposure records.

6-3.5.2.3 Identify the requirements for compiling incident reports.

6-3.5.2.4 Identify the requirements for compiling hot zone entry and exit logs.

6-3.5.2.5 Identify the requirements for compiling personal protective equipment logs.

6-3.5.2.6 Identify the requirements for filing documents and maintaining records.

6-4 Private Sector Specialist Employee A.

6-4.1 General.

6-4.1.1 Introduction. The private sector specialist employee A shall be trained to meet the competencies at the private sector specialist employee C level (Section 6-2 in this chapter) and hazardous materials technician level (Chapter 4) relative to the chemicals and containers used in their organization's area of specialization.

6-4.1.2 Definition. The private sector specialist employee A is that person who is specifically trained to handle incidents involving chemicals or containers for chemicals used in their organization's area of specialization. Consistent with their organization's emergency response plan and standard operating procedures, the private sector specialist employee A shall be able to analyze an incident involving chemicals within their organization's area of specialization, plan a response to that incident, implement the planned response within the capabilities of the resources available, and evaluate the progress of the planned response.

6-4.1.3 Goal. The goal of this level of competence is to ensure that the private sector specialist employee A has the knowledge and skills to safely perform the duties and responsibilities assigned in their organization's emergency response plan and standard operating procedures. Therefore, in addition to being competent at the private sector specialist employee C and the hazardous materials technician levels, the private sector specialist employee A shall be able to, in conjunction with the incident commander:

(a) Analyze an incident involving chemicals and containers for chemicals used in their organization's area of specialization to determine the magnitude of the incident by completing the following tasks:

1. Survey an incident involving chemicals and containers for chemicals, including the following:

a. Identify the containers involved

b. Identify or classify unknown materials

c. Verify the identity of the chemicals

2. Collect and interpret hazard and response information from printed resources, technical resources, computer data bases, and monitoring equipment for chemicals

3. Determine the extent of damage to containers of chemicals

4. Predict the likely behavior of the chemicals and containers for chemicals

5. Estimate the potential outcomes of an incident involving chemicals and containers for chemicals

(b) Plan a response (within the capabilities of available resources) to an incident involving chemicals and containers for chemicals used in their organization's area of specialization by completing the following tasks:

1. Identify the response objectives for an incident involving chemicals and containers for chemicals

2. Identify the potential action options for each response objective for an incident involving chemicals and containers for chemicals

3. Select the personal protective equipment required for a given response option for an incident involving chemicals and containers for chemicals

4. Select the appropriate decontamination procedures, as necessary, for an incident involving chemicals and containers for chemicals

5. Develop a plan of action (within the capabilities of the available resources), including safety considerations, for handling an incident involving chemicals and containers for chemicals consistent with their organization's emergency response plan and standard operating procedures

(c) Implement the planned response (as developed with the incident commander) to an incident involving chemicals and containers for chemicals used in their organization's area of specialization consistent with their organization's emergency response plan and standard operating procedures by completing the following tasks:

1. Don, work in, and doff appropriate personal protective equipment provided by their organization for use with chemicals

2. Perform control functions, as agreed upon with the incident commander, for chemicals and containers for chemicals

(d) Evaluate the results of implementing the planned response to an incident involving chemicals and containers for chemicals used in their organization's area of specialization

Chapter 7 Competencies for the Hazardous Materials Branch Officer

7-1 General.

7-1.1 Introduction.

The hazardous materials branch officer shall be trained to meet all competencies for the first responder at the awareness, operational, and technician levels and the competencies of this chapter. The hazardous materials branch officer also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

7-1.2

Definition. The hazardous materials branch officer is that person who is responsible for directing and coordinating all operations assigned to the hazardous materials branch by the incident commander.

7-1.3 Goal.

The goal of this chapter shall be to provide the hazardous materials branch officer with the knowledge and skills to perform the following tasks safely. Therefore, in addition to being competent at the awareness, operational, and technician levels, the hazardous materials branch officer shall be able to:

(a) Analyze a hazardous materials incident to determine the magnitude of the problem by estimating the potential outcomes within the endangered area

(b) Plan a response within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the response objectives for hazardous materials incidents

2. Identify the potential action options (defensive, offensive, and nonintervention) available by response objective

3. Determine the level of personal protective equipment required for a given action option

4. Provide recommendations to the incident commander for the development of a plan of action for the hazardous materials branch consistent with the local emergency response plan and the organization's standard operating procedures and within the capability of available personnel, personal protective equipment, and control equipment

(c) Implement a response to favorably change the outcomes consistent with the local emergency response plan and the organization's standard operating procedures by completing the following tasks:

1. Implement the incident management system as it directly relates to the specified procedures for hazardous materials branch operations

2. Direct hazardous materials branch resources (private, governmental, and others) with expected task assignments and on-scene activities and provide management overviews, technical review, and logistical support to hazardous materials branch resources

(d) Evaluate the progress of the planned response to ensure that the response objectives are being met safely, effectively, and efficiently and adjust the plan of action accordingly by evaluating the progress of the plan of action

(e) Terminate the incident by completing the following:

1. Conduct a debriefing for hazardous materials branch personnel

2. Conduct a critique for hazardous materials branch personnel

3. Report and document the hazardous materials branch operations

7-2 Competencies - Analyzing the Incident.

7-2.1 Estimating Potential Outcomes.

Given simulated facility or transportation incidents involving hazardous materials, the surrounding conditions, and the predicted behavior of the container and its contents, the hazardous materials branch officer shall estimate the potential outcomes within the endangered area.

7-3 Competencies - Planning the Response.

7-3.1 Selecting the Level of Personal Protective Equipment.

Given situations with known and unknown hazardous materials, the hazardous materials branch officer shall select the appropriate personal protective equipment for the action options specified in the plan of action in each situation.

7-3.2 Developing a Plan of Action.

Given simulated facility and transportation hazardous materials incidents, the hazardous materials branch officer shall develop a plan of action consistent with the local emergency response plan and the organization's standard operating procedures that is within the capability of the available personnel, personal protective equipment, and control equipment. The hazardous materials branch officer shall be able to:

7-3.2.1 Identify the order of the steps for developing a plan of action.

7-3.2.2 Identify the factors to be evaluated in selecting public protective actions, including evacuation and shelter in-place.

7-3.2.3 Given the local emergency response plan or the organization's standard operating procedure, identify procedures to accomplish the following tasks:

(a) Make ongoing assessments of the situation

(b) Command on-scene personnel (incident management system) assigned to the hazardous materials branch

(c) Coordinate hazardous materials support and mutual aid

(d) Provide resources for public protection action (evacuation or shelter in-place)

(e) Coordinate with fire suppression services as it relates to hazardous materials incidents

(f) Coordinate hazardous materials branch control, containment, or confinement operations

(g) Coordinate with the medical branch to ensure proper medical assistance (ambulance) and medical treatment (hospital)

(h) Coordinate on-scene decontamination when appropriate

(i) Coordinate activities with those of the environmental remedial action ("cleanup") services

7-3.2.4 Identify the process for determining the effectiveness of an action option on the potential outcomes.

7-3.2.5 Identify the procedures for presenting a safety briefing prior to allowing personnel to work on a hazardous materials incident.

7-4 Competencies - Implementing the Planned Response.

7-4.1 Implementing the Incident Management System.

Given a copy of the local emergency response plan, the hazardous materials branch officer shall identify the requirements of the plan, including the required procedures for notification and utilization of nonlocal resources (private, state, and federal government personnel). The hazardous materials branch officer shall be able to:

7-4.1.1 Identify the process and procedures for obtaining cleanup and restoration services in the local emergency response plan or organization's standard operating procedures.

7-4.1.2 Identify the steps for implementing the local and related emergency response plans as required under SARA Title III Section 303 of the federal regulations or other local emergency response planning legislation.

7-4.1.3 Given the local emergency planning documents, identify the elements of each of the documents.

7-4.1.4 Identify the elements of the incident management system necessary to coordinate response activities at hazardous materials incidents.

7-4.1.5 Identify the primary local, state, regional, and federal government agencies and identify the scope of their regulatory authority (including the regulations) pertaining to the production, transportation, storage, and use of hazardous materials and the disposal of hazardous wastes.

7-4.1.6 Identify the governmental agencies and private sector resources offering assistance to the hazardous materials branch during a hazardous materials incident and identify their role and type of assistance or resources available.

7-4.2* Directing Resources (Private and Governmental).

Given a simulated hazardous materials incident and the necessary resources to implement the planned response, the hazardous materials branch officer shall demonstrate the ability to direct the hazardous materials branch resources in a safe and efficient manner consistent with the capabilities of those resources.

7-4.3 Providing a Focal Point for Information Transfer to Media and Elected Officials.

Given a simulated hazardous materials incident, the hazardous materials branch officer shall demonstrate the ability to act as a resource to provide information to the incident commander or the public information officer for distribution to the media and local, state, and federal officials. The hazardous materials branch officer shall be able to:

7-4.3.1 Identify the local policy for providing information to the media.

7-4.3.2 Identify the responsibilities of the public information officer at a hazardous materials incident.

7-5 Competencies - Evaluating Progress.

7-5.1 Evaluating Progress of the Plan of Action.

Given simulated facility and transportation hazardous materials incidents, the hazardous materials branch officer shall evaluate the progress of the plan of action to determine whether the efforts are accomplishing the response objectives. The hazardous materials branch officer shall be able to:

7-5.1.1 Identify the procedures for evaluating whether the action options are effective in accomplishing the objectives.

7-5.1.2 Identify the steps for comparing actual behavior of the material and the container to that predicted in the analysis process.

7-5.1.3 Determine the effectiveness of the following:

(a) Hazardous materials response personnel being used

(b) Personal protective equipment

(c) Established control zones

(d) Control, containment, or confinement operations

(e) Decontamination process

7-6 Competencies - Terminating the Incident.

7-6.1 Terminating the Emergency Phase of the Hazardous Materials Incident.

Given a simulated hazardous materials incident, the hazardous materials branch officer shall demonstrate the ability to terminate the emergency phase of the incident consistent with the local emergency response plan and the organization's standard operating procedures. The hazardous materials branch officer shall be able to:

7-6.1.1 Identify the steps required in terminating the emergency phase of a hazardous materials incident.

7-6.1.2 Identify the procedures for conducting incident debriefings at a hazardous materials incident.

7-6.1.3 Identify the steps in transferring authority as prescribed in the local emergency response plan or the organization's standard operating procedures.

7-6.2 Conducting a Debriefing.

Given the details of a simulated hazardous materials incident, the hazardous materials branch officer shall demonstrate the ability to conduct a debriefing of the incident for all units assigned to the hazardous materials branch. The hazardous materials branch officer shall be able to:

7-6.2.1 Describe three components of an effective debriefing.

7-6.2.2 Describe the key topics in an effective debriefing.

7-6.2.3 Describe when a debriefing should take place.

7-6.2.4 Describe who should be involved in a debriefing.

7-6.2.5 Identify the procedures for conducting incident debriefings at a hazardous materials incident.

7-6.3 Conducting a Critique.

Given the details of a simulated hazardous materials incident, the hazardous materials branch officer shall demonstrate the ability to conduct a critique of the incident for all units assigned to the hazardous materials branch. The hazardous materials branch officer shall be able to:

7-6.3.1 Describe three components of an effective critique.

7-6.3.2 Describe who should be involved in a critique.

7-6.3.3 Describe why an effective critique is necessary after a hazardous materials incident.

7-6.3.4 Describe what written documents should be prepared as a result of the critique.

7-6.3.5 Identify the procedure for conducting a critique of the incident.

7-6.3.6 Identify the requirements for conducting a post-incident analysis as defined in the local emergency response plan, the organization's standard operating procedures, or federal, state, and local regulations.

7-6.4 Reporting and Documenting the Hazardous Materials Incident.

Given a simulated hazardous materials incident, the hazardous materials branch officer shall demonstrate the ability to report and document the incident consistent with the local, state, and federal requirements. The hazardous materials branch officer shall be able to:

7-6.4.1 Identify the reporting requirements of federal, state, and local agencies.

7-6.4.2 Identify the importance of documentation for a hazardous materials incident, including training records, exposure records, incident reports, and critique reports.

7-6.4.3 Identify the steps in keeping an activity log and exposure records for hazardous materials incidents.

7-6.4.4 Identify the requirements found in the local emergency response plan and the organization's standard operating procedures for compiling hazardous materials incident reports.

7-6.4.5 Identify the requirements for filing documents and maintaining records as defined in the local emergency response plan and the organization's standard operating procedures.

Chapter 8 Competencies for the Hazardous Materials Branch Safety Officer

8-1 General.

8-1.1* Introduction.

The hazardous materials branch safety officer shall be trained to meet all the competencies for the first responder at the awareness, operational, and technician levels and the competencies of this chapter. The hazardous materials branch safety officer also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

8-1.2* Definition.

The hazardous materials branch safety officer is that person who works within an incident management system (IMS) to ensure that recognized safe practices are followed within the hazardous materials branch. The hazardous materials branch safety officer will be called upon to provide technical advice or assistance regarding safety issues to the hazardous materials branch officer and incident safety officer at a hazardous materials incident.

8-1.3 Goal.

The goal of this chapter shall be to provide the hazardous materials branch safety officer with the knowledge and skills to evaluate a hazardous materials incident for safety and ensure that recognized safe operational practices are followed. Therefore, in addition to being knowledgeable at the level of operations being performed, the hazardous materials branch safety officer shall be able to:

(a) Analyze a hazardous materials incident to determine the magnitude of the problem in terms of safety by observing a scene and reviewing and evaluating hazard and response information as it pertains to the safety of all persons within the hazardous materials branch

(b) Assist in planning a safe response within the capabilities of available response personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the safety precautions for potential action options
2. Provide recommendations regarding safety considerations
3. Assist in the development of a plan of action
4. Review the plan of action and provide recommendations regarding safety
5. Review the selection of personal protective equipment required for a given action option
6. Review the decontamination operations

7. Ensure that the proper emergency medical services are provided

(c) Ensure the implementation of a safe planned response consistent with the local emergency response plan, the organization's standard operating procedures, and safety considerations by completing the following tasks:

1. Perform the duties of the hazardous materials branch safety officer within the local incident management system (IMS)

2. Identify safety considerations for personnel performing the control functions identified in the plan of action

3. Conduct safety briefings for personnel performing the control functions identified in the plan of action

4. Assist in the implementation and enforcement of safety considerations

5. Maintain communications within the incident command structure during the incident

6. Monitor status reports of activities in the hot and warm zones

7. Ensure the implementation of exposure monitoring (personnel and environment)

(d) Evaluate the progress of the planned response to ensure that the response objectives are being met safely by completing the following tasks:

1. Identify deviations from safety considerations and any dangerous situations

2. Alter, suspend, or terminate any activity that can be judged to be unsafe

(e) Assist in terminating the incident by completing the following tasks:

1. Perform the reporting, documentation and follow-up required of the hazardous materials branch safety officer

2. Assist in the debriefing of hazardous materials branch personnel

3. Assist in the incident critique

8-2 Competencies - Analyzing the Incident.

8-2.1 Determining the Magnitude of the Problem in Terms of Safety.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall observe a scene and review and evaluate hazard and response information as it pertains to the safety of all persons within the hazardous materials branch. The hazardous materials branch safety officer shall be able to:

8-2.1.1* Describe the following radioactive materials terms and explain their significance in predicting the extent of health hazards and environmental impact in a hazardous materials incident:

(a) Types

(b) Measurement

(c) Protection

8-2.1.2 Describe the following toxicological terms and exposure values and explain their significance in the risk assessment process:

(a) Parts per million (ppm)

(b) Parts per billion (ppb)

(c) Lethal dose (LD_{50})

(d) Lethal concentrations (LC_{50})

(e) Permissible exposure limit (PEL)

(f) Threshold limit value time-weighted average (TLV-TWA)

(g) Threshold limit value short-term exposure limit (TLV-STEL)

(h) Threshold limit value ceiling (TLV-C)

(i) Immediately dangerous to life and health value (IDLH)

8-2.1.3 Explain the basic toxicological principles relative to assessment and treatment of personnel exposed to hazardous materials, including the following:

(a) Acute and delayed toxicity

(b) Dose-response

(c) Local and systemic effects

(d) Routes of exposure to toxic materials

(e) Synergistic effects

8-2.1.4* Identify five conditions where the hazards from flammability would require chemical-protective clothing with thermal protection.

8-2.1.5* Identify five conditions where personnel would not be allowed to enter the hot zone.

8-2.1.6 Given the names of five hazardous materials and at least three reference sources, identify the physical and chemical properties and their potential impact on the safety of personnel at an incident involving each of the materials.

8-2.1.7 Given the names of five hazardous materials and at least three reference sources, identify the health concerns and their potential impact on the safety and health of personnel at an incident involving each of the materials.

8-2.1.8* Given the names of five hazardous materials and a description of their containers, identify five hazards or physical conditions that would impact the safety of personnel at an incident involving each of the materials.

8-2.1.9 Given at least three unknown materials, one of which is a solid, one a liquid, and one a gas, identify or classify by hazard each unknown material.

8-2.1.9.1 Identify steps in an analysis process for identifying unknown solid and liquid materials.

8-2.1.9.2 Identify steps in an analysis process for identifying an unknown atmosphere.

8-2.1.9.3 Identify the type(s) of monitoring equipment, test strips, and reagents used to determine the following hazards:

(a) Corrosivity (pH)

(b) Flammability

(c) Oxidation potential

(d) Oxygen deficiency

(e) Radioactivity

(f) Toxic levels

8-2.1.9.4* Identify the capabilities and limiting factors associated with the selection and use of the following monitoring equipment, test strips, and reagents:

(a) Carbon monoxide meter

(b) Colorimetric tubes

(c) Combustible gas indicator

(d) Oxygen meter

(e) Passive dosimeter

(f) Photoionization detectors

(g) pH indicators and/or pH meters

(h) Radiation detection instruments

(i) Reagents

(j) Test strips

8-2.1.9.5 Given three hazardous materials, one of which is a solid, one a liquid, and one a gas, and the following monitoring equipment, select and demonstrate the appropriate equipment to identify and quantify the materials:

(a) Carbon monoxide meter

(b) Colorimetric tubes

(c) Combustible gas indicator

(d) Oxygen meter

(e) pH papers and/or pH meters

(f) Radiation detection instruments

(g) Reagents

(h) Test strips

8-2.1.9.6 Demonstrate the field maintenance and testing procedures for the monitoring equipment, test strips and reagents provided by the authority having jurisdiction.

8-3 Competencies - Planning the Response.

8-3.1* Identifying the Safety Precautions for Potential Action Options.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall assist in planning a safe response within the capabilities of available response personnel, personal protective equipment, and control equipment. The hazardous materials branch safety officer shall be able to:

8-3.1.1* Identify five specific safety precautions to observe while mitigating each of the hazards or conditions identified in 8-2.1.8.

8-3.1.2* Identify five safety precautions associated with search and rescue missions at hazardous materials incidents.

8-3.2 Providing Recommendations Regarding Safety Considerations.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall provide the incident safety officer, hazardous materials branch officer, and incident commander with observation-based recommendations regarding considerations for the safety of on-site personnel. The hazardous materials branch safety officer shall be able to identify five recommendations to the incident commander regarding safety considerations on the hazards or conditions for each of the hazardous materials and containers identified in 8-2.1.8.

8-3.3 Assisting in the Development of a Plan of Action.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall assist the incident safety officer and hazardous materials branch officer in the development of a safe plan of action. The hazardous materials branch safety officer shall be able to:

8-3.3.1* Identify the importance and list five benefits of pre-emergency planning relating to specific sites.

8-3.3.2* Identify and name five hazards and precautions to be observed when approaching a hazardous materials incident.

8-3.3.3* List the elements of safety considerations.

8-3.3.4 Given an organizations pre-incident plan and a simulated hazardous materials incident involving one of the hazardous materials and containers described in 8-2.1.8, develop safety considerations for the incident.

8-3.4 Providing Recommendations Regarding Safety and Reviewing the Plan of Action.

Given a proposed plan of action for an incident involving one of the hazardous materials and containers described in 8-2.1.8, the hazardous materials branch safety officer shall identify to the incident safety officer, hazardous materials branch officer, and incident commander the safety precautions for the plan of action. The hazardous materials branch safety officer shall be able to:

8-3.4.1 Ensure that the safety considerations in the proposed plan of action are consistent with the local emergency response plan and the organization's standard operating procedures.

8-3.4.2 Make recommendations to the incident commander on the safety considerations in the proposed plan of action.

8-3.5 Reviewing Selection of Personal Protective Equipment.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall demonstrate the ability to review the selection of personal protective equipment required for a given action option. The hazardous materials branch safety officer shall be able to:

8-3.5.1 Identify the four levels of chemical protection (EPA/NIOSH) and describe the equipment required for each level and the conditions under which each level is used.

8-3.5.2 Identify five safety considerations for personnel wearing vapor-protective, liquid splash-protective, and high temperature-protective clothing.

8-3.5.3 Given the names of five different hazardous materials and a chemical compatibility chart for chemical-protective clothing, identify the chemical-protective clothing that would provide the appropriate protection to the wearer for each of the five substances.

8-3.5.4* Given the names of five different hazardous materials, identify appropriate chemical-protective clothing levels for typical action options.

8-3.5.5 Demonstrate proper methods for donning, doffing, and using all personal protective equipment provided by the authority having jurisdiction for use in hazardous materials response activities.

8-3.6 Reviewing the Proposed Decontamination Plan.

Given a site-specific decontamination plan by the hazardous materials branch officer or incident commander for a simulated hazardous materials incident, the hazardous materials branch safety officer shall review the plan to identify safety considerations prior to plan implementation. The hazardous materials branch safety officer shall be able to:

8-3.6.1 Identify the advantages and limitations and describe an example where each of the following decontamination methods would be used:

(a) Absorption

(b) Adsorption

(c) Chemical degradation

(d) Dilution

(e) Disposal

(f) Evaporation

(g) Neutralization

(h) Solidification

(i) Vacuuming

(j) Washing

8-3.6.2 Identify how personnel, personal protective equipment, apparatus, tools, and equipment become contaminated, as well as the importance and limitations of decontamination procedures.

8-3.6.3 Explain the need for decontamination procedures at hazardous materials incidents.

8-3.6.4 Identify three sources of technical information for selecting appropriate decontamination procedures and identify how to contact those sources in an emergency.

8-3.6.5 Identify the considerations associated with the placement, location, and setup of the decontamination corridor.

8-3.6.6 Identify the decontamination procedures as defined by the authority having jurisdiction for personnel and personal protective equipment at hazardous materials incidents.

8-3.6.7 Given three reference sources and a simulated hazardous materials incident involving two or more different chemicals, develop a site-specific personnel decontamination plan that is consistent with the local emergency response plan and the organization's standard operating guidelines.

8-3.7 Ensuring Provision of Proper Emergency Medical Services.

Given a simulated hazardous materials incident, the hazardous materials branch safety officer shall review the emergency medical services plan to ensure that response personnel are provided medical care. The hazardous materials branch safety officer shall be able to:

8-3.7.1* Identify the elements required in an emergency medical services plan.

8-3.7.2 Identify the importance of an on-site medical monitoring program.

8-3.7.3 Identify three resources for the transportation and care of the injured persons exposed to hazardous materials.

8-4 Competencies - Implementing the Planned Response.

8-4.1 Performing the Duties of the Hazardous Materials Branch Safety Officer.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall perform the duties of their position in a manner consistent with the local emergency response plan, the organization's standard operating procedures, and safety considerations. The hazardous materials branch safety officer shall be able to:

8-4.1.1 Identify the duties of the hazardous materials branch safety officer as defined in the organization's standard operating procedures.

8-4.1.2 Demonstrate proper performance of the duties of the hazardous materials branch safety officer as defined in the organization's standard operating procedures.

8-4.2 Monitoring Safety of Response Personnel.

Given a simulated hazardous materials incident and safety considerations, the hazardous materials branch safety officer shall ensure that personnel perform their tasks in a safe manner by identifying the safety considerations for the control functions identified in the plan of action. The hazardous materials branch safety officer shall be able to:

8-4.2.1 Identify the safe operating practices that are required to be followed at a hazardous materials incident as stated in the local emergency response plan and the organization's standard operating procedures.

8-4.2.2 Identify how the following factors influence heat and cold stress for hazardous materials response personnel:

(a) Activity levels

(b) Duration of entry

(c) Environmental factors

(d) Hydration

(e) Level of PPE

(f) Physical fitness

8-4.2.3 Identify the methods that will minimize the potential harm from heat and cold stress.

8-4.2.4 Identify the safety considerations that will minimize the psychological and physical stresses on personnel wearing vapor-protective, liquid splash-protective, and high temperature-protective clothing.

8-4.2.5 Describe five conditions where it would be prudent to withdraw from a hazardous materials incident.

8-4.3 Conducting Safety Briefings.

Given a simulated hazardous materials incident and safety considerations, the hazardous materials branch safety officer shall conduct safety briefings for personnel performing the control functions identified in the plan of action. The hazardous materials branch safety officer shall be able to demonstrate the proper procedure for conducting a safety briefing to personnel for an incident involving one of the hazardous materials and its container identified in 8-2.1.8, as specified by the organization's standard operating procedures.

8-4.4 Implementing and Enforcing Safety Considerations.

Given a simulated hazardous materials incident and safety considerations, the hazardous materials branch safety officer shall assist the incident commander, the incident safety officer, and the hazardous materials branch officer in implementing and enforcing the safety considerations. The hazardous materials branch safety officer shall be able to:

8-4.4.1 Identify whether the boundaries of the established control zones are clearly marked, consistent with the safety considerations, and are being maintained.

8-4.4.2 Identify whether the on-site medical monitoring that are required by the authority having jurisdiction is being performed.

8-4.4.3 Given an entry team, a backup team, and a decontamination team wearing personal protective clothing and equipment, identify that each team is properly protected and prepared to safely perform its assigned tasks.

8-4.4.3.1 Identify whether the selection of clothing and equipment is consistent with safety considerations.

8-4.4.3.2 Identify whether each team has examined the clothing for barrier integrity and the equipment to ensure proper working order.

8-4.4.3.3 Identify whether the protective clothing and equipment have been donned in accordance with the organization's standard operating procedures and the manufacturer's recommendations.

8-4.4.4 Identify whether each person entering the hot zone has a specific task assignment, understands the assignment, is properly trained to perform the assigned task(s), and is working with a designated partner at all times during the assignment.

8-4.4.5 Identify whether a backup team with the appropriate level of personal protective equipment is prepared at all times for immediate entry into the hot zone during entry team operations.

8-4.4.6 Identify whether the decontamination process specified in the safety considerations is in place before any entry into the hot zone.

8-4.4.7 Identify that each person exiting the hot zone and each tool or piece of equipment is decontaminated in accordance with the safety considerations and the degree of hazardous materials exposure.

8-4.4.8 Demonstrate the proper procedure for recording the names of the individuals exiting the hot zone, as specified in the local emergency response plan and the organization's standard operating procedures.

8-4.4.9* Identify three safety considerations that can minimize secondary contamination.

8-4.5 Maintaining Communications.

Given a simulated hazardous materials incident and the safety considerations, the hazardous materials branch safety officer shall maintain routine and emergency communications within the incident command structure at all times during the incident. The hazardous materials branch safety officer shall be able to:

8-4.5.1* Identify three types of communications systems used at hazardous materials incident sites.

8-4.5.2 Identify whether each person assigned to work in the hot zone understands the emergency alerting and response procedures specified in the safety considerations prior to entry into the hot zone.

8-4.6 Monitoring Status Reports.

Given a simulated hazardous materials incident and the safety considerations, the hazardous materials branch safety officer shall monitor routine and emergency communications within the incident command structure at all times during the incident. The hazardous materials branch safety officer shall be able to identify whether entry team members regularly communicate the status of their work assignment to the hazardous materials branch officer.

8-4.7 Implementing Exposure Monitoring.

Given a simulated hazardous materials incident and the safety considerations, the hazardous materials branch safety officer shall assist the incident commander, the incident safety officer, and the hazardous materials branch officer in implementing exposure monitoring.

8-4.8

The hazardous materials branch safety officer shall identify that exposure monitoring (personnel and environment) as specified in the organization's standard operating procedures and safety considerations is performed.

8-5 Competencies - Evaluating Progress.

8-5.1 Identifying Deviations from Safety Considerations and Any Dangerous Situations.

Given simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, and given simulated deviations from the safety considerations for activities in both the hot and warm zones and simulated dangerous conditions, the hazardous materials branch safety officer shall evaluate the progress of the planned response to ensure that the response objectives are being met safely. The hazardous materials branch safety officer shall be able to:

8-5.1.1 Identify those actions that deviate from the safety considerations or otherwise violate generally accepted safe operating practices, organizational policies, or applicable occupational safety and health laws, regulations, codes, standards, or guidelines.

8-5.1.2 Identify dangerous conditions that develop or are identified during work in the hot or warm zones that threaten the safety or health of persons in those zones.

8-5.1.3 Identify the signs and symptoms of psychological and physical stresses on personnel wearing vapor-protective, liquid splash-protective, and high temperature-protective clothing.

8-5.2 Taking Corrective Actions.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, and given simulated deviations from the safety considerations for activities in both the hot and warm zones and simulated dangerous conditions, the hazardous materials branch safety officer shall take such corrective actions as are necessary to ensure the safety and health of persons in the hot and warm zones. The hazardous materials branch safety officer shall be able to:

8-5.2.1 Send emergency communications to, and receive emergency communications from, the incident safety officer, entry team personnel, the hazardous materials branch officer, and others as appropriate regarding safe working practices and conditions.

8-5.2.1.1* Given a hazardous situation or condition that has developed or been identified following initial hot zone entry, demonstrate the application of the emergency alerting procedures specified in the safety considerations to communicate the hazard and emergency response information to the affected personnel.

8-5.2.1.2 Given a demonstrated emergency alert via hand signal by a member of the entry team operating within the hot zone, identify the meaning of that signal as specified in the safety considerations.

8-5.2.2 Identify the procedures to alter, suspend, or terminate any activity that can be judged to be unsafe, as specified in the local emergency response plan and the organization's standard operating procedures.

8-5.2.3 Demonstrate the procedure for notifying the appropriate individual of the unsafe action and for directing alternative safe actions, in accordance with the safety considerations and the organization's standard operating procedures.

8-5.2.4 Demonstrate the procedure for suspending or terminating an action that could result in an imminent hazard condition, in accordance with the safety considerations and the organization's standard operating procedures.

8-6 Competencies - Terminating the Incident.

8-6.1 Providing Reports and Documentation.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall complete and submit the reports, documentation, and follow-up required of the hazardous materials branch safety officer. The hazardous materials branch safety officer shall be able to:

8-6.1.1 Identify the safety reports and supporting documentation required by the local emergency response plan and the organization's standard operating procedures.

8-6.1.2 Demonstrate the proper completion of the safety reports required by the local emergency response plan and the organization's standard operating procedures.

8-6.1.3 Describe the importance of personnel exposure records.

8-6.2 Debriefing of Hazardous Materials Branch Personnel.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall debrief hazardous materials branch personnel regarding site-specific occupational safety and health issues. The hazardous materials branch safety officer shall be able to:

8-6.2.1* Identify five health and safety topics to be addressed in an incident debriefing.

8-6.2.2 Demonstrate the proper procedure for debriefing hazardous materials branch personnel regarding site-specific occupational safety and health areas of concern, as specified in the safety considerations, local emergency response plan, and the organization's standard operating procedures.

8-6.3 Assisting in the Incident Critique.

Given various simulated facility and transportation hazardous materials incidents involving nonbulk and bulk packaging, the hazardous materials branch safety officer shall provide safety and health-related critical observations of the activities that were performed in the hot and warm zones during the incident.

8-6.4

Given the safety considerations and hazardous materials branch safety officer's report for a simulated incident, the hazardous materials branch safety officer shall demonstrate the proper procedure for verbally presenting the following in accordance with the local emergency response plan and the organization's standard operating procedures:

(a) Safety and health-related critical observations of the activities that were performed in the hot and warm zones during the incident

(b) Recorded violations of the safety considerations or generally accepted safe operating practices, organizational policies, or applicable occupational safety and health laws, regulations, codes, standards, or guidelines

(c) Injuries or deaths that occurred as a result of reasonably unforeseen dangerous conditions that developed during the incident

(d) Injuries or deaths that occurred as a result of violations of the safety considerations or generally accepted safe operating practices, organizational policies, or applicable occupational safety and health laws, regulations, codes, standards, or guidelines

(e) The proper course of action(s) that would likely have prevented the injuries or deaths that occurred as a result of the safety violations identified in (d)

(f) Deficiencies or weaknesses in the safety considerations, local emergency response plan, and organizational standard operating procedures that were noted during or following the incident

Chapter 9 Competencies for the Technician with a Tank Car Specialty

9-1 General.

9-1.1 Introduction.

Technicians with a tank car specialty shall meet all competencies of the first responder awareness, operational, and hazardous materials technician levels and the competencies of this chapter. The technician with a tank car specialty also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

9-1.2 Definition.

Technicians with a tank car specialty are those persons who provide support to the hazardous materials technician, provide oversight for product removal and movement of damaged tank cars, and act as a liaison between technicians and other outside resources. These technicians are expected to use specialized chemical-protective clothing and specialized control equipment.

9-1.3 Goals.

The goal of this chapter shall be to provide the technician with a tank car specialty with the knowledge and skills to perform the following tasks safely. In addition to being competent at the hazardous materials technician level, the technician with a tank car specialty shall be able to:

(a) Analyze a hazardous materials incident involving tank cars to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Determine the type and extent of damage to tank cars

2. Predict the likely behavior of tank cars and their contents in an emergency

(b) Plan a response for an emergency involving tank cars within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Determine the response options (offensive, defensive, and nonintervention) for a hazardous materials emergency involving tank cars

2. Ensure that the options are within the capabilities and competencies of available personnel, personal protective equipment, and control equipment

(c) Implement the planned response to a hazardous materials incident involving tank cars

9-1.4 Mandating of Competencies.

This standard does not mandate that hazardous materials response teams performing offensive operations on tank cars have technicians with a tank car specialty. Technicians operating within the bounds of their training as listed in Chapter 4 of this standard are able to intervene in railroad incidents. However, if a hazardous materials response team desires to train some or all its technicians to have in-depth knowledge of tank cars, this chapter sets out the required competencies.

9-2 Competencies - Analyzing the Incident.

9-2.1 Determining the Type and Extent of Damage to Tank Cars.

Given examples of damaged tank cars, technicians with a tank car specialty shall describe the type and extent of damage to each tank car and its fittings. Technicians with a tank car specialty shall be able to:

9-2.1.1 Given the specification mark for a tank car and the appropriate reference materials, describe the car's basic construction and features.

9-2.1.2 Point out the "B" end of the car.

9-2.1.3 Given examples of various tank cars, point out and explain the design and purpose of each of the following tank car components, when present.

(a) Tank, including shell, and head

(b) Head shield

(c) Jacket

(d) Lining/cladding

(e) Heater coils - interior vs. exterior

(f) Underframe - continuous vs. stub sill

(g) Shelf couplers

(h) Body bolster

(i) Trucks (pin and bowl)

9-2.1.4 Given examples of tank cars (some jacketed; some not jacketed), point out the jacketed tank cars.

9-2.1.5 Describe the difference between "insulation" and "thermal protection" on tank cars.

9-2.1.6 Describe the difference between "jacketed" and "sprayed-on" thermal protection on tank cars.

9-2.1.7 Describe the difference between "interior" and "exterior" heater coils on tank cars.

9-2.1.8 Given examples of various fittings arrangements for pressure, nonpressure, cryogenic, and CO_2 tank cars (including examples of each of the following fittings), point out and explain the design, construction, and operation of each of the following fittings, when present:

(a) Fittings for loading and unloading tank cars, including the following:

1. Bottom outlet valves (top operated with stuffing box, bottom operated - internal or external ball, wafersphere)

2. Liquid valve/vapor valve (ball vs. plug type)

3. Excess flow valve

4. Air valve

5. Bottom outlet nozzle

6. Quick fill hole cover

7. Flange for manway, valves, etc.

8. CO_2 tank car fittings

9. Cryogenic liquid tank car fittings

(b) Fittings for pressure relief, including the following:

1. Safety relief devices (safety valve, safety vent, combination safety valve)

2. Pressure regulators on CO_2 cars and liquefied atmospheric gases in cryogenic liquid tank cars

3. Staged safety relief system for a CO_2 car

4. Vacuum relief valve (negative pressure or vacuum)

(c) Fittings for gauging, including the following:

1. Open gauging devices, e.g., slip tube

2. Closed gauging devices, e.g., magnetic

3. Other gauging devices (T-bar, long/short pole)

(d) Miscellaneous fittings, including the following:

1. Thermometer well

2. Sample line

3. Manway, manway cover plate, hinged and bolted manway cover, protective housing

4. Washout

5. Sump

9-2.1.9 Given examples of various fitting arrangements on tank cars (including CO_2 and cryogenic liquid tank cars) with the following fittings included, point out the location(s) where each fitting is likely to leak and a reason for the leak:

(a) Bottom outlet valve/top-operated bottom outlet valve (with stuffing box)

(b) Liquid valve/vapor valve (ball vs. plug type)

(c) Air valve

(d) Bottom outlet nozzle

(e) Quick fill hole cover

(f) Flange for manway, valves, etc.

(g) Safety relief valve

(h) Safety vent (with rupture/frangible) disk

(i) Combination safety valve

(j) Pressure regulators on CO_2 cars and liquefied atmospheric gases in cryogenic liquid tank cars

(k) Vacuum relief valve (negative pressure or vacuum)

(l) Open gauging devices, e.g., slip tube

(m) Closed gauging devices, e.g., magnetic

(n) Thermometer well

(o) Sample line

(p) Manway, manway cover plate, hinged and bolted manway cover, protective housing

(q) Washout

9-2.1.10 Given examples of each of the following types of tank car damage, identify the type of damage:

(a) Crack

(b) Score, gouge, wheel burn, rail burn

(c) Puncture

(d) Flame impingement

(e) Dent

(f) Corrosion

9-2.1.11* Given examples (actual or simulated) of scores, gouges, wheel burns, and rail burns, perform each of the following tasks:

(a) Use a depth gauge to measure the depth of each score, gouge, wheel burn, and rail burn

(b) Point out where each score, gouge, wheel burn, and rail burn crosses a weld, if that condition exists

(c) Measure the depth of the weld metal removed for any point where the score, gouge, wheel burn, and rail burn crosses a weld

(d) Given examples (actual or simulated) of where a score, gouge, wheel burn, and rail burn crosses a weld, determine if the "heat-affected zone" has been damaged

9-2.1.12 Given examples (actual or simulated) of dents and rail burns, perform each of the following tasks:

(a) Use a dent gauge to measure the radius of curvature for each dent or rail burn

(b) Identify those examples that include cracks at the point of minimum curvature

9-2.1.13 Given examples of damaged tank car fittings, describe the extent of damage to those fittings.

9-2.1.14 Given examples of tank car tank damage, describe the extent of damage to the tank car tank.

9-2.1.15 Given a tank car and the appropriate equipment and reference material, determine the pressure in the tank car, using either of the following methods:

(a) A pressure gauge

(b) The temperature of the contents

9-2.1.16* Given a tank car, use the car's gauging device to determine the amount of lading in it.

9-2.2 Predicting the Likely Behavior of the Tank Car and its Contents.

Technicians with a tank car specialty shall predict the likely behavior of the tank car and its contents. The technician with a tank car specialty shall be able to:

9-2.2.1 Given the following types of tank cars, describe the likely breach/release mechanisms associated with each type.

(a) Nonpressure tank cars

(b) Pressure tank cars

(c) Cryogenic liquid tank cars

(d) High-pressure tube cars

(e) Pneumatically unloaded covered hopper cars

9-2.2.2 Describe the difference in the following types of construction materials used in tank cars and their significance in assessing tank damage:

(a) Carbon steel

(b) Alloy steel

(c) Aluminum

9-2.2.3 Discuss the significance of selection of lading for compatibility with tank car construction material.

9-2.2.4 Describe the significance of "lining" and "cladding" on tank cars in assessing tank damage.

9-2.2.5 Describe the significance of the jacket on tank cars in assessing tank damage.

9-2.2.6 Describe the significance of "insulation" and "thermal protection" on tank cars in assessing tank damage.

9-2.2.7 Describe the significance of "jacketed" and "sprayed-on" thermal protection on tank cars in assessing tank damage.

9-2.2.8 Describe the significance of "interior" and "exterior" heater coils on tank cars in assessing tank damage.

9-2.2.9 Describe the significance of each of the following types of tank car damage on different types of tank cars in assessing tank damage:

(a) Crack

(b) Score, gouge, wheel burn, rail burn

(c) Puncture

(d) Flame impingement

(e) Dent

(f) Corrosion

9-2.2.10 Describe the significance of the depth of scores, gouges, wheel burns, and rail burns on tank cars in assessing tank damage.

9-2.2.11 Describe the significance of scores, gouges, wheel burns, and rail burns crossing a weld on a pressure tank car in assessing tank damage.

9-2.2.12 Describe the significance of damage to the "heat affected" zone of a weld on a tank car in assessing tank damage.

9-2.2.13 Describe the significance of a condemning dent of a tank car in assessing tank damage.

9-2.2.14 Given various types of tank cars, describe the significance of pressure increases in assessing tank damage.

9-2.2.15 Given various types of tank cars, describe the significance of the amount of lading in the tank in assessing tank damage.

9-2.2.16 Describe the significance of flame impingement on a tank car.

9-3 Competencies - Planning the Response.

9-3.1 Determining the Response Options.

Given the analysis of an emergency involving tank cars, technicians with a tank car specialty shall determine the response options for each tank car involved. The technician with a tank car specialty shall be able to:

9-3.1.1 Describe the purpose of, potential risks associated with, procedures for, equipment required to implement, and safety precautions for the following product removal techniques for tank cars:

(a) Transferring liquids and vapors

(b) Flaring liquids and vapors

(c) Venting

(d) Hot and cold tapping

(e) Vent and burn

9-3.1.2 Describe the inherent risks associated with, procedures for, equipment required to implement, and safety precautions for leak control techniques on various tank car fittings.

9-3.1.3 Describe the effect flaring or venting gas or liquid has on the pressure in the tank (flammable gas or flammable liquid product).

9-3.1.4 Describe the inherent risks associated with, procedures for, equipment required to implement, and safety precautions for lifting of tank cars.

9-3.1.5 Describe the inherent risks associated with, procedures for, and safety precautions for the following operations:

(a) Shutting off locomotives using the fuel shutoff and the battery disconnect

(b) Setting and releasing brakes on rail cars

(c) Uncoupling rail cars

9-3.1.6 Describe the hazards associated with working on railroad property during emergencies.

9-4 Competencies - Implementing the Planned Response.

9-4.1 Implementing the Planned Response.

Given an analysis of an emergency involving tank cars and the planned response, technicians with a tank car specialty shall implement or oversee the implementation of the selected response options safely and effectively. The technician with a tank car specialty shall be able to:

9-4.1.1 Given a leaking manway cover plate (loose bolts), control the leak.

9-4.1.2 Given leaking packing on the following tank car fittings, control the leak:

(a) Gauging device packing nut

(b) Liquid or vapor valve packing nut

(c) Top-operated bottom outlet valve packing gland

9-4.1.3 Given an open bottom outlet valve with a defective gasket in the cap, control the leak.

9-4.1.4 Given a leaking top-operated bottom outlet valve, close valve completely to control leak.

9-4.1.5 Given leaking fittings on a chlorine tank car, use the Chlorine C kit, as appropriate, to control the leak.

9-4.1.6 Given the following types of leaks on various types of tank cars, plug or patch those leaks:

(a) Puncture

(b) Irregular-shaped hole

(c) Cracks, splits, or tears

9-4.1.7 Given the appropriate equipment and resources, demonstrate the following:

(a) Transferring of liquids and vapors

(b) Flaring of liquids and vapors

(c) Venting

9-4.1.8 Given the appropriate resources, perform the following tasks:

(a) Shut off locomotives using the fuel shutoff and the battery disconnect

(b) Set and release brakes on rail cars

(c) Uncouple rail cars

9-4.1.9* Demonstrate bonding and grounding procedures for the transfer of flammable and combustible products from tank cars, or other products that can give off flammable gases or vapors when heated or contaminated, including the following:

(a) Selection of proper equipment

(b) Sequence of bonding and grounding connections

(c) Proper testing of bonding and grounding connections

9-4.1.10 Given a simulated flammable liquid spill from a tank car, describe the procedures for site safety and fire control during cleanup and removal operations.

Chapter 10 Competencies for the Technician with a Cargo Tank Specialty

10-1 General.

10-1.1 Introduction.

Technicians with a cargo tank specialty shall be trained to meet all competencies of the first responder awareness, operational, and hazardous materials technician levels and the competencies of this chapter. The technician with a cargo tank specialty also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

10-1.2 Definition.

Technicians with a cargo tank specialty are those persons who provide support to the hazardous materials technician, provide oversight for product removal and movement of damaged cargo tanks, and act as a liaison between technicians and other outside resources. These technicians are expected to use specialized chemical-protective clothing and specialized control equipment.

10-1.3 Goals.

The goal of this chapter shall be to provide the technician with a cargo tank specialty with the knowledge and skills to perform the following tasks safely. In addition to being competent at the technician level, the technician with a cargo tank specialty shall be able to:

(a) Analyze a hazardous materials incident involving cargo tanks to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Determine the type and extent of damage to cargo tanks

2. Predict the likely behavior of cargo tanks and their contents in an emergency

(b) Plan a response for an emergency involving cargo tanks within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by determining the response options (offensive, defensive, and nonintervention) for a hazardous materials emergency involving cargo tanks

(c) Implement the planned response to a hazardous materials incident involving cargo tanks

10-1.4 Mandating of Competencies.

This standard does not mandate that hazardous materials response teams performing offensive operations on cargo tanks have technicians with a cargo tank specialty. Technicians operating within the bounds of their training as listed in Chapter 4 of this standard are able to intervene in cargo tank incidents. However, if a hazardous materials response team desires to train some or all its technicians to have in-depth knowledge of cargo tanks, this chapter sets out the required competencies.

10-2 Competencies - Analyzing the Incident.

10-2.1 Determining the Type and Extent of Damage to Cargo Tanks.

Given examples of damaged cargo tanks, technicians with a cargo tank specialty shall describe the type and extent of damage to each cargo tank and its fittings. The technician with a cargo tank specialty shall be able to:

10-2.1.1 Given the specification mark for a cargo tank and the appropriate reference materials, describe the tank's basic construction and features.

10-2.1.2 Given examples of cargo tanks (some jacketed; some not jacketed), point out the jacketed cargo tanks.

10-2.1.3 Given examples of the following types of cargo tank damage, identify the type of damage in each example:

(a) Crack

(b) Scrape, score, gouge, or loss of metal

(c) Puncture

(d) Dent

(e) Flame impingement

(f) Corrosion (internal/external)

10-2.1.4 Given simulated damage to an MC-331 cargo tank, determine the extent of damage to the heat-affected zone.

10-2.1.5* Given an MC-331 cargo tank containing a liquefied gas, determine the amount of liquid in the tank.

10-2.1.6 Given an MC-306/DOT-406, MC-307/DOT-407, and MC-312/DOT-412 cargo tank, point out and explain the design, construction, and operation of each of the following safety devices:

(a) Internal safety valve or external valve with accident protection, including method of activation (air, cable, hydraulic)

(b) Shear-type breakaway piping

(c) Emergency remote shutoff device

(d) Pressure and vacuum relief protection devices

(e) Dome cover design

10-2.1.7 Given an MC-331 and MC-338 cargo tank, point out and explain the design, construction, and operation of each of the following safety devices:

(a) Internal safety valve or external valve with accident protection, including method of activation (air, cable, hydraulic)

(b) Excess flow valve

(c) Fusible link and nut assemblies

(d) Emergency remote shutoff device

(e) Pressure relief protection devices

10-2.1.8 Given an MC-306/DOT-406 cargo tank, identify and describe the following normal methods of loading and unloading:

(a) Top loading

(b) Bottom loading

(c) Vapor recovery system

10-2.1.9 Given the following types of cargo tank trucks and tube trailer, identify and describe the normal methods of loading and unloading:

(a) MC-307/DOT-407

(b) MC-312/DOT-412

(c) MC-331

(d) MC-338

(e) Compressed gas tube trailer

10-2.1.10 Describe the normal and emergency methods of activation for the following types of cargo tank truck valve systems:

(a) Air

(b) Cable

(c) Hydraulic

10-2.1.11 Given a cargo tank involved in an emergency, identify the factors to be evaluated as part of the cargo tank damage assessment process, including the following:

(a) Type of cargo tank (MC or DOT specification)

(b) Pressurized or nonpressurized

(c) Number of compartments

(d) Type of tank metal (e.g., aluminum vs. stainless steel)

(e) Nature of the emergency (e.g., rollover, vehicle accident, struck by object, etc.)

(f) Container stress applied to the cargo tank

(g) Type and nature of tank damage (e.g., puncture, dome cover leak, valve failure, etc.)

(h) Amount of product both released and remaining in the cargo tank

10-2.2 Predicting the Likely Behavior of the Cargo Tank and its Contents.

Technicians with a cargo tank specialty shall predict the likely behavior of the cargo tank and its contents. The technician with a cargo tank specialty shall be able to:

10-2.2.1 Given the following types of cargo tanks (including a tube trailer), describe the likely breach/release mechanisms:

(a) MC-306/DOT-406 cargo tanks

(b) MC-307/DOT-407 cargo tanks

(c) MC-312/DOT-412 cargo tanks

(d) MC-331 cargo tanks

(e) MC-338 cargo tanks

(f) Compressed gas tube trailer

10-2.2.2 Describe the difference in types of construction materials used in cargo tanks and their significance in assessing tank damage.

10-2.2.3 Describe the significance of the jacket on cargo tanks in assessing tank damage.

10-2.2.4 Describe the significance of each of the following types of damage on different types of cargo tanks in assessing tank damage:

(a) Crack

(b) Scrape, score, gouge, or loss of metal

(c) Puncture

(d) Dent

(e) Flame impingement

(f) Corrosion (internal/external)

10-2.2.5 Given simulated damage to the heat-affected zone on a MC-331 cargo tank, describe the significance of the damage in assessing tank damage.

10-3 Competencies - Planning the Response.

10-3.1 Determining the Response Options.

Given the analysis of an emergency involving cargo tanks, technicians with a cargo tank specialty shall determine the response options for each cargo tank involved. The technician with a cargo tank specialty shall be able to:

10-3.1.1 Given an incident involving a cargo tank, describe the methods, procedures, risks, safety precautions, and equipment that are required to implement spill and leak control procedures.

10-3.1.2 Given an overturned cargo tank, describe the factors to be evaluated for uprighting, including the following:

(a) Type of cargo tank and material of construction

(b) Condition and weight of the cargo tank

(c) Type and nature of stress applied to the cargo tank

(d) Preferred lifting points

(e) Selection of lifting straps and/or air bags

(f) Lifting capabilities of wreckers and cranes

(g) Site safety precautions

10-4 Competencies - Implementing the Planned Response.

10-4.1 Implementing the Planned Response.

Given an analysis of an emergency involving a cargo tank and the planned response, technicians with a cargo tank specialty shall implement or oversee the implementation of the selected response options safely and effectively. The technician with a cargo tank specialty shall be able to:

10-4.1.1 Demonstrate the methods for containing the following leaks on liquid cargo tanks (e.g., MC-306/DOT-406, MC-307/DOT-407, and MC-312/DOT-412):

(a) Puncture

(b) Irregular-shaped hole

(c) Split or tear

(d) Dome cover leak

(e) Valves and piping

(f) Pressure relief devices (e.g., vents, burst disc, etc.)

10-4.1.2 Describe the methods for containing the following leaks in MC-331 and MC-338 cargo tanks:

(a) Crack

(b) Failure of safety relief device (e.g., relief valve, burst disc, etc.)

(c) Piping failure

10-4.1.3* Demonstrate bonding and grounding procedures for the transfer of flammable and combustible products from cargo tanks, or other products that can give off flammable gases or vapors when heated or contaminated, including the following:

(a) Selection of proper equipment

(b) Sequence of bonding and grounding connections

(c) Proper testing of bonding and grounding connections

10-4.1.4 Given the following product transfer and recovery equipment, demonstrate the safe and correct application and use of each of the following:

(a) Portable pumps (air, electrical, gasoline/diesel)

(b) Vehicles with power-take-off (PTO) driven pumps

(c) Pressure transfer

(d) Vacuum trucks

10-4.1.5 Given a simulated overturned MC-306/DOT-406 cargo tank, demonstrate the safe and proper procedures for the following methods of product removal and transfer:

(a) Drilling

(b) Unloading lines

(c) Vapor recovery lines

(d) Internal safety valve

10-4.1.6 Given a simulated overturned MC-307/DOT-407 cargo tank, demonstrate the safe and proper procedures for product removal and transfer.

10-4.1.7 Given a simulated overturned MC-331 cargo tank, demonstrate the safe and proper procedures for product removal and transfer.

10-4.1.8 Given the necessary resources, demonstrate the flaring of a MC-331 flammable gas cargo tank.

10-4.1.9 Given a simulated flammable liquid spill from a cargo tank, describe the procedures for site safety and fire control during cleanup and removal operations.

Chapter 11 Competencies for the Technician with an Intermodal Tank Specialty

11-1 General.

11-1.1 Introduction.

Technicians with an intermodal tank specialty shall be trained to meet all competencies of the first responder awareness, operational, and hazardous materials technician levels and the competencies of this chapter. The technician with an intermodal tank specialty also shall receive any additional training to meet applicable United States Department of Transportation (DOT), United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), and other appropriate state, local, or provincial occupational health and safety regulatory requirements.

11-1.2 Definition.

Technicians with an intermodal tank specialty are those persons who provide support to the hazardous materials technician, provide oversight for product removal and movement of damaged intermodal tanks, and act as a liaison between technicians and other outside resources. These technicians are expected to use specialized chemical-protective clothing and specialized control equipment.

11-1.3 Goals.

The goal of this chapter shall be to provide the technician with an intermodal tank specialty with the knowledge and skills to perform the following tasks safely. In addition to being competent at the technician level, the technician with an intermodal tank specialty shall be able to:

(a) Analyze a hazardous materials incident involving an intermodal tank to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Determine the type and extent of damage to an intermodal tank
2. Predict the likely behavior of an intermodal tank and its contents in an emergency

(b) Plan a response for an emergency involving an intermodal tank within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by determining the response options (offensive, defensive, and nonintervention) for a hazardous materials emergency involving intermodal tanks

(c) Implement the planned response to a hazardous materials incident involving intermodal tanks

11-1.4 Mandating of Competencies.

This standard does not mandate that hazardous materials response teams performing offensive operations on intermodal tanks have technicians with an intermodal tank specialty. Technicians operating within the bounds of their training as listed in Chapter 4 of this standard are able to intervene in intermodal tank incidents. However, if a hazardous materials response team desires to train some or all its technicians to have in-depth knowledge of intermodal tanks, this chapter sets out the required competencies.

11-2 Competencies - Analyzing the Incident.

11-2.1 Determining the Type and Extent of Damage to Intermodal Tanks.

Given examples of damaged intermodal tanks, technicians with an intermodal tank specialty shall describe the type and extent of damage to each intermodal tank and its fittings. The technician with an intermodal tank specialty shall be able to:

11-2.1.1 Given the specification mark for an intermodal tank and the appropriate reference materials, describe the tank's basic construction and features.

11-2.1.2 Given examples of intermodal tanks (some jacketed; some not jacketed), point out the jacketed intermodal tanks.

11-2.1.3 Given examples of various intermodal tanks, point out and explain the design and purpose of each of the following intermodal tank components, when present:

(a) Supporting frame

(b) Corner casting

(c) Insulation

(d) Jacket

(e) Heater coils (steam/electric)

(f) Refrigeration unit

(g) Data plate

11-2.1.4 Given examples of various fittings arrangements for pressure, nonpressure, and cryogenic intermodal tanks, point out and explain the design, construction, and operation of each of the following fittings, when present:

(a) Spill box

(b) Manhole cover

(c) Air line connection

(d) Top outlet

(e) Bottom outlet valve

(f) Thermometer

(g) Pressure gauge

(h) Gauging device

(i) Liquid or vapor valve

(j) Sample valve

(k) Thermometer well

11-2.1.5 Given examples of various safety devices for pressure, nonpressure, and cryogenic intermodal tanks, point out and explain the design, construction, and operation of each of the following safety devices, when present:

(a) Safety relief valve

(b) Regulator valve

(c) Rupture disc

(d) Fusible link/nut assemblies

(e) Emergency remote shutoff device

(f) Excess flow valve

11-2.1.6 Given the following types of intermodal tank damage, identify the type of damage in each example and explain its significance.

(a) Crack

(b) Puncture

(c) Dent

(d) Flame impingement

(e) Corrosion (internal/external)

(f) Metal loss (gouge/score)

11-2.1.7 Given three examples of damage to the framework of intermodal tanks, describe the damage in each example and explain its significance in the risk analysis process.

11-2.1.8 Given an intermodal tank involved in an emergency, identify the factors to be evaluated as part of the intermodal tank damage assessment process, including the following:

(a) Type of intermodal tank

(b) Pressurized or nonpressurized

(c) Number of compartments

(d) Type of tank metal

(e) Nature of the emergency

(f) Container stress applied to the intermodal tank

(g) Type and nature of tank damage

(h) Amount of product both released and remaining in the intermodal tank

11-2.1.9* Given a pressure intermodal tank containing a liquefied gas, determine the amount of liquid in the tank.

11-2.1.10* Given simulated damage to a pressure intermodal tank, determine the extent of damage to the heat-affected zone.

11-2.2 Predicting the Likely Behavior of the Intermodal Tank and its Contents.

Technicians with an intermodal tank specialty shall predict the likely behavior of the intermodal tank and its contents. The technician with an intermodal tank specialty shall be able to:

11-2.2.1 Given the following types of intermodal tanks, describe the likely breach/release mechanisms:

(a) IMO Type 1/IM-101

(b) IMO Type 2/IM-102

(c) IMO Type 5/DOT-51

(d) DOT-56

(e) DOT-57

(f) DOT-60

(g) Cryogenic (IMO Type 7)

11-2.2.2 Describe the difference in types of construction materials used in intermodal tanks relative to assessing tank damage.

11-3 Competencies - Planning the Response.

11-3.1 Determining the Response Options.

Given the analysis of an emergency involving intermodal tanks, technicians with an intermodal tank specialty shall determine the response options for each intermodal tank involved. The technician with an intermodal tank specialty shall be able to:

11-3.1.1 Describe the purpose of, potential risks associated with, procedures for, equipment required to implement, and safety precautions for the following product removal techniques for intermodal tanks:

(a) Transferring liquids and vapors (pressure/pump)

(b) Hot tapping

(c) Flaring liquids and vapors

11-3.1.2 Describe the purpose of, procedures for, and risks associated with controlling leaks from various fittings on intermodal tanks, including equipment needed and safety precautions.

11-4 Competencies - Implementing the Planned Response.

11-4.1 Implementing the Planned Response.

Given an analysis of an emergency involving intermodal tanks and the planned response, technicians with an intermodal tank specialty shall implement or oversee the implementation of the selected response options safely and effectively. The technician with an intermodal tank specialty shall be able to:

11-4.1.1 Given leaks from the following fittings on intermodal tanks, control the leaks using proper methods and procedures.

(a) Manway cover

(b) Bottom outlet

(c) Liquid/vapor valve

(d) Safety relief device

(e) Tank

11-4.1.2 Demonstrate proper procedures for the following types of emergency product removal:

(a) Gas/liquid transfer (pressure/pump)

(b) Flaring

(c) Venting

11-4.1.3* Demonstrate bonding and grounding procedures for the transfer of flammable and combustible products from an intermodal tank, or other products that can give off flammable gases or vapors when heated or contaminated, including the following:

(a) Selection of proper equipment

(b) Sequence of bonding and grounding connections

(c) Proper testing of bonding and grounding connections

11-4.1.4 Demonstrate the methods for containing the following leaks on liquid intermodal tanks (e.g., IM-101 and IM-102):

(a) Puncture

(b) Irregular-shaped hole

(c) Split or tear

(d) Dome cover leak

(e) Valves and piping

(f) Pressure relief devices (e.g., vents, burst disc, etc.)

11-4.1.5 Describe the methods for containing the following leaks in pressure intermodal tanks:

(a) Crack

(b) Failure of safety relief device (e.g., relief valve, burst disc, etc.)

(c) Piping failure

11-4.1.6 Given the following product transfer and recovery equipment, demonstrate the safe and correct application and use of the following:

(a) Portable pumps (air, electrical, gasoline/diesel)

(b) Vehicles with power-take-off (PTO) driven pumps

(c) Pressure transfer

(d) Vacuum trucks

11-4.1.7* Given a simulated overturned liquid intermodal tank, demonstrate the safe and proper procedures for product removal and transfer.

11-4.1.8* Given a simulated overturned pressure intermodal tank, demonstrate the safe and proper procedures for product removal and transfer.

11-4.1.9* Given the necessary resources, demonstrate the flaring of a pressure flammable gas intermodal tank.

11-4-1.10 Given a simulated flammable liquid spill from an intermodal tank, describe the procedures for site safety and fire control during cleanup and removal operations.

Chapter 12 Referenced Publications

12-1

The following documents or portions thereof are referenced within this standard as mandatory requirements and shall be considered part of the requirements of this standard. The edition indicated for each referenced mandatory document is the current edition as of the date of the

NFPA issuance of this standard. Some of these mandatory documents might also be referenced in this standard for specific informational purposes and, therefore, are also listed in Appendix D.

12-1.1 NFPA Publications.

National Fire Protection Association, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101.

NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, 1996 edition.

NFPA 1561, *Standard on Fire Department Incident Management System*, 1995 edition.

NFPA 1991, *Standard on Vapor-Protective Suits for Hazardous Chemical Emergencies*, 1994 edition.

NFPA 1992, *Standard on Liquid Splash-Protective Suits for Hazardous Chemical Emergencies*, 1994 edition.

12-1.2 Other Publications.

12-1.2.1 U.S. Government Publications. U.S. Government Printing Office, Superintendent of Documents, Washington, DC 20402.

Title 29, *Code of Federal Regulations*, Part 1910.120

North American Emergency Response Guidebook, U.S. Department of Transportation, 1996 edition.

Appendix A Explanatory Material

This appendix is not a part of the requirements of this NFPA document but is included for informational purposes only.

A-1-1.2 Definitions of Responder Levels.

Awareness Level. First responders at the awareness level are those persons who, in the course of their normal duties, can be the first on the scene of an emergency involving hazardous materials. First responders at the awareness level are expected to recognize the presence of hazardous materials, protect themselves, call for trained personnel, and secure the area.

Operational Level. First responders at the operational level are those persons who respond to releases or potential releases of hazardous materials as part of the initial response to the incident for the purpose of protecting nearby persons, the environment, or property from the effects of the release. They should be trained to respond in a defensive fashion to control the release from a safe distance and keep it from spreading.

Technician Level. Hazardous materials technicians are those persons who respond to releases or potential releases of hazardous materials for the purpose of controlling the release. Hazardous materials technicians are expected to use specialized chemical protective clothing and specialized control equipment.

Command Level. The incident commander is that person who is responsible for all decisions relating to the management of the incident. The incident commander is in charge of the incident site.

List of Tasks by Responder Level

Analysis Tasks

(a) *Awareness Level.* The first responder at the awareness level should analyze an incident to determine both the hazardous materials present and the basic hazard and response information for each hazardous material by completing the following tasks:

1. Detect the presence of the hazardous materials

2. Survey a hazardous materials incident from a safe location to identify the name, UN/NA identification number, or type placard applied for any hazardous materials involved

3. Collect hazard and response information from the current edition of the *North American Emergency Response Guidebook*

(b) *Operational Level.* The first responder at the operational level should be competent at the awareness level and be able to analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Survey the hazardous materials incident to identify the containers and materials involved, determine whether hazardous materials have been released, and evaluate the surrounding conditions

2. Collect hazard and response information from material safety data sheets (MSDS), CHEMTREC/CANUTEC/SETIQ, and shipper/manufacturer contacts

3. Predict the likely behavior of a material and its container

4. Estimate the potential harm at a hazardous materials incident

(c) *Technician Level.* The hazardous materials technician should be competent at the awareness and operational level and be able to analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Survey the hazardous materials incident to identify special containers involved, to identify or classify unknown materials, and to verify the presence and concentrations of hazardous materials through the use of monitoring equipment

2. Collect and interpret hazard and response information from printed resources, technical resources, computer data bases, and monitoring equipment

3. Determine the extent of damage to containers

4. Predict the likely behavior of released materials and their containers when multiple materials are involved

5. Estimate the size of an endangered area using computer modeling, monitoring equipment, or specialists in this area

(d) *Command Level.* The incident commander should be competent to analyze a hazardous materials incident to determine the magnitude of the problem in terms of outcomes by completing the following tasks:

1. Collect and interpret hazard and response information from printed resources, technical resources, computer data bases, and monitoring equipment

2. Estimate the potential outcomes within the endangered area at a hazardous materials incident

Planning Tasks

(a) *Awareness Level.* No requirements.

(b) *Operational Level.* The first responder at the operational level should be competent at the first responder awareness level and be able to plan an initial response within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Describe the response objectives for hazardous materials incidents

2. Describe the defensive options available by response objective

3. Determine if the personal protective equipment provided is appropriate for implementing each action option

4. Identify the emergency decontamination procedures

(c) *Technician Level.* The hazardous materials technician should be competent at both the first responder awareness and operational levels and be able to plan a response within the capabilities of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the response objectives for hazardous materials incidents

2. Identify the potential action options available by response objective

3. Select the personal protective equipment required for a given action option

4. Select the appropriate decontamination procedures

5. Develop a plan of action, including safety considerations, consistent with the local emergency response plan and the organization's standard operating procedures and within the capability of the available personnel, personal protective equipment, and control equipment

(d) *Command Level.* The incident commander should be competent to plan response operations within the capabilities and competencies of available personnel, personal protective equipment, and control equipment by completing the following tasks:

1. Identify the response objectives for hazardous materials incidents

2. Identify the potential action options (defensive, offensive, and nonintervention) available by response objective

3. Approve the level of personal protective equipment required for a given action option

4. Develop a plan of action, including safety considerations, consistent with the local emergency response plan and the organization's standard operating procedures and within the capability of available personnel, personal protective equipment, and control equipment

Implementation Tasks

(a) *Awareness Level.* The first responder at the awareness level should be able to implement actions consistent with the local emergency response plan, the organization's standard operating procedures, and the current edition of the *North American Emergency Response Guidebook* by completing the following tasks:

1. Initiate protective actions

2. Initiate the notification process

(b) *Operational Level.* The first responder at the operational level should be competent at the awareness level and be able to implement the planned response to favorably change the outcomes consistent with the local emergency response plan and the organization's standard operating procedures by completing the following tasks:

1. Establish and enforce scene control procedures, including control zones, decontamination, and communications

2. Initiate an incident management system (IMS)

3. Don, work in, and doff personal protective equipment provided by the authority having jurisdiction

4. Perform the defensive control actions identified in the plan of action

(c) *Technician Level.* The hazardous materials technician should be competent at both the first responder awareness and operational levels and be able to implement the planned response to favorably change the outcomes consistent with the organization's standard operating procedures or safety considerations by completing the following tasks:

1. Perform the duties of an assigned position within the local incident management system (IMS)

2. Don, work in, and doff appropriate personal protective clothing, including, but not limited to, both liquid splash- and vapor-protective clothing with appropriate respiratory protection

3. Perform the control functions identified in the plan of action

(d) *Command Level.* The incident commander should be competent at the operational level and be able to implement a response to favorably change the outcomes consistent with the local emergency response plan and the organization's standard operating procedures by completing the following tasks:

1. Implement the incident management system, including the specified procedures for notification and utilization of nonlocal resources (including private, state, and federal government personnel)

2. Direct resources (private, governmental, and others) with expected task assignments and on-scene activities, provide management overview, technical review, and logistical support to private and governmental sector personnel

3. Provide a focal point for information transfer to media and local elected officials through

the IMS structures

Evaluation Tasks

(a) *Awareness Level.* No requirements.

(b) *Operational Level.* The first responder at the operational level should be competent at the awareness level and be able to evaluate the progress of the actions taken to ensure that the response objectives are being met safely, effectively, and efficiently by completing the following tasks:

1. Evaluate the status of the defensive actions taken in accomplishing the response objectives
2. Communicate the status of the planned response

(c) *Technician Level.* The hazardous materials technician should be competent in evaluating the progress of the planned response by evaluating the effectiveness of the control functions.

(d) *Command Level.* The incident commander should be competent at the operational level and be able to evaluate the progress of the planned response to ensure the response objectives are being met safely, effectively, and efficiently and adjust the plan of action accordingly by evaluating the effectiveness of the control functions.

Termination Tasks

(a) *Awareness Level.* No requirements.

(b) *Operational Level.* No requirements.

(c) *Technician Level:* The hazardous materials technician should be competent to terminate an incident by completing the following tasks:

1. Assist in the incident debriefing
2. Assist in the incident critique
3. Provide reports and documentation of the incident

(d) *Command Level:* The incident commander should be competent to terminate an incident by completing the following tasks:

1. Transfer of command (control) when appropriate
2. Conduct an incident debriefing
3. Conduct a multi-agency critique
4. Report and document the hazardous materials incident and submit the reports to the proper entity

A-1-2 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A-1-2 Authority Having Jurisdiction. The phrase "authority having jurisdiction" is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A-1-2 Hazardous Material. There are many definitions and descriptive names being used for the term hazardous material, each of which depends on the nature of the problem being addressed.

Unfortunately, there is no one list or definition that covers everything. The U.S. agencies involved, as well as state and local governments, have different purposes for regulating hazardous materials that, under certain circumstances, pose a risk to the public or the environment.

Hazardous Materials. The U.S. Department of Transportation (DOT) uses the term *hazardous materials* to cover 11 hazard classes, some of which have subcategories called divisions. DOT includes in its regulations hazardous substances and hazardous wastes as Class 9 (Miscellaneous Hazardous Materials), both of which are regulated by the U.S. Environmental Protection Agency (EPA), if their inherent properties would not otherwise be covered.

Hazardous Substances. EPA uses the term *hazardous substances* for chemicals that, if released into the environment above a certain amount, must be reported, and, depending on the threat to the environment, federal involvement in handling the incident can be authorized. A list of the hazardous substances is published in Title 40, *Code of Federal Regulations,* Part 302, Table 302.4. The U.S. Occupational Safety and Health Administration (OSHA) uses the term *hazardous substance* in Title 29, *Code of Federal Regulations*, Part 1910.120, which resulted from Title I of Superfund Amendments and Reauthorization Act (SARA) and covers emergency response. OSHA uses the term differently than EPA. Hazardous substances, as used by OSHA, cover every chemical regulated by both DOT and EPA.

Extremely Hazardous Substances. EPA uses the term *extremely hazardous substances* for chemicals that must be reported to the appropriate authorities if released above the threshold reporting quantity. Each substance has a threshold reporting quantity. The list of extremely hazardous substances is identified in Title III of SARA of 1986 (Title 40, *Code of Federal Regulations*, Part 355).

Toxic Chemicals. EPA uses the term *toxic chemicals* for chemicals whose total emissions or releases must be reported annually by owners and operators of certain facilities that manufacture, process, or otherwise use a listed toxic chemical. The list of toxic chemicals is identified in Title III of SARA.

Hazardous Wastes. EPA uses the term *hazardous wastes* for chemicals that are regulated under the Resource, Conservation, and Recovery Act (Title 40, *Code of Federal Regulations*, Part 261.33). Hazardous wastes in transportation are regulated by DOT (Title 49, *Code of Federal Regulations*, Parts 170-179).

Hazardous Chemicals. OSHA uses the term *hazardous chemicals* to denote any chemical that would be a risk to employees if exposed in the workplace. Hazardous chemicals cover a broader group of chemicals than the other chemical lists.

Dangerous Goods. In Canadian transportation, hazardous materials are called *dangerous goods*.

Highly Hazardous Chemicals. OSHA uses the term *highly hazardous chemicals* for those chemicals that fall under the requirements of Title 29, *Code of Federal Regulations*, Part 1910.119, "Process Safety Management of Highly Hazardous Chemicals." *Highly hazardous chemicals* are those chemicals that possess toxic, reactive, flammable, or explosive properties. A list of covered substances is published in Appendix A of the OSHA rule.

A-1-2 Incident Management System. For more information, see NFPA 1561, *Standard on Fire Department Incident Management System.*

A-1-2 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A-1-2 Planned Response. The following site safety plan considerations are referenced from the Standard Operating Safety Guides, EPA, June 1992:

(a) Site description

(b) Entry objectives

(c) On-site organization

(d) On-site control

(e) Hazard evaluations

(f) Personal protective equipment

(g) On-site work plans

(h) Communication procedures

(i) Decontamination procedures

(j) Site safety and health plan

A-2-2.1.1 See A-1-2 Hazardous Material.

A-2-2.1.2, A-2-2.1.3 Definitions of Department of Transportation Hazard Classes and

Divisions. Title 49, *Code of Federal Regulations*, Parts 170-180.

Class 1 (Explosives)

An explosive is any substance or article, including a device, that is designed to function by explosion (i.e., an extremely rapid release of gas and heat) or that, by chemical reaction within itself, is able to function in a similar manner even if not designed to function by explosion. Explosives in Class 1 are divided into six divisions. Each division will have a letter designation.

Division 1.1 consists of explosives that have a mass explosion hazard. A mass explosion is one that affects almost the entire load instantaneously.

Examples of Division 1.1 explosives include black powder, dynamite, and TNT.

Division 1.2 consists of explosives that have a projection hazard but not a mass explosion hazard.

Examples of Division 1.2 explosives include aerial flares, detonating cord, and power device cartridges.

Division 1.3 consists of explosives that have a fire hazard and either a minor blast hazard or a minor projection hazard, or both, but not a mass explosion hazard.

Examples of Division 1.3 explosives include liquid-fueled rocket motors and propellant explosives.

Division 1.4 consists of explosive devices that present a minor explosion hazard. No device in the division may contain more than 25 g (0.9 oz) of a detonating material. The explosive effects are largely confined to the package and no projection of fragments of appreciable size or range are expected. An external fire must not cause virtually instantaneous explosion of almost the entire contents of the package.

Examples of Division 1.4 explosives include line-throwing rockets, practice ammunition, and signal cartridges.

Division 1.5 consists of very insensitive explosives. This division is comprised of substances that have a mass explosion hazard but are so insensitive that there is very little probability of initiation or of transition from burning to detonation under normal conditions of transport.

Examples of Division 1.5 explosives include pilled ammonium nitrate fertilizer-fuel oil mixtures (blasting agents).

Division 1.6 consists of extremely insensitive articles that do not have a mass explosive hazard. This division is comprised of articles that contain only extremely insensitive detonating substances and that demonstrate a negligible probability of accidental initiation or propagation.

Class 2 (Gases)

Division 2.1 (flammable gas) consists of any material that is a gas at 20ºC (68ºF) or less and 101.3 kPa (14.7 psi) of pressure, a material that has a boiling point of 20ºC (68ºF) or less at

101.3 kPa (14.7 psi), and that:

(a) Is ignitable at 101.3 kPa (14.7 psi) when in a mixture of 13 percent or less by volume with air

(b) Has a flammable range at 101.3 kPa (14.7 psi) with air of at least 12 percent regardless of the lower limit

Examples of Division 2.1 gases include inhibited butadienes, methyl chloride, and propane.

Division 2.2 (nonflammable, nonpoisonous compressed gas, including compressed gas, liquefied gas, pressurized cryogenic gas, and compressed gas in solution) consists of any material (or mixture) that exerts in the packaging an absolute pressure of 280 kPa (41 psia) at 20ºC (68ºF).

A cryogenic liquid is a refrigerated liquefied gas having a boiling point colder than -90ºC (-130ºF) at 101.3 kPa (14.7 psi) absolute.

Examples of Division 2.2 gases include anhydrous ammonia, cryogenic argon, carbon dioxide, and compressed nitrogen.

Division 2.3 (poisonous gas) consists of a material that is a gas at 20ºC (68ºF) or less and a pressure of 101.3 kPa (14.7 psi or 1 atm), a material that has a boiling point of 20ºC (68ºF) or less at 101.3 kPa (14.7 psi), and that:

(a) Is known to be so toxic to humans as to pose a hazard to health during transportation

(b) In the absence of adequate data on human toxicity, is presumed to be toxic to humans because, when tested on laboratory animals, it has an LC_{50} value of not more than 5,000 ppm

Examples of Division 2.3 gases include anhydrous hydrogen fluoride, arsine, chlorine, and methyl bromide.

Hazard zones associated with Division 2.3 materials are the following:

(a) Hazard zone A - LC_{50} less than or equal to 200 ppm

(b) Hazard zone B - LC_{50} greater than 200 ppm and less than or equal to 1,000 ppm

(c) Hazard zone C - LC_{50} greater than 1,000 ppm and less than or equal to 3,000 ppm

(d) Hazard zone D - LC_{50} greater than 3,000 ppm and less than or equal to 5,000 ppm

Class 3 (Flammable Liquid)

Flammable liquid is any liquid having a flash point of not more than 60.5ºC (141ºF).

Examples of Class 3 liquids include acetone, amyl acetate, gasoline, methyl alcohol, and toluene.

Combustible Liquid

Combustible liquid is any liquid that does not meet the definition of any other hazard class and has a flash point above 60ºC (140ºF) and below 93ºC (200ºF). Flammable liquids with a flash point above 38ºC (100ºF) can be reclassified as a combustible liquid.

Examples of combustible liquids include mineral oil, peanut oil, and No. 6 fuel oil.

Class 4 (Flammable Solids)

Division 4.1 (flammable solid) consists of any of the following three types of materials:

(a) Wetted explosives - explosives wetted with sufficient water, alcohol, or plasticizers to suppress explosive properties

(b) Self-reactive materials - materials that are liable to undergo, at normal or elevated temperatures, a strongly exothermic decomposition caused by excessively high transport temperatures or by contamination

(c) Readily combustible solids - solids that can cause a fire through friction and any metal powders that can be ignited

Examples of Division 4.1 materials include magnesium (pellets, turnings, or ribbons) and nitrocellulose.

Division 4.2 (spontaneously combustible material) consists of any of the following materials:

(a) Pyrophoric material - a liquid or solid that, even in small quantities and without an external ignition source, can ignite within five minutes after coming in contact with air

(b) Self-heating material - a material that, when in contact with air and without an energy supply, is liable to self-heat

Examples of Division 4.2 materials include aluminum alkyls, charcoal briquettes, magnesium alkyls, and phosphorus.

Division 4.3 (dangerous when wet material) consists of materials that, by contact with water, are liable to become spontaneously flammable or to give off flammable or toxic gas at a rate greater than 1 L/kg of the material per hour.

Examples of Division 4.3 materials include calcium carbide, magnesium powder, potassium metal alloys, and sodium hydride.

Class 5 (Oxidizers and Organic Peroxides)

Division 5.1 (oxidizer) consists of materials that can, generally by yielding oxygen, cause or enhance the combustion of other materials.

Examples of Division 5.1 materials include ammonium nitrate, bromine trifluoride, and calcium hypochlorite.

Division 5.2 (organic peroxide) consists of any organic compound containing oxygen (O) in the bivalent -O-O- structure that can be considered a derivative of hydrogen peroxide, where one or more of the hydrogen atoms have been replaced by organic radicals.

Division 5.2 (organic peroxide) materials are assigned to one of seven types:

Type A - organic peroxide that can detonate or deflagrate rapidly as packaged for transport. Transportation of Type A organic peroxides is forbidden.

Type B - organic peroxide that neither detonates nor deflagrates rapidly, but that can undergo a thermal explosion.

Type C - organic peroxide that neither detonates nor deflagrates rapidly and cannot undergo a thermal explosion.

Type D - organic peroxide that detonates only partially or deflagrates slowly, with medium to no effect when heated under confinement.

Type E - organic peroxide that neither detonates nor deflagrates and shows low, or no, effect when heated under confinement.

Type F - organic peroxide that will not detonate, does not deflagrate, shows only a low, or no, effect if heated when confined, and has low, or no, explosive power.

Type G - organic peroxide that will not detonate, does not deflagrate, shows no effect if heated when confined, and has no explosive power, is thermally stable, and is desensitized.

Examples of Division 5.2 materials include dibenzoyl peroxide, methyl ethyl ketone peroxide, and peroxyacetic acid.

Class 6 (Poisonous Materials)

Division 6.1 (poisonous material) consists of materials, other than gases, that either are known to be so toxic to humans as to afford a hazard to health during transportation, or in the absence of adequate data on human toxicity, are presumed to be toxic to humans, including materials that cause irritation.

Examples of Division 6.1 materials include aniline, arsenic compounds, carbon tetrachloride, hydrocyanic acid, and tear gas.

Division 6.2 (infectious substance) consists of viable microorganisms, or their toxin, that cause or can cause disease in humans or animals. Infectious substance and etiologic agent are synonymous.

Examples of Division 6.2 materials include anthrax, botulism, rabies, and tetanus.

Hazard zones associated with Class 6 materials are the following:

(a) Hazard zone A- LC_{50} less than or equal to 200 ppm

(b) Hazard zone B- LC_{50} greater than 200 ppm and less than or equal to 1,000 ppm

Class 7 (Radioactive Materials)

Radioactive material is any material having a specific activity greater than 0.002 microcuries per gram (mCi/g).

Examples of Class 7 materials include cobalt, uranium hexafluoride, and "yellow cake."

Class 8 (Corrosive Materials)

Corrosive material is a liquid or solid that causes visible destruction or irreversible alterations in human skin tissue at the site of contact or a liquid that has a severe corrosion rate on steel or aluminum.

Examples of Class 8 materials include nitric acid, phosphorus trichloride, sodium hydroxide, and sulfuric acid.

Class 9 (Miscellaneous Hazardous Materials)

Miscellaneous hazardous material is a material that presents a hazard during transport, but that is not included in another hazard class, including the following:

(a) Any material that has an anesthetic, noxious, or other similar property that could cause extreme annoyance or discomfort to a flight crew member so as to prevent the correct performance of assigned duties

(b) Any material that is not included in any other hazard class, but is subject to the DOT requirements (a hazardous substance or a hazardous waste)

Examples of Class 9 materials include adipic acid, hazardous substances (e.g., PCBs), and molten sulfur.

ORM-D Material

An ORM-D material is a material that presents a limited hazard during transportation due to its form, quantity, and packaging.

Examples of ORM-D materials include consumer commodities and small arms ammunition.

Forbidden

Forbidden means prohibited from being offered or accepted for transportation. Prohibition does not apply if these materials are diluted, stabilized, or incorporated in devices.

Marine Pollutant

A marine pollutant is a material that has an adverse effect on aquatic life.

Elevated Temperature Material

An elevated temperature material is a material that, when offered for transportation in a bulk packaging, meets one of the following conditions:

(a) Liquid at or above 100ºC (212ºF)

(b) Liquid with a flash point at or above 37.8ºC (100ºF) that is intentionally heated and is transported at or above its flash point

(c) Solid at a temperature at or above 240ºC (464ºF)

A-2-2.1.11 These clues would include odors, gas leaks, fire or vapor cloud, visible corrosive actions or chemical reactions, pooled liquids, hissing of pressure releases, condensation lines on pressure tanks, injured victims, or casualties.

A-2-2.3 It is the intent of this standard that the first responder at the awareness level be taught the noted competency to a specific task level. This task level would be to have knowledge of the contents of the current edition of the *North American Emergency Response Guidebook* or other reference material provided. Awareness level responders should be familiar with the information provided in those documents so that they can use it to assist with accurate notification of an incident and take protective actions.

If other sources of response information [including the material safety data sheet (MSDS)] are provided to the hazardous materials responder at the awareness level in lieu of the current edition of the *North American Emergency Response Guidebook*, the responder should identify hazard information similar to that found in the current edition of the *North American Emergency Response Guidebook*.

A-2-2.3.1 Three methods for determining the appropriate guide page include the following:

(a) Using the numerical index for UN/NA identification numbers

(b) Using the alphabetical index for chemical names

(c) Using the "Table of Placards and Initial Response Guides"

A-2-4.1 Those jurisdictions that have not developed an emergency response plan can refer to the document NRT-1, *Hazardous Materials Emergency Planning Guide*, developed by the National Response Team.

The National Response Team, composed of 14 federal agencies having major responsibilities in environmental, transportation, emergency management, worker safety, and public health areas, is the national body responsible for coordinating federal planning, preparedness, and response actions related to oil discharges and hazardous substance releases. Under the Superfund Amendments and Reauthorization Act of 1986, the NRT is responsible for publishing guidance documents for the preparation and implementation of hazardous substance emergency plans.

A-2-4.1.3.3 This would include thermal, mechanical, poisonous, corrosive, asphyxiation, radiation, and etiologic. This can also include psychological harm.

A-2-4.1.3.4 General routes of human exposure are contact, absorption, inhalation, and ingestion. Absorption includes entry through the eyes and through punctures.

A-2-4.1.4 If other sources of response information [including the material safety data sheet (MSDS)] are provided to the hazardous materials responder at the awareness level in lieu of the current edition of the *North American Emergency Response Guidebook*, the responder should identify response information similar to that found in the current edition of the *North American Emergency Response Guidebook*.

A-2-4.1.4.2(c) "In-place protection," "sheltering in-place," and "protection in-place" all mean the same thing.

A-3-2.1 The survey of the incident should include an inventory of the type of containers involved, identification markings on containers, quantity in or capacity of containers, materials involved, release information, and surrounding conditions. The accuracy of the data should be verified.

A-3-2.1.1 Examples should include all containers, including nonbulk packaging, bulk packaging, vessels, and facility containers such as piping, open piles, reactors, and storage bins. Refer to the Chemical Manufacturers Association/Association of American Railroads Hazardous Materials Technical Bulletin *Packaging for Transporting Hazardous and Non-hazardous Materials*, issued June 1989.

A-3-2.1.4 The list of surrounding conditions should include: topography; land use; accessibility;

weather conditions; bodies of water; public exposure potential; overhead and underground wires and pipelines; storm and sewer drains; possible ignition sources; adjacent land use such as rail lines, highways, and airports; and nature and extent of injuries. Building information such as floor drains, ventilation ducts, air returns, etc., also should be included when appropriate.

A-3-2.3 Predicting the likely behavior of a hazardous material and its container requires the ability to identify the types of stress involved and the ability to predict the type of breach, release, dispersion pattern, length of contact, and the health and physical hazards associated with the material and its container. Reference can be made to *A Textbook for Use in the Study of Hazardous Materials Emergencies,* the National Fire Academy's training program, *Hazardous Materials Incident Analysis, Hazardous Materials*; *Managing the Incident*, or "Managing the Hazardous Materials Incident," *Fire Protection Handbook*.

A-3-2.3.2 The three types of stress that could cause a container to release its contents are thermal stress, mechanical stress, and chemical stress.

A-3-2.3.3 The five ways in which containers can breach are disintegration, runaway cracking, closures opening up, punctures, and splits or tears.

The performance objectives contained in 3-2.3.3 through 3-2.3.5 should be taught in a manner and language understandable to the audience. The intent is to convey the simple concepts that containers of hazardous materials under stress can open up and allow the contents to escape. This refers to both pressurized and nonpressurized containers. This content release will vary in type and speed. A pattern will be formed by the escaping product that will possibly expose people, the environment, or property, creating physical and/or health hazards. This overall concept is often referred to as a general behavior model and is used to estimate the behavior of the container and its contents under emergency conditions.

A-3-2.3.4 The four ways in which containment systems can release their contents are detonation, violent rupture, rapid relief, and spill or leak.

A-3-2.3.5 The seven dispersion patterns that can be created upon release of hazardous materials are hemisphere, cloud, plume, cone, stream, pool, and irregular.

A-3-2.3.6 The three general time frames for predicting the length of time that an exposure can be in contact with hazardous materials in an endangered area are short-term (minutes and hours), medium-term (days, weeks, and months), and long-term (years and generations).

A-3-2.3.7 The health and physical hazards that could cause harm in a hazardous materials incident are thermal, mechanical, poisonous, corrosive, asphyxiation, radiation, and etiologic.

A-3-2.3.8 Health Hazard Definitions.
(a) *Carcinogen:* A chemical that falls within any of the following categories:

1. It has been evaluated by the International Agency for Research on Cancer (IARC) and found to be a carcinogen or potential carcinogen

2. It is listed as a carcinogen or potential carcinogen in the *Annual Report on Carcinogens* published by the National Toxicology Program (NTP) (latest edition)

3. It is regulated by federal OSHA as a carcinogen (can be regulated additionally by states)

(b) *Corrosive:* A chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the site of contact

(c) *Highly toxic:* A chemical that falls within any of the following categories:

1. A chemical that has a median lethal dose (LD_{50}) of 50 mg or less per kg of body weight when administered orally to albino rats weighing between 200 g and 300 g each

2. A chemical that has a median lethal dose (LD_{50}) of 200 mg or less per kg of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 kg and 3 kg each

3. A chemical that has a median lethal concentration (LD_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 mg per L or less of mist, fume, or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 g and 300 g each

(d) *Irritant:* A chemical that is not corrosive but that causes a reversible inflammatory effect on living tissue by chemical action at the site of contact

(e) *Sensitizer:* A chemical that causes a substantial proportion of exposed people or animals to develop an allergic reaction in normal tissue after repeated exposure to the chemicals

(f) *Toxic:* A chemical that falls within any of the following categories:

1. A chemical that has a median lethal dose (LD_{50}) or more than 50 mg per kg but not more than 500 mg per kg of body weight when administered orally to albino rats weighing between 200 g and 300 g each

2. A chemical that has a median lethal dose (LD_{50}) of more than 200 mg per kg but not more than 1,000 mg per kg of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 kg and 3 kg each

3. A chemical that has a median lethal concentration (LD_{50}) in air of more than 200 parts per million but not more than 3,000 parts per million by volume of gas or vapor, or more than 2 mg per L but not more than 200 mg per L of mist, fume, or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 g and 300 g each

(g) *Target organ effects:* A target organ categorization of effects that can occur, including examples of signs and symptoms and chemicals that have been found to cause such effects. These examples are presented to illustrate the range and diversity of effects and hazards that can be encountered and is not intended to be all-inclusive.

1. *Hepatotoxins*. Chemicals that produce liver damage (signs and symptoms: jaundice, liver enlargement; chemicals: carbontetrachloride, nitrosamines)

2. *Nephrotoxins*. Chemicals that produce kidney damage (signs and symptoms: edema, protein urea; chemicals: halogenated hydrocarbons, uranium)

3. *Neurotoxins*. Chemicals that produce their primary toxic effects on the nervous system
a. *Central Nervous System Hazards:* Chemicals that cause depression or stimulation of consciousness or otherwise injure the brain

b. *Peripheral Nervous System Hazards:* Chemicals that damage the nerves that transmit messages to and from the brain and the rest of the body (signs and symptoms: numbness, tingling, decreased sensation, change in reflexes, decreased motor strength; examples: arsenic, lead, toluene, styrene)

4. Agents that decrease hemoglobin in the blood of function; deprive the hematopolatic body tissues of oxygen system (signs and symptoms: cyanosis, loss of consciousness; chemicals: carbon monoxide, benzene)

5. Agents that irritate the lung or damage the pulmonary tissue (signs and symptoms: cough, tightness in chest, shortness of breath; chemicals: silica, asbestos, HCL)

6. *Reproductive toxins*. Chemicals that affect the reproductive capabilities, including chromosomal damage (mutations) and effects on fetuses (teratogenesis) (signs and symptoms: birth defects, sterility; chemicals: lead, DBCP)

7. *Cutaneous hazards*. Chemicals that affect the dermal layer of the body (signs and symptoms: defatting of the skin, rashes, irritation; chemicals: ketones, chlorinated compounds)

8. *Eye hazards*. Chemicals that affect the eye or visual capacity (signs and symptoms: conjunctivitis, corneal damage; chemicals: organic solvents, acids)

A-3-2.3.8(b) Chronic health hazards include carcinogen, mutagen, and teratogen.

A-3-2.4 The process for estimating the potential outcomes within an endangered area at a hazardous materials incident includes determining the dimensions of the endangered area, estimating the number of exposures within the endangered area, measuring or predicting concentrations of materials within the endangered area, estimating the physical, health, and safety hazards within the endangered area, identifying the areas of potential harm within the endangered area, and estimating the potential outcomes within the endangered area.

A-3-2.4.1 Resources for determining the size of an endangered area of a hazardous materials incident is the current edition of the *North American Emergency Response Guidebook* and plume dispersion modeling results from facility pre-incident plans.

A-3-2.4.4 The factors for determining the extent of physical, health, and safety hazards within an endangered area at a hazardous materials incident are surrounding conditions, an indication of the behavior of the hazardous material and its container, and the degree of hazard.

A-3-3.3.1 The minimum requirement for respiratory protection at hazardous materials incidents (emergency operations until concentrations have been determined) is positive pressure self-contained breathing apparatus. Therefore, the minimum for the first responder at the operational level is positive pressure self-contained breathing apparatus.

A-3-3.4, A-3-4.1.5 Refer to *Hazardous Materials Response Handbook*, National Fire Protection Association, Quincy, MA.

A-3-4.1.6 Refer to NIOSH/OSHA/USCG/EPA *Occupational Safety and Health Guidance*

Manual for Hazardous Waste Site Activities.

A-3-4.2 See A-2-4.1.

A-3-4.2.6 The hazardous materials safety officer should meet all the competencies for the responder at the level of operations being performed.

A hazardous materials branch safety officer is an individual who directs the safety of operations within the hot and warm zones. A hazardous materials branch safety officer should be designated specifically at all hazardous material incidents (CFR 1910.120). The hazardous materials safety officer has the following responsibilities:

(a) Obtains a briefing from the incident commander or incident safety officer and the hazardous materials branch safety officer

(b) Participates in the preparation of and monitors the implementation of the incident safety considerations (including medical monitoring of entry team personnel before and after entry)

(c) Advises the incident commander/sector officer of deviations from the incident safety considerations and of any dangerous situations

(d) Alters, suspends, or terminates any activity that is judged to be unsafe

A-4-1.3 The following site safety plan considerations are referenced from the *Standard Operating Safety Guides,* EPA, June 1992:

(a) Site description

(b) Entry objectives

(c) On-site organization

(d) On-site control

(e) Hazard evaluation

(f) Personal protective equipment

(g) On-site work plans

(h) Communication procedures

(i) Decontamination procedures

(j) Site safety and health plan.

A-4-2.1.3 Suggested materials to identify can include the most commonly released materials that are identified on several lists annually (EPA, State of California).

A-4-2.1.3.4 These factors include, but are not limited to, operation, calibration, response time, detection range, relative response, sensitivity, selectivity, inherent safety, environmental conditions, and nature of hazard. Also refer to NIOSH/OSHA/USCG/EPA *Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities,* October 1985.
